We regret to observe a tendency, in some quarters to reflect upon the present Commissioner of Patents, Mr. W. E. Simonds, because information of the allowance of the Berliner patent reached interested parties before it reached the press and public. The allowance of an application is, as a matter of course, notified to the applicant or his assignee by the office; the issue of the patent following sooner or later upon the payment of final fees. This necessary practice accounts for the early information that reached some persons and not others. From all the facts now available, it would seem that Commissioner Simonds and Examiner Bissing bestirred themselves very soon after Mr. Simonds came into office to clear up and dispose of the case.

A large amount of litigation over telephone patents may confidently be looked for during some years to come, and it remains to be seen whether the American Bell Telephone Company will achieve, in the Berliner case, the conspicuous success that attended its prolonged fight over the Bell patent.

ELECTRIC MOTOR REGULATION.

The methods of regulating electric motors and of governing their action so as to conform to various conditions of service have probably only been equaled in variety and number by the methods designed for the regulation of dynamo electric machines, of which, indeed, they are in many cases the direct corollary. But as in the case of the latter, few of these methods have survived the test of extended use, and, as a result, it may be said that three or four methods of regulation at present cover the entire range of motor application. What the possibilities in this direction are may be readily discerned when we consider the various types of machines at present available and the various elements in their construction which can be utilized to bring about changes necessary for regulation. Such a scheme was very cleverly worked out some time ago by Prof. Francis B. Crocker in an admirable paper read before the American Institute of Electrical Engineers, and he demonstrated the possibility of devising methods aggregating more than a score in number. The discussion of that paper brought out still other methods, more particularly mechanical in their character. But that the field is still open for investigation is shown by the work of Mr. H. Ward Leonard, which he describes in detail on another page. For all such work, where both speed and power are constantly varying, as is pre-eminently the case in electric railway practice, a method of regulation such as that advocated by Mr. Leonard will do much towards increasing the efficiency of operation, and its effects will be felt, especially on roads involving heavy grades. Some other operations to which such a system will successfully lend itself have been well pointed out in Mr. Leonard's paper, and they form but a fraction of the many to which it is directly applicable.

LONG-DISTANCE TELEPHONY.

The practical limits to which telephony is confined at the present time are so thoroughly understood that the hopes for increasing the distances of practical transmission apparently can be looked for only in the reduction of the resistance of the lines and more particularly of their static capacity. It is the latter which is most generally lost sight of and which, as a rule, is ignored by those who have advocated ocean telephony. The speed at which an impulse can be transmitted over a line of given capacity is so well known that success in this direction with any method of transmission at present in use seems hopeless, but a most suggestive method is that brought forward by Mr. J. W. Gibboney, described elsewhere in this issue, in which he proposes to employ the phonograph as an intermediary to reduce the speed of transmission, and again to increase it to the original pitch of the voice at the other end of the line. While the practicability of this mode of transmission still remains to be proved, the method is one certainly worthy of consideration.

THE MEASUREMENT OF THE LOSS BY HYSTERESIS.

BY

Chas. Steinmetz.

WITH considerable interest I have read in THE ELECTRICAL ENGINEER of Nov. 11th the proposition of Mr. Th. Spencer, to determine the loss of energy by hysteresis by means of two specially-designed electro-dynamometers, though I hardly think that Mr. Spencer tried his method by applying it to actual testing.

Having spent a good deal of time myself with this phenomenon of hysteresis, theoretically and practically, I may be allowed to make a few remarks on this proposition. Reduced to its principle it means as follows: Let I_1 and I_2 denote the *effective* values of primary current and secondary current respectively, and i_1 and i_2 their instantaneous values. Let I denote the effective value of the resulting current (which is produced by combining I_1 and I_2 by the parallelogram of electric currents), that is, the effective value of $i = i_1 + i_2$. Then the two electro-dynamometers give the effective values, I^2 and $I I_2 \cos (I I_2)$.

Hence, it being impossible to determine by means of *two* instrument-readings the *three* unknown quantities contained therein, $I, I_2, \cos (I I_2)$, this method cannot give the absolute values of primary and of secondary current. Therefore it does not give the secondary or induced E. M. F., or, what is the same thing, the intensity of magnetization; that is, the number of lines of magnetic force per square centimetre to which the determined hysteretic loss corresponds.

But the loss by hysteresis depends largely upon the intensity of magnetization, and therefore, if this is not determined—as it cannot be done by the proposed method—the hysteretic loss tells just as little as does the current strength about the resistance of a wire, if the E. M. F. between its terminals is not known. Therefore it is not possible to determine the hysteretic loss by less than *three* electro-dynamometers, because the determination involves the knowledge of *three* unknown quantities. Besides, this method has the serious objection, that its result is really not the hysteresis proper, but includes the loss of energy caused by the electric resistance of primary and secondary coils and cannot be freed therefrom, because both currents remain unknown.

Now in a well-designed transformer, especially of large size, the loss in the copper for full load is almost as great as, or even greater than, the loss in the iron (2.0 per cent. against 1.5 per cent., Ganz & Co. 20 h. p. converter). Hence the loss in the copper must be subtracted from the whole loss, to get the hysteretic loss, and for this the currents must be determined.

The self-induction of the secondary circuit can *not* be neglected either. For the hysteretic loss is the difference between the primary and the secondary energy, and a rather small difference at that. Therefore a small error in the secondary energy, as it is caused by neglecting the self-induction, must cause an enormous error in the value for the hysteresis. This I consider the reason we have not yet got exact values for the hysteresis in a converter at full load. This explains the alleged decrease of hysteresis for increasing load, which, theoretically, is beyond comprehension, for it cannot be understood what difference it can make for an iron molecule, whether some trillion molecules away a secondary current circulates or not, if the iron molecule undergoes the same magnetic cycle. The self-induction of the instruments has to be taken into account also, and this depends upon current strength.

I have tried several times to use multiple electro-dynamometers, that is, instruments fed with two currents through parallel wires, but have always been obliged to abandon them as entirely unreliable. For the two parallel wires of the instrument, fed with separate currents, constitute a real transformer, or rather each instrument two transformers, one being the fixed, and the other the movable coil, and therefore act and react upon each other, either current inducing E. M. F. in the circuit of the other. To calculate even this mutual induction and reduce the readings for it, is far too complicated to be of any practical value, and is impossible if the strength of the two currents is not known. Considering all this, we see that the determination of the hysteresis by means of electro-dynamometer is far more difficult than assumed.

If the secondary circuit is open there must be a voltmeter, a wattmeter and an ammeter, that is, three instruments, in the primary circuit. Besides this, means must be provided to determine the exact number of pulsations of the alternating current, either by reading the speed of the dynamo alternator proper, or the speed of synchronizing devices. All the resistances of the primary coils and the coils of the instruments must be known, and also the self-induction of the different coils of the instruments.

In case of tests for hysteresis with secondary circuit closed, we need at least a wattmeter and a voltmeter in the secondary—if it is almost non-inductive—and an ammeter and a wattmeter in the primary circuit, at least four instruments, and cannot expect any great accuracy, because of the great error in the result, caused by a very slight error in one of the readings.

I wish also to make a few remarks on another method for the determination of hysteresis, lately proposed by Ewing, to determine the hysteretic energy by comparing the heating of a converter with that of an apparatus exactly like it, but with bifilar-wound primary and secondary coils to produce no magnetism, and supplied with continuous current through a third coil. As soon as the temperature of both apparatus remains stationary at the same point, the energy expended by the continuous current in the third coil measures the hysteretic energy in the other apparatus.

Unfortunately, this very ingenious method can be applied only between very narrow limits; for it can give exact results only in the special case where the iron of the magnetic circuit is *completely* and *evenly* covered by the primary and secondary coils. In all other cases it must give *wrong* results.

Take, for instance, a Westinghouse converter. Build an apparatus exactly like it and of the same material, with its coils connected in series to those of the first converter, but bifilar-wound, and supply it with continuous currents through a third coil. Now even supposing both apparatus consume exactly the same energy, then in the converter a great part of the energy is consumed in the iron; in the other apparatus none is consumed in the iron but all in the copper. Hence in the converter, the iron will be hotter and the copper cooler than in the other apparatus, with the same consumption of energy, and if a thermometer be placed on the iron and adjusted for equal stationary temperature, too large a value for the loss of energy by hysteresis is obtained, while if the thermometer is placed on the copper, it gives too small a result.

Hence it almost looks as if the only way to determine the hysteretic loss of a converter at full load is to put it in an ice-calorimeter, measure the heat given off, and subtract the heat developed in the copper, derived from current-strength and resistance. This way is anything but promising.

HANDY AND PITHY.

A READER of THE ELECTRICAL ENGINEER writes us: "Of late, though I take several electrical journals, yours is the only one that I regularly open. It was a felicitous conceit to adopt so convenient a form. I like the editing, too."

ELECTRIC RAILWAYS AT THE FRANKFORT ELECTRICAL EXPOSITION.

There were several interesting systems of electric railways exhibited at the Frankfort Electrical Exposition which are worthy of notice.

Two overhead systems were in practical operation, that of Siemens & Halske, of Berlin, and Schuckert & Co., of Nüremburg. The Siemens & Halske system was operated between the Exposition and the Opernplatz. The accompanying illustration shows clearly the peculiar sliding contact used by the company.

The system of Schuckert & Co. was operated between the Main Exposition and the Marine Exposition on the River Main. These cars have trolley poles similar to those of the Short system, and make a sliding contact with the trolley wire.

The Siemens & Halske road also had a storage battery car which was used mornings and evenings, before and after the dynamos at the Exposition were stopped. This car had two motors of 7 h. p. each, one on each truck. The armature was connected to one set of gears, and these were connected by means of chains to the axles, thus avoiding the double-reduction gear. The chains were of peculiar construction, being made up of small tubes of steel with rods and external connecting straps, admitting of great flexibility. This chain ran in oil, making no noise. The armature speed was 1,000 revolutions per minute when the speed of the car was 12 kilometres. This car was run four hours in the morning and two hours in the evening, while the overhead system was not in use. The storage batteries were of the Tudor type, and there were 162 cells connected in series. The potential of the motors being

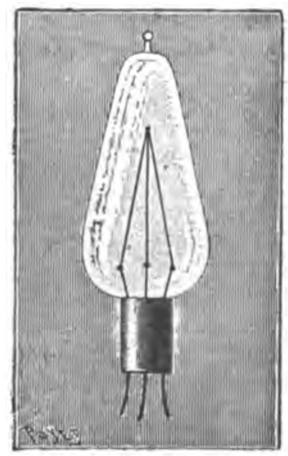
Siemens & Halske Car at the Frankfort Exposition.

300 volts, a large number of small cells were used as a make-shift because the motors had been built for the overhead system of 300 volts, the capacity of the accumulators being 60 ampere hours. There were three connections used in changing speed. On starting, the 4 sets were connected in parallel; when running slowly the cells were connected in two series, and at full speed all the cells were connected in series. The battery for this car weighed 2 tons. The total weight of car loaded was 10 tons, including 40 passengers. The cells of the battery car were charged in 3 set series with a charging current of 48 amperes.

The closed underground conduit system of Mr. C. Pollak, of Paris, was of great interest to all. Mr. Pollak had a working model of his system on exhibition in the Railway Exhibition Hall. This system will be exhibited on a large scale at the World's Fair, at Chicago, in 1893, and Mr. Pollak claims he has several roads now about to be constructed in Germany and France. The "Helios" Company, of Köln, also had a working model on exhibition of a system of rapid transit to be used between Vienna and Budapesth.

THREE FILAMENT INCANDESCENT LAMP FOR MULTIPHASE CIRCUITS.[1]

Anticipating the time when multiphase circuits will become general, M. Dolivo-Dobrowolsky has constructed an



Three-Filament Lamp for Multiphase Circuits.

incandescent lamp adapted to be placed on such circuits. The lamp, which is illustrated in the accompanying engraving, consists of three filaments joined at their tops, the free ends being connected to the three circuits of the multiphase transformer. For the proper operation of the lamp, the current passing through each one of the filaments must be equal, at every instant, to the sum of the currents in the other two filaments, and this is exactly the property of three-phase circuits.

THE NEW GERMAN PATENT LAW.

According to the provisions of the new German patent law which went into effect October 1st, an invention is considered new if at the date of filing the application for patent it has not been so described in public prints within the last century, or so publicly employed in the German Empire that the use of the same by persons skilled in the art appears possible. The official foreign patent specifications are only considered equal to public prints after the lapse of three months from the date of publication, in so far as the patent is applied for by the foreign patentee or his legal successor. This exception only refers to the official publications of those States in which (according to an official publication) reciprocity is guaranteed.

Another new departure is a "Law for the Protection of Useful Models," by which all kinds of tools and implements which cannot be patented can be protected by this law—even the subjects of refused patent applications can now in many cases be protected. A most important provision is that applications are accepted without examination. The protection lasts six years, and promises to prove of value for all kinds of small inventions not perhaps worth patenting fully.

1. *La Nature.*

A MOTOR OPERATING AUTOMATICALLY AT ANY DESIRED SPEED OR TORQUE AND WITH MAXIMUM EFFICIENCY UNDER ALL CONDITIONS.

BY

H. Ward Leonard

In the operation of electric motors there are three principal factors to be considered, the speed, the torque and the efficiency. Under any variations in power the efficiency should remain as nearly constant as possible. For one class of work it is desirable to keep the speed constant when the torque varies. For a second class of work it is desirable to keep the torque constant at one particular amount when the speed varies. For a third class it is desirable to operate at many different speeds, and yet automatically at any particular speed desired regardless of the torque. For a fourth class it is desirable to operate at many different torques and yet automatically at any desired torque regardless of the speed; and for a fifth kind it is desirable to keep the amount of power supplied constant, regardless of a change in torque, that is, so that if the torque changes by the requirements of practice, the speed would automatically change so that the power consumed would remain constant.

The shunt-wound motor, operating on a constant potential circuit, is well adapted to the first class of work mentioned, where but one fixed speed is desired, practically regardless of the torque and with a practically constant efficiency.

The second class of work mentioned, having one particular constant torque and a speed variable at will, cannot be performed by existing electric motors without great sacrifice of efficiency. In this class of work we find hoists lifting a constant weight, certain printing presses, swing bridges, stamp mills, pumps, etc.; that is, such work as requires that we should start up from dead rest with full torque and run at any desired speed with the same torque and with perfect efficiency.

The third and fourth classes of work are more common than would at first appear evident, but since neither the steam engine nor the water-wheel can be operated under conditions where both speed and torque will vary, and where the speed or torque can be held automatically fixed at any point desired, regardless of variation of the other, we do not find work of this kind existing in such shape as to be operated by an electric motor instead of some other power. Nor has the electric motor been available for such duty heretofore. A familiar instance of the third kind of work is met with in the printing of fabrics, where the presses have a large number of rolls upon which the torque depends, and the speed of the presses must be varied as desired, and yet at any given speed must hold that speed constantly, regardless of the number of rolls set down, that is, regardless of the torque. Similarly, lathes, drill presses, wood-working machinery, etc., belong to this class. Certain variations in the speed are possible by existing methods by the use of cone pulleys and equivalent devices, but no motor of any kind has heretofore existed which, directly applied, would conform to the requirements of this kind of work.

The fourth kind of work has, as a familiar example, the passenger elevator, where the weight, and consequently the torque, is variable, and where at any torque the speed should be controllable at will, with constant efficiency. Another example is the pumping of water against a variable pressure with the speed controllable at will, and independent of the pressure. This result is not obtained directly by any motor to day.

The fifth class of work, where the speed is automatically varied to keep the power consumed constant, no matter how the torque varies, is not met with in practice as far as I know, yet oftentimes we may have a constant source of power from which we wish to get a torque variable to the requirements of a variable load and do not care particularly about the speed. An electric street railway operated by water power is a familiar example of this class of work.

It will be seen from the above that of the five principal classes of work there is only one, namely, constant speed and variable torque, which we can take care of with reasonable efficiency and from our existing supply circuits.

It is well known that when a street car is first started and is scarcely in motion the actual power represented by such motion is almost nothing, for, although the pounds pull is large, the feet per minute is extremely small; consequently the power required must be exceedingly small. What do we find in practice? We find that in order to develop a power of but a fraction of a horse-power we must, on account of the slow speed demanded, develop about 30 h. p., and then waste about 98 per cent. of this h. p. in order to utilize the remaining 2 per cent. in the way it is desired. The efficiency of the modern electric street-car is not probably more than 2 per cent. when just starting from dead rest and moving at the rate of one-half foot per second.

When we come to investigate this, we find that the explanation is that in order to get the necessary large torque with freedom from excessive sparking we must have a very large current in a nearly constant field; and since our E. M. F. is constant we must use an amount of power which will vary almost directly with the torque, and will be regardless of the speed. Or, in other words, the efficiency of the motor will vary directly as the speed with an efficiency of perhaps 80 per cent. at full speed.

As a result of my investigation of this subject I have concluded that the operation of electric motors should conform to what, apparently, is a new law and which may be stated as follows:

Vary the voltage as the speed desired.

Vary the amperes as the torque required.

In other words, make the speed dependent upon the voltage only and independent of the current, and make the torque dependent upon the current only, and independent of the voltage. Since the product of the speed and torque represents the work being done, and the product of the volts and amperes represents the power supplied, it is evident that if we can operate in conformity to this law, we shall have a constant efficiency under all conditions, disregarding, of course, the small fixed losses in the field and armature.

One way in which this law can be followed is to supply the field of the motor from one source of electric energy and supply the armature from another source, the E. M. F. of which can be varied. It will be noticed that when the speed is fixed a fixed voltage will be necessary in order to conform to the law, and the shunt motor is found to conform perfectly to the law; but it is the only motor I know of which does conform to the law which seems to be generally applicable.

A simple case will be the operation of a printing press for printing fabrics. Suppose the press has 10 rolls, that is, the torque will vary from 1 to 10 in amount. Suppose also that it must be run at any speed from that represented by 1 to that represented by 20, and at any speed it must hold its speed constantly, whether 1 or 10, or any intermediate number of rolls be brought into use. Also that the efficiency must be independent of the speed or torque. In order to conform to the law in a simple way, we will install a generator A and motor B of the same size (see Fig.) and connect their armatures by two conductors. We will supply their fields from a small separate exciter, C, in the shape of a shunt-wound dynamo. In the circuit leading to the field of the generator we will place a rheostat D. If now we drive our generator at a constant speed, the E. M. F. it will produce will depend upon its field, which in turn will depend upon the amount of resistance in the rheostat in its field circuits. The strength of the motor field is constant, being supplied by the constant E. M. F. exciter. Now, evidently the speed of the motor will depend solely upon the E. M. F. supplied to its brushes, and this can be varied from 0 to the maximum limit by varying the rheostat, which will preferably be placed beside the motor itself. The current will automatically vary in proportion to the torque, the speed will vary directly as the voltage and the efficiency will be constant and independent of the speed or torque.

If we wish to operate an elevator from central station conductors of constant E. M. F., we supply a shunt-wound motor mechanically connected directly with a generator, whose armature is connected to the armature of the elevator motor. The field of the generator is supplied from the central station conductors, but a loop goes up to the elevator car, where a rheostat and reversing switch Q is placed, so that the E. M. F. of the generator can be varied and reversed at will. The field of the elevator motor is excited from the line constantly.

It will be evident that we can control the elevator perfectly from the car and run in either direction, at any desired speed, and with perfect efficiency. It is worthy of notice that the non-sparking point is entirely independent of the speed, and that for any particular weight the non-sparking point is absolutely fixed and independent of the power used. Also that, since the maximum weight alone determines the maximum amperes, it will be impossible to send more than the normal full load in amperes through the armature; consequently the liability of burning out of armatures is reduced to a minimum. The elevator in coming down generates current to assist the central station, and since the efficiency is practically constant under all conditions, and since as many foot-pounds of work are done by the elevator in descending as it requires in ascending, the consumer will in reality pay only for the energy wasted in charging the fields, in heating the armatures, and that represented by the friction of the gearing, which will be the least possible. The starting up of the elevator requires a minimum of power, and hence does not subject the central station to large, sudden fluctuations of load.

Suppose we want to operate a swing bridge by an electric motor. We connect as in the case of a printing press, but instead of a hand-field rheostat we use an automatic field rheostat, such as is used by the Edison Company. We place an amperemeter in the armature circuit of our motor, and when the amperemeter needle indicates full load it touches a contact leading to the relay magnets of the automatic rheostat, which causes it to throw in resistance in the field circuit of the generator and reduces its E. M. F. Similarly, just below full load, the amperemeter needle makes contact, closing a circuit in the automatic rheostat so as to throw out resistance and raise the E. M. F. of the generator.

To start up the bridge we insert all of our resistance in the field of the generator and have, let us say, no volts. Now we close the main-line switch to the motor; we will have no current; hence the amperemeter needle will be on the lower contact, which will gradually throw out resistance and cause the generator to generate an E. M. F. The current will increase and will finally cause the needle to leave the lower contact. The full torque is now being developed and the bridge, if the motor be of proper size, will start to move. As it does so, the counter E. M. F. of the motor will tend to reduce the current, but this will cause the needle to again make the lower contact and raise the E. M. F. and speed and hold the current and torque constant.

Thus, the bridge will start from rest with a minimum of power but full torque, and will gradually accelerate in speed until the full E. M. F. and speed of the motor is reached. To vary the speed by hand we merely move the amperemeter needle to make either contact desired. In case the bridge should meet an obstruction which would slow it down, the amperes would not increase, but would remain constant, as the volts would be immediately and automatically reduced to just that amount necessary to keep the amperes constant. With this arrangement it will be practically impossible to overload the motor armature.

Another good application of this method of keeping the torque constant will be in any case where a tool is cutting certain material which may vary in hardness or when the feed may vary. If the torque be kept constant it will be impossible to break the cutting tool or injure the apparatus. An electric coal-cutter is a case in point. The cutter may be advancing through slate, fire clay or coal, and occasionally it will meet a layer of hard iron pyrites, known in the mines as "sulphur." This may stop the cutter-bar entirely, and with an ordinary or series or shunt motor the result would probably be a burnt-out armature. With the system I have described the current would be constant in any event and the cutter would automatically go faster in soft material and slower in hard material.

In pumping by an electric motor operated on this system the head alone determines the torque, and hence the current. Consequently, for any lift the non-sparking point will be fixed and the number of strokes per minute can be controlled at will from 0 up to the maximum by varying the volts.

For operating an electric railway we will place a shunt-wound motor on the car, and directly driven by this motor will be a special generator, which will be connected to the electric motor below the car. It is evident that the generator and working motor armatures may be wound for any voltage desired, say 20 volts, which will make the problem of insulating the street-car motor an extremely simple one. If desirable, we can supply several cars of a common train from one special generator on the forward car. With this outfit we will be able to take any car up any practicable grade or around any curve with no more power than is required to move the car on a level, and always consume the same power, regardless of weight, grades or curves. That is, the automatic increase of current, to take care of any increased torque, will be compensated for by a corresponding decrease in the volts and speed. We may start a car up on any grade or curve with but a small fraction of the power required for normal speed on a level.

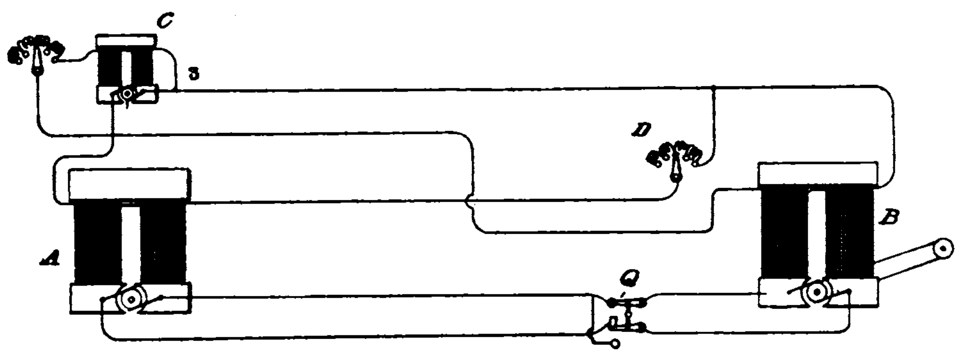
I wish to call attention to a very important development leading out from this, namely, that we will be able to use alternating currents for operating our street cars, for it is well known that the ordinary alternating current generators will operate perfectly as motors, if the speed and torque be kept constant. Since by this system we can, from a constant torque and speed, get any other torque and, automatically, a corresponding speed, we shall be able to run street cars perfectly by alternating currents. This again will enable us to dispense with trolleys, conduits, storage batteries, etc. We will place between our tracks, in manholes, converters whose primary pressure can be anything required for proper economy and whose secondary will be, say, 15 volts. This secondary circuit will connect directly with the rails. The road will be divided in sections, each a few hundred feet long, and each section will be supplied by its own converter.

This system also lends itself very readily to the transmission of power. We may transmit by alternating currents and the alternating current motor running at a constant speed and at a nearly constant torque will drive special generators to operate hoists, pumps, locomotives, etc., at the varying torques and speeds demanded by practice, and yet without subjecting the alternating-current motor to a sudden or wide fluctuation in its torque and without any necessity of varying its speed. With this system of operating electric motors there seems to be no work met with in practice which cannot be perfectly performed.

On first consideration, the additional apparatus necessary would seem to make the system prohibitory in practice; but the capacity of the present single motor is greater than the combined capacity of the apparatus this system would require, and the capacity of the prime motor is very much reduced.

In order to reduce the first cost to a minimum and yet secure the advantages of different automatic speeds and high efficiency I have devised two modifications of the arrangement described above. The first is adapted to power in which a smooth, efficient acceleration of a load from rest is required, as in the case of passenger locomotives and elevators. The second case is where various automatic speeds are desired, but no especial importance attaches to the starting of the load from rest, as is the case in machinery in general.

For the first case we have the trolley system of electric street cars as the most important. Let us suppose we have two motors of 15 h. p. each for the car. We find that for full speed upon a level we require about 15 amperes at 500 volts. Upon heavy grades we find that about 50 amperes are required, and, as before, we have 500 volts. With this consumption of energy we find that we get a speed upon the heavy grade which is about one-quarter of the speed upon a level. In order to operate upon my system, let us place upon the car a motor generator, the motor part of which is wound for 500 volts and $12\frac{1}{2}$ amperes and the generator part of which is wound for 125 volts and 50 amperes. The fields of the motor and generator part are distinct and are wound for 500 volts, as are the fields of the two propelling motors, under the car. All these fields are supplied from the 500 volt trolley circuit. In the field of the auxiliary generator is placed a rheostat.



THE LEONARD METHOD OF MOTOR REGULATION.

Now, suppose the car at rest upon a grade. The motor generator is running, but the generator has a very weak field. Its armature is connected by a controlling switch to the propelling motors. We now gradually cut out resistance from the generator field circuit and finally get about 20 volts at the brushes of the generator. With this E. M. F. we get sufficient current to produce 50 amperes through the armatures of the propelling motors in a saturated field. This gives us the full torque and the car starts at a speed of, perhaps, half a foot a second. This speed can be maintained constantly and indefinitely and the consumption of energy will be less than 2 h. p. This is less than 3 amperes from the trolley line. In practice, however, the speed will be rapidly but gradually accelerated until we have 125 volts upon the terminals of the propelling motors. We will now be running at one-quarter speed and will be consuming 125 volts and 50 amperes, that is, $6\frac{1}{4}$ K. W. instead of 25 K. W. to get the same result with existing motors. To put it another way, we will not be using as much energy as is represented by the 500 volts and 15 amperes necessary for full speed on a level.

The next step on the controlling switch will disconnect the armatures of the propelling motors from the auxiliary generator and put the two armatures in series across the trolley line direct. We will now go at a speed represented by 250 volts, that is, one-half full speed. The next step of our switch will place the two armatures in multiple across the 500 volts, and the next and last step will place the 120 volt auxiliary generator in series with the main central station generators and give us 625 volts on our armatures and a correspondingly increased speed. We will be able to go up a grade of six to eight per cent. at full speed, with 50 amperes and 500 volts, which, with the present motors, gives us only about one-quarter of that speed.

Under this arrangement it will be noticed that the only apparatus which could be called additional is the small motor of 500 volts for the generator part of our motor generator, which is useful not only for starting, but for full speed also. In stopping the car we have an electric brake action delivering back energy to the line at full efficiency and not through a rheostat, as at present.

If we have a train of, say, three cars, so that we have six motors, we can start from rest with sufficient smoothness by placing all six armatures in series, which will give us something less than one-sixth speed as the first step. Then we can place three in series with two multiples, which gives us one-third speed. Next, two in series with three multiples, which gives us one-half speed; and finally all in multiple, which gives us full speed. Under such conditions, we can dispense with the small converting plant altogether.

For an elevator requiring, say, 15 h. p. we will put in a motor generator of 3 h. p., with which we will control the starting and stopping and the operation up to one-fifth of full speed. Then for full speed we will connect direct to the line and operate without any conversion of energy.

For power in which smoothness of motion in starting and stopping is not essential I have devised a new system of distribution as follows: Three dynamos, all having the same current capacity and having voltages of 62½, 125 and 250 respectively, are placed in series and from conductors led off in multiple one from each terminal of the machines. These conductors will have potentials which can be represented by 0, 62½ 187½ and 437½. Let us now take a shunt-wound motor, and, disconnecting the field from the armature circuit, excite the field from the outside two of the four conductors, that is, by an E. M. F. of 437½ volts. By connecting the armature terminals to the four conductors in various ways we shall be able to operate in either direction at six different automatic speeds represented by the following voltages: 62½, 125, 187½, 250, 275, 437½. By varying the field strength of the motor we can, if required, get any intermediate speed.

In many cases two dynamos will answer, one of, say, 110 volts already in use for incandescent lighting, and a second of, say, 30 volts. With this arrangement we could run in either direction and with automatic speeds represented by 30, 110 and 140.

With the four-wire six-voltage system of distribution in a shop we can take out all countershafting, belting, pulleys and gears, if desired, and place a motor upon every tool, which we can operate in either direction at any automatic speed desired. Lathes, planers and all tools can be perfectly operated, and by getting rid of all countershafts and belts we can introduce the greatest of modern tools, the traveling crane, which we will also operate from our general system. We can also readily operate ventilating fans, hoists, elevators and factory tramways from the system.

The addition of one dynamo and one new conductor to any existing three-wire system will probably give all the flexibility required to meet practical conditions of varying speeds. For the alternating system a synchronous motor driving our three continuous-current generators will give us the four-wire system in any distant factory or town. For 500-volt street railway circuits a small motor generator plant for the slow speeds and a direct connection for full speeds will give us perfect results. For storage battery work we have the most perfect condition, as we can get any E. M. F. desired, with a corresponding speed, while keeping the field separately excited.

Now, that we have the rotary field at command, I think I may safely assert that the time is not far distant when we shall have transformers which will, without motion, convert an alternating current in the primary into a continuous in the secondary; and this seems to me to be the ideal system of the future, that is, one in which energy will be transmitted by alternating currents of constant E. M. F. transformed without motion into continuous currents for use at the translating devices and used where motors are concerned, in conformity with the law of efficiency for motors: Vary the voltage as the speed desired; vary the amperes as the torque required.

AN AMERICAN PLANT IN MADRID.

An exhaustive account of the installation of the electric light plant in Equitable Life Assurance Company's Building in Madrid has been written and published in pamphlet form by Don Francisco Rojas y Rubio. Detailed descriptions are given of the engines, dynamos, switchboards, measuring and testing instruments, etc. Mr. W. T. Wheeler, an old New Yorker, who had charge of the fine U. S. plant in the Equitable Building in this city, and has installed other plants for the Equitable Assurance Co., has had charge of this important piece of foreign work.

FIRE HAZARDS FROM ELECTRICITY.[1]—II.

(*Concluded.*)

BY C. J. H. WOODBURY.

As the objection to overhead wires is largely based upon their unsightliness, so, on the other hand, the safety of underground wires is far more an assumption than a reality. The maintenance of insulation from the earth with currents of high electromotive force seems to be impracticable, even when the material of the conduit, as well as the covering upon the wires, is of high resistance.

In addition to the grounds on the buried wires, which may be the primary cause of difficulties elsewhere, there have been numerous destructive explosions wherever underground wires have been used. These explosions have been generally, and I believe incorrectly, ascribed to leakage of illuminating gas into the conduits. Even if there was such a leakage, there would not be any arc or undue heating of wires causing an ignition of the gas unless there was a connection to earth, and in such a case the explosions would vary in force and only be severe in case of the coincidence of a certain mixture of gas and air.

As these explosions have always been of a violent nature, we must look elsewhere for a cause which will always produce a high detonation; and this is accounted for by the presence of water in the conduit. Water being readily dissociated by electrolysis into a highly explosive mixture, an explosion would occur whenever the supply of water diminished sufficiently to produce an arc.

It is, however, undoubtedly true that gases from sewage as well as illuminating gas penetrate into conduits, and the lead covering on the insulation of wires in conduits is in some instances actively attacked from such causes.

In one city, where there are numerous underground telephone wires of this class, the corrosion of the lead covering was stopped by forcing sulphureted hydrogen gas into the conduits, forming a sulphate of lead on the outside of the coating. Some of the gas escaped, causing loud calls summoning the local Board of Health for gross dereliction of duty, but all complaints were appeased by the gentle hand of time, which wafted the unwelcome perfume away.

It should not be forgotten that the network of wires over the cities has been of great service in robbing the lightning of its dangers, more largely by induction than by dividing the charge and conducting it to earth. It is a fact that injurious effects from lightning in cities have been diminished of late years, and notwithstanding the density of occupation by buildings, they are far less than in the country.

In the present state of the art overhead wires must be recognized as necessary for the maintenance of electrical service. The few instances where they are put underground are in accordance with peculiar conditions and scarcely numerous enough to be considered as an exception to prove the rule.

Wires should be carried well above buildings and attached to fixtures rather than directly to the buildings themselves, being placed high enough not to interfere with firemen or others passing over the roofs. They should also be clear of other wires and protected with dead guard wires whenever there is any possibility that they may fall and come in contact with other wires.

The question of the insulation of such outside wires is far from being a settled one to the extent of actual practice. The greater part of the insulating material on these wires has become so deteriorated as to present but little electrical resistance, and it is necessary to place wires in such a way that the reliance will be upon the freedom from contact with other conductors rather than upon the insulation itself.

An insulating material upon outside wires should be waterproof and also able to resist the severe and almost continuous abrasion liable to come upon them, and where these wires enter buildings they should be bent in what is termed a water loop, so that the immediate approach to the building shall be upwards. They should also be provided with a double-pole switch capable of being operated from the outside, entirely cutting off all electrical connection from the inside of the building when so desired.

Whenever outside underground service is in use, still greater precautions are necessary at the entrance of the building. It is essential that there should not be any free opening from the cellar of the building to the conduit, and that the insulation of the wires should be maintained at this point and up to some suitable location where a double-pole switch can be placed.

The greatest danger from wires outside of buildings is that due to contact with other electrical wires, imposing upon them currents of greater volume than they can withstand, and heating the various parts to such an extent that the injury is not limited to the mere fusion of the coils of such apparatus, but the surrounding combustible material is ignited.

On account of the various widely differing characteristics of these foreign currents, there has not as yet been found any single device which will protect them against injury. These elements of defence have been carried to great perfection by the telephone companies.

The form of apparatus is fourfold in its nature;—first the ordi-

1. A lecture delivered at Cornell University, Nov. 6, 1891.

nary serrated lightning arrester, which is generally able to protect the system by reason of the extent to which the lightning is divided by the numerous wires in its course, and, as has been mentioned before, this lightning is very often inductive in its nature rather than a direct stroke.

Second, the telephones are protected against currents originating from incandescent lighting or power circuits by means of pieces of easily fusible wire about four inches in length inserted in the line of the telephone system. These wires are enclosed in glass tubes, not merely to protect them from injury, but also to prevent any damage being caused by the hot metal of the fuse igniting anything when it is thrown about by the explosive violence which occurs whenever a heavy current melts it.

A similar device consists of a strip of tinfoil rolled up with asbestos paper and forming a part of the circuit, the tinfoil being instantly vaporized by an abnormal current.

Third, for protection against the currents proceeding from arc lighting apparatus and those used for the transmission of power, particularly the overhead trolley system, the most efficient means has been the air cut-out, consisting of two pieces of gas carbon separated a very short distance by means of a thin film of mica containing perforations. One of these pieces of carbon is connected to the earth and the other forms a part of the circuit. Whenever a current on a grounded circuit, having a tension of 350 volts, passes along the telephone circuit, it leaps the narrow space separating the two carbons, and, forming a very short arc, continues to the ground. Small bits of easily fusible metal are inserted in holes in the carbon, and, if the current is maintained for any particular length of time, the metal becomes melted and establishes a conductor of low resistance to the earth. A film cut-out can be used for the same purpose, but in this case is not quite so suitable because of the necessity of readjustment in every case where it is called into operation.

Third, another class of accidents are those arising from a cause more difficult to manage, and that is what are known as sneak currents, being generally foreign currents connected with the system by something serving as a shunt of high resistance, so that the current is very small, but yet enough to injure the electro-magnets and also to cause fire when they are maintained for a long time; for it should be remembered that the insulating material upon the wires used in electrical apparatus is also a non-conductor of heat, and it is not possible for them to safely conduct as great currents, as if they were not covered with insulation and were exposed to the air, allowing the heat to pass off by radiation instead of becoming cumulative.

The only form of apparatus which has thus far controlled these sneak currents is simply a ball, principally composed of wax, and about half an inch in diameter, held against the electromagnet by a strip of spring metal. Whenever the electromagnet becomes warm this ball softens, and the movement of the spring operates a switch which shunts the telephonic apparatus out of circuit.

There have been a great many devices invented for the purpose of protecting telephonic circuits, but many of them involve the introduction of electromagnets in the circuit,—a measure which would interfere very much with the service on account of the impedance given to the undulating currents to an extent that would diminish the clearness of the transmission of speech by the telephone. They are frequently of such large dimensions that it would not be practical to apply them to the switchboard of any extensive central station. Moreover it is found by experiment that these devices do not control the whole range of foreign currents liable to be met with at any instant in the telephone service.

The method which has been described, however, furnishes the most satisfactory results in actual service, being the outcome of investigations of electricians connected with the telephone companies,—corporations whose interests are far greater than those of any individual, for it should be remembered that the telephone companies own all the apparatus.

The installation of conductors for arc lighting circuits inside of buildings should be made with the utmost care. The use of the high electromotive force for arc lighting imposes conditions of insulation far more severe than those of incandescent lighting. Not only should the wires be covered with an insulation which is waterproof, if there is the least danger of water or dampness reaching the wires, but wires of opposite polarity should be separated at least a foot apart.

The specifications for insulation usually require that it will not fray by friction and will stand a temperature of 150 degrees without softening, and to this should be added that the insulation shall withstand as low a temperature as it will ever be exposed to without cracking.

Whenever wires are run in places liable to dampness, reliance should not be placed on the insulation alone, but the wires should be fastened to glass or porcelain insulators, and wherever wires pass through floors, walls, or partitions, they should be further protected by insulating tubing projecting on both sides. The lightning arresters should be grounded outside of the building, and preferably connected to a water pipe.

Inside wiring on incandescent work also requires especial care. All parties are agreed that no wires smaller than No. 18 Birmingham wire gauge or No. 16 Brown & Sharpe should be used. These have a nominal capacity of conducting five amperes of current, but the limitation of size of wires depends on their position, as the resistance is converted into heat, and exposed wire will safely carry a greater current than when confined behind mouldings or in tubes, the ordinary ratio of practice being one and two-thirds.

No doubt some of the mishaps attending the use of underground wires have been due to the heat of the wires evaporating volatile matters in the insulating material. On shipboard, wires should be tinned before the insulation is applied, in order to prevent any tendency to corrosion. Whenever wires are laid in moulding, there should be a strip at the back in order to prevent the wire from lying against the wall.

Imbedding of wires in plaster is not generally endorsed; but improvements in insulation will render this more permissible, although in any case such wires are subject to interference caused by contraction and settlement of buildings, and furthermore they cannot be arranged to provide for additions and alterations to an electric plant installed in a building.

Dr. A. F. Mason recently informed me of a contract to install 48½ miles of electric lighting wire in a building under a contract guaranteeing the wires to resist cement, lime, and salts found in the materials used in the construction of fireproof buildings, and to sustain an insulation of 1,000,000 ohms for one year.

The usual methods of conducting electrical wires, to which reference has been made, are confessedly of more or less temporary character, and wholly inconsistent with the well-established position of electrical illumination in its practical applications, and such methods of installation are necessarily more or less obtrusive in the manner of their construction, interfering with methods of decoration.

Wires have sometimes been concealed in insulating tubing known as interior conduits. These tubes are placed out of sight in a building, comparable in arrangement to a system of gas pipes. The wires are run through these tubes by inserting a stiff steel tape with a knob at the end, which is easily pushed through any portion of the tubing. Afterwards a line is drawn through, and then in turn the electric wires. These wires can be inserted or withdrawn without disturbance to the system. Such tubes, when made of incombustible waterproof material which is a non-conductor of electricity, can safely be installed in the manner indicated, and serve a very useful purpose in widening the field of applications for electric lighting.

Fuses should be double-pole mounted on incombustible bases, and should be used whenever the diameter of the conductors changes.

Each cut-out should interrupt the passage of the current in excess of the amount to which any portion of the apparatus which it protects is adequate to transmit, and the strip of fusible metal should be marked with the current which it will transmit.

There should not be any joints or fuses or switches in rooms containing inflammable vapors or highly combustible material fine enough to float in air.

Arc lamps should be provided with globes with tight stands, so that sparks from the carbons shall not reach combustible materials. They should also be provided with some stop which will render every assurance that the lower carbon will not fall in case the usual clamp should not secure it. In addition to the hand-switch they should also have an automatic switch which will shunt the current around the carbons if they should fail to feed properly.

Incandescent lamps are not usually a source of hazard in themselves as directly causing a fire; yet there are some precautions to be observed, the most important being the prohibition of wrapping the lamp in paper or other material which would retain the heat, because it is possible to ignite easily combustible material in that manner. It is considered that a very serious fire once resulted from this cause.

In damp places the sockets should be rendered waterproof, and wherever there are inflammable vapors the lamps should be protected by glass receivers. When incandescent lamps are attached to gas fixtures, an insulating coupling should be inserted in the gas pipe.

In lighting vessels, when it is necessary to have lights near the compasses, the effect of the electric current on the compass should be carefully considered, and whenever an electric wire approaches within six feet of a compass, a wire of opposite polarity should be run parallel to it. I do not feel sure that this distance of six feet should be regarded as the minimum to which this rule should apply, and trust that the matter will receive careful investigation, on account of the importance of any question pertaining to the adjustment of compasses.

In the presence of inflammable vapors there should not be any hand switches; and as a general rule, wherever the conditions of illumination from a number of incandescent lamps are uniform, it is frequently desirable to use a main switch to throw them in or out, although the varying conditions of load or current on the dynamo are such that it is not recommended that over fifty lights should be so connected with any one switch unless the conditions of the case are thoroughly understood and agreed upon. All switches used in the conductors of electric lighting installations, apart from those at the lamps, should be double pole, and should be mounted on incombustible bases with an indicator showing whether the switch is open or shut.

Every electric lighting plant should be provided with instruments of precision for measuring the output of the dynamo. These instruments should be placed on the switchboard in a position where they will not be affected by magnetism from the dynamo.

The conditions of the operation of electric plants generally do not admit of the use of ordinary methods of measuring the resistance of the insulation between the earth and the system, and the magneto is used as a feasible method of indicating to some extent the presence of any ground of low resistance. Although this instrument has been severely criticised, yet it fills a useful purpose within the proper limits of its service. It is portable, can be used by any one, and the indications can be relied upon within the limits of the instrument. It is far more delicate than the galvonometer of 10 or 20 ohms resistance used in connection with two or three cells of a battery.

A magneto may not always be suited for use on extensive incandescent installations, because the static charge of the circuits is sometimes sufficient to ring the bell. A convenient method of indicating grounds of low resistance is by means of incandescent lamps placed on a conductor between the earth and the system, but such lamps should be connected with a spring switch in order that the ground may not be a permanent one.

The use of electric lighting and power apparatus is so firmly established as to render it undoubtedly one of the most permanent of appliances in use, and the time is past when temporary and makeshift methods can be tolerated.

There is a tendency towards the increased use of currents of higher electromotive force, wherever it is feasible to reach an economy of copper wire by such methods.

This tendency received a setback a few years ago by the failure of experiments attempted in France, involving the use of currents of electromotive force of six thousand volts. As late as three years ago, at a meeting of the National Electric Light Association, one of the members expressed the opinion that in the immediate future currents of as high as ten thousand volts electromotive force would be distributed. So deep was the feeling that the speaker was in error, indignation was expressed that such an opinion should be held by any one engaged in a discussion before that organization, and the president left the chair to engage in the debate and to place the seal of condemnation upon such radical ideas. It was only two years later that currents of ten thousand volts electromotive force were actually used in some cities.

The status of the uses of electricity for illumination and power is so well established upon a practical basis, as regards the service to be expected and the character of the attendance required, that there is but little of a tentative or experimental nature in such work, and there is therefore no excuse for the continuance of many of the temporary methods of installation which have been in such general use.

One of the pernicious results liable to occur as a consequence of such methods of installation is the depreciation of such apparatus—from which I apprehend that difficulties may arise in the future.

Because there is much that is strange, wonderful, and unprecedented in these applications of electricity, there has been a tendency on the part of the general public to expect too much from them, both by way of advantage and of mishap. In case of fire, the press frequently ascribe the results to electrical wires purely on presumption without any evidence to establish the fact. Furthermore, in many instances such allegations are made when the known facts or weight of presumptive evidence indicate a contrary cause. It has been fully established by the experience of the past twelve years that a well-installed electric lighting plant is the safest method of illumination.

Society and Club Notes.

OHIO TRAMWAY ASSOCIATION.

THE OHIO TRAMWAY ASSOCIATION held its annual meeting at Akron, O., on Nov. 11, and then enjoyed a banquet at the Hotel Buchtel. Thirty-five roads were represented by about fifty delegates. The officers of last year were re-elected as follows: John N. Stewart, of Cleveland, president; John Harris, of Cincinnati, vice-president; J. B. Hanna, of Cleveland, secretary and treasurer, and E. A. Stewart, chairman of the executive committee. A pleasant incident of the convention was the presentation of a handsome cane to J. A. Hanna, secretary and treasurer of the association, for efficient services rendered; and the gift of a like present to Vice-President John Harris, the oldest member of the association. The next annual convention will be held at Zanesville.

THE NEW YORK ELECTRICAL SOCIETY.

AT the invitation of Superintendent J. Elliot Smith, of the New York fire telegraph system, the society met at the Fire Headquarters, in East 67th street, on Thursday evening, Nov. 19. After a few introductory remarks, the president, Prof. Francis B. Crocker, introduced Mr. Smith, who outlined in brief the work accomplished by his department and then proceeded to explain the workings of the new apparatus with which the department has recently been equipped. Formerly the signals from the box were received at the central office and then transmitted to the fire companies by transmitters, which required the insertion of a toothed wheel corresponding to the box number from which the signal was sent. In order to gain time in the transmission of the box number, the following improvement was introduced. The signal box repeats its number five times. The first round is received at the central office only; but as soon as this is finished the attendant in charge throws a switch so that the remaining four rounds are relayed directly into the circuits connected to the fire houses; in this manner saving the time required to select and insert the numbered wheel in the automatic repeater formerly in use. In order to insure absolute accuracy, however, the signals are again transmitted in two rounds by the old repeaters.

After explaining the apparatus, Mr. Smith gave a demonstration of the speed at which the men answer the calls, and for that purpose pulled a signal box at a distance of about 1,000 feet from headquarters, where a fire company is situated. The company was on the ground and the hose connected 70 seconds from the time the alarm was sent in. Another interesting feature of the evening was an exhibition by the life saving corps, who manœuvred an extension ladder and showed how it could be readily applied to the rescue of persons imprisoned in the upper stories of burning buildings. The evening was one of the most pleasant which has yet been arranged by the secretary, Mr. Geo. H. Guy, whose intelligent work is bringing constant accessions to the ranks of the society.

PITTSBURGH ELECTRIC CLUB.

THE Electric Club met last week at the office of the Ft. Wayne Electric Company, on Wood street, president Morris Mead presiding. The constitution reported by the committee appointed to frame it was adopted. It was also reported that a suitable clubhouse on Penn avenue could be secured, and a committee was appointed to secure a lease of the property and also to furnish it. The building is a commodious one and will be adapted to social enjoyment. There will also be a large assembly-room, where lectures on scientific subjects will be given.

There are fifty applications for membership pending, and the club, now that the constitution has been agreed on, is expected to advance rapidly.

Reports of Companies.

THE WEST END COMPANY'S ANNUAL MEETING.

THE WEST END STREET RAILWAY COMPANY, of Boston, held its annual meeting Thursday, November 12. The principal business transacted was the election of 15 directors and the presentation of the annual report.

President Henry M. Whitney reiterated his belief in the advantage of electricity as a motive power, and stated that the sum paid out on account of accidents last year was smaller than the amount the year before, the claims for September, 1890, being 61, while for the same month this year there were but 44. He believed from what he had seen that the number of accidents by the electric cars will be proportionately less than by the horse cars. He advised increasing the capital stock and paying off the floating debts, of which nothing now remains but some long-time notes held by the savings banks, amounting to about $1,000,000.

The company introduced a large number of long cars during the year, and is now thoroughly convinced that the cost of running them is about the same as that for the short cars, while the increased earning capacity, as well as the increased accommodation to the public, is considerably greater. The increase in the earnings during the past year has been mainly in the places where the electric system is in operation. The company intends to change its entire system to electric traction as rapidly as possible. By the 1st of January 175 more long cars which have been ordered are expected to be added to the electric system.

During the past year the cars of the company have made 2,328,274 round trips, covering 17,462,572 miles, and carrying 119,264,401 passengers. The passenger receipts were $5,889,179.98, making the average receipt per passenger 4.94 cents.

The directors elected were: G. T. W. Braman, Isaac T. Barr, T. Jefferson Coolidge, Joseph S. Fay, Jr., Eustace C. Fitz, Henry B. Hyde, Walter Hunnewell, E. D. Jordan, Samuel Little, William Powell Mason, Theophilus Parsons, Dexter N. Richards, Nathaniel Thayer, Walter S. Swan, Henry M. Whitney.

Letters to the Editor.

ERRORS IN URQUHART'S "DYNAMO CONSTRUCTION."

DOUBTLESS Urquhart's "Dynamo Construction" will be extensively used by that large class interested in electrical work and not prepared to make their own methods of designing. Chap. XII. furnishes the first readily accessible, concise, practical guide for those who desire not simply to build a dynamo from specific directions, but to design a dynamo for any required use. It is unfortunate that there are several errors in this chapter. The following eight or ten corrections may be valuable to some who wish to make practical use of the matter:

(1) Near the bottom of page 192, R_m is here, and on page 193, the electrical resistance of the series field coil; and not the reluctance of the magnetic circuit, as on pages 190, 191.

(2) Page 193, $(R_s \times R_m)$ should be $(R_s + R_m)$.

(3) Page 193, $= 330\ P_w :: 100 : X_s$ should be

$$\therefore 7100\ P_w : 330\ P_w :: 100 : X_s$$

(4) and (5), page 194, 10^6 should be 10^{-6}, in two places.

(6) Page 194, 106 should be 10^{-6}.

(7) Page 194, 50 should be 500.

(8) Page 199, $C_s = 1.3$ ampere should be above the equation that precedes it.

I. THORNTON OSMOND.

Pennsylvania State College, Nov. 13, 1891.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED NOVEMBER 10, 1891.

Accumulators:—

Secondary Battery, N. H. Edgerton, 462,698. Filed Jan. 14, 1891.
A containing cell or jar, filled with an electrolytic fluid, contains a battery of electrodes arranged in sets of three each: each electrode is contained within and insulated from a metallic cell filled with active material; the central electrode in each set is of different polarity from the other two.

Alarms and Signals:—

Police Signal Telegraph System, C. A. Rolfe, 462,741. Filed Mar. 9, 1891.

Call-Box, E. R. Wilder, 462,785. Filed Dec. 17, 1890.
For district telegraph service.

Fire-Alarm Box, E. R. Wilder, 462,786. Filed Jan. 2, 1891.
A non-interference box.

Police-Signal System, N. B. Cregier, 462,808. Filed Nov. 26, 1889.
Adapted for the transmission of two or more signals simultaneously from different boxes to the central station.

Signaling Device for Elevators, C. G. Armstrong, 462,834. Filed Jan. 17, 1891.

Electrical Indicator for Elevators, C. G. Armstrong, 462,835. Filed Mar. 10, 1891.

Electrical Annunciator, J. B. Smith, 463,001. Filed Aug. 21, 1889.

Conductors, Conduits and Insulators:—

Electric Conductor, J. A. Barrett, 462,681. Filed Jan. 8, 1891.
The conductor is covered with a fibrous or meshed air-containing serving which is surrounded by a sized envelope, which in turn is covered with a sealing material. The sizing consists of either a mucilagenous, gelatinous or albuminous compound.

Electric Conductor, C. T. Snedekor, 463,079. Filed May 8, 1891.
Has a rubber covering, an adhesive substance upon the rubber covering, a powdered refractory material over the adhesive substance and a tape saturated with a silicate, and a suitable finish over the tape.

Electric Conductor, F. E. Degenhardt, 463,107. Filed Sept. 1, 1890.
Conducting wire is constructed with a strip having alternate elevations and depressions surrounding the wire and forming receptacles for the retention of air or gas.

Dynamos and Motors:—

Commutator, S. H. Short, 462,880. Filed May 26, 1891.

Armature for Dynamo Electric Generators, S. H. Short, 462,881. Filed June 12, 1891.
Consists of a laminated core of ribbon wound upon itself, bobbins wound around the core, and blocks of non-magnetic material secured between the bobbins and forming open-air spaces between the blocks, and also ensuring open-air spaces between the sides of the bobbins.

Armature for Dynamo Electric Machines, S. H. Short, 462,882. Filed June 19, 1891.
Comprises a laminated core slotted at its opposite edges, forming teeth, bobbins wound between the teeth, and flat magnetic rings secured to the sides of the armature outside of the bobbins.

Brush Holder for Dynamo Electric Machines, S. H. Short, 462,883. Filed July 6, 1891.

Brush Holder for Dynamo Electric Machines, E. Thomson, 462,973. Filed Feb. 20, 1891.

Steam Dynamo Electric Machine, F. M. Garland, 463,121. Filed. Feb. 4, 1891.
A design and construction adapted for mounting an engine and direct-driven dynamo upon the same base.

Lamps and Appurtenances:—

Electric Arc Lamp, J. E. Giles, 462,698. Filed Jan. 29, 1891.
Relates to an arc lamp cut-out.

Carbon Holder for Arc Lamps, J. J. Wood, 462,756. Filed Dec. 10, 1890.

Electric Arc Lamp, J. E. Gaston, 463,065. Filed Jan. 15, 1891.
Adapted to a head-light for locomotives.

Medical and Surgical:—

Electric Belt, P. E. Petterson, 462,732. Filed Mar. 11, 1891.

Miscellaneous:—

Phonograph, W. Bruening, 462,687. Filed Jan. 14, 1891.

Process of Purifying Tannin Solutions by Electrolysis, A. Foelsing, 462,694. Filed Apr. 23, 1891.

Telegraph Table, K. V. Miller, 462,720. Filed Sept. 23, 1890.
For support of telegraph instruments; an operating table.

Method of Producing Rainfall, L. Gathmann, 462,795. Filed July 16, 1891.
Inventor contemplates employing an electric circuit to fire off his balloons.

Mechanical Cut-Out, H. W. Burnet, 462,836. Filed Apr. 7, 1891.

Electric Safety Cut-Out Device, A. G. Waterhouse, 463,086. Filed June 24, 1891.

Railways and Appliances:—

Electric Railway System, H. C. Camp, 462,688. Filed June 30, 1890.
A conduit system. Relates to the construction of the conduit and of contact devices.

Device for Removing Ice from Overhead Wires, G. Hipwood, 462,707. Filed Aug. 24, 1891.

Electric Railway Motor, C. J. Van Depoele, 462,761. Filed Dec. 20, 1890.
Combines with the driving axle and wheels an armature fixed upon and carried by the axle, a circular field-magnet surrounding the armature and also carried by the axle and journaled thereon; has means, carried by the armature, for shifting the polarity of the field.

Electric Car Brake, J. D. Collier and J. K. P. Miller, 462,793. Filed Feb. 4, 1891.
Relates especially to methods of connecting electrical conductors between cars.

Electrical Connection and Signal for Railway Cars, J. D. Collier and J. K. P. Miller, 462,794. Filed Mar. 25, 1891.

Electric Car Coupling, J. D. Collier and J. K. P. Miller, 462,807. Filed Feb. 18, 1891.

Life Guard for Railway Motors, H. E. Harris, 462,814. Filed June 27, 1891.

Electric Circuit Closing and Breaking Device for Railway Tracks, T. H. Patenall, 462,850. Filed Feb. 20, 1891.

Heating and Lighting System, R. M. Hunter, 462,926. Filed Jan. 12, 1887.
Relates to heating and lighting railway cars.

Electric Railway System, G. T. Woods, 463,020. Filed Aug. 31, 1891.
Relates to distribution, and comprises a group of electromagnetically controlled contacts outside of the road-bed and accessible, each contact being electrically connected with one exposed terminal head in the road-bed.

Reversible Electric Trolley, J. W. Bates and C. E. Blake, 463,024. Filed Dec. 22, 1890.

Station Indicator, J. M. Nelson, 463,072. Filed May 14, 1891.

Telegraphs:—

Duplex and Quadruplex Telegraphy, F. W. Jones, 462,901. Filed Nov. 11, 1885.
Claim 1 follows:
In a duplex or quadruplex telegraph apparatus, the combination, with the device for preventing mutilation of signals received on the neutral relay at the instant of reversal, of an induction apparatus whose secondary is connected with such devices, while its primary consists of two coils, one in the main and the other in the artificial line.

Telephones and Apparatus:—

Signal Device for Telephone Pay Stations, W. Gray, 462,813. Filed Dec. 15, 1890.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED NOV. 17, 1891.

Alarms and Signals:—

Thermo Circuit Closer for Electric Fire-Alarms, J. Wrigley and G. P. Chambers, 463,298. Filed June 26, 1891.

Fire-Alarm Telegraph Repeater, G. M. Stevens, 463,340. Filed April 30, 1891.

Base Ball Indicator, J. L. Cutler, 463,491. Filed Feb. 24, 1891.

Fire-Alarm, A. Bichet and R. W. Whitney, 463,570. Filed Feb. 19, 1891.
Employs the action of water upon a turbine wheel for actuating the alarm.

Automatic Fire-Alarm System, G. W. Brown, 463,608. Filed Aug. 21, 1891.
Designed to prevent the sounding of false alarms.

Conductors, Conduits and Insulators:—

Insulator Support, T. C. Smith, 463,172. Filed Feb. 12, 1890.

Electrical Conduit, J. C. Love, 463,197. Filed Feb. 10, 1891.
Relates to the construction of the conduit and the support of conductors therein.

Machine for Covering Wire, M. D. Liddell, 463,389. Filed Nov. 3, 1890.

Coupling for Electric Wires, F. X. Gartland, 463,420. Filed July 16, 1891.

Electrical Conductor, P. H. Holmes, 463,512. Filed June 2, 1891.
A material adapted for use as a pencil for arc lights, commutator brushes, etc. Composed of plumbago united by a drying oil as a binder.

Insulator Bracket, V. A. Thomas, 463,587. Filed May 21, 1891.

Insulator Bracket, V. A. Thomas, 463,588. Filed May 21, 1891.

Dynamos and Motors:—

Armatures for Dynamos or Electric Motors, B. D. Southard, 463,174. Filed March 2, 1891.
A ring armature. Has a series of separable longitudinal sections, a series of coils wound upon such sections and wound parallel to the axis; has portions rigid with the sections projecting outside of the coils and adapted to maintain them in place against centrifugal force.

Electromagnetic Switch, C. H. Herrick, 463,192. Filed Oct. 20, 1890.
Adapted especially for use with shunt-wound motors. Operates to break the continuity of the circuit whenever the current is accidentally interrupted, and thus prevents a sudden inrush of current to the motor when the interruption has ceased.

Dynamo Electric Machine, M. C. Bert, 463,242. Filed Jan. 21, 1891.
Relates to the design and construction of the frame, and also to devices for cooling the armature.

Alternating or Pulsating Current Motor, L. Gutmann, 463,314. Filed April 7, 1890.
Adapted for working from a single exciting source. In addition to the usual field magnet coils, has a secondary set of field-magnet coils placed at an angle to the former and an armature enclosed by both sets of field coils and provided with one or more closed windings, each containing an odd number of closed circuits.

Electric Blower or Fan, W. B. Snow, 463,585. Filed April 7, 1891.

Circuit and Switch for Electric Motors, W. Lahmeyer, 463,605. Filed March 26, 1891.
Has a secondary armature on the same shaft with the main armature and means for switching the driving current through both the armature coils and the field coil, and to switch the driving current through the main armature coils and the current from the secondary armature coils through the coils of the field magnet.

Galvanic and Thermo-Electric Batteries:—

Galvanic Battery, W. A. Crowdus, 463,247. Filed Nov. 21, 1890.
An overflow receptacle is provided to receive the excess of liquid as it increases in volume.

Galvanic Battery, W. A. Crowdus, 463,248. Filed Jan. 24, 1891.
Relates to the construction of the porous cell and to the destruction of the fumes given off by a battery.

Lamps and Appurtenances:—

Electric Arc Lamp, W. Jandus, 463,154. Filed Dec. 4, 1886.
Intended to retard the waste or consumption of the electrodes.
Claim 1 follows:
In an arc lamp, an arc-inclosing chamber hermetically closed at all points excepting at its lower end.

Cut-Out, H. Lemp, 463,218. Filed June 21, 1887.

Mast Arm for Electric Lights, V. A. Thomas, 463,586. Filed Oct. 6, 1890.

Duplex Arc Lamp, E. P. Clark, 463,595. Filed Feb. 16, 1891.
Claim 3 follows:
In an electric arc lamp having a plurality of pairs of carbons and separate regulating mechanism therefor, an automatic switch for controlling the circuits, and an independent electromagnet located in the circuit of one pair of carbons and having its armature connected with the switch.

Measurement:—

Apparatus for Measuring and Recording Electric Currents, W. Thomson, 463,558. Filed Feb. 18, 1891.
An electromagnetic meter employing a recorder actuated by clockwork or by an electric motor.

Metallurgical:—

Ore Separator, W. D. Hoffman, 463,305. Filed July 15, 1891.

Metal Working:

Process of Welding Metals Electrically, C. L. Coffin, 463,486. Filed June 9, 1890.
Consists in first separately subjecting the articles to be welded to the action of a heating current and the voltaic arc, then pressing the articles together to form the weld.

Electric Welding or Working of Metals, C. L. Coffin, 463,487. Filed Mar. 4, 1891.
Similar to the next above.

Miscellaneous:—

Electric Lock, W. J. O. Johnson, 462,155. Filed Feb. 25, 1891.

Shoe Blacking Machine, F. G. Norton, 463,164. Filed May 5, 1890.

Electric Stop Mechanism, L. Mellett, 463,198. Filed March 21, 1890.
For instantaneously cutting off the steam from an engine.

Electric Lock, F. H. Starrett, 463,297. Filed Nov. 3, 1890.

Electric Switch, E. J. Bagnall, 463,311. Filed Aug. 3, 1891.
Adapted for use on high-potential circuits. Includes a safety fuse.

Electric Cigar-Lighting Apparatus, W. W. Foster, 463,384. Filed Aug. 14, 1881.

Electrical Switch, A. Swan, 463,396. Filed May 7, 1891.
A quick-acting switch.

Railways and Appliances:—

Ice Breaker and Electric Current Trnnsmitter, O. Smith, 463,257. Filed Jan. 31, 1891.
For clearing ice, snow, etc., from electric railway tracks and for making electrical contact with the rails.

Crossing for Electric Railway Conductors, W. J. Silver, 463,310. Filed Feb. 12, 1891.

Power Storing Mechanism for Electric Locomotives, J. A. Hockett, 463,315. Filed Oct. 22, 1890.
A clutch-and-spring device adapted to graduate the power of the motor when applied to the wheels.

Electric Locomotive, S. H. Short, 463,356. Filed April 8, 1891.
Employs beveled gears and flexible connections between each end of the motor shaft and the shaft of the beveled gearing.

Motor Cars for Electric Railways, T. E. Adams, 463,359. Filed May 28, 1890.
Consists of glazed sight openings or windows, enabling the driver of the car to keep the trolly line in view for some distance ahead.

Electrical Train Signal, J. B. Strauss, 463,395. Filed July 20, 1891.

Telegraphs:

Telegraph Sounder, J. Maret, 463,428. Filed Feb, 3, 1891.

Telephones and Apparatus:

Telephony, J. W. Gibboney, 462,188. Filed July 28, 1891.
Claim 1 follows:
The method of telephoning, consisting in making a record of the sound waves, causing such record to produce slower electric waves, impulses, or undulations of current of corresponding shape or character, transmitting such slow electric waves or undulations of current over an electric circuit, and recording such waves at the receiving end of the circuit.

Telephonic Relay, E. E. Weaver, 463,207. Filed Feb. 18, 1891.

Multiple Telephone Switchboard, F. A. Pickernell, 463,544. Filed Aug. 17, 1891.
Improvements in the class of multiple switchboards having normally discontinuous branches.

Multiple Switchboard, F. A. Pickernell, 463,545. Filed Aug. 17, 1891.
Further improvements as next above.

Speaking Tube Attachment for Telephones, L. H. Snyder, 463,556. Filed Jan. 28, 1891.

Combined Telegraph and Telephone, E. Berliner, 463,569. Filed June 4, 1877.
For part of the specification and the claims in full see Supplement with THE ELECTRICAL ENGINEER of Nov. 18, No. 185.

THE LIGHTING OF THE WORLD'S FAIR.

EVERY Exposition building in Jackson Park is to be supplied with complete electric light service during the period of the World's Fair. Plans have already been completed for lighting nine of the great buildings, and thus far the scheme contemplates the employment for those buildings of 5,180 arc lamps of 2,000 candle power each, and 14,700 incandescent lamps of 16 candle power each. The following arrangement of lamps had been agreed upon by the Committee on Electricity, the Committee on Grounds and Buildings, and the Chief of Construction: Arc lights—Machinery Hall, 600: Agricultural, 600; Electricity Building, 400; Mines and Mining Building, 400; Transportation Building, 450; Horticultural Hall, 400; Forestry Building, 150; Manufactures Building, 2,000.

The Fine Arts Building will be completely lined with incandescent lamps, and it is estimated that one mile of wall space, on which pictures may be hung, will have to be lighted. The number of lamps agreed upon is 12,000. There are to be no arc lights in this building.

The Woman's Building is to be lighted by both systems. It has been decided to place in it 180 arc lights and 2,700 incandescent lamps. The reception and dressing-rooms will be furnished with the incandescent lamps.

The Administration Building will also be supplied with incandescent lamps. The exact number has not been agreed upon, but an approximate estimate is 10,000.

THE CENTRAL AND SOUTH AMERICAN TELEGRAPH COMPANY.

THE Central and South American Telegraph Company has purchased the Transandine Telegraph Company, having a mileage of 1,200, and connecting Valparaiso with Buenos Ayres. The purchase price is $587,000, and to raise this the capital stock of the Central and South American Company is increased from $6,000,000 to $6,500,000, the balance of purchase price to be paid from the surplus of the company.

The Transandine lines were built in 1872, and the annual reports for the past ten years show its net earnings have amounted to $1,582,682.48 currency, and its dividends to $1,176,000 currency being an average of nearly 17 per cent. on a capital of $700,000 Chilian currency.

The gross traffic of all lines south of Galveston, derived from the east coast of South America by means of the Transandine Telegraph Company, for the three years, 1888, 1889 and 1890, was $885,000 gold. During those years the Central and South American Company divided this traffic with the West Coast Telegraph Company, but now that the former and the Mexican Telegraph Company will own the whole line between Galveston, Tex., and Buenos Ayres, Argentina, it will be in a position through its ownership of this important link to improve its service and thereby command a profitable share of the east coast traffic. Notwithstanding the financial depression in Argentina and recent war in Chili, the present receipts of the company are highly satisfactory, and if maintained will provide the usual dividend on $6,500,000 and yet leave a surplus estimated at over $225,000.

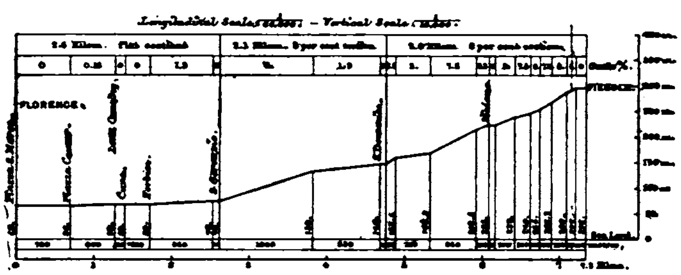
TELEGRAPHERS' MUTUAL BENEFIT ASSOCIATION.

A VERY encouraging report was read by President Merrihew at the 24th annual meeting of this association. It showed that 37 deaths were reported during the year, and a net gain in membership of 147, bringing the total membership to 3,628. The treasurer's report showed the amount received from assessments and fees during the year, $39,445.50, (there were but 11 assessments). The interest from the reserve fund and current deposits during the year amounted to $6,314.28. The sum of $7,373.65 was added to the reserve fund during the year, raising the reserve fund to a total cost value of $107,557.06. It was a very enthusiastic meeting. Steps were taken to insure a proper celebration of the twenty-fifth anniversary, which will take place November, 1892. The president was authorized to appoint a committee of fifteen whose mission it will be to awake enthusiasm throughout the country and incidentally arrange the plans for the next meeting. In this the association expects the co-operation of the telegraph and electrical press.

All the old officers were re-elected, and the meeting was followed by a most enjoyable dinner of the Magnetic Club.

A DESCRIPTION OF THE FLORENCE-FIESOLE RAILWAY.

FIESOLE is situated 800 feet above the town of Florence, of which it is a suburb. The large residential and tourist traffic between the two places has, within the last few years, led to several proposals for carrying a railway up the steep slope to the centre of Fiesole at the summit of the hill. But there were difficulties in the way, for the authorities resolutely set their faces against the employment of steam, and owing to the peculiar nature of the place cables were impracticable. It was not until 1889 that the problem appeared to be solved, and it was then resolved to build an electric railway. The line, which measures 4½ miles between the terminal points, has gradients up to 8 per cent. It is the first continuous steep-grade railway in Europe. The system employed is an improved form of Sprague. The line was constructed and worked by the Chianti and Florentine Hills Railway Co. It was open for traffic under a provisional order in September, 1890, but in consequence of the accident which occurred on the 29th of that month, and by which five passengers were killed, the service on the steep-grade section was, by order of the government authorities, suspended pending an inquiry. This inquiry having conclusively shown that the accident was in no way due to any defect in the permanent way, electric plant, rolling stock or brake power, but solely to the negligence of the brakeman, the line was reopened throughont in the month of April, 1891, and has ever since worked with perfect safety and regularity. The line is laid throughout with steel rails of special Vignoles section, weighing 48 pounds per yard. The cost of the permanent way does not exceed $8.25 per lineal yard. Of the total length of the line, 4½ miles, no less than 52 per cent. is in curves, the sharpest of which chiefly occur on the steep-grade section. The guard rails are used only on curves sharper than 262 feet radius. The electric works are situated at S. Gervaise, 1½ miles from the Florence terminus and three miles from that at Fiesole. Three return flue boilers, supplied by Messrs. Tosi, of Legnano, near Milan, of 80 h. p. each, feed three compound en-



PROFILE OF FLORENCE-FIESOLE RAILWAY.

gines with vertical cylinders working at 225 revolutions per minute; these drive three No. 20 Edison compound dynamos, which at 900 revolutions give 110 amperes at 500 volts each, the dynamos developing 75 effective h. p., or 93 per cent. of the engine power. One dynamo is sufficient for the ordinary winter service as well as for lighting the cars and the works; while on feast days and holidays and in the summer season, when the service is increased, the requisite power is supplied by two dynamos, one engine and one dynamo being always kept in reserve. The circuit is arranged as follows:

An overhead main conductor, consisting of a covered copper wire, is carried on poles placed at a distance of from 6½ to 13 feet from the centre of the line, and 130 feet apart on straight sections, and 80 feet on curves. The contact wire, which is of silicon bronze of one-fifth of an inch in diameter, is suspended over the centre of the line from the brackets fixed on iron poles. The main conductor, which has a resistance of 0.8 ohm per kilometre, transmits the current to the contact wire in sections of about 130 feet, there being, moreover, between S. Gervaise and Fiesole two subsidiary conductors which are connected with the main conductor. No earth plates are used, but the rails are connected by a copper wire fixed to small iron pins. The car seats 24 passengers, and including platform is 20 feet in length. Curves of 45 and even 36 feet radius can be passed with perfect safety, as the width of the wheels, including the flange, and that of the rail-head is 2 inches, while the space between the rail and the guard rail in sharp curves is widened to 2.2 inches. Each car is lighted by 5 incandescent lamps. Each platform is fitted with a regulator disc, a valve handle, a mechanical chain brake, and an electric safety brake, all four being within easy reach of the driver, while the guard on the back platform has to watch the trolley. The whole of the electric plant including car frames and motors was supplied by the Edison General Electric Co., of New York, and mounted by Mr. Sprague's agent. The brakes are possessed of singular power, are quite independent of each other, and can stop the car at top speed in an incredibly short length. Mr. Scheibner, commenting upon the recent accident, gave the following explanation: The accident occurred about 875 yards from the summit. It appears that the driver started with an over-loaded car and at an excessive initial speed, and after having applied the hand brake, he tried in addition to reverse the motors, but instead of doing so put the current on again, thereby accelerating the motion of the car, which, on passing through a polycentric curve of 120, 45 and 60 feet radius on an intermediate incline of 3 per cent., was thrown off the rails against a parapet. The car having covered the distance of 2,400 feet in a little over a minute must have acquired a speed of 30 miles an hour, so that the centrifugal force in the 45-foot curve was equal to 8.32 tons, which, being in excess of the weight of the car, accounts for its being thrown off the point. This sharp curve, which has since been widened, probably averted a greater disaster which might have happened if the car had continued its downward course. The rigidity and solidity of both the rolling stock and permanent way are attested by the fact that, while the superstructure of the car was broken, the frame and motors sustained only trifling damage, and the permanent way was found in perfect condition. The total cost of the line was $120,000, or nearly $30,700 per mile. The working of the line is estimated to cost a little over 14 cents per car mile, but it is said that the cost will be decreased when a proposed extension is carried out. The number of passengers carried per day averages 600 and 2,500 on feast days. The fares charged are about 3 cents per mile. There seems to be no doubt that for a steep grade line, such as the Florence line with a 10 or 20 minute passenger service, electric motive power offers advantages far superior to those of any other system of traction. Considering the ease and elastic motion of the car, its adaptibility to sharp curves, the ease with which it can be run in either direction without being turned and with a total absence of smoke, etc., it may be safely averred that electric traction on the Florence line has been brought to a high state of perfection. I am informed that various economies are being introduced into the working, and the accounts which are to be shortly published will show satisfactory results.

H. S.

GERMAN GAS AND ELECTRIC LIGHT STATISTICS.[1]

BY CLARENCE FELDMANN.

UNDER the title of "How Shall We Build Our Central Stations?" Herr Friedrich Ross, director of the Helios Company of Ehrenfeld, has published a pamphlet written especially for municipal authorities. The author states in the preface that he is a partisan of the alternate-current transformer system, and then gives some details of a few German central stations working with accumulators, from which we extract the following: The central station of Barmen delivered to the mains from the 1st of May, 1890, till the 10th of the same month 1,771,653 watt-hours, the total output of the dynamos being 2,681,970 watt-hours. The charge of the accumulators was 1,759,731 watt-hours, and their discharge 547,356, giving a mean efficiency of 37 per cent. Shortly afterwards the battery had to be reconstructed on account of buckling of the plates. From the 20th to the 28th of September, 1890, the efficiency amounted to 55.8 per cent., the total output of the dynamos being 3,769 kilowatt-hours, and the consumption in the net-work 2,985 kilowatt-hours, the accumulator charge 1,784 kilowatt-hours, and the discharge 996.5 kilowatt hours. Similarly the mean efficiency of the central station of Darmstadt was 38.6 per cent. in 1889, and 55.9 per cent. in 1890, after the accumulators had been reconstructed towards the end of August, 1889.

All central stations working with accumulators have been planned on the assumption of a rather low number of hours of daily maximum consumption; and the author asserts that such statements are erroneous, or are so in most cases. He shows from the gasworks statistics of 24 of the largest German gasworks that the gas supply for heating and power purposes amounts to only 6½ per cent. of the total output, and that for 16 other gasworks the hours of heavy consumption were, on an average, 8.7. Another table contains the maximum consumption in one day, and in one hour of this day, for several electric stations, and shows the quotient of these two quantities, which gives the hours of maximum load: Berlin, 8.8; Barmen, 6.9; Elberfeld, 5.6; Hamburg, 8.2.

Some interesting details of the Düesseldorf central station are then given. It is stated, among other things, that in Darmstadt the total length of gas main is about 116 kilometres for, approximately, 35,000 gas lights, or 3.3 metres of main per gas burner, corresponding to one 16 candle-power lamp. The electric network is planned with about 32 kilometres of mains for about 20,000 16 candle-power lamps, or with 1.6 metres of mains per lamp. For the central stations at Darmstadt and Elberfeld, Herr Ross gives the cost of current production per 16 candle-power lamp-hour as 2.45 and 1.33 pfennigs (one pfennig = .12d.), respectively, the annual cost per lamp being 3.55 marks in Darmstadt and 4.8 marks in Elberfeld. For these two stations the maximum consumption is nearly equal, but the average annual number of lamp-hours is 289 in Darmstadt and 730 in Elberfeld.

In the last table are given some average values for the annual lamp-hours, the length of main per light, and the ratio of daily maxima to total lamps installed, all calculated from the statistics of 35 gasworks of various sizes; these three numbers varying from 1,610 to 1,270 hours; 2.49 to 4.4 metres, and 50 to 57 per cent.

1. London *Electrician*.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

When you have engaged advertising space, help the paper make it pay you by putting in some effective "ads."

THE WIRT DYNAMO BRUSH.

THE Wirt dynamo brush was designed with the intention of combining the good qualities of carbon and copper brushes, and it is claimed that by its use sparking, with its attendant wear and damage to the commutator, has been almost entirely eliminated. The principle involves the use of a lamination of perfect and imperfect conducting materials, the good conductor being placed between two layers of higher resistance. The result is that the main current is carried away principally by the middle portion with a minimum of heat, while the wasteful currents are partly prevented and in part "wire drawn" to the point where the energy is too small to do mischief. The construction of the brush gives a cushion touch on the commutator, permitting the use of a very light tension.

The resistance metal in these brushes is new and has a resistance about fifty times that of copper, or three times the resistance of German silver. It is used in sheets as thin as letter paper, with the result of great flexibility and smooth running, and as the contact on each successive commutator bar is made first with this high-resistance metal, and broken also on the high-resistance metal, the destructive short-circuiting currents which cause sparking are almost entirely prevented. At the same time there is sufficient pure copper in the middle of the brush to carry the main current to the brush holder without undue heating.

A number of letters from engineers who have used these brushes speak highly of their merits. They are manufactured by the Electrical Supply Co., of Chicago.

BURTON HEATERS.

F. D. CASSANAVE, E. C. Bradley, M. C. Bristol, W. M. Grafton, L. L. Summers, and C. H. Summers, all officials of the Pennsylvania Railroad and Western Union Telegraph Company have visited Chicago for the purpose of arranging with the Burton Electric Company to put on the Pennsylvania limited Chicago and New York trains the Burton electric heater.

The Electric Merchandise Company received, a few days since, the following dispatch, the latter part of it referring to a duplicate order for four additional sets just ordered by mail:

"OTTUMWA, IOWA, Nov. 14, 1891.

"Heaters working satisfactorily. Hurry the others along as soon as possible.

"OTTUMWA ELECTRIC RAILWAY."

CROWN ELECTRIC MANUFACTURING COMPANY.

THE CROWN ELECTRIC MANUFACTURING COMPANY, of 99 Cannon street, Bridgeport, Conn., has recently been organized with the following named officers, gentlemen who are well known in electrical circles: President, F. H. Bryant; vice-president and general manager, E. L. Smith; secretary and treasurer, Chas. J. Norton; electrician, Geo. B. H. Foster. The Crown Electric Manufacturing Company will manufacture a full line of electrical supplies, including sockets, switches, ceiling cut-outs, etc., all of which specialties will be entirely new. The success in the past of the several gentlemen composing this company gives the new concern bright prospects.

A BIG ORDER FOR KERITE.

J. H. BUNNELL & Co., of 76 Cortlandt street, New York City, who have a large and growing trade in insulated wires and cables, have just taken an order for no less than 700,000 feet of Kerite wire for telegraphic work, to be used in this vicinity. Bunnell & Co. are also very busy on all their other lines of work, and find no cause for complaint as to the outlook.

THE TAPER-SLEEVE PULLEY WORKS.

THE new Taper-Sleeve friction clutch, illustrated on page 565 of our last number, we are requested to state was patented Sept. 10, 1889, and is controlled by the Taper-Sleeve Pulley Works, of Erie, Pa.

GREAT WESTERN ELECTRIC SUPPLY CO.

THE Great Western Electric Supply Co., sole agents of the Sun arc lamp, are receiving many orders for this specialty and the sale is increasing wonderfully. The Sun arc lamp is specially adapted for use in theatres, central stations, halls, stores, or in fact any place where the ordinary arc lamp is not desirable. It gives a steady, clear, bright, white light, and for direct current, incandescent circuits is strongly recommended.

The Great Western Electric Supply Co. are also agents for the celebrated K. K. wire, a large amount of which they sold last month, and the amount sold so far this month shows that they will have an even larger sale than ever.

The Great Western Electric Supply Co. are now preparing to manufacture their own fixtures. They are doing a very large business in this line, and will be able in the future to fill orders very promptly, and also set up any special designs that may be desired. Their new lighting catalogue is out and is complete in every detail. It is now ready for distribution.

THE NATIONAL ACOUSTIC TELEPHONE.

THE National Manufacturing Co. has recently installed several telephone lines for the Old Colony R. R. Co., which are giving good service. An important line connects the train despatcher with a signal station at the drawbridge. Another line is ordered for depot service, also one for use at freight station at Middleboro.

The Hotel Brunswick enjoys the use of this telephone on a line connecting the house and stables. The Oliver Ames and Sons Corporation also uses the service at their plant in North Easton. The outlook for the company is quite promising. Orders are being daily received from the West and South, to say nothing of the many cheap systems that give satisfactory service.

THE RIES ELECTRIC SPECIALTY CO.

THE Ries Electric Specialty Co. of Baltimore, Md., have just issued a very neat, pithy and interesting pamphlet, letter envelope size, on their specialties, and devoted chiefly to their well-known regulating sockets for alternating incandescent lamps. In the power to control the amount of current used and the quantity of light emitted, this socket has recommendations that cannot be neglected by a single station superintendent or consumer of current, and its universal adoption is simply a question of time. This little brochure points out its many merits, explains simply its operation, and quotes several complimentary opinions expressed about it.

WILMOT & HOBBS MANUFACTURING COMPANY.

THIS company has recently issued a little article combining the element of usefulness with that of ornament—something not always found in catalogues and the like. The article in question is a 12-inch ruler, which may also be used as a paper cutter.

The obverse of this ruler tells where Wilmot & Hobbs Manufacturing Company may be found for business purposes, and names in a modest way the goods handled by this company, and in addition gives the price of the ruler. The reverse shows a table of gauges, and gives a little law for determining the weight of sheet steel, brass and copper.

DETROIT ELECTRICAL WORKS.

THE Detroit Electrical Works have just closed a contract with the Kokomo City Electric Railway Co., of Kokomo, Md., for one 80,000 watt generator and five 30 h. p. Standard motor equipments. The whole outfit is to be delivered on the cars at Detroit for shipment East by December 15. The works are quite busy on a number of contracts, and expect to be very active all winter.

WHITMAN & WILKINSON.

THE above firm of patent solicitors and counselors in patent causes, of the Atlantic Building, Washington, D. C., have issued a sixth edition of their neat little pamphlet, "Notes on Patents." It contains in brief space a vast amount of useful information on the subject of patents, and contains a number of very warm testimonials from clients in various parts of the country.

WILLETTS POINT, L. I.—The iron roof for the storehouse which the U. S. Government is building at Willetts Point, L. I., will be furnished by the Berlin Iron Bridge Co., of East Berlin, Conn.

THE WAGNER-QUEEN PORTABLE VOLTMETER FOR ALTERNATING AND DIRECT CIRCUITS.

MESSRS. QUEEN & Co., of Philadelphia, are just putting upon the market a new voltmeter which is claimed to present many valuable features never before found in a single instrument. The voltmeter is the invention of Mr. Frank Wagner, for a number of years connected with the Thomson-Houston Electric Co., in charge of their Mexican business, and now on the mechanical engineering staff of the University of Michigan, at Ann Arbor. It is of the "hot-wire" type, depending, like the Cardew, on the expansion of a stretched wire which is heated by the passage of a current due to the E. M. F. being measured. This stretched wire is connected with a long and very light aluminum index in such a way that the amount of expansion is greatly magnified. The "hot-wire" is only about five inches long and has in series an extra resistance wound anti-inductively. By altering this extra resistance the instrument may be adjusted to different ranges. The stretched wire is exceedingly thin, and therefore immediately assumes the maximum temperature due to the E. M. F. being measured. The voltmeter is thus exceedingly dead-beat and readings may be taken very quickly.

The voltmeter is direct-reading for both alternating and direct circuits, the resistance being "non-inductive." Two ranges are offered with a maximum of 55 and 125 volts respectively; both ranges are graduated in single-volt divisions from 1.5, their maximum reading, these divisions being nearly equal and covering about $\frac{1}{12}$ inch each in the 55-volt instrument and about $\frac{1}{32}$ inch each in the 125-volt instrument. A mirror is inlaid in the scale so that parallax is avoided in taking readings.

Messrs. Queen & Co., as well as Mr. Wagner, have spent considerable time in developing and perfecting this voltmeter and believe that they have made it an instrument indispensable to every working electrician and electric light inspector in the country. The form, as now exploited, is intended only for general testing work, and is not a station instrument in any sense of the word. It is made almost entirely of aluminum, a metal which Messrs. Queen & Co. are now using extensively, and is believed to be the lightest voltmeter made. Complete and calibrated it weighs but 22 ounces. It is rectangular and smooth and can easily be slipped into a good-sized pocket. It measures, outside, 7¾ inches x 4 x 2

WAGNER-QUEEN PORTABLE VOLTMETER.

inches. The instrument has few parts and these are very strong; it is thus well adapted for transportation.

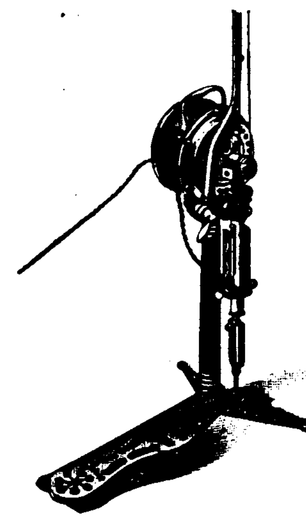
The outside case of the "Wagner-Queen" voltmeter is an emery-finished bronze, having a beveled glass over the scale. Each instrument is furnished in a neat carrying case with leather handle. An attractive descriptive circular, No. 265, has been issued by the makers.

PATENT OFFICE FACTS.

WE have received a pamphlet entitled "Information and Advice Relative to Patents," from C. A. Snow & Co., patent attorneys, of Washington, D. C. It contains directions for, and cost of, procuring patents in the United States and foreign countries; information about the registration of trade-marks, copyrights, caveats and designs; also abstracts of court decisions in patent cases, and much other matter of interest to inventors, patentees, manufacturers and others interested in patents. It will be mailed free to any one addressing C. A. Snow & Co., Washington, D. C.

THE EMERSON ALTERNATING CURRENT DENTAL ENGINE.

DURING the past summer the Emerson Electric Manufacturing Co., St. Louis, have perfected and successfully placed upon the market a very simple and quite efficient alternating-current motor of small size suitable for operating fans, sewing machines, jewelers lathes and dental apparatus. The illustration shows the motor attached to a dental engine. The operation is similar



EMERSON ALTERNATING CURRENT DENTAL ENGINE.

to that of their sewing machine motor attachment, that is, the speed of the motor is controlled by a foot treadle. The farther the treadle is pressed down the greater the speed of the motor. Any desired speed can be produced, the motor responding instantaneously to the movement of the foot treadle. A special form of regulator has been perfected for this purpose, giving the operator more thorough control of the speed.

The dental engine is of the usual standard form, containing both drill and automatic mallet attachments. By means of a handle attached to the top of the motor the entire machine can be lifted and moved at pleasure. The parts are so balanced that the machine retains its vertical position while being moved. The entire machine is substantially constructed and finely finished.

ELECTRIC MOTORS IN NEW YORK CITY.

THE Crocker-Wheeler Electric Motor Company are doing a very flourishing business. Among their recent installations may be mentioned the following in New York City: Three 5 h. p. and two ¼ h. p. motors for Mr. Louis Sherry, the well-known caterer, 37th street and 5th avenue; one 5 h. p. in the Marlborough Hotel, running ice cream freezers; and five ¼ h. p. to the well-known Otis Brothers Elevator Co., to run in connection with their new pump; four 3 h. p. motors, each driving a 48-inch fan, in the Stock Exchange; two 1 h. p. and several small outfits to the Madison Square Garden; one 1½ h. p. new style combination motor and organ attachment for Miss K. Drexel, 103 Madison Avenue, neatly encased in a black walnut cabinet, placed in the elegant music room at her residence; one 2 h. p. and several smaller sizes to Mr. F. S. Blackall, 239 Broadway; one each ½, ¼, and ⅛ h. p. fan outfits to the Irving Bank, corner of Warren and Greenwich streets; one 2 h. p., running printing press for the *Jewelers' Review*, 58 Maiden Lane. They have also furnished one 3 h. p. motor for Prof. Browning's Industrial Institute, West 55th street; two 1 h. p. motors in Dennett's restaurant, at 140 East 14th street; one 3 h. p., one 2 h. p. and two 1 h. p. at Dennett's new restaurant, 25 Park Row; also one 1 h. p. combination triplex pump with automatic tank switch, and a dumb waiter operated by 1 h. p. motor at same place.

THE KNAPP ELECTRICAL WORKS.

THE Knapp Electrical Works, Chicago, are selling quite a number of Bain compensating voltmeters and ammeters that they have just placed upon the market. These instruments are very accurate and do not get out of calibration.

This company are also agents for the Perkins Electric Lamp Co. and the Safety Insulated Wire and Cable Co., and report an excellent business in both of these branches.

NEW YORK NOTES.

THE JOHN E. BEGGS MACHINERY & SUPPLY CO.—We would call the attention of our readers to the advertisement of the John E. Beggs Machinery & Supply Co. The machinery listed will be found as Mr. Beggs represents it, and was taken from a central station near New York City. A considerable quantity has been sold, but there still remain some dynamos and electrical apparatus of the most modern type. It will be at once seen that the list presented would enable any contractor to put up at a reasonable figure a complete central station or isolated plant. Mr. John E. Beggs can be seen daily at his office, 74 Cortlandt street, New York City; and as the mentioned apparatus has been purchased outright by him, no delay will be encountered in delivery.

E. G. BERNARD & CO., of Troy, N. Y., have been awarded the contract for equipping the West Troy station with new machinery, etc., as their bid was the lowest available, and at the same time conformable to specifications. The equipment is to consist of a new and latest improved 50-light dynamo (Edison Gen. Elec. Co.) with automatic regulator, lightning arrester, and other safety apparatus, together with twelve new arc lamps of 2,000 candle power each, and the entire machinery to be set up in first-class order. Work is expected to begin in a few days.

THE W. S. HILL ELECTRIC CO., 54 Devonshire street, Boston, New York offices 136 Liberty street, have just issued a very neat and pretty supplementary catalogue devoted to the illustration and description of their excellent specialties, including motors and dynamos, cut-out switches, double-pole converter switches, transfer switches, station switches, fuse blocks, bus-bar connections, rheostats, arc lamps, etc. These specialties are the invention of Mr. W. S. Hill, the well-known electrician of the company.

BARTLETT & CO. now announce their removal to 21 and 23 Rose street, this city, where they have added extensive printing to their designing and engraving establishment. They are now equipped for executing every description of printing on their premises, and will be pleased to submit quotations for anything required in these lines.

THE CONNECTICUT ELECTRIC LIGHT ASSOCIATION met at New Haven last week, with Mr. J. E. English, president, in the chair. The usual business was transacted, including re-election of officers, etc. The proceedings wound up with a most enjoyable dinner.

ST. LOUIS NOTES.

THE EMERSON ELECTRIC MANUFACTURING CO., since their removal to their new quarters, are doing a large business in their various specialties. Their capital stock is to be increased from $50,000 to $75,000. They have just perfected and have ready for the market an improved dental engine motor for alternating currents. Before the close of the year they expect to get out a catalogue covering all their merchandise.

THE HEINE SAFETY BOILER CO. have made the following sales recently: 200 h. p. boiler to the Forest City Electric Light and Power Co., Rockford, Ill., and five 200 h. p. boilers to the Denver Consolidated Electric Light Co., Denver, Col. Among their orders outside of electrical interests is a notable one of 18 250 h. p. boilers for the Broadway and Seventh Avenue Cable Railway, New York.

W. L. ARNOLD, agent for the Thomson-Houston Electric Co., has made the following sales: 650-light alternating to Mascoutah, Ill.: 30-arc light to the Howard Allen Iron Co., Bessemer, Ala.; 100-light to the south side plant of the St. Louis Sanitary Co., and 300-light, alternating, to Morrellton, Ark.

THE INTERSTATE COMPLETE ELECTRIC CONSTRUCTION CO. have put in 160 Heisler lights additional at Kingman, Kan., and are now engaged in rebuilding the Heisler plant at Liberty, Clay Co., Mo. Fifteen Excelsior arc lights will be added to the plant.

WESTERN NOTES.

MR. W. T. RICHARDSON, formerly of the Southern Electric Company, of St. Louis, is now connected with the Central Electric Company. That company is now receiving a number of large orders for its Acme lead covering cable for underground work. This cable is giving especially good satisfaction, and possesses eminently the properties of durability, high insulation and conductivity, making it particularly adapted for underground work.

THE TRIUMPH COMPOUND ENGINE COMPANY, Cincinnati, O., report inquiries coming from all parts of the country for their various styles of engines, and thus far the fall trade has, beyond their most sanguine expectations, demonstrated the increasing popularity of their engines. They have lately been compelled to run overtime in order to meet the increasing demand.

THE BAIN ELECTRIC MFG. CO., 47-49 South Jefferson street, Chicago, among recent orders have received the following: Barnett & Record, Minneapolis, Minn., one dynamo, 12,000 watts, eight arc lamps, 150 incandescent lamps; Mosher Arc Lamp Co., one alternator and converter for arc lamps, one 3,000-watt constant potential dynamo, 110 volts; Indiana Novelty Mfg. Co., Plymouth, Ind., one 8,000-watt constant potential dynamo, 110 volts; Boyd-Conklin Electric Co., St. Louis, Mo., one 3,000-watt constant potential dynamo, 110 volts; Francis Dupont, Wilmington, Del., one 12,000-watt constant potential dynamo and extra armature, one 8,000-watt constant potential dynamo and extra armature; Chicago Paper Co., one 1½ h. p. motor, 220 volts.

MR. WM. HOOD, 239 La Salle street, agent for the "Jewel" incandescent lamps, is gathering around him considerable electrical talent. In addition to Mr. J. G. Nolen, who is now with him, Mr. W. F. Matterson, who has been his electrician for a long time past, is still with him and attending to various special work. Mr. Matterson is a young man, bright and energetic, and well versed in electrical science, and particularly so in the management of storage batteries, to which subject he has devoted a large amount of time and attention.

MR. J. G. NOLEN, a well-known expert electrician and one of the old timers in the business, having been associated with the Brush Co. in its early days and later with the Thomson-Houston Co., for both of which concerns he has installed a large number of plants, is now with Mr. Wm. Hood, of Chicago, looking after his incandescent and arc-lighting business.

LITTLE ROCK, ARK.—The City Electric Street Railway Co. have contracted with the Pond Engineering Company, of St. Louis, for three Hoppes live steam feed-water purifiers for immediate shipment. Each of these purifiers is to have a capacity sufficient to take care of the feed-water for 250 h. p. boilers.

CICERO, ILL.—Rapid progress is being made towards the enlargement of the plant of the Cicero and Proviso Street Railway Co. They have placed orders with the Chicago office of the Pond Engineering Company for an 800 h. p. Hoppes exhaust feed-water heater, and one 8-inch and one 6-inch Pond separators.

THE CHICAGO ELECTRIC MOTOR CO. are manufacturing and placing on the market a perfected oil paper for insulating purposes. This company is also doing a large amount of repair work, rewinding dynamos and motors, and have received quite a number of very flattering testimonials from their patrons.

MR. C. T. RUTTY, the general traveling representative of the McCreary Electrical Specialty Co., of New York, was in Chicago last week and found trade in his line of specialties first rate. Mr. Rutty is making an extended Western trip, looking after the requirements of his numerous customers.

THE ELECTRIC APPLIANCE CO. are rapidly getting their handsome new store, at 242 Madison street, into business shape and a stock of general electrical supplies of all kinds is being received. They have already booked some nice orders for "Paranite" wire, and they state that it sells at sight.

THE UNION ELECTRIC WORKS, Springer Building, Chicago, report the demand for their new annunciators as considerably in excess of their expectations, and they are working hard to keep pace with their orders.

Mr. H. H. Burke has been appointed superintendent of the Mt. Forrest Road Electric and Gas Co., of Mt. Forrest, Ia. Mr. Burke was in Chicago recently and left last week to assume his new duties.

HELLO "CENTRAL."—Attention is called to the special announcement of the Central Electric Co. in our advertising columns this week. Peruse their munificent offer and take advantage of it.

MR. H. A. STUCKY, of the National Electric Manufacturing Co., of Eau Claire, is at present in Chicago superintending some important installation work.

NEW ENGLAND NOTES.

MR. M. A. CARTER, who almost from the start has been superintendent and electrician of the Skowhegan Electric Light Co., has resigned to accept a more lucrative position as superintendent of the North Attleboro and West St. Railroad Co.

MR. H. S. QUINT of the Thomson-Houston Electric Light Company, of Lynn, Mass., has assumed the duties of superintendent of the electric light company at St. Albans, Vt.

☞ ***Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Miscellaneous, etc., will be found in the advertising pages.***

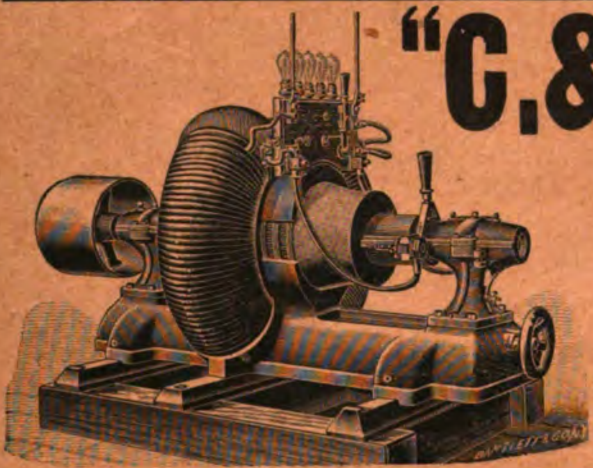
"C. & C." ELECTRIC MOTORS AND DYNAMOS.



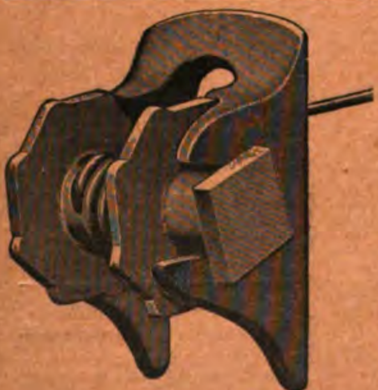
ELECTRIC MOTORS in all standard sizes, up to and including 100 H. P., for operating Elevators, Pumps, Printing Presses, and machinery for general manufacturing purposes.
POWER GENERATORS. ELECTRICAL MINING MACHINERY of all kinds, Hoists, Tram-Cars, etc.
FAN OUTFITS, Electric Plants for Pumping Church Organs.
DYNAMOS for isolated plants and the equipment of Mills, Banks and Office Buildings with Electric Lights.
ELECTRIC BLOWERS for ship ventilation. Have equipped 18 U. S. and foreign War Ships with ventilating apparatus.

New England Office, 63 Oliver Street, Boston. Philadelphia Office, 38 S. Fourth Street. Chicago Office, Phenix Building. San Francisco Office, 35 Market Street. St. Louis Office, 421 Olive Street. New Orleans Office, 78 Custom House Street.

We call the Special Attention of Station Superintendents to the fact that our machines are absolutely unsurpassed for economy of Electric Current.

The C. & C. Electric Motor Co., 402-404 Greenwich St., N. Y.

Why Use the Things?



Why not do without a Span-Wire Tightener? It don't take much time to bore a hole through the Pole and fasten the Span-Wire into an eye-bolt, and hunt around for the nut and washer, and find the monkey-wrench, and turn and twist until your arm is about ready to drop off. We have all the implements of war—the Auger, the Eye-Bolts, the Nuts and Washers, and the Monkey-Wrenches, and we also have

The Safety Span-Wire Tightener.

It is a simple arrangement and answers the question. You can put up 4 of them while you are getting the eye-bolt brigade into line. Made to use with iron or wood poles; and cheap.

MULTIPOLAR DYNAMOS AT THE FRANKFORT EXHIBITION.—II.

BY

E. Kolben.

THE field of the Schuckert dynamo in appearance is quite similar to the Fritsche field, but upon examination a considerable difference is found. In the Fritsche machine the poles directly opposite each other are of opposite polarity, but in the Schuckert machine these are of the same polarity. The Schuckert machine has a flat ring armature made out of a continuous iron band, and is wound in the regular manner with cotton-insulated copper wire. The largest machines of this type at present built are those at the central stations of Hamburg and Hanover, which have an output of 345 K. W. (300 volts and 1,150 amperes).

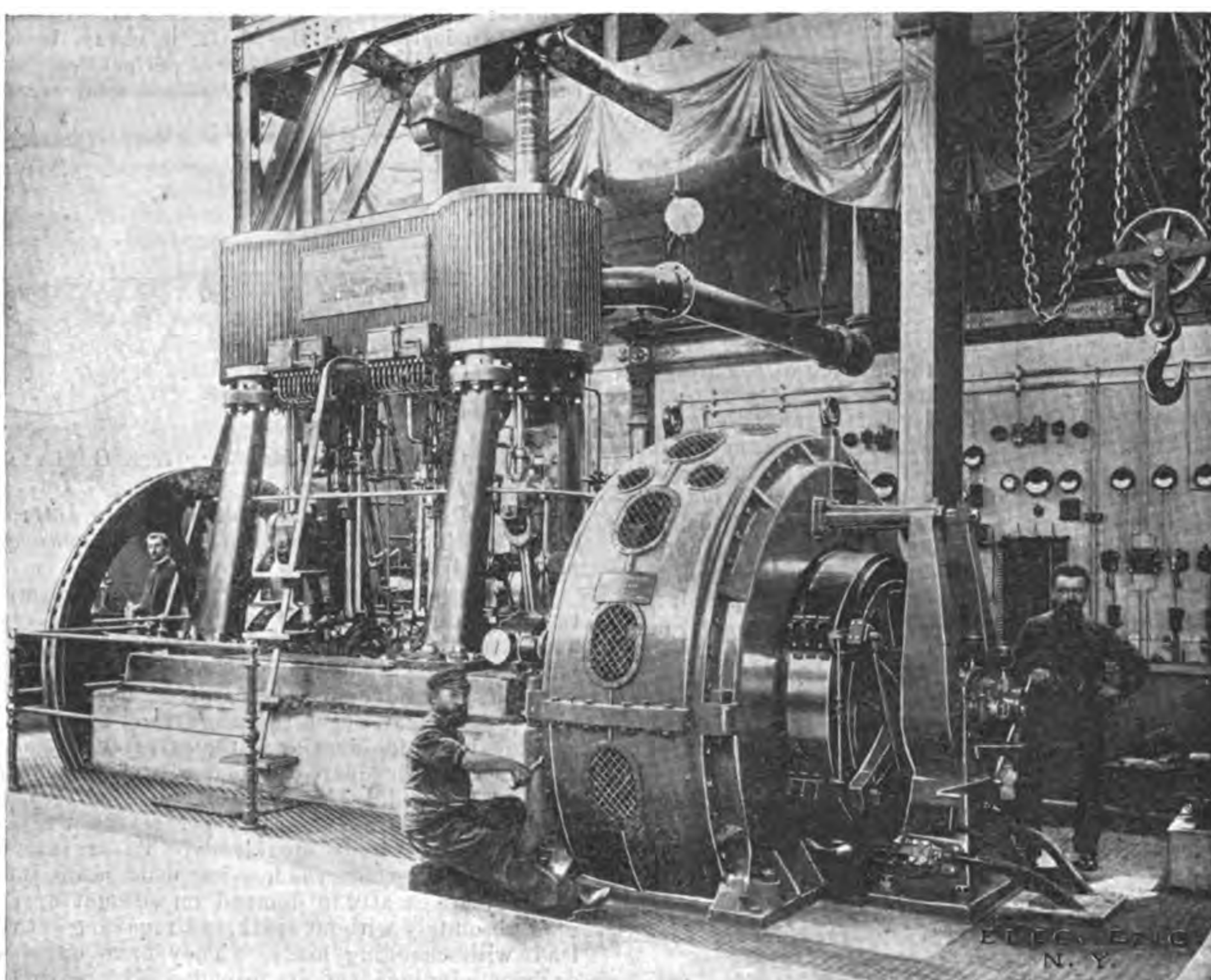

FIG. 9.—SCHUCKERT 220. K. W. MULTIPOLAR DYNAMO.

The exhibition machine is a 220 K. W. dynamo, illustrated in Fig. 9. It runs at a speed of 150 revolutions per minute, giving 220 volts and 1,000 amperes. The flat ring armature has an external diameter of 98 inches, so that the circumferential speed is 64 feet per second. This high circumferential speed, which is double that of the Siemens innerpole machine, is perfectly safe on flat ring armatures only, as the iron core is made of continuous bands, and, unlike a ring armature where the discs are made in part, will stand an enormous strain, due to centrifugal force. The strain on the external bands of the winding due to centrifugal force is also small, as the armatures are flat and narrow. The armature has a commutator the diameter of which is 5 feet, and which has 560 divisions. The armature is wound with two turns per division, and has a combined series and multiple arc connection. This is so made that four sets of brushes can be used. Thrust bearings are used, which permit adjustment of the amount of end play on the shaft.

No. 1, or Iron Clad Type.—The chief makers of this type are the Allgemeine Elektricitäts-Gesellschaft, Oerlikon Works and G. Kapp.

The machine of the Allgemeine Elektricitäts-Gesellschaft is made wholly of cast iron. They have not, however, developed larger sizes than their pattern G T-500, which is a 66 K. W. machine. The following data is given by the makers: Number of poles, 12; E. M. F. at terminals, 120 volts; current, 550 amperes; speed 220 revolutions per minute; total weight, 16,000 pounds; driving power required 103 h. p. (German horse-power = 736 watts). The commercial efficiency figures out at $\frac{66,000}{103 \times 736} = 0.87$, or 87 per cent.

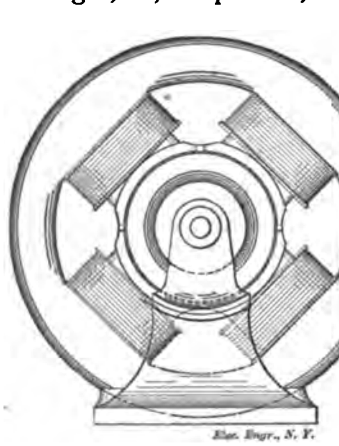

FIG. 10.—FIFTY-FOUR KILOWATT "A. E. G." DYNAMO.

The use of so many poles for a comparatively small sized machine is doubtless a miscalculation; this the makers acknowledge to be the case. A special feature of the magnet frame is a cast-iron pole bushing magnetically connecting all the poles, Fig. 10. It is a device of Mr. Dolivo von Dobrowolsky, who designed these machines. The object of this pole bushing is to reduce the weight of copper on the fields, sparking at the brushes, reduce the lead, and reduce the heating of the armature conductors due to eddy currents, as the conductors are made of rectangular solid copper bars arranged edgewise. With cast iron, and still more with wrought iron machines of this type, a spreading out of the core by means of a pole-piece of larger area becomes necessary, for it is not economical to operate at the same amount of magnetic induction per square centimetre in the air gap as in the iron. For if the iron induction density is high, then an enormous magnetizing power is required to overcome the air gap reluctance; and the weight of copper on the field magnets will very much increase the cost of the machine. If the induction density is made low in order to reduce the air gap reluctance, then the cross section of the cores would become too large. The machine would be heavy in iron, and also in copper, on account of the increased circumference of the magnet spools. A special outspreading pole-piece therefore becomes absolutely necessary in a well-designed machine. Instead of using special pole-pieces, which, if made separate, would be very awkward to finish, and would involve a large percentage of the cost of production in labor and special tools, a solid cast-iron bushing of special shape, Fig. 10, is introduced between the poles and a number of holes drilled in the neutral places. The frame can then be simply bored out, the spools slipped in position and the bushing driven in afterwards. The loss due to direct leakage from pole to pole is comparatively small on account of the very small cross-section and consequent high induction in the thin iron bridges left around the holes; this loss is more than counterbalanced by the simplicity and cheapness of the process of manufacture. The use of such a bushing, however, can only be recommended on cheap machines for small plants, where economy is only a secondary consideration. For central station work a machine made entirely of cast iron should not be used. The field cores, at least, should be of wrought iron or soft steel with outspreading pole-pieces.

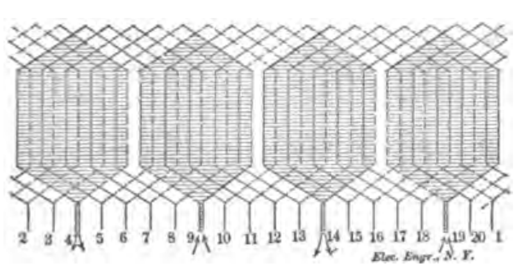

FIG. 11.—DIAGRAM OF MULTIPLE ARC CONNECTION FOR 4-POLAR DRUM WINDING.

The armature of the Allgemeine Elektricitäts-Gesellschaft machines are of large diameter and are provided with drum windings made up of copper bars of special shape laid upon the external surface of the drum, the cross-connections being made on the ends, as shown in the diagram, Fig. 11. The armature body is built up in a very solid manner, as will be seen in Fig. 12. The spider pulley supporting the body is of cast iron, and has fan-shaped arms, and is made in two halves, which are bolted together under hydraulic pressure. This construction is very substantial; it supports the armature discs all around, insulates them electrically from the shaft, is cheap, because only cast-iron is used, and it allows of perfect ventilation. Of course it can only be used for drum-wound armatures on account of the additional leakage on the interior of the body, which would be detrimental to armatures wound after the Gramme type.

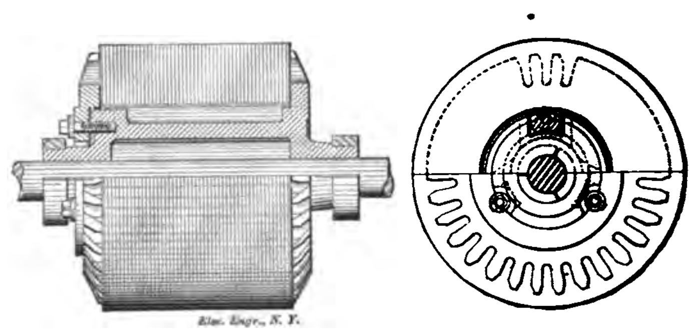

FIG. 12.—DRUM ARMATURE OF "A. E. G." DYNAMO.

Dynamos of the Oerlikon Works.—This company was the first to recognize the valuable features of type No. 1, and hence this type is sometimes called the "Oerlikon" or "Brown" type. The magnet frames are also made of cast iron, but they have no pole bushings nor extension pole-pieces. The material in the magnetic circuit is very heavy, as a low induction density in the cast iron, 3,500 to 4,500 C. G. S. lines per square centimetre, is employed and a very strong field used. The armature has comparatively few turns; about 80 ampere-turns per centimetre circumference, and runs quite sparklessly. These machines are, consequently, perhaps the heaviest machines in the market, but they are greatly in demand on account of their running absolutely without spark, and requiring but very small lead with changing loads. They have either Gramme or drum windings, and are provided with special commutators.

On sizes of larger output and large current capacities use is made of solid copper bars of circular section for winding the armatures. These bars pass through holes below the surface of the iron body, which entirely prevents the generation of eddy currents in them. According to C. E. L. Brown's experiments, a copper bar as large as two inches in diameter when placed in a hole armature does not heat at all, even when run in a very strong field. The bodies are supported by light brass spider pulleys, made in two halves, so as to clamp the discs tightly together, as shown in Figs. 13 and 14. No bolt holes are made through the discs.

The central station machines of G. Kapp, in London, have fields of Type No. 1, with cast-iron cores, wrought-iron extension pole-pieces and a cast-iron keeper, Fig. 15. The writer had an opportunity of discussing the design of this machine with Mr. Kapp himself, and found that he adopted this type of field for the same reasons which led the Edison General Electric Company, of this country, to adopt it for their large direct-driven central station machines, Fig. 16. This form gives the highest efficiency, is

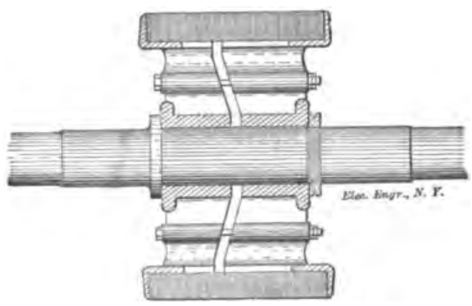

FIG. 13.—RING ARMATURE OF OERLIKON DYNAMO.

comparatively cheap to manufacture, has the best "running value" and does not spark. Kapp uses multiple arc drum winding and provides his machines with as many sets of brushes as there are poles. For large machines he uses flexible insulated cables of circular cross-section made of bare copper wire. According to tests made by him, this prevents eddies to the same extent as a cable stranded of insulated wires. The writer can fully indorse this practice from his own experience. Kapp finds objection to the wide, flattened cable of Crompton's, which, although it may prevent heating from eddies, nevertheless generates an E. M. F. within its own width, and causes wasteful currents within the cable itself. On a 120 K. W. machine an

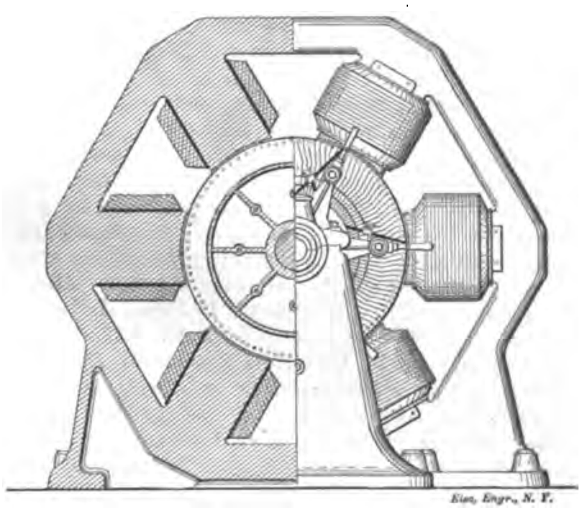

FIG. 14.—SIX-POLE OERLIKON DYNAMO.

experiment showed a gain of 7 h. p. in favor of using circular cable made of bare wire instead of the flat stranded Crompton cable.

BELT-DRIVEN DYNAMOS.

It is noticeable that there is a general tendency to reduce the speed of belt-driven machines, partly for mechanical and partly for electrical reasons. Mechanically, the friction in the bearings is reduced and the efficiency increased. Electrically, slow-speed machines permit the design of an armature of large diameter and large radiating surface, so that machines built on these lines have less tendency to heat than high-speed machines. The armatures of most dynamos of American make reach high temperatures, in fact temperatures which would not be considered safe by European makers. The main reason for this high temperature is that the induction density in the armature core is very high, and that the armatures have small diameters because the machines are required to run

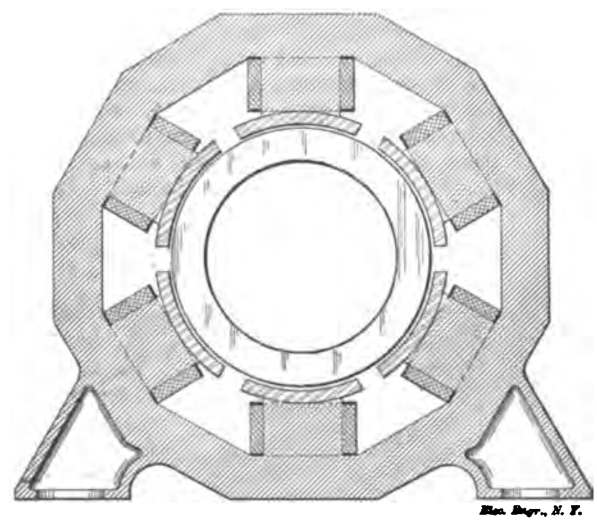

FIG. 15.—FIELD OF KAPP DYNAMO.

at high axle speeds. American machines are built on these lines on the score of economy, but a multipolar design now permits economy of manufacture together with slow speed. This fact points plainly to the gradual development of dynamo design. Many English makers are still building bipolar dynamos, but at the Frankfort Exhibition most of the belt-driven dynamos exhibited were of the multipolar type.

The Allgemeine Elektricitäts-Gesellschaft, Berlin; Oerli-

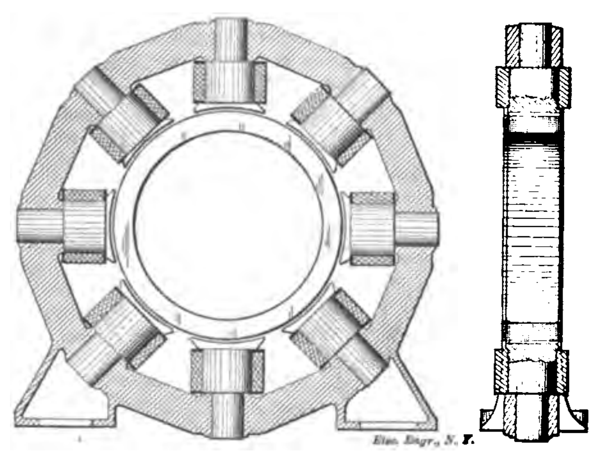

FIG. 16.—ONE HUNDRED KILOWATT EDISON GENERAL ELECTRIC CO. DYNAMO, WITH SOFT STEEL CORES AND CAST-IRON YOKE.

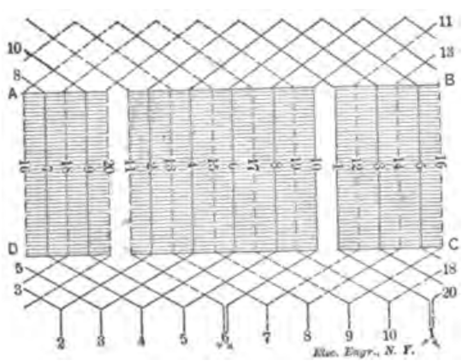
kon Works, Oerlikon; Siemens & Halske, Berlin; Schuckert & Co., Nuremberg; Lahmeyer & Co., Aix la Chapelle; O. L. Kummer, Dresden; Esslingen Machine Works; Naglo Brothers, Berlin; C. E. Fein, Stuttgart;—all make multipolar belt-driven machines. Either one of the three types of field already described for the direct dynamos is also used for the belt-driven machines. Nearly all have cast-iron field magnets, and here again Type No. 1 is generally used. Most of them have drum armatures with multiple arc connection, as shown in diagram Fig. 11, or with series connection, Fig. 17. In the latter case only two brushes are used. Machines of smaller output have toothed Pacinotti ring armatures.

The reason why the use of toothed armatures is limited to the smaller machines is because of the heavy armature effect which they necessarily exercise on full loads on account of the small air-gap reluctance, and also the fluctuations in the magnetic flux from tooth to groove, causing eddies in the teeth and heating them. A very satisfactory arrangement has been devised, by Lahmeyer, in combining tooth and surface winding; this is shown in Fig. 18. The body is toothed, and in winding this armature the grooves are wound with one set of coils first. This winding is then covered with insulation and a perfectly smooth surface obtained, on which a second set of coils can be wound. By this arrangement the air gap is reduced, as compared with a smooth armature, and at the same time a strong field can be produced economically without creating a heavy armature effect upon the field. In addition, the fluctuations in the magnetic induction are smaller because the depth of the grooves is reduced considerably, and the loss from eddies and hysteresis in the teeth is reduced to a minimum.



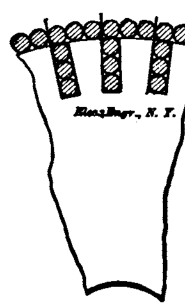


FIG. 17.—DIAGRAM OF SERIES CONNECTIONS FOR DRUM ARMATURES.
FIG. 18.—LAHMEYER'S COMBINED TOOTH AND SURFACE WINDING.

One of the lightest and cheapest multipolar belt-driven machines is the four-pole Oerlikon dynamo for ship lighting, similar to the new type of the Edison Co.'s dynamo shown in Figs. 19 and 20. To Mr. Kapp should belong the credit of first using this type of field. In it the length of the magnetic circuit is reduced to a minimum, and the machine is perfectly iron clad. This type has the great commercial advantage that the height of the machine is reduced, which makes it a very stable machine, particularly valuable as a motor. The field magnet frame can be cast with the bed plate in one piece, while one boring out with one setting of the tool is the only finishing operation on the frame. The type has been applied quite successfully in a form modified for the use of cast steel by the Edison General Electric Company, in this country. It is exemplified in their single-reduction street car motor, the excellent qualities of which the writer has had many opportunities of proving.

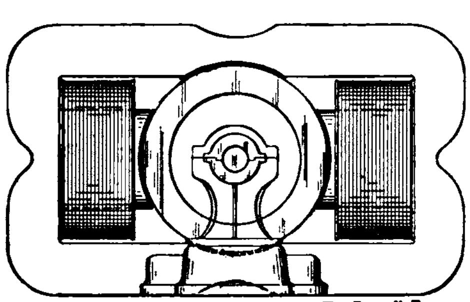

FIG. 19.—EDISON GENERAL ELECTRIC COMPANY'S 50-KILOWATT BELT-DRIVEN MULTIPOLAR DYNAMO.

From the universal favor that the multipolar machine has found on the European continent it is evident that electrically, as well as commercially, it has many advantages over the bipolar form. American electricians are quick to grasp the merits of any new development in electrical design and the American electrical industry is quicker still to find a field for it. There is no doubt that in the very near future the manufacture of multipolar machines will become quite general in this country, and with the superior commercial opportunities offered they will soon surpass their European models.

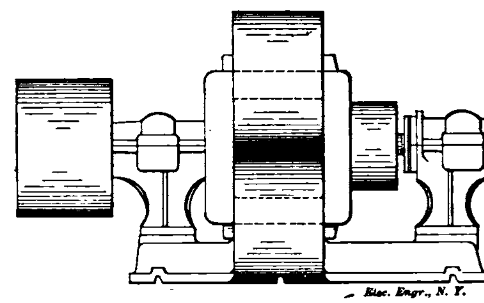

FIG. 20.—EDISON GENERAL ELECTRIC COMPANY'S 50-KILOWATT BELT-DRIVEN MULTIPOLAR DYNAMO.

THE BERLINER AND BELL PATENTS.

BY

Edwin J. Houston

THE recent issue of a broad patent to Emile Berliner for a microphone transmitter for telephones, a patent which is now the property of the American Bell Telephone Company, will undoubtedly attract considerable attention in this country, where inventors have been anxiously waiting for nearly seventeen years for an opportunity to improve the telephone service.

The ingenious defence of the original Bell telephone patent is so well known to the electrical world as to need no comment. It has been broadly held by the defenders of the original Bell telephone patent, and such contention has been sustained by the decision of the United States Supreme Court, that it practically covers all cases by means of which electrical undulations, similar in form to the sound waves accompanying the sounds produced by articulate speech, are transmitted over a line or conductor connecting a transmitting with a receiving telephone station.

In the litigation to which the original Bell telephone patent was subjected in the case of Dolbear, Judge Gray said, in speaking of the apparatus of Bell: "The evidence in this case clearly shows that Bell discovered that articulate sounds could be transmitted by undulatory vibrations of electricity, and invented the art and process of transmitting such sounds by means of such vibrations. If that art or process is (as the witnesses called by the defendant say it is) the only way by which speech can be transmitted by electricity, that fact does not lessen the merit of his invention, or the protection which the law will give to it."

"The mode or apparatus by which Bell effects his purpose is by using an electromagnet in the transmitter and another electromagnet in the receiver. But the essence of his invention consists not merely in the form of apparatus which he uses, but in the general process or method of which the apparatus is the embodiment."

The Berliner patent, number 463,569, of November 17, 1891, is exceedingly broad. Witness, for example, claims 1, 2 and 3.

"1st. The method of producing in a circuit electrical undulations similar in form to sound waves, by causing the sound waves to vary the pressure between electrodes in constant contact so as to strengthen and weaken the contact and thereby increase and diminish the resistance of the circuit, substantially as described."

"2d. An electric speaking telephone transmitter operated by sound waves and consisting of a plate sensitive to said sound waves, and electrodes in constant contact with each other and forming part of a circuit which includes a battery or other source of electric energy, and adapted to increase and decrease the resistance of the electric circuit by the variation in pressure between them caused by the vibrational movement of the said sensitive plate."

"3d. The combination, with the diaphragm and vibratory electrode, of a rigidly held opposing electrode in constant contact with the vibratory electrode, substantially as described."

I submit that considerable difficulty should be experienced by the American Bell Telephone Company in sustaining these claims in the courts for many reasons, among which I would note the following:

1. The prior state of the art; that is, the state of the art prior to the date of the filing of Mr. Berliner's application, namely, prior to June 4, 1877.

2. The public use which has been made of the alleged invention disclosed by Mr. Berliner's application during the many years that it has been allowed to slumber in the Patent Office, namely, between June 4, 1877, and November 17, 1891.

3. The repeated disclosure and publication in printed matter which has been made of the principles of this alleged invention or of the apparatus which it describes.

The prior state of the art concerning the invention of the telephone has been discussed in electric journals to such an extent that it is a matter of common history, and it is therefore not necessary to refer to it. It is sufficient to say that, apart from the modified form of "Bored Block" Reis Transmitter, in which a metallic contact point rests against a second metallic contact point suitably supported at the centre of a diaphragm set in motion by the sound waves produced by articulate speech, there would appear to be other anticipations of substantially the form of transmitter claimed so broadly in Mr. Berliner's patent.

But, leaving Reis' claims as to the invention of the articulate telephone out of the question, and assuming for mere matter of argument that Mr. Bell's original patent is valid, and bearing in mind the statement made by Mr. Bell in his original patent, number 174,465, dated March 7, 1876, namely, that "electrical indulations may also be caused by alternately increasing and diminishing the resistance of a circuit;" or, as claimed in claim fourth of said patent, "The method of producing undulations in a continuous voltaic circuit by gradually increasing and diminishing the resistance of the circuit or by gradually increasing and diminishing the power of the battery, as set forth," the question arises, Can the broad claims of the Berliner patent be sustained?

The invention of the microphone by Hughes is a matter of history. Assuming Mr. Hughes to be the first inventor of the microphone, after the disclosures of the method of transmitting speech by transmitting over a conductor electrical undulations similar in form to sound waves accompanying said sounds, and especially after the statement that such undulations may be produced by means of changes in the resistance, it will remain for the courts to decide whether any application of Hughes' microphone to the case of the telephone transmitter can properly, in view of the notorious public use of such applications, be regarded as such an invention as would justly entitle the holders thereof to seventeen years' monopoly of the apparatus and the processes it covers. And this also in view of the fact that so many years have been permitted to elapse between the date of filing such application and the date of issue of the letters patent for the same.

It is hardly necessary to add that the Berliner microphone patent referred to has been drawn up with exceeding skill. Witness the following disclaimer:

"I do not claim that I am the first inventor of the art of transmitting vocal and other sounds telegraphically by causing electrical undulations similar in form to the sound waves accompanying said sounds. Neither do I claim that I am the first who caused such electrical undulations by varying the resistance of an electric circuit in which a current is passing."

The validity of this patent, however, will without doubt be called in question, and it will remain for the courts to decide whether or not its exceedingly broad claims can be sustained. In the resulting litigation, which will beyond any doubt attend the holding of this patent, the voluminous literature which exists concerning the original Bell patent will afford a rich field for exploration and will furnish facts which will place many experts and witnesses *hors de combat* concerning views which they might wish to hold in order to sustain the Berliner patent.

THE ECONOMIC LIMITS OF LARGE POWER UNITS IN ELECTRIC WORK.

BY

Wm Lee Church

RESPONDING to the request of THE ELECTRICAL ENGINEER to contribute information on the above subject, it becomes a first duty to recognize the rare combination of mechanical-commercial judgment displayed by "Carleton" in his initiatory article in the issue of November 4. The editorial endorsement of him as a "practical man" in the only worthy sense of the term, is, on its face, "a work of supererogation."

I cannot refrain from repeating, at the outset, two of his statements for their terseness and force: "No well-organized and well-regulated gas company would put all of its gas into one holder, if such a thing were possible," and "The vital question to be considered by electrical promoters is not what a steam horse power costs at the station, as obtained from an improved and complicated engine designed to show at its official trial a unit of power for a pound and a fraction, of coal; but what does it cost to *produce light* commercially *at the permanent location of the lamp?*"

Are not these axioms? Both of them, and especially the last, should be printed in black letters and hung in a strong light over the desk of every manager.

But while "Carleton" is right in every particular up to the point where he stops, he stops too soon by just one step. Permit me to quote again: "The compound non-condensing engine has had quite a run, much to the disgust of the shareholder, who finds that, with variable loads and pressures, the direct-acting, non-condensing engine is more economical." In support of this opinion, which is unquestionably candid, he quotes briefly from the London *Engineering*, of which the full extract reads as follows: "Non-condensing compounds are built, but do not as yet give great satisfaction, unless carefully designed for a constant load. With variable loads, where the variation is great, they are of little value; until higher pressures become more common they are impracticable under such conditions. With good loads, such as to maintain constantly about six expansions and with 120 pounds boiler pressure, these engines have about the same economy as a simple Corliss non-compound engine with 80 lbs. boiler pressure."

He further confirms his position by the statement, which is understood to be literally true, that the Corliss Steam Engine Co. and the Armington & Sims Engine Co., builders, respectively, of long-stroke slow-speed, and short-stroke high-speed engines, refuse to build non-condensing compound engines.

Not only London *Engineering* and "Carleton," but, it would seem, all engine builders also, so far as I know, with but one exception, have reasoned and practiced along substantiated lines on the above facts, and in the end running against an apparently impassable conclusion, have said *finis*, and abandoned further investigation. Let us go briefly over the blazed line of facts, and see where the blind trail leads off.

Compounding, as to fuel duty, aims at two things: To utilize all the available pressure above the return pressure line (whether vacuum or atmosphere); and at the same time to reduce the resulting fluctuations of cylinder temperature by dividing them between two or more cylinders. To this the high-speed compound adds the further advantage of diminishing the *time* during which the low-pressure cylinder is open to the atmosphere or to vacuum. Since the economy of the engine varies, (*a*) in some inverse ratio to the terminal pressure exhausted, (*b*) in inverse ratio to the square of the differences of temperature, and (*c*) in inverse ratio to the duration of the exhaust, it will be seen how compounding makes for economy. The improved fuel duty thus obtained is indisputable in the case of compound condensing engines, and has become standard. But the same factors of economy,—utilization of pressure and division of temperature range—also exist when non-condensing. Then why not expect relative results? So we may; and get them too, so long as the load on the engine is heavy enough to keep the terminal expansion in the low-pressure cylinder always above atmosphere. But, unfortunately, this condition confines the engine to a very limited range of power; so limited as to take it practically out of commercial consideration, except in cases where both load and steam pressure are virtually constant, and the proportions of each engine can be designed with reference to its individual service. It naturally follows that compound engines have come to be rated nearer to their ultimate capacity than simple engines, in order to get further away from the fatal underload, and even then a variation of twenty-five per cent. in their load brings them down to the danger line. Now, no operator of electric interests needs to be told how far short this comes of meeting the requirements of a service in which the load varies from practically friction alone up to the utmost extension of the valve motion, every few hours in electric lighting, and every few seconds in electric railways.

Next; in just what way does underload kill economy in a non-condensing compound? To this question, the indicator diagram, Fig. 1, is a perfect answer. It was taken

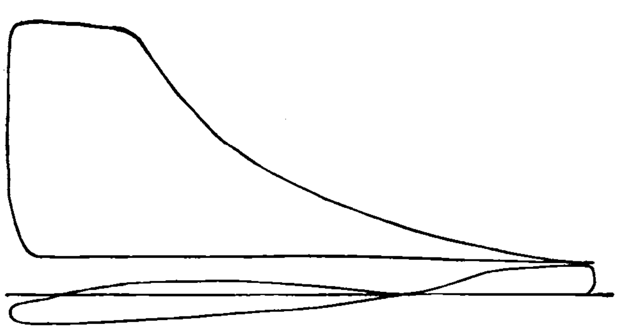

FIG. 1.

(not by the writer) from a Corliss cross-compound non-condensing engine doing ordinary mill work, and it will be seen that the load is by no means abnormally light, and really bears no comparison to the load found almost momentarily in any electric railway power station. For a better study of the work of the low-pressure cylinder a second diagram, Fig. 2, was taken from the low-pressure cylinder alone with a 10-lb. spring so as to magnify the results.

Now let us examine what the compounding of this engine did for its owner. It will be seen that the expansion line crosses the atmospheric line at a point representing $\frac{3}{10}$ of the stroke. The motive value of the low-pressure cylinder is represented by the area A D, equivalent in this engine to 50.4 h. p., and operating through $\frac{3}{10}$ of the stroke. For the remaining $\frac{7}{10}$ of the stroke, the low-pressure cylinder was dragged against an average vacuum of $5\frac{1}{2}$ lbs., and returned against an average back pressure of 3 lbs., representing a total resistance of 170.5 h. p. The net result of the low-pressure cylinder was, therefore, 50.4 *minus* 170.5 h. p., or a dead load, within the engine itself, of 120.1 h. p. What rational manufacturer would think of running an engine with 120 h. p. constantly applied to a brake on the band-wheel? Yet this is precisely what is done in this case. Or, to put it still more forcibly, the high-pressure cylinder was developing 186 h. p., of which 120 h. p. was used up in dragging the low-pressure piston against vacuum, and 66 h. p. was left for useful work, at the cost of a net fuel consumption far worse than the rudest full-stroke engine of fifty years ago.

I do not wish to be understood that this particular engine was put in for regular service under the conditions obtaining at the time the cards were taken. The engine

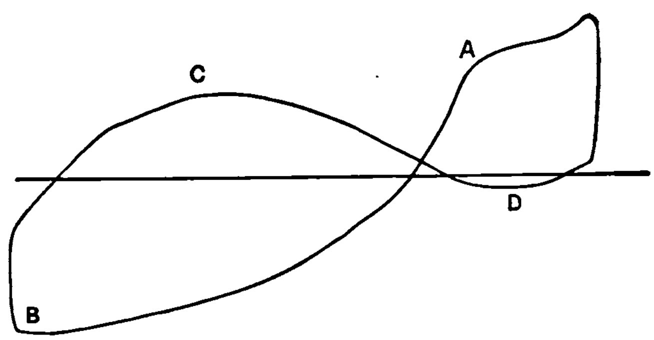

FIG. 2.

was ultimately intended to condense, and to carry a much heavier load, but in the meantime the proprietor was compelled to submit to the terrible performance shown by the diagrams. The engine was so piped that the low-pressure cylinder could not be temporarily disconnected, otherwise the engine might have been run on the high-pressure side alone, until such time as the increase of load would advantageously call for compound expansion. In a tandem compound engine it would, of course, be impossible to disconnect the two cylinders, and the dilemma is therefore unavoidable in all cases where the load and steam pressure and piston displacement cannot be at once definitely proportioned to each other, and the conditions allowed to remain unchanged. The cards are reproduced here as a general and striking illustration of what will inevitably take place with a compound non-condensing engine under a variable load, which is a simple recital of the conditions found in their most aggravated form in every electric railway plant.

From the foregoing it will be seen that decrease of load tells upon the compound engine somewhat sooner, and much more heavily, than upon the simple engine. The loss commences the moment the low-pressure expansion line crosses the atmosphere; or, more strictly, the moment it crosses a line parallel to atmosphere and at a distance above it representing the mean effective pressure necessary to carry the frictional load of the engine. The moment expansion falls to this point the low-pressure cylinder becomes an air pump for more or less of its stroke, the power to drive which must come from the high-pressure cylinder alone, enormously reducing the capacity of the engine and raising its fuel consumption to a point unpleasant to contemplate. In electric railways, particularly, the low-pressure cylinder of the non-condensing compound will act as a positive load upon the engine for the greater portion of the time.

Thus there has been ample ground for the statement made by your correspondent and the London authority. The fact that users of engines have been so quick to understand the nicer points of engineering involved is an evidence of the growing intelligence on the part of manufacturers whose business depends upon correct engineering, over which they have no direct control. Perhaps this intelligence has been fertilized in its growth by the "disgust of the stockholder" to which your correspondent graphically alludes.

Precisely this conditition of things confronted the writer and his associates when the question of compounding the single-acting engine was taken up by them some five years ago. It did not require any acute commercial instinct to understand that in order to command any general market a compound engine must not merely give a high duty condensing, but must give a proportionately high duty non-condensing, and that not only at its rated load, but at all loads. If this cannot be accomplished, then the compound engine is limited to those locations where there is sufficient water for condensing, or to other conditions where the load and the steam pressure are practically constant, and the engine can be proportioned with reference to them. This may be engineering, but certainly is not business. Understanding fully, as we did, the nature of the apparently inevitable dilemma, we squarely faced the following problem.

The compound engine to be commercially successful must show a high duty non-condensing. Being non-condensing, it must still be able to meet all ranges of load with economy. This is simply saying that the expansion in the low-pressure cylinder *must not* fall below atmosphere at any load, but must leave a mean effective pressure in the low-pressure cylinder sufficient to make it a motor and not a resistance. But how to do it? To be a motor the low-pressure cylinder must have steam, and this steam must come from the high-pressure cylinder, even when the high-pressure cylinder is cutting off at the earliest point. This immediately suggested a special high-pressure clearance large enough to hold a volume of steam that, passed into the low-pressure cylinder, would hold its terminal up to atmosphere even at the lightest load. Very good so far, and no harm done to the high-pressure economy, since the low-pressure cylinder gets the use of the steam anyway, and the higher expansion curve in the high-pressure cylinder is scarcely of theoretical loss. Yes, but here comes a trouble; there will be enough steam in this clearance to run away with the engine on the low-pressure side when the load falls of. No, for on the other hand a single eccentric valve motion can be made to give excessive compression at early cut-offs, and so we will use our large artificial clearance to hold in check a purposely early compression

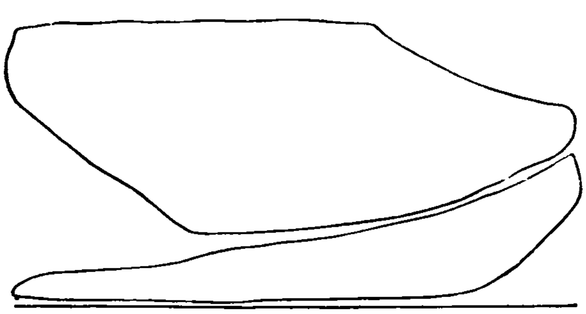

FIG. 3.

on the return stroke, which we otherwise could not stand. That is to say, we will use this special clearance on the first half of the return stroke to keep a little pluck in the low-pressure cylinder, and on the last half to cushion on, and so govern our engine on its compression. When you come to think of it, there is no reason why governing must necessarily be done by cutting off steam; it is just as well, in fact better, on several accounts, to do part of the governing by compression, to wit, a variable steam spring judiciously thrown in ahead of the piston, for the good reason that the steam spring not only gives out all the power it absorbs, but performs the very important function of keeping the temperature up into the bargain. This is one of the blessed things about a single eccentric governor, you can do these things so easily.

So now we have provided a means of keeping up the low-pressure terminal above atmosphere at all loads, and there is no longer any danger of making an air pump out of our low-pressure cylinder under any circumstances. It only remains to determine proportions, build an engine, and prove the theory by the test. To arrive at proportions, theoretical indicator diagrams were laid down and trimmed at until the best results were reached, and from these diagrams it was finally determined that the volume

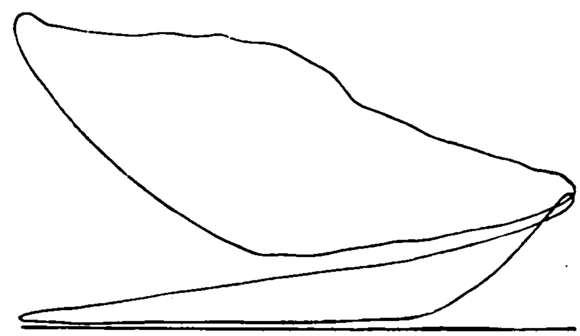

FIG. 4.

of the controlling clearance should bear the same ratio to the volume of the high-pressure cylinder that the latter bears to the low-pressure cylinder. This work was greatly facilitated by the fact that since the two edges of a single valve controled all the admission and expansion events on both cylinders, corresponding events were necessarily simultaneous at every point of cut-off.

The work of designing was next proved in the building of a 14-24x14 engine rating at 150 h. p. on 100 pounds steam. The engine was then sent to the test-room, where a surface condenser received all exhaust from the engine; but, being vented to the atmosphere, no vacuum was carried. Variable loads were supplied by a Prony brake, with check readings on the indicator. This method of test was somewhat unfair to the engine, as it left it charged with all water of entrainment and condensation in the pipes. The error was on the safe side, however. A number of tests were made covering a continuous period of months. At 120 pounds pressure non-condensing, the following average results in pounds of water per indicated horse-power per hour at the respective powers were obtained:

210	h. p.	22.6	pounds	of water	per	I. H.	P.
170	"	21.9	"	"	"	"	
140	"	22.2	"	"	"	"	
115	"	22.2	"	"	"	"	
100	"	22.4	"	"	"	"	
80	"	24.6	"	"	"	"	
50	"	28.8	"	"	"	"	

These tests were also repeated under variable pressures down to 60 pounds and gave approximately one pound more water for every drop of 20 pounds pressure. The highest water-rate obtained was 30.3 at 60 pounds pressure and 50 h. p.; that is to say, under conditions under which an ordinary compound engine would give a rating far worse than a plain slide-valve engine. Similar tests without number have been made during the last five years, both in the test-room and in service, and the fact is now conclusively settled that a compound non-condensing engine can be so designed, that so far from being unfitted for variable loads, it is of all engines the most uniform in its duty and the least sensitive to extreme fluctuations of load. And that, too, not by a slight margin, but by a difference so great as to solve the whole question of economy.

Figs. 3, 4 and 5 are diagrams from such an engine in use in the Wilmington Street Railway, Wilmington, Del. The point to notice is the persistence of the terminal pressure above atmosphere, even at the great range of load. We could fill every page of the ENGINEER with cards of this character from actual service, and none of them would show characteristics different from the above.

Another factor which entered strongly into the proportioning of the controlling clearance and the valve functions, was the desirability of dividing the load equally between the two cylinders at all points of cut-off. This is a result which it is practically impossible to get with the ordinary means of steam distribution in a non-condensing compound. If correctly proportioned for equalizing load at its rated horse-power, one or the other cylinder will take much more than its share, as the load varies either up or down. This is independent of the sudden break which takes place when the load allows the expansion to fall below atmosphere, as already discussed, and refers only to to those changes of load which occur between the maximum capacity of the engine and the least load which it will carry without expanding below atmosphere. It is obvious that equal division of load is essential to a refined economy, since one of the objects of compounding is to reduce the internal condensation to one-quarter in each cylinder, by letting one-half of the total fluctuation of temperature take place in each of the two cylinders. To get the maximum result, of course, demands that the range of temperature should be equally divided, since, if divided in any other proportion, one cylinder will have a greater range of temperature than it otherwise would have and would operate with correspondingly greater loss. The indicator

FIG. 5.

diagrams show how perfectly this has been accomplished, bearing in mind the ratio of cylinder volumes, which is in general about three to one.

It is an odd fact, which we have often observed, that many persons are skeptical about the results, simply from the absurd simplicity of the means employed. If they could see the "multiplicity of valves and intricate connections" which "Carleton" speaks of, they would probably admit the case; but the idea of doing so much by simply graduating the size of the neck of a spool-shaped valve looks out of proportion to the results. They are more apt to believe that we built the valve and invented the excuse.

I am much interested in the final paragraph of "Carleton's" article, as indicating how his impartial and intelligent search for good practice has led him to the same conclusion which we have already reduced to practice. He says: "Why not continue and proceed on this line of advancement, and arrive at the extreme power unit of the future for large central stations, which is to be a compound condensing (?) engine of 500 h. p., with a speed of not less than 200 revolutions per minute, and piston speeds of 600 or 700 feet? Stroke should be 18 inches or 20 inches, which will permit of direct-acting piston valves without complication. Armatures should be part of the engine shaft, and of as great a diameter as practicable, to compensate for the absence of driving pulleys or balance wheel; a most essential requisite. Simplicity reduces to a minimum the liability of disaster." Substitute for his limitation of a compound condensing engine the words, "compound engine, condensing or non-condensing, as circumstances may permit," and you have the case exactly. We seem to have followed these specifications to the letter in one of our present patterns, as witness the following dimensions:

Diameter of high-pressure cylinder.......	20 inches.
" " low-pressure "	36 "
Stroke	20 "
Speed, in revolutions per minute................	210.
Piston speed, feet per minute..................	700.
H. P. at 125 pounds pressure, non-condensing...	500.

A single direct-acting piston valve controls both cylinders from a single eccentric. This engine is now coupled direct to both railway generators and alternating dynamos of corresponding power on a single base as a unit machine. The armature is abundantly large to give the full necessary fly-wheel value. The point wherein we differ from your contributor is in the fact that in heavy station work the dynamo should necessarily be insulated from the engine and from the bed-plate, so as to prevent the coming in of ground leakage through the boiler and steam pipes. We therefore interpose a flexible insulating coupling; but, essentially, the dynamo is a part of the engine. In small isolated plants where ground currents are not to be feared, the armature is directly on the engine shaft close to the engine, and without any out-board bearing.

In view of the above discussion, it is interesting to see how completely builders have seemed to miss the one road which leads to compound non-condensing economy by contenting themselves with what is already known, and without attempting to meet new difficulties with new expedients. We find in a late circular such advice as the following, perfectly candid and exact from the standpoint of the builder, but wholly misleading as a general statement: "When compound engines are to be used without a condenser, high steam pressures are very desirable. Indeed, except with expert management, it is a questionable propriety to use the compound construction with steam of less than 125 lbs. pressure, and higher pressures are still more desirable from an economic standpoint Such engines should be most carefully constructed, and the builder should be made aware of the conditions under which they are to operate, that he may proportion the cylinders and design the working parts, so that the engine may do its work safely and to best advantage." The simple expedient of a controlled clearance unlocks the situation completely, and so far from the above limitations being impossible, compound engines, either condensing or non-condensing, can now be built of fixed proportions and carried in stock and shipped to fill any combination of conditions with the perfect certainty of a uniform fuel duty of the highest order. As high an authority as Prof. Thurston recognizes this fact in a leading paper in *Cassier's Magazine.*[1] Comparing the relative gain in compounding in slow-speed and high-speed engines, he says of the latter: "Compounding the single valve high-speed automatic engine reduces the consumption of fuel from about 3.5, or 4 lbs., to 3 or $2\frac{1}{2}$ lbs., the best practice being considered, the gain being thus a larger percentage in the less economical class of motor." The above is about the result got in ordinary practice with the compound non-condensing engine of the type under discussion, with a boiler evaporation of 8 to 10 lbs. of dry steam. It is also interesting to note that the fuel duty is very nearly as good in the smallest sizes of engine as in the largest. An actual fuel duty of better than $2\frac{1}{2}$ lbs. has been obtained under ordinary working conditions in a compound engine developing 35 h. p. non-condensing.

Another writer in the same magazine says: "Success is shown in the amount of business done through a period of years, and by the repetition of orders from the same locality or firms. For men are not so constituted as to be

1. See abstract of this paper on page 612.

easy victims to the same imposition the second and third times, and this point is frequently overlooked." This statement is the summation of all argument, and the evidence in this line lies in the fact that upwards of 600 engines containing the constant-clearance feature have been built and put in operation within the past five years, and of this number fully two-thirds are duplications of orders from two to thirty-eight times. These engines are not only operated by parties whose sole object in continuing business is to make money, but are to a large extent in the hands of concerns who are in themselves mechanics and engineers.

I have trespassed upon your space to an unwarrantable extent, but the subject is of the largest economic importance, and cannot be too well understood by manufacturers. So much misapprehension now exists on this point, and so many statements emanating from excellent, but not fully posted, authority, are now in circulation, that it becomes a direct challenge to a full exposition of the facts. I do not deem that I have transgressed propriety in the matter of advertising. The question under discussion is intensely practical, and practical affairs are in the hands of practical men, and if progress is progress at all, it is bound to turn up in practical shape in the form of business. No paper will more surely recognize this fact than The Electrical Engineer, and I consider that an apology for the above article is unnecessary.

TESLA'S ALTERNATING MOTOR OPERATED WITH CONDENSER.

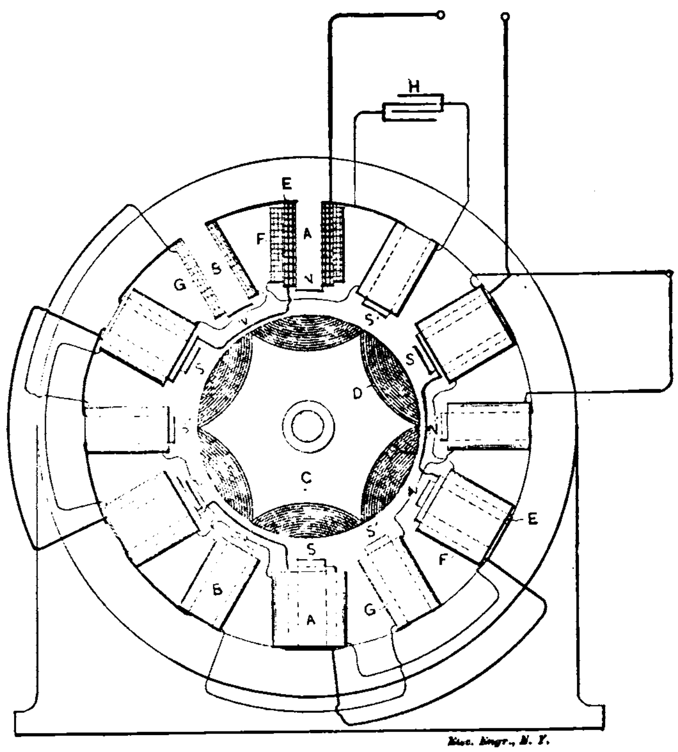
It is a well-known fact that if the field or energizing circuits of a motor, in which the action is dependent upon the inductive influence upon a rotating armature of independent field magnets exerted successively and not simultaneously, be both derived from the same source of alternating currents, and a condenser of proper capacity be included in one of the same, that approximately the desired difference of phase may be obtained between the currents following directly from the source and those flowing through the condenser. The great size and expense of condensers for this purpose that would meet the requirements of the ordinary systems of comparatively low potential, however, are practically prohibitory to their employment in practice.

Another well-known method or plan of securing a difference of phase between the energizing currents of motors of this kind is to induce by the currents in one circuit those in the other circuits, but no means have thus far been proposed that would secure in this way between the phases of the primary or inducing, and the secondary or induced currents, that difference—theoretically, ninety degrees—that, in the type illustrated, is best adapted for practical and economical working.

To accomplish this, Mr. Nikola Tesla has devised a means which renders practicable both the above described methods, and by which he is enabled to obtain an economical and efficient alternating current motor. Mr. Tesla obtains this result by placing a condenser in the secondary or induced circuit of his well-known type of motor, and raising the potential of the secondary currents to such a degree that the capacity of the condenser, which is in part dependent on the potential, need be quite small. The capacity of this condenser is determined, as usual, with reference to the self-induction and other conditions of the circuit so as to cause the currents which pass through it to differ from the primary currents by a quarter phase.

The accompanying diagram illustrates the principle as embodied in a motor in which the inductive relation of the primary and secondary circuits is secured by winding them inside the motor partly upon the same cores. Here A, B, represent the poles of an alternating-current motor, of which C is the armature, wound with coils D, closed upon themselves as is now the general practice in motors of this kind. The poles A which alternate with poles B, are wound with coils of coarse wire E, in such direction as to make them of alternate north and south polarity, as indicated in the diagram by N, S. Over these coils are wound long, fine wire coils F, F, and in the same direction throughout as the coils E. These coils are secondaries in which currents of very high potential are induced. Mr. Tesla, as a rule, connects all the coils E in one series and all the secondaries F in another.

On the intermediate poles B are wound fine wire energizing coils G, which are connected in series with one another and also with the series of secondary coils F, the direction of winding being such that a current impulse induced from the primary coils E imparts the same magnetism to the poles B as that produced in poles A by the primary impulse. This condition is indicated by the letters N′ S′. In the circuit formed by the two sets of coils F and G is introduced a condenser H, the circuit being otherwise closed upon itself, while the free ends of the circuit of coils E are connected to a source of alternating currents.



Tesla Motor With Condenser.

As the condenser capacity which is needed in any particular motor of this kind is dependent upon the rate of alternation or the potential, or both, its size and hence its cost, as before explained, may be brought within economical limits for use with the ordinary circuits. It is evident that by giving to the condenser proper value any desired difference of phase between the primary and secondary energizing circuits may be obtained.

EXHIBITION AT ST. PETERSBURG.

An international electrical exhibition is announced to be opened on 1st December, 1892, to extend to March 15th. The object is to show the Russian municipalities the various systems of electric distribution of light and power, and their particular advantages. Space has been retained by Ganz & Co., Siemens & Halske, the Continental Edison Company, and others. The tariff is about \$6.75 per square foot of floor space, and \$3.50 for wall space. The Russian railways will reduce the transportation charges by 50 per cent. for goods addressed to this exhibition.

THE
ELECTRICAL ENGINEER.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XII. NEW YORK, DECEMBER 2, 1891. No. 187.

It has been computed that in a single cubic foot of ether which filled all space there were locked up 10,000 foot tons of energy which had hitherto escaped notice. To unlock this boundless store and subdue it to the service of man is a task which awaits the electrician of the future. The latest researches give well-founded hopes that this vast storehouse of power is not hopelessly inaccessible.—Prof. W. Crookes.

THE ELECTRIC AND THE STEAM LOCOMOTIVE.

THE discussion which has been called forth by recent publications on the possibility of applying electricity directly to the propulsion of trains on standard-gauge railways for both passenger and freight service has aroused the interest not only of the technical, but of the daily press. It is but natural to suppose that the journals devoted more especially to steam locomotion would follow this subject very closely as bearing particularly upon the nature of the motive power for railways, admittedly one of the most important branches of the service. It was with an evident recognition of this fact that the *Railroad Gazette* in a recent editorial took up the question of the feasibility of the application of electric locomotives for regular passenger and freight work, and showed, or attempted to show, just wherein electricity would fail. The writer in the *Gazette* cited the usual arguments to the effect that the various conversions of energy between the stationary engine and the motor on the track would entail a consumption of coal not inferior to that of the steam locomotive of to-day; and that the cost of operating the stations and the size of the conductors, etc., would make the expense of the undertaking prohibitory. Then he had also to consider that even if it were practical to run trunk lines with electric motors so far as the mechanical work was concerned, the question arose, What would become of the service in case the conductors were broken through an accident, such as would be caused by a washout or a wreck? Then we were also told that an electric motor would cost as much as a steam locomotive of equal power, and, finally the *Gazette*, although it mentions the City and South London motors of 100 h. p., asks to have pointed out to it a single instance where a 100 h. p. motor has been constructed, adding that what is needed for steam railroad work is an 800 h. p. motor at the least, since it is folly to talk of subdividing motors for train work, as has been proposed. With all due respect to our excellent contemporary, we may be allowed to remark that it does "protest too much." Every intelligent electrical engineer of to-day has well-defined ideas as to the limits to which electric construction is practical and economical, and this was clearly demonstrated a short while ago by Mr. O. T. Crosby in his admirable paper on high-speed long-distance electric railway work read before the American Institute of Electrical Engineers, in which he defined the limits above referred to, and which were arrived at as the result of an elaborate and painstaking investigation. Mr. Crosby showed that there were unquestionably commercial opportunities for the electric high-speed railway for trunk-line service, but when our contemporary throws down the gauntlet to electricians and challenges them to produce an electric locomotive of 800 h. p., it is apparently unaware of the resources of the electrical engineer. We venture to say that, if called upon to furnish such a motor, any one of the electrical companies engaged in electric railway work would undertake to furnish the same under guarantees, and indeed it may surprise our contemporary to learn that electric locomotives aggregating very closely in power the figure named by it have been quite recently designed in anticipation of the near demand for such a machine. The actual progress in this direction is well illustrated by the standard gauge Thomson-Houston electric freight locomotive which we illustrate in another column. Our contemporary has also, in substantiation of its arguments, stated that a standing offer had been before the electric companies of Europe for a whole year to equip one of the new elevated roads in Chicago with a system for the propulsion of cars by electricity. This we must confess is news to us, and we can only say that if the same offer has been made to any of our large companies in this country, the contract would probably not have gone begging. As a matter of fact, we have ourselves inspected well worked-out American designs for the electrical equipment of this very road. As our contemporary remarks, it is a big jump from 100 to 800 h. p. in electric locomotives, but it is not so long since, that far lesser marvels were considered impossible in steam railroading, and we have no fear that when electric locomotives of such size are called for, they will be forthcoming, and promptly, too. It would be strange indeed, if the electrical engineer who has succeeded in entirely revolutionizing surface street railway traffic in the space of a few years, should not be equal to the task of equipping a road, such as the Chicago elevated, which offers every advantage for the application of the electric motor.

THE MOST ECONOMICAL STATION POWER-UNIT.

THE discussion on this most important subject is taken up in this issue in a manner which brings out prominently some points in steam engineering that are still matters of dispute. Mr. Church argues well for the economy, when properly designed, of non-condensing compound engines employed in work involving widely fluctuating loads. The means employed for obtaining this economy are well worthy of the closest study, and the results obtained by utilizing high compression in the low-pressure cylinder are remarkable, considering especially the simplicity of the means depended upon to effect them. While Mr. Church differs from "Carleton" as to the means for obtaining high economy, he agrees with him as to the size of the future power unit, which he places at 500 h. p. with an engine running at a speed of not less than 200 revolutions per minute, and piston speed of 600 or 700 feet, with the armature directly connected to the engine shaft. Nevertheless, while the writer in this issue appears to differ in only one, though an important, point from "Carleton," we have still to hear from others whose ideas of engine practice in connection with central station work may be characterized as radically opposed, and involving the economy of the high-speed direct connected, as against the slow speed with countershaft.

MULTIPOLAR DYNAMO MACHINES.

A CLOSE analysis of the changes and improvements which have marked the progress of dynamo electric machinery during the last ten years reveals the fact that, as in many other arts, it has required some time to effect modifications which of necessity entail the discarding of much valuable material and the expensive abandonment of old processes. In no one direction have more marked changes taken place than in the design of dynamos, and more particularly in the adoption of the multipolar type of field. Looking for the course of events which have led to this type, it will be hardly denied that the mechanical success of the multipolar alternating machine contributed not a little to the rapid recognition of the merits of that type of construction, wholly aside from its electrical properties. The direct mechanical and electrical advantages of the multipolar type of continuous current machine are well pointed out and discussed in our columns, by Mr. E. Kolben, who describes the machines of this type exhibited at the Frankfort Electrical Exposition, and thus affords the student a valuable means of comparison of the relative merits of each practical type. But aside from the advantages obtained in the operation of these machines, practical experience has demonstrated the important fact that their cost of manufacture is considerably below that of bi-polar machines of equal output. It is true that the construction of the commutators of such machines may involve an expenditure in excess of that required for the ordinary bi-polar type, but the saving in weight of material as well as in the machine work required in multipolar machines far overbalances this single disadvantage. But even this drawback, it is safe to assume, will be overcome at no distant day by the introduction of special machinery. Hence, even if the multipolar machine offered no other advantages, its reduced cost of manufacture in these times of lively competition would be a powerful factor in its adoption by dynamo manufacturers, and one can clearly discern the drift in this direction. The question naturally obtrudes itself at this point as to the limits to which the increase in the number of poles should be pushed. While this consideration, as applied to alternating machines, would be governed largely by conditions of working, number of alternations, etc., the necessity for a commutator in continuous current introduces a factor which cannot be ignored in any commercial apparatus, and more especially in that under consideration, and that is, simplicity. In this direction, therefore, we must look principally for the limit in multipolar continuous current machines. And this again brings out prominently the immediate necessity for, and general applicability of, a continuous current machine without a commutator. We venture to predict that this machine or apparatus when introduced will be multipolar in its character, and that it will bear close relationship with alternating apparatus, which has recently been the subject of so much interest and discussion.

OPERATING ALTERNATING MOTORS WITH CONDENSERS.

THE operation of alternating motors by currents differing in phase has called forth a number of methods for obtaining the lag required to secure a high output and efficiency, and the most recent development in this direction is exemplified in the application of the condenser for this purpose. In the methods thus far proposed, the condenser was designed to operate at the same potential as the motor itself, usually a low one, and hence to obtain the required capacity necessitated the employment of condensers of such size as to make this otherwise advantageous assistance prohibitory. As the capacity of a condenser, other things being equal, is a function of the potential, Mr. Tesla very ingeniously operates the condenser at a greatly increased E. M. F. generated directly in the motor itself by secondary coils arranged on the magnet limbs. By this means, evidently, the size of the condenser is proportionally reduced, and at the same time the lag desired obtained in a motor requiring only two wires for its operation. In this manner Mr. Tesla is enabled to operate any of his types of motors either with two or more phases. It will be observed that the working conditions in the type of motor illustrated are such as to insure a maximum output and efficiency with such a combination. The cores which perform the office of transformers are made to work as transformers under overload with a closed inductionless secondary, and the primary current passes through at a low E. M. F., and the poles developed in the armature are made to coincide with those developed in the auxiliary cores. While the latest arrangement of Mr. Tesla's is highly ingenious and reduces the cost of the condenser, it seems impossible that as high economy can be obtained with this method as compared with the ordinary system devised by him, and involving the use of differential phase generators. Mr. Tesla also employs currents of high frequency in connection with his condenser motor, with the object of reducing the cost of the condenser.

OSCILLATING MAGNETIC FIELDS.

BY

ALTHOUGH the rotary field system received only passing notice from electricians, when it was first brought to light by Messrs. Tesla and Ferraris, a few years ago, this has more than been compensated for by the marked attention it is now receiving. That the system and principles first used and laid down by the inventors should have received so

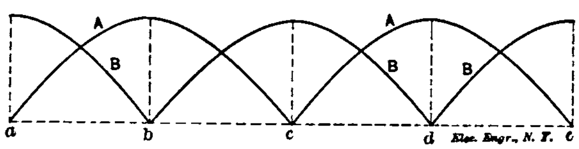

FIG. 1.

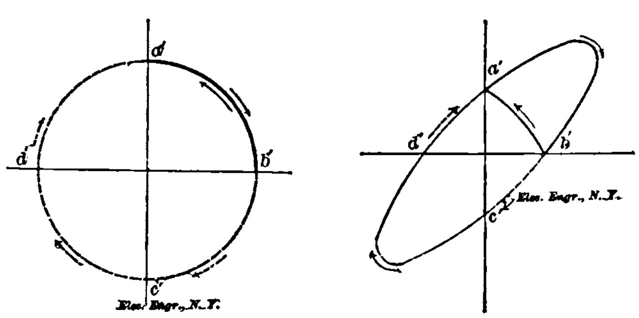
little development until now is rather phenomenal, and especially so, considering the period which has elapsed since its discovery, was one of great activity in every branch of applied electricity. Perhaps one of the explanations of this apathy is that there has been some doubt as to its commercial value, on account of the failure of Mr. Tesla to introduce his motor in a general commercial way, it being applied only in a few isolated cases. That the system which has been so elaborated by Messrs. Dobrowolsky and Brown will be more successful than that of their predecessor we must wait for time to decide. But I cannot



FIGS. 2 AND 4.

help but feel that a principle, which is in itself so simple and beautiful, must have a prominent place among the many future applications of electricity. In fact, we can already point to the case where it has solved the meter question as far as alternating currents are concerned, and as time goes on many more uses will be found for it; besides, the principle is sure to receive new development, now that attention is again called to it, and many of its difficulties will be cleared away.

What I want to call attention to is a branch of the subject, which, as far as I am aware, has never before been

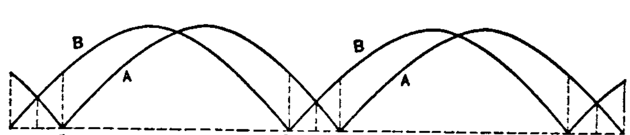


FIG. 3.

touched upon. I shall only deal with it in its most simple aspect, but this will be sufficient to illustrate the principle. We will suppose that an ordinary four-coil Tesla motor is used and, to still further simplify matters, that the armature is without windings, though this simplicity is by no means essential.

First, let us study the law which the resulting pole follows, as regards strength and direction when the phase difference of the two currents has any value α, and the amplitudes are unequal and denoted by A and B. As the component poles are at right angles, we can use these values as co-ordinates of a curve, which will show the law of variation. Thus we have:

$$x = A \sin p\, t,$$
$$y = B \sin\, (p\, t + \alpha),$$

By trigonometry;

$$y = B \sin p\, t \cos \alpha + B \cos p\, t \sin \alpha.$$

Substituting from above, we have:

$$y = \frac{B}{A}\, x \cos \alpha + B \sqrt{1 - \frac{x^2}{A^2}} \sin \alpha.$$

Transposing, squaring and reducing,

$$A^2 y^2 + B^2 x^2 - 2\, A\, B\, x\, y \cos \alpha - B^2 A^2 \sin^2 \alpha = 0.$$

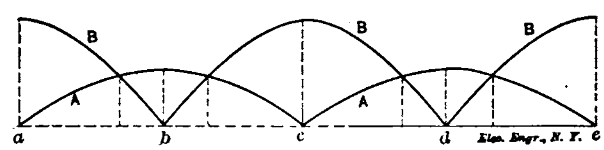

FIG. 5.

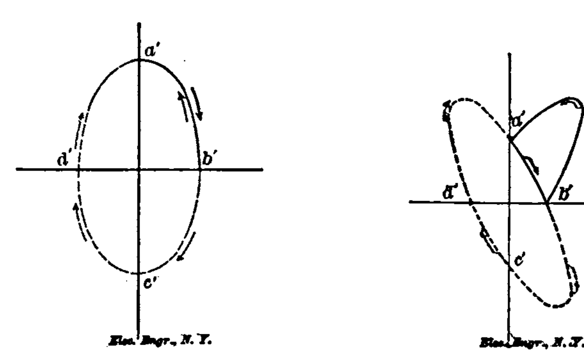
This equation we know from treatises on conic sections is that of an ellipse, whose centre is the origin of the co-ordinates, but whose axes are oblique to those of the co-ordinates.

Now, let us examine the form which these curves will take, where, instead of an alternating current, we use those that have been commutated, and, assuming for the present that the commutation takes place instantaneously, where the currents reach their zero values and there is no reaction to change the form of the current curves. Let us take as a fresh case that which is the simplest, viz., two currents of equal amplitudes, but differing by a quarter phase.



FIGS. 6 AND 8.

Referring to Fig. 1 we see that we have the following series of relations:

$x = A \sin p\, t,$

$y = A \cos p\, t,$ between a and b;

$x = A \sin p\, t,$

$y = A \cos p\, t,$ between b and c,

$-x = A \sin p\, t,$

$-y = A \cos p\, t,$ between c and d, and

$-x = A \sin p\, t,$

$y = A \cos p\, t,$ between d and e.

If there had been no commutation, the curve would have been the circle shown by the dotted lines in Fig 2; but on account of the commutation which changes the sign of y, between b, c, Fig. 1, our values, instead of being represented by the portion of the circle b^1, c^1, Fig. 2, are represented by b^1 c^1 that is, the same values, gone over in going from a to b, only repeated backward, and also by the

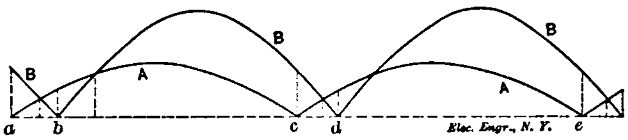


FIG. 7.

double change of signs between c, d, we get instead of c,' d^1, a repetition of a^1, b^1, and similarly as regards d, e, and d^1, e^1. So we see that our resulting pole, instead of revolving, oscillates back and forth inside of an angle of 90°, and in this case remaining constant in strength.

Using the same reasoning as above for the case of equal amplitudes, but of any difference of phase, we get what is shown in Figs. 3 and 4, and for unequal amplitudes, but a quarter phase difference, Figs. 5 and 6; and again for unequal amplitudes and any difference of phase, Figs. 7

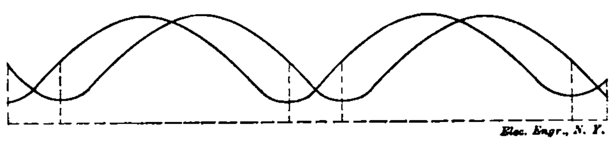

FIG. 9.

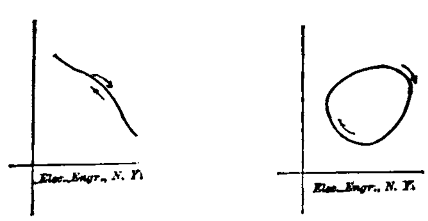
and 8. By inspecting the curves of Figs. 3, 4, 6 and 8, we see that the magnetic poles, whose actions they represent, would so act on the armature of the motor mentioned as to produce rotation, except in the case where the phase difference was a quarter, because the average strength of the pole going one way is greater than when going the other. There will be in practice a slight modification of these curves due to the fact that the assumptions we made about commutation being instantaneous, and about reactions, are not quite correct. The actual form of the current curves will be as shown in Fig. 9, which will modify, as an example,



FIGS. 10 AND 11.

the curves shown in Figs. 2 and 3 to those shown in Figs. 10 and 11; an inspection of which will show that this change will not effect the general principle given above.

That an oscillating field system has any commercial application it is very difficult to say at this time; the difficulty of commutating high E. M. F.'s stands rather in the way, but as these are direct currents, and have nearly all the good properties of that system, I should not be surprised if it were turned to some practical use.

BUILT BY STUDENTS.

Comparatively few people are aware that Chicago has a building almost wholly built by the students of an industrial school. The new building of the Institute of Technology, 147 Throop street is the first building west of New York City ever put up wholly, or in part, by students. No better evidence of the practical character of the instruction of a school could be desired.

The teaching of trades is in accordance with the broad plan of this Institute, which proposes to teach "any person, any study, day and evening." It now announces the organization of evening classes in electricity, plumbing and bricklaying, as well as architure and engineering, beginning Dec. 1 next. Draughting of all kinds is made a specialty, three instructors being employed.

HOEPFNER'S ELECTROLYTIC PROCESS FOR EXTRACTING COPPER AND SILVER DIRECTLY FROM ORES.

FOR a number of years electro-metallurgists have endeavored to establish between the electrolysis and the lixiviation of ores a process constituting a cycle, in such a manner that the lixiviating liquid is produced by electrolytic means in the baths, and that the original electrolyte is reproduced by the chemical process of dissolving the parts of the ore which contain metal. Now it will at once be noticed that in this case not only the arrangement of the baths, but also the chemical composition and the circulation of the electrolytes, must be of the highest importance.

Dr. Hoepfner, of Giessen, in carrying out his new electrolytic process (German Patent No. 53,782, dated March 2, 1888) employs a bath or a system of baths divided by diaphragms into two compartments. One compartment of the same contains anodes that cannot be dissolved by electrolysis, and the other compartment cathodes of sheet copper.

A solution of a halogen salt and cuprous chloride circulates by itself past the anodes, and a similar solution flows past the cathodes. At the latter is precipitated metallic copper, namely, 2.36 grams for each ampere-hour, or double as much as is deposited by the current unit when use is made of a solution of an oxide salt, such as, for instance, a solution of copper sulphate.

At the anodes free chlorine would be produced if no cuprous chloride were present there; accordingly a tension of 1.8 volt would be necessary at the poles. The chlorine, however, at once combines in the nascent state with the cuprous chloride, always present, to form cupric chloride. By this means is produced an electromotive force which, as experience shows, amounts to about one volt, and by which the work of the current profits. Therefore, the electrolysis proceeds practically with a tension of only 0.8 volt at the poles.

Cuprous chloride (Cu_2 Cl_2) develops in its formation 65.75 calories. Now as 45 calories of heat thus developed correspond to one volt of electromotive force dissociating power, $\frac{65.75}{45}$ or 1.46 volt is that electromotive force in volts which is needed for decomposing Cu_2 Cl_2 into Cu_2 and Cl_2.

But in order to overcome the resistances in practice the potential must actually be increased to 1.8 volt, as with 1.46 volt the dissociating and combining power only just balance each other, so that a quantitative decomposition cannot as yet take place.

When, however, chlorine in a nascent state oxidizes the cuprous chloride present at the anodes, the following action takes place:

$$Cu_2\ Cl_2 + Cl_2 = 2\ Cu\ Cl_2.$$

As 2 Cu Cl_2 represent 125.4 calories, 125.42 — 65.75, or 59.67 calories become free and aid the work of the current. Theoretically the electrolysis therefore commences in Hoepfner's process when applying only 65.75 — 59.67 = 6.08 calories, or 0.13 volt.

The liquor at the cathodes, while it flows past a number of cathodes in succession, becomes poorer in copper and is ultimately almost free from copper. It then leaves the electrolytic bath and is reserved for further use in the process forming the complete cycle above referred to. The liquor at the anodes retains the quantity of copper it contains. The copper is, however, ultimately not present as cuprous chloride, but as a liquor of cupric chloride; the latter now leaves the electrolytic bath as a continuous current.

At the electrodes the following action takes place: Cu_2 Cl_2 yields 2 Cu to the cathode plates. By an electrolytic displacement of atoms, Cl_2 passes to the anode and combines with $Cu_2\,Cl_2$ to form $Cu_2\,Cl_4$, or $2\,Cu\,Cl_2$.

For one atom of separated copper there is therefore formed one molecule of $Cu_2\,Cl_2$ at the anodes.

The solution of cupric chloride coming from the anodes is then employed for extracting the copper and silver from milled copper and silver ores. For this process special lixiviating apparatus is employed.

In copper ores containing sulphur the action, for instance, takes place according to the following formula:

$$Cu\,Cl_2 + Cu\,S = S + Cu_2\,Cl_2.$$

This shows that the liquor of cuprous chloride formed has taken up exactly as much copper as had previously been precipitated by electrolysis as metallic copper. As compared with the quantity of copper the concentration of the liquor is now double as much as before. In order, therefore, to re-establish the original concentration, the liquor which was deprived of the copper and had flowed from the cathode cells, and which, as above stated, was reserved, is added again to the liquor which had come from the anodes and was used for the lixiviation of the ores. Of course this mixing of the liquors may be effected at once when they flow from the electrolytic bath, so that in the lixiviating apparatus the original concentration is already re-established.

The regenerated solution of cuprous chloride flows again to the anodes and cathodes; at the former the chloride is formed, while at the cathodes the freeing from copper takes place. With the solution of chloride is mixed the part of the liquor which is freed from the copper; the mixture passes to the lixiviating apparatus, and so on. It will therefore be seen that there is a continuous process forming a cycle.

It deserves to be especially mentioned that simultaneously with the copper, any silver which may be contained in the ores is dissolved, which is not the case when use is made of the other extracting liquids, such as, for example, when ferric sulphate is employed.

The cycle is disturbed only by the gradual dissolution of small quantities of iron, arsenic, antimony, bismuth and the like in lieu of the copper. These impurities must not be precipitated at the cathodes, because the quality of the precipitated copper would be greatly reduced thereby. Moreover, by a greater quantity of iron in the liquor, the dissolving capacity of the latter for copper is diminished to about one-third, as has been found in practice. This defect is, however, effectually obviated by the removal of such impurities, more especially the iron from the liquor, by the purely chemical method through the medium of oxides of copper, before the liquor is conveyed to the cathodes.

Simultaneously with the iron disappear from the liquors, as proved by experience, the arsenic, bismuth, antimony and, generally, all these substances which may pollute the copper.

Any silver which may be contained in the liquors derived from the extraction is either separated by electricity, then deposited on the first cathode plates of the first bath, or by chemical means before the precipitation of the copper. The resulting copper is therefore chemically pure, or it contains, like all electrolytic copper, only very small traces of impurities that do not diminish its value in any respect.

As regards the commercial value of this process, it possesses several advantages which are such as to raise it above nearly all similar processes which have hitherto become known. In the first place, the effect of using solutions of cuprous chloride is that with the same expenditure of current, double as much copper is produced as in the electrolysis of solutions of sulphate. By this means the cost of the electrolytic installation is reduced to one-half.

In the second place the halogen salts of the alkaline and earthy alkaline metals possess such dissolving capacity for cupric chloride and cuprous chloride that, in the case of solutions which are free from iron, the treatment can be effected with concentrations, which cannot even be remotely attained with solutions of sulphate.

From this it follows that with the slight volume of the liquor to be moved in Hoepfner's process also the lixiviating apparatus can be constructed at much less cost than in the case of other similar electro-metallurgical processes.

Lastly, it may be mentioned as a considerable advantage that even from the most impure, that is to say, comparatively valueless, ores, almost chemically pure copper can be produced, and that from ores containing silver also the latter can be extracted simultaneously.

From the following calculation it follows that by Hoepfner's process 43.9 kilograms of copper can be produced with one (1) horse power.

A mechanical horse power gives, with large dynamos, 690 (volt-amperes) watts; at 0.8 volt, therefore, 862 amperes. As, for every ampere hour, 2.26 grams are precipitated, this gives for 862 amperes in 24 hours:

$$\frac{862 \times 2.36 \times 24}{1,000} = 48.8 \text{ kilograms.}$$

Deducting 10 per cent. loss, 43.9 kilograms remain for 1 horse power per day.

When larger direct coupled steam engines are employed, one (1) horse power in the same time requires 30 kilograms of coal, as is well known.

If, then, the work of the necessary pumps and for the mechanical movement of the lixiviating apparatus is reckoned at ($\frac{1}{4}$) one-quarter, and the electro-dynamic power at ($\frac{3}{4}$) three-quarters of the entire work required, it follows that by Hoepfner's process, including a loss of current of 10 per cent., nearly 33 kilograms of chemically-pure copper are obtained from milled ore with 30 kilograms of coal, a result which has not heretofore been attained and which enables even the poorest copper ores to be utilized. This is the more so, if the lixiviated, very finely pulverized residues need not, like, for instance, the peacock ores, be used for the production of iron.

It is evident from the foregoing statements that Hoepfner's process, which is already in use in Silesia, Westphalia, Norway, etc., has been technically worked out to its smallest details and will in future probably attain to great importance. It will no doubt become particularly valuable for those countries in which coal is dear, as, for example, in Spain, South Africa, and in Chili, which is the most important copper-producing country of South America, especially as it is also adapted for the extraction of silver with or without the simultaneous production of copper.

ELECTRICITY IN OYSTER CULTURE.

An application of electricity to the cultivation of oysters has recently been made by Mons. Lacase Duthier, the well known authority on oyster culture. He makes use of the electric light in examining the stages of development through which the spawn passes. A glass cylinder is mounted in a cylindrical skeleton cage which serves as a support; into this glass the water containing the spawn is placed. At the bottom is a plane, silvered reflector; the cover forms a parabolic reflector in the centre of which is fixed a small incandescent lamp. The reflectors and the sides of the glass cylinder act in such a way that but few rays of light emerge from the apparatus directly; hence the liquid is suffused with a soft illumination which is admirably suited to the examination of the contents. This little apparatus, or a modification of it, is now being employed in various researches into the life processes of ferments and the culture of microbes, the illumination by the incandescent electric light being much more suitable for the study of these low forms of life than that from other artificial sources.

ELEMENTARY GEOMETRICAL THEORY OF THE ALTERNATE-CURRENT TRANSFORMER.—XIX.

BY

Chas. Steinmetz.

WE are now able to discuss the polar diagram, Fig. 33, for constant secondary E. M. F., E_1. This figure shows an exceedingly flat diagram, so flat, that the phase of the primary impressed E. M. F. entirely disappears in the drawing, amounting only to .02°. This form of the diagram directly proves that this transformer has a very high efficiency even for light load, and will give almost perfectly constant secondary E. M. F. From the diagram, or calculations on the hand of the diagram, we get the values of the electric quantities of this transformer given in the table.

1. For full load, 7870 watts sec. output
2. " half " 3987 " " "
3. " $\frac{1}{10}$ " 78.08 " " "
4. " open circuit.

} for the primary impressed E. M. F., E_0 = 2723 volts max. value.

It is most remarkable that the efficiency even for $\frac{1}{10}$ load is still as high as 75 per cent., while the drop of potential at the secondary terminals, between full load and no load, amounts to only 2 volts effective = 2 per cent.

B.—Westinghouse High-Frequency 10-*Light Transformer.*

The small 1 h. p. Westinghouse transformer shows quite a different diagram. This was tested by Prof. Ryan at Cornell University, and the data, published in the "Transactions of the American Institute of Electrical Engineers," Jan., 1890, give the complete curves of instantaneous values for 1, full load, 10 lights; 2, half load, 5 lights; 3, $\frac{1}{10}$ load, 1 light; 4, open circuit.

Looking over the curves of instantaneous values we notice that the phase of the secondary E. M. F. lags behind the phase of primary E. M. F., and that this lag increases with increasing secondary current. If, however, there is no self-induction, that is, magnetic leakage, present, the secondary E. M. F. must be slightly in advance of the primary impressed E. M. F., as explained before. Hence the lag of secondary E. M. F. proves the existence of self-induction in the primary coil. At the same time, we see that the primary current, especially for open circuit, is very unlike a sine wave, so that this transformer will give us a good method of testing how near the assumption of sine-shape will come to the real facts, even in non-sinusoidal waves.

To find the phases and differences of phases in the fully loaded transformer, we make use of the definition of the cosine of the angle of difference of phase between two non-sinusoidal waves, given in chapter X., as the ratio of the mean product of instantaneous values, into the product of their effective means. Thus the difference of phase between primary impressed E. M. F., E_0, and secondary induced E. M. F., E_1, is given by

$$\cos \psi = \cos (E_1 E_0) = \frac{\text{mean } (e_1 e_0)}{\sqrt{\text{mean}^2 e_1 \times \text{mean}^2 e_0}}$$

and gives for full load the angle $\psi = -10.5°$, the phase of primary current, angle $\varphi = (E_1 C)$ is derived in the same way; angle $\varphi = 12.5°$, and the difference of phase between primary current and impressed E. M. F., angle $\omega = (E_0 C)$, angle $\omega = 23°$.

ELECTRICITY AND ADULTERATION.

AT the meeting of the Bavarian Society of Applied Chemistry, one of the speakers, Director Koehler, of Berlin, made a rather remarkable statement. He said that during a visit to the Strassburg Exhibition his attention had been attracted to the remarkably beautiful green color of some preserved beans, and upon inquiring as to how this color had been imparted he was told that it was a trade secret. Subsequently he had learned that during the boiling of these vegetables in a copper vessel an electric current was passed through the whole, the copper of the vessel acting as an anode, and that in this way a large quantity of copper was carried into solution, giving the vegetables a fine tint.

THE NEW 100 H. P. THOMSON-HOUSTON FREIGHT LOCOMOTIVE.

The continued success of electric street cars and the demands made by street railway companies for larger and more powerful motors to handle their cars has led others interested in transportation to investigate the advantages of electric locomotion, with the result that not a few electric tramways are in operation hauling freight about in cotton mills, iron works, mines, etc. In this department of work, also, there has been a constant demand for more powerful motors, so that where the electric locomotive formerly hauled a few bales of cotton it is now called upon to handle a fair-sized train. It was in compliance with a demand of this nature that the Thomson-Houston Motor Co., of Boston, some time ago undertook the construction of an

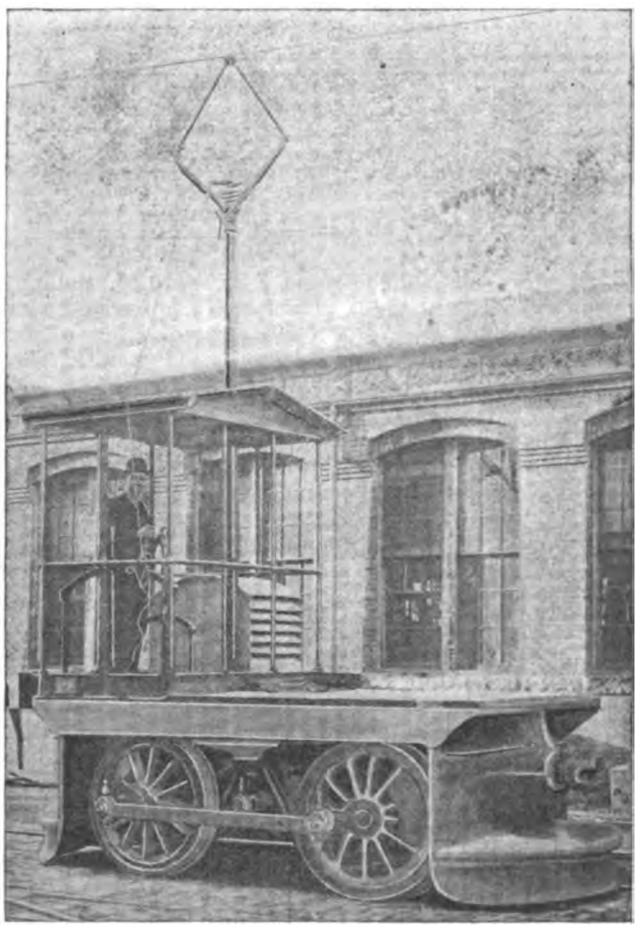

Fig. 2.—100 H. P. Thomson-Houston Freight Locomotive.

electric locomotive which is designed to obviate the necessity of employing a steam locomotive, and it may, indeed, be said to represent the first large freight locomotive displacing steam on a standard-gauge railroad. The Whitinsville Machine Co., of Whitinsville, Mass., for whom the locomotive was built, purpose to carry their merchandise back and forth from the railway station to their works, a distance of 1½ miles, by means of electric power.

At the invitation of the Thomson-Houston Motor Co., a large number of visitors assembled at the Lynn Works, on the afternoon of Saturday, Nov. 28, and witnessed the operation of the new motor.

The locomotive, which is illustrated in Figs. 1 and 2 of the accompanying engravings, is built in a square form with a platform for carrying loads, and cow-catchers and draw-bars at each end. The power is to be furnished by a large generator located at the works of the Whitin Machine Co., and conveyed over a trolley wire from which it is taken by means of a universal trolley bar attached to the locomotive.

The construction of the truck is well shown in the engraving, Fig. 3. The motor employed is one of the well-known "G" type of the Thomson-Houston Electric Co., and the power is communicated from the armature to the rear axle by means of double reduction-gearing, and from the rear axle to the forward one by means of parallel rods. The motor consists of wrought iron field magnets, which are bolted to magnetic yokes of mitis iron. One of these yokes carries the bearings which support that end of the motor on the axle, while the other yoke is spring supported from the other axle. This keeps the gears always in line, and meshing correctly with each other, and at the same time provides considerable spring support for the motor.

The gearing consists of aluminum bronze pinions and mitis iron gear wheels. This gearing runs in gear cases, in which a plentiful supply of grease is placed. This decreases the noise, friction and wear, and increases the life of the gears very materially. On the intermediate shaft is heavily keyed a mitis iron brake drum, which is covered with wood lagging. It is embraced by two half bands of steel, tightened upon it by means of the brake drum lever, situated in the operating stand.

The wheels are 42 inches in diameter and are heavily steel tired, and the frame consists of two heavy side plates in which are located the main axle bearings. Two heavy cast iron end plates in which are cast the cow-catchers are bolted to the side plates by means of heavy through bolts, which are a driving fit in reamed holes. These end plates carry the heavy spring draw-bars and bumpers.

The operating platform is located at one end of the main platform and is encased in a railing and covered with a protecting roof. On this platform are located the levers for operating the controlling mechanism, the brake and the double-acting sand boxes. The universal trolley bar also extends upwards from the locomotive at this point, as shown in Fig. 2.

The controlling mechanism consists of two large rheostats of the well known Thomson-Houston railway type. These are so arranged with their contact shoes that no reversing switch is needed. The operator stands so that he always faces in the direction in which the locomotive is to go, and being in this position, he pushes the rheostat lever from him to make the locomotive go forward, and pulls it towards him to make it go backward. A positive centre lock is provided, so that in turning the current off there is no danger of passing the neutral point on the rheostat, and so reversing the locomotive with the current on. When the operator stands in the above-mentioned position he pushes the brake lever from him in order to apply the brake. The bands are so arranged on the brake-drum that the friction tends to tighten them up more upon the wood lagging, and so assists the operator in braking the train.

The following data give the details of construction of the new locomotive, the construction of which has been under the direct supervision of Mr. J. P. B. Fiske, who is in charge of all the motor work of the company, except that relating to street railways and long-distance transmission:

Wheel base	6′ 4″
Diameter of wheels	42″
Speed reduction between armature and axle	1 to 25
Gauge	4′ 8½″ standard.
Wheel base	6′ 4″
Measured height above rail platform	4′ 4″
Greatest length of loco. (at cowcatcher)	15′ 9¼″
Greatest length of platform	12′ 7¼″
Greatest width of platform	7′ 1¼″
Weight of complete locomotive, less trolley pole	42,525 lbs.
Approximate weight of motor	5,400 lbs.

A combined main switch, lightning arrester and fuse-box is placed within easy reach of the motorman, so that he can instantly shut the current off from the locomotive by a slight movement of the hand.

The construction of the motor is of the most rigid and waterproof character, the field spools having their wire enclosed and entirely sewed up in canvas bags, which are covered with a heavy coating of waterproof paint.

The locomotive, which weighs 42,525 lbs., is designed to operate at 500 volts and to develop 100 h. p. at the draw-bar. This will enable it to pull a train of 4 to 6 heavily loaded cars, or an aggregate load of 200 to 300 tons, at a speed of 5 miles an hour on a level.

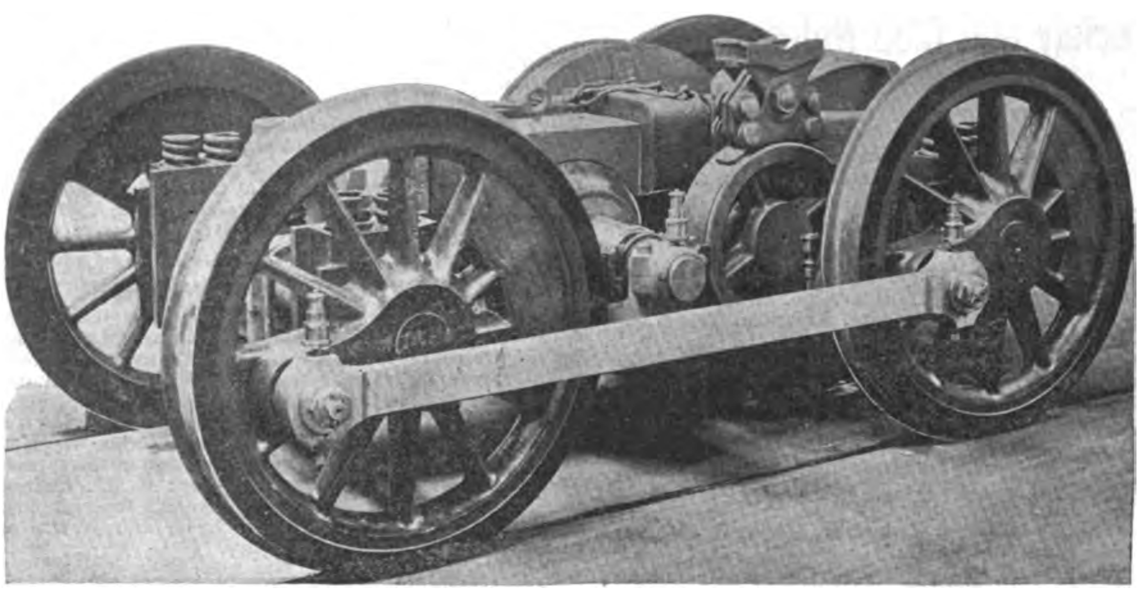

Fig. 3.—Truck of 100 H. P. Thomson-Houston Freight Locomotive.

THE ELECTRICAL PREPARATION OF CINNABAR.

Cinnabar is now being prepared by means of electrolysis, according to a French contemporary, from the metal, mercury, itself. The apparatus seems to be simple, and it is stated that the process is economical, while the product is of excellent quality. A vat, a metre in diameter and two metres in height, is the chief feature in the plant. On the sides of this vat are fixed two round metallic plates, each 15 centimetres in diameter. The mercury is placed in the vat, and the plates are connected up to the positive pole of a dynamo. At the bottom of the vat is a plate of copper covered with galvanized iron; this is connected to the negative pole of the machine. The vat is filled up with an aqueous solution of ammonium nitrate and sodium nitrate, and there is an ingenious device for supplying a constant and regular flow of sulphuric acid. The nitrate solution should contain

Ammonium nitrate...........	8 kilogrammes.
Sodium nitrate...............	8 "
Water......................	100 litres.

The liberated gas escapes by a tube in the cover of the vat, and in doing so keeps the liquid well mixed, and a precipitate of sulphide of mercury—cinnabar—falls to the bottom.

WATER POWER IN SWITZERLAND.

A scientist of Berne has been studying the subject of the water power that can be made available in Switzerland for the generation of electricity for light and power, and finds that 600,000 effective horse power can be obtained.

ECONOMY OF MULTIPLE EXPANSION ENGINES.

PROFESSOR ROBERT H. THURSTON contributes in the November issue of *Cassier's Magazine*, the new engineering monthly, a very interesting article on the "Philosophy of the Multiple-Cylinder Engine," in which he says the true action of the multiple-cylinder is now easily perceived. It is subject only to the wastes, apparently, of a single cylinder, of that one of the series which is itself most affected by wastes. The losses by internal condensation which would take place in a simple engine of equal total range of expansion, and working between the same extreme limits of temperature and pressure, which increase rapidly as that range is increased, are, in the multiple-cylinder engine, divided practically by the number of cylinders in series. This would indicate that the greater the number of such cylinders, the better; but it must be remembered that each new element thus introduced brings with it increased wastes externally, more friction, greater cost, and that these factors, in turn, limit the number of cylinders advisable, in the very best examples of high economy, to a very small number. Experience shows that it is, on the whole, not advisable to increase the number beyond about one to each four or five atmospheres pressure; or perhaps better, that the ratio of expansion should not exceed about three in any one cylinder, nor be less than two and a half. Thus it has been found by the best builders that the simple engine is best, as a rule, up to about 50 or 60 pounds per square inch, by gauge, the two-cylinder or double-expansion engine from that limit up to about 100 or 120, the triple-expansion up to 180 or 200, and the quadruple-expansion engine—four cylinders in series—beyond that point. Taking the limit of the expansion ratio at 8 and the terminal pressure at 10 pounds, and assuming hyperbolic expansion, we have the following as illustrating good practice, condensing engines being understood:

Engine	Ratio, Total.	Ratio, Single.	Limit of Pressure.
Single cylinder....	5	5	50 lbs.
" "	6	6	60 "
Double-expansion..	9	3	90 "
Triple-expansion...	27	3	270 "
Quadruple-expansion............	81	3	810 "
Quintuple-expansion...........	243	3	2,430 "

This would indicate that the four-cylinder engine is likely to answer all purposes up to quite as high a pressure as is ever to be expected to be used in the steam engine, so far as we can see, to-day.

Society and Club Notes.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

AT the council meeting of the American Institute of Electrical Engineers, November 24, the following gentlemen were admitted to associate membership:

F. W. Cushing, secretary, Central Electric Co., 118 Franklin street, Chicago, Ill.
S. W. Huff, manager, Electrical Department of Factory, Baxter Electric Motor Co., 2100 Druid Hill avenue, Baltimore, Md.
Angus S. Hibbard, general superintendent, American Telephone and Telegraph Co., 18 Cortlandt street, New York City.
Francis N. Sanborn, Manhattan Electric Lighting Co., 13 Spencer place, Brooklyn, N. Y.
Harold Babbitt Smith, Adj. Prof. in charge of Electrical Engineering Department, Arkansas State University, Fayetteville, Ark. Barre, Mass. (till Mar. 2).
James A. Vandergrift, assistant superintendent and electrician, Sawyer-Man Electric Co., 534 West Twenty-third street, New York City.
Elmer G. Willyoung, electrician, James W. Queen & Co., 924 Chestnut street, Philadelphia, Pa.
Charles H. Wilson, general superintendent, Chicago Telephone Co., 203 Washington street, Chicago, Ill.

The following associate members were transferred to full membership:

Herbert H. Eustis, president and electrician, Eastern Cable Co., 61 Hampshire street, Boston, Mass.
F. B. H. Paine, consulting electrical engineer, Chas. Paine & Sons, 71 Broadway, New York City.
George F. Curtiss, electrician, Thomson-Houston Electric Co., Lynn, Mass.
Edward C. Boynton, Elektron Manufacturing Co., Springfield, Mass.
H. W. Weller, railroad inspector, Edison General Electric Co., New York City.
P. B. Delany, inventor, South Orange, N. J.

MR. ROSEWATER AT THE ELECTRIC CLUB.

IT is now announced that the lecture on the Government Telegraphs of Europe by Mr. E. Rosewater, editor of *The Omaha Bee*, and president of the Old Time Telegraphers' Association, will be given at the Club on Thursday, December 3, at 8 P. M. The lecture will enter into a large number of details, and Mr. Rosewater's mission to Europe, as the special representative of Postmaster-General Wanamaker, has placed him in possession of a vast amount of most important and interesting information on the subject. Mr. Rosewater will have many of the original documents, forms, etc., with him. Several public men will participate in the subsequent discussion, and it is expected that the meeting will be one of the largest the club has seen.

MR. CARL HERING ON THE FRANKFORT EXHIBITION.

A VERY instructive and interesting lecture on the Frankfort Exhibition was delivered before the American Institute of Electrical Engineers, at the Electric Club, by Mr. Carl Hering, on Tuesday evening, November 24, before a large audience. The lecture was well illustrated by magic-lantern, and was heard with much pleasure by a large gathering of members of the Club and the Institute.

CHICAGO AMATEUR ELECTRICAL SOCIETY.

THE Chicago Amateur Electrical Society has decided to change its name to "The Chicago Society of Operative Electricians."

The objects of this society are the advancement of its members in the knowledge of electrical science by lectures to be given by prominent electricians interested in the society, and by a thorough course of study, using standard works under the supervision of an instructor. Mr. H. G. Brownell, a college graduate of several years' practical experience, has been chosen for this position. As soon as the finances of the society will permit, a library will be started, in connection with which a laboratory will be fitted up in order that theory may be demonstrated by practical experiment, a manner of study which has been adopted by our best colleges and manual training schools.

Another feature of the society will be an amateur electrical display at the World's Fair. Mr. J. Allen Hornsby, secretary of the Electrical Department of the Columbian Exposition, in an address to the society, stated that the department would endeavor to secure for it the same honors given the professionals in all departments which could possibly come in its sphere. He also promised that heat, light, and power would be furnished for the exhibit. A committee has been appointed to make arrangements for an exhibition, and is already hard at work. Considerable interest in the society is being manifested by young men interested in electrical work and a large membership will soon be had. The regular meetings are held on the first and third Thursdays of each month. On Monday evenings the members come together for informal study and discussions.

It is earnestly requested that all young men interested in the study of electricity will take an interest in the work of the society, and that similar societies and experimental clubs will correspond and co-operate with this society in its endeavor to secure a creditable amateur electrical display at the World's Fair.

All communications should be addressed to the corresponding secretary, S. G. Arnold, room 5, 120 Quincy street, Chicago.

THE CRANFORD TELEGRAPH ASSOCIATION.

THIS association, of Cranford, N. J., has a membership of 13, who have formed themselves into a fire and police department for the protection of the town. Monthly meetings are held, and a knowledge of the practice and principles of commercial and railway telegraph is required. All members are pledged to turn out on general alarms. The individual members own all instruments, while the association owns the batteries, wires, etc., which are in the charge and under the supervision of the superintendent. The officers are E. K. Adams, president; F. E. Friedrichs, secretary and treasurer; W. B. Rosencranz, superintendent. The example set by this association might be followed with advantage in many another small community.

Appointments, Etc.

MR. L. K. PEROT, late of the Thomson-Houston Electric Co., has been appointed assistant engineer of the Equitable Engineering & Construction Co.

MR. J. H. REEVES, late superintendent of the Huntington Reformatory electric light plant, has been placed in charge of the station of the Home Electric Light Co., Tyrone, Pa.

MR. HARRY W. HAMBLIN, ex-manager of the Pawtucket Electric Light Co., of R. I., and Consolidated Electric Light Co., of Portland, Me., has connected himself with H. W. Leonard & Co., Electrical Exchange Building, New York City.

College Notes.

UNIVERSITY OF MINNESOTA.

THE Department of Electrical Engineering of the University of Minnesota has bought a nine-light Thomson-Houston arc machine, with a number of lamps of different makes. It has already received two Edison motors, which are in use, with a 10-kilowatt Edison generator. A 300-light alternator is to be ordered immediately, and other additions are in prospect. The number of students at the University this year is the largest in its history, and is continually increasing.

TULANE UNIVERSITY OF LOUISIANA.

TULANE UNIVERSITY, New Orleans, has recently added to its electrical equipment 12 dynamos, 14 arc lamps, and a variety of meters, instruments and accessories. Among the additions are three arc systems, a Thomson-Houston 6 light, an Edison 5 light, and a Wood 15 light. There is a 300 light Slattery alternator with converters, instruments, etc., and four Edison motors of different styles and sizes. The course is very popular, and has an increased number of students this session.

Reports of Companies.

THOMSON-HOUSTON ELECTRIC CO.

IT was b lieved at the beginning of the year, says the Boston *Transcript*, that the Thomson-Houston Electric Company would earn this present fiscal year from $2,000,000 to $2,500,000 net or not far from $4,000,000 above all dividend requirements. Of course it was not expected that the phenomenal earnings of $3,000,000 net made last year were to be repeated this year but the Boston News Bureau says that it now looks as if $2,500,000 net might be reached the present fiscal year, ending Feb. 1, 1892, or more than $1,000,000 surplus over the $1,240,000 required for dividends upon the present basis. There is, therefore, says the Bureau, good basis in earnings for expectation by Thomson-Houston stockholders of something more than $4 per share from present earnings. Below is a comparative statement of the business of the Thomson-Houston Company for the three months ended Oct. 31, 1891 and 1890, and for the nine months ended the same dates in both years. The profits shown, however, are for the Boston office only.

Quarter :—	18891.	1890.	Increase.
Gross sales............	$3,098,573	$2,785,073	$313,500
All exp. and com's......	2,273,408	2,078,896	194,522
Net profit...	$825,165	$706,187	$118,978
9 months ended Oct. 31—			Decrease,
Gross sales............	$7,163,411	$7,514,520	$439,109
All exp. and com's....	5,600,628	5,788,421	287,806
Net profit...	$1,562,783	$1,626,069	$63,309

STANLEY ELECTRIC MANUFACTURING CO.

AT the annual meeting of the Stanley Electric Manufacturing Company, practically the old board of directors were chosen. They then re-elected the old board of officers. Manufacturing has been going on the past six months, and the result has been most gratifying to the shareholders.

Legal Notes.

BRUSH CO. vs. WESTERN ELECTRIC CO.—ARC LAMP INFRINGEMENT.

SUIT to restrain the Western Electric Company, of Chicago, from manufacturing and selling electric arc lamps has been begun in the United States Circuit Court at Chicago by the Brush Electric Light Company, of Cleveland. The defendant company, it is alleged, is now manufacturing and selling a large number of the lamps similar in construction to those covered by the Brush patent. An injunction, with accounting, is asked for.

ENGINE FOR THE WORLD'S FAIR.

THE Bureau of Construction of the Worlds' Columbian Exposition have contracted for a 400 h. p. Armington and Sims' engine for use in connection with their temporary light and power plant. The engine was shipped immediately, and is probably in operation by this time. The matter is in the hands of the Pond Engineering Company, general Western agents for the Armington and Sims engine.

Patent Notes.

A BROAD PATENT ON POWER TRANSMISSION GRANTED TO H. W. LEONARD.

A VERY full description was given in THE ELECTRICAL ENGINEER last week of the new and ingenious method of motor regulation invented and employed by Mr. H. Ward Leonard. A very broad patent has now been granted to that well-known engineer, No. 463,802, dated November 24, 1891, with 26 claims. To show its scope it will suffice to quote a few of the claims;

1. The method of operating and regulating an electric motor, consisting in maintaining the strength of its field-magnet and the position of its commutator-brushes constant and altering its speed by varying the electromotive force supplied to its armature, substantially as set forth.

5. The method of performing work by the use of electric energy, which consists in varying the electromotive force in proportion to the "foot" element of the foot-pounds per second of the power required and varying the current in proportion to the "pounds" element, substantially as set forth.

8. The combination of an electro-dynamic motor, a source of supply for its armature, a separate constant source of supply for its field-magnet, and means for varying the potential of the armature-supplying source, located at the point of work performed, substantially as set forth.

12. The combination, with a wheeled vehicle, of an electric motor mounted thereon to propel the same, said motor having its armature and field-magnet energized by separate circuits, and means on the vehicle for varying the electromotive force of the energy supplied to the armature of said motor, substantially as set forth.

24. The combination of a source of alternating current of high tension, means for converting such current into a continuous current of lower tension, and a motor having its armature supplied by such continuous current and its field-magnet separately excited, substantially as set forth.

26 The method of transforming the energy of a prime motor at any speed nto propelling energy at any desired speed, which consists in operating an electrical generator by said prime motor, supplying the armature of an electric motor running in a constant field from said generator, and varying the electromotive force of said generator to vary the speed of said electric motor, substantially as set forth.

A NEW GALVANIZING PROCESS.[1]

A NEW process for protecting iron and steel is being introduced into England by Messrs. Joseph Westwood & Co., Napier Yard, Millwall, London, E. The metal to be coated is passed through an acid pickling bath, then through an alkaline bath to remove acid, treated with a flux of zinc chloride and stannous chloride, and when thus prepared covered with metallic lead by immersion in a bath of that metal. The point of novelty in the process appears to be the attainment of a close adherence of the lead to the iron by scrupulous attention to cleanliness and the use of specially devised fluxes. The preliminary pickling is accomplished by the passage of a week current of electricity through the bath in which it is conducted, and on this somewhat slender ground the method has been termed an "electro" lead process. It will be seen that the *modus operandi* and the result attained bear striking resemblance to those of the process of the London Metallurgical Company.

As far as can be judged from the statements that have been made public, the chief difference consists in the use by the latter of a lead alloy and by the former of pure lead. However, this may be the products of the two processes are much alike in appearance, and presumably in properties.

As far as could be seen from tests made of the material at Messrs. Westwood & Co.'s works, the adhesion of the lead coating was remarkably perfect. Sheet iron thus protected was bent double without causing the appearance of any tendency to crack or exfoliate, and specimens of bar were shown which had been twisted spirally upon themselves and were similiarly perfect. Sheet metal can also be flanged or corrugated without the coating suffering injury, and the method is also said to be applicable to wire in an equal degree. Wire netting is susceptible of treatment by this method, and the coating it receives is distinctly better in appearance than that produced by galvanizing. The non-tendency of the coating to separate from the metal it is designed to protect is one of the advantages claimed, another of importance being the retention of its tensile strength by the iron or the steel coated, contrasting favorably in this respect with the effect produced by zinc. Indeed, it is claimed that in some cases the strength of the material is enhanced by the coating process, the good effect upon hard steel wire being specially noticeable.

There remains, however, some hope for the galvanizing trade proper. Although lead is much less corrodible than zinc by most of the destructive agents to which coated articles are exposed, yet it by no means follows that the powers of resistance of the articles protected stand in the same order. It is needless to elaborate upon this point; a short consideration of the electro-chemical relations of iron, lead, and zinc will suffice to show wherein the weakness of the new method lies. Zinc is a brittle metal, and one little adapted for a protective coating, but its chemical properties make it the best metallic preservative for iron known, and it will be pushed from its pre-eminence with great difficulty. At the same time there are numerous applications open to lead-covering processes such as that we have described.

1. *Industries.*

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED NOVEMBER 24, 1891.

Accumulators :—

Separator for the Plates of Secondary Batteries, C. F. Waldron, 463,879. Filed Jan. 19, 1891.
Separators are in the form of wooden pockets or folds, each inclosing one of the plates of each pair.

Clocks :—

Electric Programme-Clock, J. L. McCaskey, 463,848. Filed May 12, 1890.

Conductors, Conduits and Insulators :—

Wire-Hanger, C. A. Jacobs, 463,756. Filed Feb. 14, 1891.

Machine for Covering Conductors, C. Klotzbach, 463,809. Filed Aug. 1, 1891.

Machine for Covering Conductors, C. Klotzbach, 463,810. Filed Aug. 1, 1891.

Electric-Wire Insulator, H. F. Newell, 463,955. Filed Feb. 28, 1891.

Dynamos and Motors :—

Brush-Holder for Electric Motors, J. E. Lyons, 463,635. Filed Mar. 19, 1891.

Electric-Motor Mechanism, S. E. Mower, 463,639. Filed June 16, 1891.
Relates to speed-reducing devices, and is specially applicable to railway motors.

Armature-Core for Dynamo-Electric Machines, E. Thomson, 463,671. Filed Aug. 5, 1889.
The core is built up from plates of sheet iron having a thin scale or coating of hard insulating substance formed naturally in the process of manufacturing sheet iron, and thin interposed distinct separating plates of non-magnetic metal.

Electric Motor and Generator, I. E. Storey, 463,693. Filed Apr. 16, 1889.
A novel construction of a shunt-wound machine.

Commutator for Electrical Machines, W. W. Vail, 463,694. Filed June 23, 1890.
A pole-changer, for shifting from a continuous to an alternating current.

Electric Motor and Dynamo, A. L. Parcelle, 463,704. Filed Apr 2, 1891.
A ring armature machine. Relates especially to details of construction.

Carbon-Brush Clamp for Dynamos, S. Morse, 463,748. Filed July 25, 1891.

Electrical Transmission of Power, H. W. Leonard, 463,802. Filed Aug, 14, 1891.
Claim 1 follows:
The method of operating and regulating an electric motor, consisting in maintaining the strength of its field-magnet and the position of its commutator-brushes constant and altering its speed by varying the electromotive force supplied to its armature. See "Patent Notes," page 613.

Lamps and Appurtenances :—

Electric-Arc Lamp, W. S. Hays, 463,720. Filed July 27, 1891.
Relates to mechanical construction.

Lamp Socket, E. Voigt, 463,763. Filed Nov. 18, 1890.

Means for Suspending Electric Lamps, T. H. Brady, 463,778. Filed Feb. 18, 1891.

System of Electric Lighting, E. J. Hodgson & J. W. Stearns, Jr., 463,793. Filed Feb. 26, 1891.
Employs a cut-out located in proximity to the lock of a door and adapted to be operated by the mechanism of the lock, whereby lamps may be lighted or extinguished upon entering or leaving a room.

Measurement :—

Electric Meter, A. Reckenzaun, 463,711. Filed Nov. 1, 1890.
Claim 1 follows:
An apparatus for measuring electric currents or the product of time and currents, comprising indicating mechanism, electromagnets, gravitating means intermediate of said magnets and indicating mechanism and acting by gravity to move said indicating mechanism, and a member periodically making circuit with said magnets in alternation for energizing them to lift said gravitating means.

Medical and Surgical :—

Electrical Surgical Instrument, F. L. Connable & T. V. Harper, 463,785. Filed Jan. 15, 1891.

Therapeutic Electric Battery, J. A. Crisp, 463,945. Filed Mar. 31, 1891.

Miscellaneous :—

Electric Controller for Elevators, W. Baxter, Jr., 463,615. Filed Jan. 29, 1891.
Employs an electromagnetic shifter for operating the coupling between the motor shaft and the hoisting pulley.

Electric Cigar Lighter, G. N. Engert, 463,754. Filed Dec. 24, 1890.

Electric Arc Interrupter, E. Thomson, 463,762. Filed Dec. 15, 1890.
Claim 1 follows:
The combination, with an electric circuit-breaker, of an arc distorter acting to drive the arc out of position, and a bundle of insulated conducting plates for receiving and extinguishing any arc formed at the circuit breaker.

Multiple Fuse Cut-Out, G. K. Wheeler, 463,764. Filed Nov. 26, 1890.

Electric Cut-Out, E. W. Rice, Jr., 463,770. Filed Dec. 2, 1890.

Electric Subway Switch, L. A. Fehr, 463,808. Filed Nov. 28, 1890.

Automatic Safety Cut-Out for Electrical Conductors, R. A. Morgan, Jr., and G. C. Bosson, Jr., 463,867. Filed Nov. 28, 1890.

Phonograph, H. T. Holtz, 463,989. Filed April 23, 1891.

Starting and Stopping Device for Phonographs, H. T. Holtz, 463,990. Filed July 11, 1891.

Railways and Appliances :—

Railway Signal, E. J. Samuels and F. E. Behrendt, 463,691. Filed May 14, 1891.
Relates to the operation of train order signals from a telegraph office and at some distance.

Conductor and Guide for Electric Railway Trolleys, J. I. Conklin, 463,715. Filed Feb. 10, 1891.

Self-Lubricating Trolley Wheel, W. Duncan, 463,733. Filed Sept. 24, 1890.

Electric Conductor for Railways, C. E. Sargent, 463,760. Filed July 10 1891.
Conductor is U-shaped in cross-section and has insulation on the outside; it is mounted with the open side downwards, the trolley making contact on the inside.

Section Insulator and Lightning Arrester, for Electric Railroads, E. Thomson, 463,761. Filed Sept. 1, 1890.
Comprises separate conducting plates secured in place, but spaced apart and insulated at points somewhat above their contact surfaces and having such contact surfaces separated entirely from each other by an air insulation space, but rounded and arranged in line to form a continuation of the path of travel of the contact device.

Trolley for Electric Railways, G. H. Alton, 463,765. Filed Feb. 16, 1891.

Switch for Electric Railways, F. O. Blackwell, 463,766. Filed Jan. 26, 1891.

Trolley Wire Hanger, E. T. Birdsall and L. W. Serrell, 463,894. Filed Dec. 1, 1890.

Telegraphs:

Synchronous Telegraph, C. S. Bradley, 463,852. Filed Jan. 28, 1887.
Claim 1 follows:
In a telegraphic system, the combination of two alternating current machines located at different points, mutually reacting to maintain continuous synchronous movement, an electric connection between them, and telegraphic transmitters and receivers located at such points, the connecting circuit of which passes through synchronously driven mechanism controlled by said alternating machines.

AN ELECTRIC RAILROAD OF 149 MILES.

OF the proposed electric railroad between Budapest and Vienna, further details are given in a late number of the *Verkehrs Zeitung*. According to these, there will be for the 149 miles of road two main power stations with 100 substations, and only three or four stopping places. The cars will be 131 feet long, and will be fitted with four two-axle bogie trucks. At each end of a car there will be two large electric motors, to which the current will be transmitted by contact wheels running on conductor rails. The speed which it is proposed to attain in regular working is 200 kilometres (124.2 miles) per hour, and in order to diminish the air resistance the ends of the cars will be shaped like ships' bows. The distance between Vienna and Budapest is to be covered in 75 minutes, and cars are to be run at quarter-hour intervals. Up to the present, permission to build the road has not been granted by the authorities, but there is thought to be little doubt that the line will be taken in hand in the near future.

ELECTRICAL ENGINEERING PUPILS IN ENGLAND.

A CASE, which must be significant both to teachers of electrical engineering and to pupils, has been heard in the English law courts, writes our London correspondent. Mrs. Uniacke claimed, against Mr. Ronald Scott, a well-advertised teacher of electrical engineering, the repayment of a premium of £150 paid for the apprenticeship of her son to the defendant. The action was based on an alleged breach of deed. It was proved that Mr. Ronald Scott had failed, during a nine months' apprenticeship, to teach to his apprentice anything which would be useful to an electrical engineer. The boy, Uniacke, had been kept to the work of filing and fitting brass rods; he had also, for some slight inattention, been sent away from the works. Mr. Justice Romer made strong comments on the conduct of the defendant and finally gave a judgment in favor of the plaintiff with damages. It was stated in the evidence that Mr. Scott had 65 apprentices in his workshops, and only 7 workmen, including manager and foreman.

THE CENTRAL ELECTRIC CO.

THE Central Electric Company report a large increase in their lamp business since they have taken the agency for the Swan lamp. The 16 candle-power lamp of the Swan make has an efficiency of between 3.3 and 3.4 watts per c. p. and an average life of from 600 to 1,000 hours, and does not blacken even when nearly burned out. The company claims that the demand is for high efficiency and good average life rather than low efficiency and extra long life. The company have issued a circular giving low prices on a number of standard supply articles. This circular covers sockets, switches, cut-outs, receptacles, attachment plugs, branch blocks, wire guards, tape, shades, lamps, etc. They have just taken the agency for the Washington carbon and will carry a large stock. These carbons are designed for both high and low-tension systems. They are claimed to give long life and are perfectly straight and uniform.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

The object of advertising is to keep in touch with old customers and to secure new ones.

THE "C. S." COMBINATION REFLECTOR LAMP SHADE AND HOLDER AND PORTABLE LAMP STAND.

THIS lamp shade, which is about to be put upon the market by the Cutter Electrical and Manufacturing Company, 27 South Eleventh street, Philadelphia, presents some unique claims to favor. It will carry any size or style of lamp, and is provided with its own shade-holder which is adapted to automatically fit any and all systems. It permits the renewal of an exhausted lamp with the least expenditure of time and trouble. It directs the light exactly where it is wanted and to no other point. It is made of aluminum and glass, weighs less than five ounces, and may be "knocked down" and "nested" for shipment. It has but one destructible part—the glass diffusion plate—which if accidentally broken is easily replaced at a trifling cost.

Briefly, this reflecting shade may be described as a combination of a parabolic with a plane radiating reflector to which is attached a diffusion plate of ground glass, and the arrangement of these different parts is such as to direct the main portion of the rays of light into a given zone of illumination, while a minor portion is radiated and diffused throughout the room. The diffusion plate is fixed securely to the radiating portion of the shade by means of a simple interlocking device, which admits of an easy separation of the two parts when it is necessary to remove or replace a lamp. At the apex of the parabolic reflector is an aperture sufficient only for the passage of the stem or shank of the lamp, and upon the rim of this aperture is affixed the automatic shade-holder, which is a novel arrangement of three spiral springs

THE "C. S." COMBINATION REFLECTOR, LAMP SHADE AND HOLDER.

that close in upon the shoulder formed by the junction of the bulb with its brass mounting when the stem of the lamp is passed through it; thus, the top of the shade fits closely around the stem of the lamp, shutting off all vertical rays, the general result being a strong white light immediately in front of the shade, and a gentle diffused light throughout the room, there being no marked boundary to the zone of illumination.

The portable lamp stand consists of an upright metal tube mounted upon an ornamental base of spun metal and marble. From the upper end of this standard projects a hollow flexible arm to the end of which is affixed the ordinary lamp socket.

This flexible arm is so arranged that it may be bent in any direction or coiled upon itself if desired, and in whatever position it be placed it remains. The stand is wired by means of a fireproof flexible cord, which, entering the fixture through an ebonite sleeve placed in the ornamental base, passes up through the standard and the flexible arm to the lamp socket. The interior construction of the flexible arm is such as to protect the conducting cord from being crushed or abraded, however the arm may be coiled or bent, and is practically indestructible.

This flexibility of the arm enables the user not only to concentrate his light upon any desired point at will, but permits him in so doing to form the arm into almost any graceful curve that may be suggested. This flexible arm may also be used as a wall bracket.

THE "DICK & CHURCH" TANDEM COMPOUND ENGINE.

The following notice has been issued by the Phœnix Iron Works Co., of Meadville, Pa.

To all whom it may concern:

It lately having come to our notice that some builders of Tandem compound engines are copying our construction and design, we deem it no more than proper to give notice that this improved construction was patented November 18, 1890, and is the exclusive property of this company, and that we shall protect our rights as against all builders or users of engines.

The 'Dick & Church" Tandem compound engine, as built by us was illustrated in this journal in the issue of September 30, 1891, in which was shown cuts of the engine together with a full description of same. The advantages of this construction, as against any other known design, are manifest, and others, as well as ourselves, evidently recognize it, but we trust this will be sufficient to prevent any further acts of piracy; at all events we hav endeavored to protect the general public by publishing this notice. It is our good fortune to own this design for tandem construction, and we suggest that other builders who recognize its important advantages should at least have the courtesy to write us before making use of it, no matter whether they propose to use an exact reproduction or merely copy as near as they think will be safe and evade our claims. We should like them to at least do us the honor of letting us have the credit of possessing the merit of originality.

H. WARD LEONARD & CO.

LARGE manufacturing companies are quick to appreciate the advantages of having in their employ experienced and neutral electrical engineers to advise them as to applications of electricity in their business. This is evidenced by the success in this line which H. Ward Leonard & Co. are obtaining. Among the concerns of importance who have recently retained them as consulting electrical engineers are Wm. Sellers & Co., the well-known machine tool builders of Philadelphia; Otis Brothers & Co., of elevator fame, and the Ingersoll-Sergeant Drill Co. No large manufacturing concern whose product involves the use of power can afford to neglect the rapid progress of electrical motor applications.

H. Ward Leonard & Co. charge a definite sum per year for their services as consulting engineers, and the manufacturing concerns seem to like this feature of definiteness rather than a percentage or a retainer and individual charge for individual service.

H. W. BURNET.

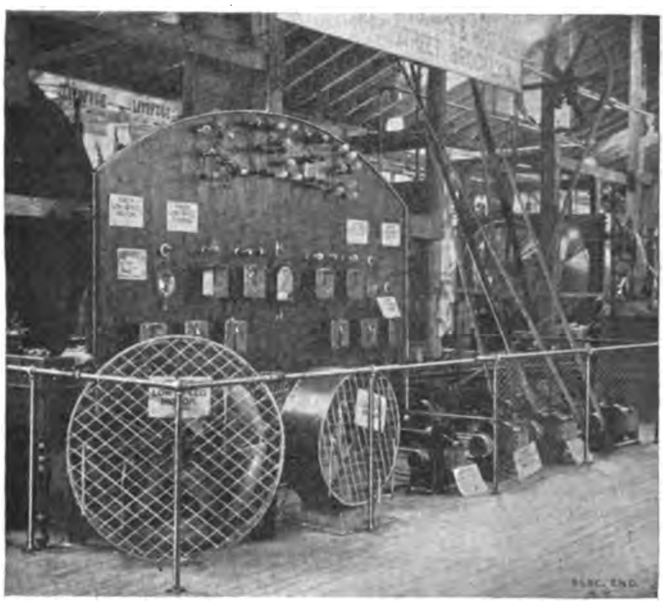
ON another page will be seen an article by Mr. H. W. Burnet, electrical engineer, of 12 North Grove street, East Orange, N. J., describing the new rosette and switch designed by him. Mr. Burnet also manufactures dynamos, motors, electrical instruments, experimental apparatus, etc., and has recently made several push-button sockets for the various standard lamps, which are said to be perfect in action, simple in construction and low in price, and have the additional advantage of being operated with one hand where the lamp is suspended or on a shaky fixture.

THE ELECTRIC MERCHANDISE CO.

ON account of a steady increase of business, the Electric Merchandise Co., of Chicago, have been obliged to lease the upper part of their building and will remove their offices to the second floor, thus giving them needed room for stock and also enabling them to handle their shipping in better shape. The company deserve all the success which has come to them. The decision of General Manager Mason to confine the business of the company to "electric railway supplies only" was a wise one and has resulted in the company's being recognized as headquarters for such supplies.

THE RIKER EXHIBIT AT THE AMERICAN INSTITUE FAIR.

ONE of the finest electric motor exhibits at the fair for many years is that of the Riker Electric Motor Co. On the extreme right can be seen three 50 light generators, each covering 29 inches by 10 inches, running at the low speed of 850 revolutions per minute. Next is a 3 h. p. 220 volt motor running at 750 revolutions, driving a 25 light dynamo. Then a 2 h. p. motor of 770 revolutions belted to a 15 light dynamo running at 830 revolutions. Also a 1 h. p. motor speeded to 800, driving an 8 light dynamo at 870 revolutions. Near the main aisle may be seen their low-speed motors directly connected to the Huyett & Smith and the Blackman ventilating fans. One of the prominent features of the exhibit is their switchboard on which are arranged the numerous regulating and controlling devices for the machines above mentioned, including their fireproof, slate-topped dynamos, regulators and motor boxes, and their new 2-speed fan switch.



RIKER EXHIBIT AT THE AMERICAN INSTITUTE FAIR.

In the centre of the board will be seen a Walker ammeter so attached to the three fifty light dynamos that the current of any separate generator can be read at any time without opening or disturbing the circuits of either of the two remaining generators. The dynamos are all compound wound to rise 2 per cent. under full load, and the armature and fields are so balanced that when the load is changed from full to light there is no sparking. The laminated field answers so readily to the change of load that when all but one lamp is thrown out of circuit there is no perceptible difference in the pressure on the circuit. The same close regulation will also be found in the motors, not only incandescent, but arc.

The arrangement and installation of this exhibit reflects great credit upon the assistant electrician, Mr. Churchward.

ELECTRIC APPLIANCE COMPANY.

THE Electric Appliance Co. report having secured the general Western agency for the swinging ball lightning arrester and Walker ammeter. The Swinging Ball lightning arrester has successfully stood the test of the past two years. Testimonial letters from every user tell the story, and the manufacfurers have yet to record a single instance where it has failed to do its work. The swinging ball lightning arrester has no fuse and needs little or no attention. It is entirely protected from moisture, and has no electromagnet or intricate parts to adjust. Each arrester is provided with a terminal wire to be joined to the line, and a binding post for the ground connection. They are adapted for either arc, incandescent or street railway circuits. Where converters are in use it is desirable that one be placed between each converter, and on straight incandescent circuits on the outside of the building or pole where the circuit enters; the idea being not to allow the lightning to enter the station at all, but to carry it to ground at different points along the line. From the results claimed it would appear that the swinging ball solves the long-unsettled lightning-arrester problem. The Walker ammeter is too well known to need comment, and fills the demand for a reliable instrument at a moderate cost.

SILICON BRONZE SPAN WIRE FOR ELECTRIC ROADS.

MR. F. STONE, of the Aluminum Brass & Bronze Co., 53 Chambers street, N. Y., reports a most gratifying increase in the demand for their new No. 2, silicon bronze span wire, of which Mr. G. W. Mansfield spoke so highly at the Pittsburgh Street Railway Convention, as the result of hard, practical experience. His figures were:

	Diameter.	Breaking Weight.	Breaking Weight per sq. in.	Elongation in six feet.	Twists in six inches.
No. 1, Silicon Bronze,..	.200	2,550	81,800	.8 per ct.	37.4
Galvanized Iron,......	.205	1,730	52,000	7.8 "	19

The following is also of interest, being a comparative table showing size of galvanized iron and copper wire to give the same strength as silicon bronze wire:

	Dia.	Breaking Wgt.	Per sq. in.	Wgt. per mile.
Silicon Bronze......	.200	2,550 lbs.	81,800 lbs.	639 lbs.
Gal. Iron...........	.250	2,550 "	52,000 "	874 "
Copper W....	.310	2,550 "	35,850 "	1,538 "

A wire that shows such an extraordinary combiniation of desirable qualities is likely to become the first and only choice of those who want good and lasting line construction.

RECENT WESTINGHOUSE SALES.

THE Philadelphia office of the Westinghouse Electric and Manufacturing Co., C. A. Bragg, manager, reports the following recent sales: Columbia Electric Light Co., Phila., one 3,000 light alternating current dynamo; Faraday Heat, Power and Light Co., Morton, Pa., one 750 light alternating current dynamo; Merchants' Electric Light Co., of N. Front street, Phila., one 1,500 light alternating current dynamo; Pennsylvania Steel Co., Sparrows Point, Md., one 60 light alternating current arc dynamo; E. & G. Brooks Iron Co., Birdsboro, Pa., 225 light plant, U. S. direct current system; Alexander Bros., Phila., 100 light plant, U. S. system; Onderdonk Heating and Ventilating Co., Phila., 50 light plant, U. S. system; Aldine Hotel, Phila., 1,000 light plant, U. S. system; Boothby's Restaurant, Phila., 800 light plant, U. S. system; G. and H Barnett, Phila., 300 light, increase, U, S. system.

THOMSON-HOUSTON CARBON CO.

THE factory of the Thomson Houston Carbon Co., at Tremont, O., was destroyed by fire on November 24, with a loss of $200,000; insurance, $120,000. A special dispatch from the company to THE ELECTRICAL ENGINEER says: "While we had a bad fire last evening, our stock-room was saved, with many millions of carbons. We shall be able to supply all our customers and others promptly, and shall rebuild at once."

ELECTRIX CHINA SWITCH.

THE accompanying illustration shows a new china decorated switch introduced by the Star Electrix Co., of Philadelphia. This switch is made entirely of china, cover and all, and is extremely

ELECTRIX CHINA SWITCH.

popular already among architects and others who have seen it, as it is the only article in the market that meets the requirements of an artistic taste, in connection with installations in residences, clubs and hotels where the finest finish is required. These switches are made in plain ivory, jet, and all tints, and variously decorated.

THE AKRON ELECTRICAL MFG. CO.

THE Akron, O., Electrical Mfg. Co. are pushed to the utmost in their new works in turning out their new style slow-speed automatic motors and dynamos. They have just installed motors of 500 volts potential in the following places: Schumacher & Gammeter, coffee roasters, etc., 3 h. p.; the Seaman Mfg. Co, saddlery and harness works, 5 h. p.; Capron & Curtiss printing house, 8 h. p.; Akron Engraving and Printing Co., 8 h. p.; the Geo. Jackson Printing Co., 2 h. p.; the Cohn Awning Company, 8 h.p.; C. H. Allen, printer, 1½ h. p.; N. Laskaris & Co., confectioners, 2½ h. p.; Yeomans & Co., confectioners, 1½ h. p.; City of Akron Municipa lBuilding, 100 lights, the Webster Camp & Lane Machine Company, eight 1,200 c. p. arc light dynamo, all in Akron, Ohio; one 1 h. p. motor in Warner's harness works at Zanesville, Ohio, and have numerous orders on their books for more machines, which they are pushing through their works. They are making a specialty of small incandescent lighting plants with very successful results. Their slow-speed machines, while costing more money to manufacture, are being sold at popular prices and are giving excellent satisfaction. All of their work is guaranteed, and their fire-alarm apparatus is being installed in a number of the smaller cities throughout the West, and is reported upon as very satisfactory.

THE NEW "SECURITY" INSULATOR.

THE accompanying illustration shows a novel form of insulator about to be introduced by the Security Insulator Co., of 136 Liberty street. As will be readily understood, the wire is easily and quickly adjusted, and is securely held in position without injury to the insulation. The wire is pressed into the groove and

THE "SECURITY" INSULATOR.

held by the cap, while a cam movement allows different sizes of wire to be held equally well.

This insulator entirely obviates the necessity of tie wires, thus effecting a great saving of both time and labor in wiring. The insulator here illustrated, which is full size, will take wire ranging from ⅛ to ⅝ inch. Other sizes are made to suit various requirements. They are made of the best vitrified and non-absorbent porcelain, and are as durable as they are simple and effective.

THE ASTORIA ELECTRIC MANUFACTURING CO.

THE above company has been incorporated for the manufacture of motors for street railways, whether operated by the trolley, accumulator, or conduit systems, and also for stationary work. The shops will be situated at Steinway, L. I.

The company will be under the general managership of Mr. Wm. M. McDougall, whose patents on electric railway devices have been acquired by the company, and Mr. Townsend Wolcott will have immediate charge of the electrical work.

Within a short time it is proposed to have a storage car in operation in New York, and an overhead car on the Silver Spring branch of the Steinway road, Astoria. Active preparations for manufacturing motors are already in progress.

The officers of the company are: Conrad N. Jordan, president; Herman Redder, treasurer; Charles W. Spear, secretary; W. M. McDougall, general manager. Those gentlemen, together with Edward Uhl and E. R. Burpee, constitute the board of directors.

ELECTRIC MERCHANDISE CO.

COLD, wintry weather obliges street railway managers to decide how their cars shall be heated and their tracks cleaned. The large business of the Electric Merchandise Company, Chicago, in Burton electric heaters, Brand's patent track brooms, Wardwell's track broom holders and other similar devices is proof that confidence is placed in material, of whatever sort, handled by that company. The past week, equipment of from one to fifteen sets of heaters has been furnished electric roads in the following places: Ottumwa, Iowa; Reading, Pa.; McKeesport, Pa.; Cleveland, Ohio; Lincoln, Neb.; Martinsburg, W. Va.; Salt Lake City, Utah; Sioux City, Iowa., Marquette, Michigan; Wheeling, W. Va; Quincy, Ill.; Williamsport, Pa.; St. Louis, Mo.; Ottawa, Can.; Wilkesbarre, Pa.; Shamokin, Pa.; Bloomington, Ill. Pratt's portable fare register also is meeting with great success.

THE "NOVELTY" ELECTRIC WIRE GAUGE.

THE accompanying illustrations show front and back views, respectively, of a pocket wire gauge recently introduced by the Novelty Electric Co. of 50 to 54 North Fourth street, Philadelphia.

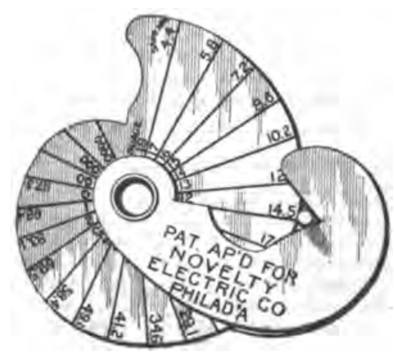


FIG. 1.—THE "NOVELTY" ELECTRIC WIRE GAUGE.

As will be seen, the wire is placed in the V-shaped opening between the movable arm and the edge of the gauge. The arm is then moved around until the wire is tightly bound between it and the gauge, when the radial line from the short square shoulder of the arm will indicate the B. & S. gauge of the wire,

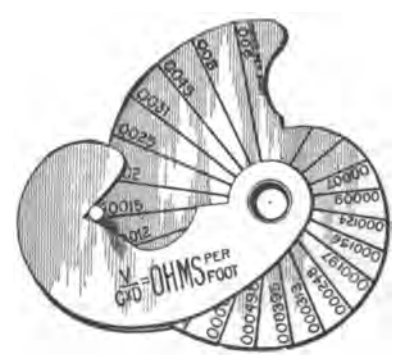

FIG. 2.—THE "NOVELTY" ELECTRIC WIRE GAUGE.

the safe current it will carry in amperes, and the resistance per foot of copper wire in ohms.

With this information, the size of wire required to carry any number of lamps any distance with any loss can readily be calculated by means of the formula stamped on the arm.

THE CRAMP SHIPBUILDING YARD.

WM. CRAMP & SONS Ship & Engine Co., of Philadelphia, are making extensive changes in their plant and have placed the contract for a new boiler shop with the Berlin Iron Bridge Co., of East Berlin, Conn. This boiler shop will be constructed entirely of iron and will be composed of two parts, one part 55 feet in width by 350 feet in length, made very high between joints on account of moving large marine boilers over each other. This portion of the building is controlled by a 50 ton traveling crane, which is to be furnished by Wm. Sellers & Co., of Philadelphia. Connected with this main portion will be a wing 58 feet wide by 370 feet long served the whole length by a 20 ton Sellers traveling crane. The building is composed entirely of iron from the designs of the Berlin Co., and will be one of the most complete in every detail.

AN ELECTRIC ROAD FOR DELWARE, O.

THE city council of Delaware, O., has passed an ordinance granting an individual franchise to Mr. James K. Newcomer, of the *Delaware Democratic Herald*, for a street railroad in that city. The road will in all cover tracks of about four miles in length, with a view to extensions afterwards. The lines will traverse populated portions of the city, one line terminating at the pleasure grounds and lake. It will not be in any sense of the word a road to boom or build up an addition to the town.

Mr. Newcomer wishes to negotiate for the construction of the road and for equipping the same. He proposes to raise the means by bonds, letting the business of the road pay interest and finally liquidate the bonds. He has not yet adopted any system.

TORONTO CONSTRUCTION AND ELECTRICAL SUPPLY CO.

THE above concern, of Toronto, Can., have been appointed by the Thomson-Houston International Electric Co., exclusive selling agents for the Dominion of Canada. The Toronto Co. have their headquarters at 63–69 Front street, Toronto, where they exhibit Wood arc dynamos, Thomson recording watt-meters, mining apparatus, alternating dynamos and transformers, etc., as well as a full line of supply materials manufactured by the International Co. Mr. F. Nicholls, the general manager of the Toronto company, is well-known in the United States, being a member of the Executive Committee of the National Electric Light Association.

NEW YORK NOTES.

THE EASTON ELECTRIC COMPANY has recently completed the installation of a fine incandescent plant in the machine shops of Mr. M. T. Davidson, Keap street near Kent avenue, Brooklyn, N. Y. The plant consists of their No. 6 250-light incandescent dynamo, 180 incandescent lamps of different candle power, and seven Easton "X" arc lamps, burning on the same circuit. The shops are brilliantly illuminated, and Mr. Davidson is now wondering how he ever managed to conduct his extensive business without the light.

THE NEW YORK SAFETY STEAM POWER COMPANY have been awarded the contract for furnishing the Bullitt Building, Philadelphia, with three 13 x 12 horizontal automatic engines for dynamo service. The foundations for the engines are now being constructed and it is expected the plant will be in operation early in December. The Bullitt Building is centrally located, and it is intended to make this the finest and most complete electric light plant in Philadelphia.

MESSRS. CHAS. A. SCHIEREN & CO. have just shipped the Franklin Electric Co., Franklin, Venango, Co., Pa., a 20-inch perforated electric double-ply leather belt. Other belts were shipped last spring when the station was put up, and have been so satisfactory that they have now ordered a main belt.

J. JONES & SON, 602 and 604 West 22d street, New York, continues to put out time stamps. They make a business of manufacturing specialties, and it will pay those who have any new article to put on the market to communicate with them.

WESTERN NOTES.

R. S HUNTON, one of the leading mine owners of Colorado, says that electricity opens up a new era for mine development in Colorado as well as in other localities. Many mines in the higher altitudes, of great promise, have been almost valueless on account of the expense of transporting fuel to them. Now with Pelton wheels and electric motors, mines in the most inaccessible localities can be reached and operated at less expense than those most favorably located as regards fuel supply. The several plants of this character now running at Aspen, Ouray, Telluride and other places have demonstrated beyond all question the practicability and economy of this system.

THE ELECTRIC MERCHANDISE CO., owing to their growing business in electric street railway supplies, to which they devote their entire attention, have leased the entire floor above their sto re at 11 Adams street, and will mo ve their office upstairs. They have built a handsome stairway communicating with the offices, which will be fitted up elegantly and in a manner most advantageous for handling their business. This departure will enable them to take care of their growing trade, carry a larger and more complete stock, and ship more promptly than ever.

THE KNAPP ELECTRICAL WORKS have issued a very neat catalogue of their "Safety" seamless insulated wires and cables for underground, aerial, submarine and inside use. It is of very convenient size and handsomely gotten up with cuts of all the various sylyes of wire, and a number of useful and valuable tables of dimentsions and other data. Attention is also drawn to the general electrical supplies handled and manufactured by the firm and their many specialties.

MR. GEO. H. MEEKER, manager of the Chicago office of the New York Insulated Wire Co., has just received a shipment from the factory of another car-load of wire. Grimshaw is selling as fast as ever, and this large shipment is not likely to remain on Mr. Meeker's hands for any length of time. He is now carrying a very large stock in all the standard sizes, enabling him to make very quick shipments.

THE leading electrical event in Chicago during the past week seems to have been the Chicago Edison Co.'s order for one million feet of braided rubber wire. The supply men made the contest an interesting one, and the decision in favor of Simplex wire is evidently a victory for the unique practice of making a wire with a moderate thickness of rubber, protected by several well-insulated braids. The order was awarded to George Cutter.

THE CENTRAL ELECTRIC CO. are now selling the well-known Soran incandescent lamps, putting in a very large stock of various voltages and candle-power, and are in a position to ship the largest orders with the greatest promptness and despatch. This lamp has an exceedingly good average life, with a small absorption of current, and is said to be highly economical.

THE ILLINOIS ELECTRIC MATERIAL CO. have recently issued a little folder containing price-list, sizes and particulars regarding their Bishop india rubber wires and cables.

MR. H. M. UNDERWOOD, general sales agent of the Knapp Electrical Works, has returned from a trip through the West, and reports business as prosperous and the outlook very favorable for the coming season.

MR. WM. HOOD, No. 239 La Salle street, reports orders for the Jewel incandescent lamps as coming in as rapidly as ever, and the amount of business done as considerably on the increase. The users of the lamp are well satisfied.

MR. R. B. WATSON, of Detroit, is now with the Electrical Fibre Carbon Co. as manager of the sales department. Mr. Watson was in Chicago last week in the interests of the company.

PHILADELPHIA NOTES.

MR. G. A. WILBUR, Philadelphia agent for the Fort Wayne Electric Co., reports the following recent installations: A 150 arc light plant for R. D. Wood & Co., Millville, N. J., to be used for lighting the town; a 40 arc and 600 incandescent plant for the Waynesboro, Pa., Electric Light Co., and two 60 Wood arc light machines for the Frankford Electric Light Co., of Philadelphia.

THE PENNSYLVANIA ELECTRIC ENGINEERING CO. have come out with a new lamp, "The Pennsylvania," which they claim to be superior to other lamps. These lamps are exhausted without the aid of mercurial pumps by a metallic pump, which is capable of producing fine attenuation for incandescent lamp work.

MESSRS. S. A. CROZER & SON, of Chester, Pa., were so well pleased with their 10-inch Westinghouse engine and 400-light plant that they have ordered from Messrs. M. R. Muckle, Jr., & Co., an additional 200 light dynamo which has just been put into operation. This plant displaces gas in every part of the mills.

MR. H. B. GROSS, the proprietor of Brookes' Crystal Soap, has ordered an incandescent light plant of 150 lights for his factory in this city from Messrs. M. R. Muckle, Jr. & Co. Brookes' soap claims "I polish the earth, the moon brightens the sky," and it now falls to the electric light to brighten Brookes' Soap.

THE IMPERIAL ELECTRIC CO. are making a specialty of a ceiling cut-out for a few days. The extremely low price for which they are placing them on the market is making them very popular.

NEW ENGLAND NOTES.

THE GERMANIA ELECTRIC CO., of Boston, has recently installed a Germania dynamo for the Fahys Watch Case Co., Sag Harbor, L. I. This dynamo is made for the especial purpose of running motors throughout their factory, and, like all other Germania dynamos, is giving entire satisfaction and the demand for them is on the increase.

THE CONSOLIDATED ELECTRIC MFG. CO., 154 Franklin street, Boston, Mass., have been obliged by the pressure of their growing business to lease the whole corner of Franklin and Congress streets.

☞ ***Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Miscellaneous, etc., will be found in the advertising pages.***

TELEGRAPH.

Seattle, Wash.—The Western Union Telegraph offices are in a most satisfactory condition. The company proposes extending its lines northward into territory abandoned years ago.

Montana.—The Southern Montana Telegraph and Electric Company has filed articles of incorporation. The capital stock is $25,000, and the principal office at Virginia City. The company will erect telegraph lines from Virginia City to Dillon, Whitehall and Norris, and conduct a general electrical business.

TELEPHONE.

Massillon, O.—The Central Union Telephone Company is rebuilding the city lines. Already 20 miles of the new wire has been stretched.

Reynoldsville, Pa.—The Central District and Printing Telegraph Company, of Pittsburgh, will establish a telephone exchange at Reynoldsville, and also Punxsutawney, this county, and Du Bois, Clearfield county. One has already been established at Brookville, the county seat.

ELECTRIC LIGHT.

Key West, Fla.—The Key West Gas and Electric Light Co. was organized in 1884 with $75,000 capital stock. The Thomson-Houston arc and incandescent systems are used, the circuits being 10 miles in length. Power is supplied by three Ball engines of 315 h. p. N. P. Loring is superintendent.

See further, page xiv.

ELECTRIC RAILWAYS

Delaware, O.—James K. Newcomer is negotiating for a franchise for an electric railway about four miles long. The system has not yet been decided upon.

St. Joseph, Mich.—The St. Joseph and Benton Harbor Street Railway Co. will build three miles more of track, making about eight miles in all. The company want a 250 h p. engine and boiler, two generators and all the necessary suppl es for electrical equipment. W. Worth Bean is president and superintendent.

Defiance, O.—The Defiance Light and Power Co. was organized Aug. 31, 1891, with $100,000 capital stock. The Westinghouse overhead system is used on a track 1½ miles long. There are two Pullman motor cars at present. Power is derived from two Russell engines. About 1½ miles of extension is projected. The officers are: W. B. McKinley, president; E. O. Harris, vice-president; S. L. Nelson, secretary.

Beatrice, Neb.—The Beatrice Rapid Transit and Power Co. was organized Aug. 12, 1890, with $250,000 capital stock. The track is three miles long and three cars equipped with Baxter motors and Brill trucks are in use. Power is supplied by a 100 h. p. Ball engine, with an Erie boiler. An extension of three miles is projected. The officers are: N. N. Brumback, president; G. M. Johnston, vice-president; L. E. Spencer, secretary and treasurer.

See further, page xv.

ELECTRIC LIGHT.

Du Bois, Pa.—An extension of the electric light system is being put in at a cost of $1,200. There will be six more arc lights.

Rahway, N. J.—The new management of the electric light plant is busily engaged in replacing the arc with the incandescent system.

De Land, Fla.—The directors of the Electric Light Company will remove their plant and ice factory from West De Land into De Land proper.

Lambertville, N. J.—The franchise to erect an electric light plant in Lambertville has been granted to the New York Electric Construction Company.

Pittsburgh, Pa.—The Westinghouse Electric Company has now in the course of construction several incandescent light generators and street railway power generators which in capacity and size dwarf all similar machines built in this country. The light generators or dynamos have a capacity sufficient for 10,000 16 c. p. incandescent lamps. The largest previously built have a capacity of 3,000 lights of the same candle power. The new giant railway dynamos will have a capacity of 1,000 h. p., or 750 h. p. greater than the largest generators for this purpurpose previously constructed. The first of these immense street railway dynamos, which is being constructed for a Los Angeles company, is now nearly completed.

ELECTRIC RAILWAYS.

Oakland, Cal.—A site has been purchased for the car and motor house of the Oakland and San Leandri Electric R. R. Co. and work will soon be commenced.

Manchester, N. H.—The Stark Mills are being wired for 2,000 incandescent lights. The Stark corporation is also putting in two No. 32 Edison compound dynamos of 1,300 light capacity each.

San Francisco, Cal.—C. C. Butler, N. Ohlandt and J. A Buck have invested large amounts in the San Francisco and San Mateo Electric R. R. and work will be pushed as fast as men and money can do it.

Ashley, Pa.—The Wilkesbarre and Wyoming Valey Traction Co., capital stock, $5,000,000, expect to extend their line to a total of about fifty miles. The Short system is used. The officers are: B. F. Myers president; John Graham, secretary and treasurer.

Williamsbridge, N. Y.—The certificate of incorporation of the Williamsbridge, Woodlawn and Westchester Railroad Company has been filed in the office of the County Clerk. The road is to run twenty-four miles, from Fordham, through Westchester, Mount Vernon, and to Yonkers. The capital stock of the company is to be $240,000. Among the shareholders are: C. R. Dean, N. B. Thurston, P. W. Cochran, Herbert N. Curtis, Thomas B. Inness, H. D. Lange, John A. Bowers, and W. W. Inness.

MISCELLANEOUS.

Kankakee, Ill.—The Novelty Electric Works is a new institution started here. A. L. Wheeler is the electrician.

See further page xvi.

ELECTRIC LIGHT.

Lenoirs, Tenn.—Dempster & Plummer will put an electric light plant in their flour mill, as reported lately; contract has been let.

Fernandina, Fla.—The Fernandina Light and Power Co. will, it is stated, improve and increase the capacity of its electric light plant.

Washington, D. C.—Walter Hanson, Luke Strider and Frank Aldrich have incorporated the Hanson Battery, Light and Power Co. to produce and furnish electricity for light and power. The capital stock is $1,500,000.

See further, page xvii.

ELECTRIC LIGHT.

Hope, Ark., is to have electric lights. J. H. Black is mayor.

Lynchburg, Va.—The Piedmont Electric Illuminating Co. has put a new boiler in its plant.

Calvert, Tex.—The Calvert Water, Ice and Electric Light Co. will put in an electric light plant.

Sutherland, Fla.—Imhoff & Elliott, of Lincoln, Neb., may erect an electric light and power plant in Sutherland.

Victoria, Tex.—The Victoria Light, Power and Ice Co. will put in a new dynamo to increase the capacity of its plant.

Jonesboro, Tenn.—The Watauga Electric Light and Power Co. is reported as to light the town of Jonesboro with electricity.

Baltimore, Md.—An Edison incandescent electric light and power plant may be erected at Baltimore, as negotiations are now being made to organize a $1,000,000 stock company for that purpose.

See further, page xix.

ELECTRIC LIGHT.

Oakesdale, Wash., will probably have electric lights.

Aurora Springs, Mo., is to be lighted by electricity.

Idaho Falls, Ind., is thinking of erecting an electric light plant.

Roseburgh, Ore.—The electric light plant will soon be in operation.

North Platte, Neb.—The council has been petitioned to light the streets with electricity.

Piqua, O.—The committee on an electric light plant for the city has given a favorable report.

Bangor, Pa., East Bangor and Penn Argyl will be lighted by electricity if rumor speaks with authority.

Lynn, Mass.—The Woodward Underground Electric Light and Cable Co. has petitioned for authority to open streets for the purpose of laying conduits.

Santa Fe, N. M.—According to report, the local Electric Light Company is figuring with the Santa Fé, N. M., Gas Co., with a view of consolidating the two interests.

Washington, Pa.—At a meeting of the directors of the Electric Light and Power Co., it was decided to issue the remainder of the capital stock. The entire issue is $50,000.

See further, page xxi.

ELECTRIC LIGHT.

Chelsea, Mich.—Strong Bros. cf Homer will put in an incandescent plant.

Albany, N. Y.—Funds have been asked for furnishing 31 additional street lights.

Adrian, Mich.—Contracts have been made for the erection of a large addition to the Gilliland Electric plant at Adrian.

Ogen, U.—The Payson Electric Light and Manufacturing Company has been incorporated with a capital stock of $10,000, divided into 200 shares of $50 each.

Bay City, Mich.—The Bay County Electric Co. was organized in April, 1891, with $135,000 capital stock. The Thomson-Houston and Westinghouse systems are used. Power is supplied by three Westinghouse and two Ball engines. The officers are: S. G. M. Gates, president; A. M. Haines, secretary.

Stafford Springs, Conn.—Work is being pushed on the new dam of the Stafford Spring Electric Light Co., and it will probably be completed before the end of the year.

Warren, Mass.—Work on poles and wires for the electric lights is being pushed. The Thomson-Houston system has been adopted. Power will be furnished for 35 arc lights of 1,200 c. p. each, and 45 incandescents of 35 c. p. each.

Mechanicville, N. Y.—An organization to be known as the Mechanicville Electric Light and Power Company has been formed with the following officers: President, Hon. C. R. Sheffer; vice-president, Stephen Lee; secretary, Dr. A. C. Kniskern.

Le Mars, Ia.—J. H. Winchill has been granted a franchise for an electric light plant. The Thomson-Houston alternating system will be used. The circuit will be 35 miles long and composed of K. K. wire. Power will be supplied by a 300 h. p. Sioux City Corliss engine.

Lander, Wyo.—The Lander Electric Light and Power Co. was organized Sept. 7, 1891, with $10,000 capital stock. The Edison incandescent system is used. Power is derived from a 60 h. p. Reynolds-Corliss engine. The officers are: J. D. Woodruff, president; E. Amoretti, treasurer; W. A. Wallace, secretary and manager.

ELECTRIC RAILWAYS.

Iron Mountain, Mich.—J. H. Stevens, of Ironwood, has been granted a franchise for an electric street railway.

Hartford, Conn.—The subject of the trolley electric road to East Hartford has been discussed. The construction is to be under the direction of the street commission and subject to its control.

Lynn, Mass.—The new power station for the Lynn and Boston Railway Co., on Washington street, will be the second largest power station for generating current for railways in the United States, the first being that of the West End of Boston. The capacity of the engines will be 4,000 horse power.

Houston, Tex.—As soon as the 7 new cars are properly equipped the Houston City Street Railway Co. will operate the Glenwood line by electricity. The company will put in a duplicate power plant, and then the other lines will be equipped with electricity as quickly as possible.

Shenandoah, Pa.—The work of building the Mahanoy City, Shenandoah, Girardville and Ashland Electric Railway has been begun. The line, when completed, will be one of the longest electric railways in the State, the length being about eighteen miles. It will connect the four towns above mentioned

Waco, Tex.—The Waco Electric Railway and Light Co. was organized Feb. 26, 1890, with $250,000. The Thomson-Houston overhead system is used on a track 5 miles long. There are 10 motors and 5 trail cars. The light plant furnishes 2,500 lights. Power is supplied by two 150 h. p. Sioux City Corliss engines. The officers are: J. W. J. Hobson, president; H. Moore, vice-president; S. A. Hobson, secretary and superintendent; J. Sleeper, treasurer.

New Castle, Pa.—The city councils have granted the electric street railway right of way through the park. Twenty of the most prominent ladies of New Castle, members of the Park Association, were present and through an attorney protested against the passage of the ordinance. A largely signed petition from business men had been presented urging its passage. The measure went through with only two dissenting votes. The ladies feel very bitter toward councils for its action, and are determined to prevent the proposed encroachment at all hazards. They think this action is a precursor of the ultimate destruction of the park,

ELECTRIC LIGHT.

Madison, Ga.—The electric light plant, previously mentioned, is now being installed.

Greensburgh, Pa.—The proposed Westmoreland Electric Company, but as yet doing business under the name of Morris Painter, has awarded the contract of furnishing the boilers, engines, steam fittings and automatic stockers for the new electric arc light plant to the Russell Manufacturing Company, of Massillon, O., by which the said company have obligated themselves to have the plant in active operation on or before December 21, under a forfeiture of $25 per day for each and every day thereafter until actually completed. The Corliss type of the Russell engine, with four valves, will be used. Western Electric dynamos and lamps will be used.

See further, page xxiii.

ELECTRIC LIGHT.

Newark, N. J.—The Wolverton Arc Electric Light Co. has been formed with $250,000 capital by J. E. Wolverton, W. McCubben and J. L. Cox of New York City.

Milton, Ore.—Milton has bought an electric light plant, Edison system, for 15 arc and 200 incandescent lights, at a cost of $4,025. The power will be furnished by the mill wheel, which is driven by water from the Walla Walla river.

South St. Louis, Mo.—The Carondelet Electric Light Plant will soon be ready for operation. The engines and mammoth dynamos are in position, and Col. O. A. Haynes, manager of the plant, will make the final test of the machinery.

Missoula, Mont.—It is said that a Missoula syndicate, represented by J. R. Cox, have purchased the electric light plant, which was built by Bowen Bros. & Thompson, the foundry men. The new concern is said to contemplate extensive improvements, including an arc system, which will be extended to Granite.

Somerville, Mass.—The Somerville Electric Light Company is constantly adding to its plant, taking on new business and increasing its facilities. The new 300 h. p. engine is now running and the 300 horse boiler will soon be steamed up. Another dynamo for incandescent lighting is expected within a week for 1,300 lights.

Delaware, O.—One of the new dynamos ordered by the Electric Light Co. has arrived. It is a 50-light (arc) Sperry automatic dynamo made in Chicago. The other to arrive is a 1,500 light (incandescent) Westinghouse machine. There are already in use three Thomson-Houston dynamos, two arc lights with a capacity of 50 lights each, and an incandescent 550 lights. The latter is greatly overtaxed, having carried at times as high as 200 extra lights. The power for these is furnished by automatic engines of 180 and 150 h. p.

ELECTRIC POWER.

Tarkio, Mo., will in all probability be given an electric road early in 1892.

Buffalo, N. Y.—The Thomson-Houston Company of this city is establishing power circuits independent of lighting circuits. They are of 500 voltage each, and each one furnishes 100 h. p.

St. Louis, Mo.—The gearless motor car of the Short Electric Railway Co., which was exhibited at the annual meeting of the American Street Railway Association, Pittsburgh, has been purchased by the Lindell Railway Co., and will be put in their regular service.

See further, page xxiv.

ELECTRIC RAILWAYS.

Ottawa, Ill.—The Electric Power Railway is about ready to commence operations.

Montgomery, Ala.—The Council has refused a franchise for an electric car line.

Middletown, Pa.—The Middletown Highspire and Steelton Railway Co. has been granted right of way through this borough.

Oshkosh, Wis.—The Oshkosh Railroad Company amended its articles of incorporation, increasing its capital stock from $60,000 to $100,000.

East Side, Ore.—The power house of the East Side Railway is being pushed rapidly. It is being built near a saw mill so that the sawdust can be used as fuel.

Camden, Pa.—A $5,000 Edison generator has been contracted for by the Camden Lighting and Heating Company for the use of the Camden Street Railroad Company.

Spokane Falls, Wash.—The Spokane Street Railway Co. has asked for permission to haul freight cars over the tracks of its electric lines in the city between the hours of 12 midnight and 6 o'clock a. m.

Braddock, Pa.—The Braddock Electric Street Car Company has decided to sell annual tickets for $25 each, which will entitle the holder to as many rides daily on the company's cars as he may wish.

Washington, Pa.—During the first six months of the operation of the electric street railway of Washington, Pa., 155,000 passengers were carried. This shows that the electric road will pay a handsome dividend.

Ronceverte, W. Va.—The Ronceverte Electric Company has been incorporated for the purpose of operating electric street railways, supplying electric power for the same and supplying the citizens of Ronceverte with water. The principal office is to be kept at Ronceverte. The capital is $500, with the privilege of increasing to $100,000. Col. E. C. Best, of Ronceverte, and other parties, from Baltimore, are the incorporators.

See further, page xxv.

ELECTRIC RAILWAYS.

Modesta, Cal., is now lighted by electricity.

Oakland, Cal.—The car-house and motive power plant of the Oakland and San Leandro electric road has been definitely located on the Warner tract, which will be the centre of a new suburb.

Beverly, Mass.—The Beverly selectmen gave a hearing at the town hall on Nov. 19, on the petition of the Naumkeag Street Railroad Co. to extend its trolley wires to the Wenham line, through Rantoul street. The hall was crowded and the most intense partisan excitement prevailed. H. P. Moulton closed the argument for the Naumkeag road, showing that the opposition came from the Beverly & Danvers Railroad because the Naumkeag would not buy it. The petition was refused, the vote resulting: 332 no; 325 yes. At the last hearing the vote was: Yes, 240; no, 299.

See further page xxvi.

ELECTRIC LIGHT.

New Orleans, La.—The inhabitants of the Sixth District want electric lighting.

Southwest Greensburgh, Pa.—The town council of Southwest Greensburgh borough has decided to purchase arc lights for the borough.

Columbus, Ind.—The 10-years' franchise which was granted to H. Bailey for an electric light plant was almost immediately sold to the present company for $6,000.

Provo, Utah.—A water power has been taken up on the river northeast of Provo by parties whose names are unknown, but it is rumored that an electric company is preparing for operations.

Fairfield, Me.—The blasting for the wheel pits at the electric light station has been finished. The flume will be 48 feet long, 13 feet wide and 11 feet deep, and upon the bottom will be set the three wheels.

Hudson, Mass.—The town has voted 84 to 60 that it was not expedient or advisable to purchase or operate an electric plant, after listening to the minority report in favor and the majority report against the project.

Greensburgh, Pa.—The dynamos and engine for the electric light plant for the Frick company's new Standard shaft have arrived and are being set up. It is expected to have the plant in operation by December 1.

Melrose, Mass.—Action on the report of the committee upon the manufacture by the town of its own gas and electricity was postponed by the annual town meeting until an adjourned meeting, which will be held in March.

Greensburgh, Pa.—The People's Electric Light Company are now taking bids for two 45 arc dynamos, in addition to the three incandescent dynamos now in operation. The additional dynamos will, it is thought, be in operation inside of fifteen days.

Latrobe, Pa.—The Electric Light Company, of Latrobe, refused to accept the amendment submitted by the council, at a former meeting, in reference to a penal clause for permitting a lamp or lamps to be in darkness beyond a reasonable time. The matter was referred to the finance committee and solicitor.

Sanger, Cal.—Says the *Sanger Herald:* "The Sanger Electric Light Company, of which Messrs. H. W. Chase and N. G. Kittle are the principal stockholders, are erecting a steam power house on the east side of the railroad. The cellar has been excavated for a one story brick building 32x80 feet, the walls to be of brick and the roof corrugated iron."

Chester, Mass.—A subscription paper is being circulated to raise funds necessary to light the streets with electric lights. Some $200 has already been pledged and the solicitors feel confident they will get enough for 12 lights. The Hudson & Chester granite company are putting electric lights into their works and will furnish for private individuals and the streets.

See further, page xxvii.

ELECTRIC LIGHT.

Brightwood, Ind., wants electric lights.

Kewascum, Wis., is to have electric lights.

Bremen, Ind.—Electric lighting is contemplated.

Elk Rapids, Mich.—The citizens are in favor of electricity.

Xenia, Ind.—A municipal electric light plant is spoken of.

Gibson City, Ill., will probably soon have electric lights.

Marshalltown, Ia.—The recently incorporated Marshall Electric Light Co. has a capital of $50,000.

Sioux City, Ia.—The Storage Battery Co. has been formed by E. M. Dunbar, J. F. Peavey and C. S. Wallis. Capital, $1,000,000.

Meyersdale, Pa.—The Electric Light Company will probably spend from $15,000 to $20 000 on its plant.

See further, page xxviii.

ELECTRIC LIGHT.

Frankfort, Ind., is now lighted by electricity.

Paragould, Ark., wants electric lights.

Grand Rapids, Mich.—The Grand Rapids Electric Light Co. has received permission to build a large oil tank on the west side, the oil to be used for running the plant.

Litchfield, Ill.—The Litchfield Light, Heat and Power Company has been formed with a capital stock of $50,000; incorporators, H. H. Beach, J. B. Wamsden and Robert M. Foster.

Houlton, Me.—A 650 incandescent light alternating machine, from the Thomson-Houston Works, has been purchased by the Houlton Electric Co. When this machine is in running order the plant will have a capacity of 1,000 lights.

Taylor, Tex.—At the initial meeting of the Taylor Electric Light, Gas and Power Company, held a few days ago, the capital stock was placed at $40,000, in shares of $100 each, and a charter was ordered to be prepared.

Duluth, Minn.—The Phœnix Electric Company has filed articles of incorporation with the register of deeds. The capital stock is $110,000; directors and incorporators, Joseph M. Anderson, Robert B. Eyster, Henry R. Fisk, Jr., and Margaret Eyster, all of Duluth.

White Plains, N. Y.—The Gas and Electric Company and the Westchester Telephone Co. have been directed to remove some large new poles recently erected. The companies, having received permission in the first instance, will probably invoke the aid of the law.

ELECTRIC RAILWAYS.

Colfax, Col.—An electric storage battery road from Colfax to Barnum is proposed by F. A. Arbuckle, L. L. Gray and M. S. Noah.

Sandusky, O.—The People's Electric Street Railway Co. has been accorded permission to lay its tracks on the Milan road.

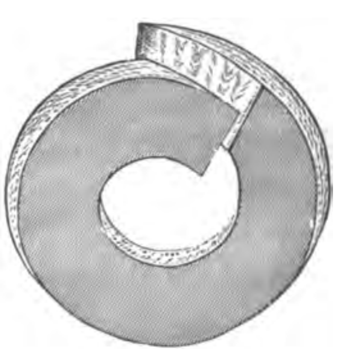
Brooklyn, N. Y.—The Coney Island and Brooklyn Railway Co. has been given permission to convert its road to a single-trolley overhead electric system.

Galveston, Tex.—A franchise has been granted to the South Galveston and Gulf Shore Electric Railway Co. for a line 13 miles long. President, Geo. J. Gray, of Denver, Col.

Bradford, Pa.—The petition from the Electric Light and Power Company asked the right to use the streets and alleys of Bradford for constructing and maintaining a track for electric street cars of the overhead trolley system. Signed by H. G. Rose, secretary.

Raleigh Springs, Tenn.—The Raleigh Springs Electric Railway Co. will build an electric road 11 miles long to Memphis, and track-laying will be commenced in December. The Thomson Houston Co. will furnish the electrical equipment. President, Daniel O'Connor; general manager, W. R. Hall; chief engineer, E. T. Lynch.

See further, page xxix.



ELECTRIC RAILWAYS.

Sacramento, Cal.—Large amounts have been pledged for the electric road to Perkins.

Salem, Ore.—The Capital City Railway Co. has asked for permission to extend two of its lines.

Chicago, Ill.—The International Electric Railway Co. has been formed by J. T. Hanna, M. M. Wood, D. L. Coe. Capital, $2,500,000.

San Francisco, Cal.—Work has been commenced on the car house of the Metropolitan Electric Railway, which will cost about $14,000. The company's franchise is for an electric road to Golden Gate Park. About $125,000 have already been expended in track-laying, &c.

Aspen, Col., has outgrown the horse car system and work on the electric car lines will be commenced early in the spring.

Colma, Cal.—The petition of J. W. Ellis and associates for a franchise from Colma to Half Moon Bay, for an electric road, has been allowed by the San Mateo board of supervisors. Work is to begin at both ends of the road within six months.

St. Louis, Mo.—An application has been made by the St. Louis and Kirkwood Rapid Transit Company for the privilege of constructing and operating an electric railway from the limits of the city of St. Louis to Kirkwood. The petition was signed by George Johnson and Joseph Lawson, of New York, and George M. Keeley, Edward P. Dickson and Edwin B. Sherzer, of St. Louis.

ELECTRIC LIGHT.

Niles, O.—By action of the council, the Niles Electric Light and Power Company were granted the privilege of hanging their wire on the city poles.

Newport, R. I.—A special dispatch of Nov. 22 from Newport says: A sensation is expected to-morrow when it is known that the Edison Electric Light Company of this city has made an assignment. John Whipple is the assignee. He declined to talk on the subject to-night. Col. Hovey, the counsel for the company, said that the action was taken by vote of the stockholders. For some time the company has owed $5,000 to John N. A. Griswold, and it has other debts in Newport, he said, amounting to $50,000. Griswold pressed for payment and threatened an attachment, which was withheld upon the promise that an assignment would be made.

See further, page xxx.

ELECTRIC LIGHT.

Woodstock, Ill., is thinking of electric lights.

Montgomery City, Mo.—After a trial the city has decided on having electric lighting.

Creston, Ia.—The electric light plant of O. Q. Holman has been greatly improved.

Farmington, Ill., has a franchise and has contracted for incandescent electric lights.

Clifton Forge, Va.—Electric lighting is found to be very satisfactory in this place.

Springport, Mich.—Springport citizens say the town will have electric lights.

Brooklyn, Mich.—Electric lighting is being discussed.

Melrose, Mass.—The service of the Malden Electric Light Co. here is being improved.

Louisville, Ky.—Electric lights have been accidentally delayed, but are now ready for operation.

Burlington, N. J., wants arc instead of incandescent lights at the street corners.

Gardner, Mass.—The Gardner Electric Light Co. has been formed with $30,000 capital. R. L. Bent is president.

So. Framingham, Mass.—The chimney of the Milford Electric Light Company's factory has been blown down. Damage, $250.

McKeesport, Pa.—A decision in favor of the Edison Company has been rendered by Judge Stowe in the suit between the two factions of the McKeesport Light Company.

TELEPHONE.

Albany, N. Y.—It is said that there is a possibility that the Law telephone system will be adopted for the new telephone exchange at Albany.

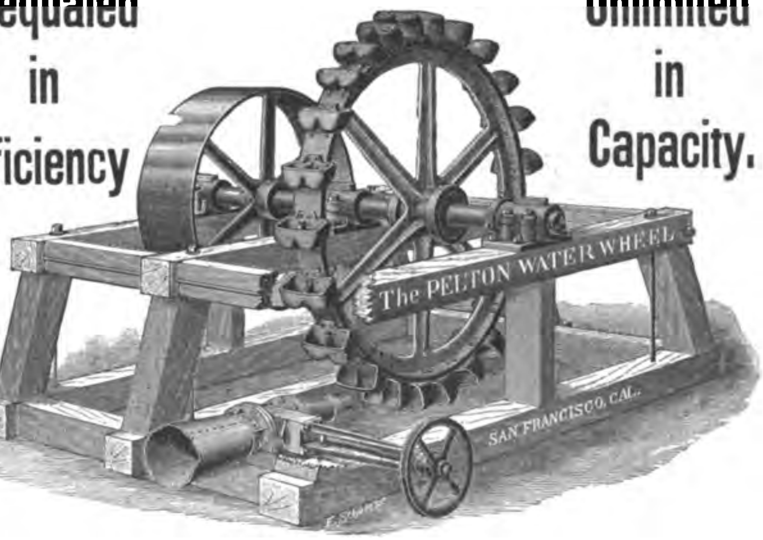
See further, page xxxv.

THE PELTON WATER WHEEL

Gives the Highest Efficiency of any Wheel in the World. Over 2,000 in actual use.

Unequaled in Efficiency

Unlimited in Capacity.



Affords the most simple and reliable power for all mining and manufacturing machinery. Adapted to heads running from 20 up to 2,000 or more feet. From 20 to 30 per cent. better results guaranteed than can be produced from any other Wheel in the country.

ELECTRIC POWER TRANSMISSION.

The advantages the PELTON WHEEL affords in the way of a uniform and reliable power, close regulation and the facility of adaptation to varying conditions of speed and pressure, have brought it into special prominence and extensive use for this class of work. All applications should state amount and head of water, power required, and for what purpose, with approximate length of pipe line. *Send for Catalogue.*

PELTON WATER MOTORS.

Varying from the fraction of 1 up to 100 horse power, unequaled for all light running machinery. Warranted to develop a given amount of power with one-half the water required by any other.

☞ Send for Motor Circular. Address as above.

Deliveries made from San Francisco or New York, as may afford the most favorable freight rates.

It having come to the notice of the undersigned that their patent rights are being infringed upon, intending purchasers are hereby warned that all such infringements will be duly prosecuted.

THE PELTON WATER WHEEL CO.

SPEED! ACCURACY!! ECONOMY!!!

In weighing Coal, Coke, Grain, Lumber, Stock and heavy car-load freight of all kinds, on Railroad Track Scales, are the three necessary elements to be considered and sought for. These are absolutely guaranteed by the use of

THE

Davis Automatic Electric Track Scale.

This Scale is entirely automatic in operation, weighing the car and PRINTING THE WEIGHT, without manual intervention, by the mere act of rolling the car upon the platform.

The weight is printed in plain figures on the bill of lading, the card-way-bill or a ticket, as desired.

SPEED.—An absolutely correct balance is obtained within one second after the car comes upon the platform. Cars can be weighed while in motion (if disconnected from other cars), rolling over the platform.

ACCURACY.—The Scale MUST be at a correct balance before any weight is recorded. The car must be entirely on the platform before the poise begins to move. The Scale will not weigh or register a weight unless all the wheels of the car are on the platform, or if more than one car be touching the platform. The weight is printed automatically the instant the Scale comes to a correct balance.

ECONOMY.—The Scale saves the labor (and wages) of a weigh-master. Being absolutely infallible, it saves thousands of corrections and claims for over and short weights, over charges, etc., etc. It simplifies the claim agent's department, eliminating as it does all doubt as to accuracy of the weight.

For information, estimates of cost of installation, photographs of the Scale in use, Address

WHAT ARE YOU?

ARE YOU AN ELECTRICAL ENGINEER?	Then you will find it worth your while to be a constant reader of THE ELECTRICAL ENGINEER, a paper in which all topics and questions that interest the profession are frequently, freely, and fully discussed.
ARE YOU AN ELECTRICAL INVENTOR?	Then you cannot afford to miss any of the hints, suggestions, and pointers that are given every week in THE ELECTRICAL ENGINEER as to the inventions of the present and the future.
ARE YOU A CENTRAL STATION MAN?	Then it will help you to run your station with efficiency and economy and success to read THE ELECTRICAL ENGINEER, in which all improvements in apparatus are described, and all the latest ideas in practical work are set forth.
ARE YOU AN ELECTRICAL STUDENT?	Then you need to know what is being said and found out in all departments of the science, and this THE ELECTRICAL ENGINEER enables you to do in a very thorough and satisfactory manner.
ARE YOU INTERESTED IN TELEGRAPHY?	Then you will find a practical guide to all the new and old departments of your work in THE ELECTRICAL ENGINEER, whose columns show that there are plenty of improvements to be made in the telegraph.
ARE YOU A TELEPHONIST?	Then you want to know all you can about batteries, circuits, and the best ways of operating an exchange. THE ELECTRICAL ENGINEER will tell you.
ARE YOU AN INVESTING CAPITALIST?	Then you will be better able to judge of the possibilities and opportunities of the new electric arts, and of the various local plants, by watching the descriptions and statistics furnished by THE ELECTRICAL ENGINEER.
ARE YOU IN THE SUPPLY BUSINESS?	Then you will find every week hundreds of chances of making sales to customers, large and small, through the items in the news columns of THE ELECTRICAL ENGINEER.

Whatever your connection with electricity may be, it is THE ELECTRICAL ENGINEER you want, in order best to carry out your purposes and ideas.

If you subscribe to THE ELECTRICAL ENGINEER, it will cost you less than a cent a day to enjoy all the latest, most useful, and most trustworthy information on the subject to which you are devoting your life.

ELECTRIC RAILWAYS.

Ashland, Ky.—The Ashland and Catlettsburgh Street Railroad Co., W. L. Ringo, president, will take steps at once to extend its road to Catlettsburg and change from animal to electric power.

Baltimore, Md.—William H. Parmenter, of New York City, and S. L. Dows, of Cedar Rapids, Ia., are said to contemplate the purchase of the Highlandtown and Point Breeze Street Railway for a New York syndicate. If the sale is made the road will probably be operated by cable through the city and by electricity in the suburbs.

Galveston, Tex.—The South Galveston and Gulf Shore Railroad Co., previously reported as to build an electrical railroad from Galveston down the island to South Galveston, a distance of about 18 miles, has been granted right of way on certain streets by the city council. The company expects to commence work at once and build the line as speedily as possible.

See further page xxxvii.

Conduits for the National Capital.

PRESIDENT BENJAMIN HARRISON, under authority of an ACT OF CONGRESS, having appointed a Commission to report on the disposal of the electric wires in the DISTRICT OF COLUMBIA; that Commission, composed of ANDREW ROSEWATER, C. E.; PROF. HENRY A. ROWLAND, and LIEUT. F. R. SHUNK, U. S. A. Engineer Corps, has reported unanimously in favor of the

Lynch and Lake System of Underground Electric Wire Conduits.

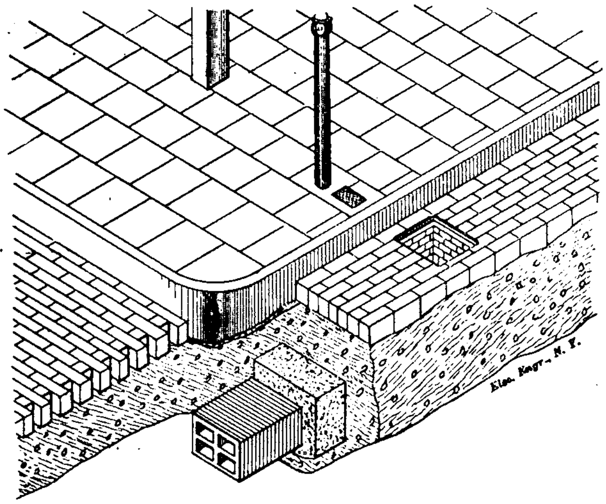

Fig. 1.

This endorsement is the more striking and convincing from the fact that this Expert Commission made a most thorough and exhaustive personal investigation of all the work done in Europe and the United States in placing wires underground. In other words, and not to put it too strongly, the Lynch and Lake System is declared by these authorities to be **the best and most practical in the world,** and the only one fit for adoption at the seat of Government.

****

In view of this important decision, a few words descriptive of the system will be interesting.

The main idea embodied in this conduit is to provide a system which shall permit of the ready insertion and withdrawal of the conductors, while at the same time being of a nature such that its life is practically indefinite. Evidently a construction embodying only terra-cotta and concrete employed in a suitable manner fulfills these conditions exactly. The Lynch and Lake Conduit is composed of ducts built up in tiers of terra-cotta, which lasts forever, in the shape of rectangular troughs, the bottom of the upper forming the top of the lower. These ducts are covered above and below by a cover. This is set in a bed of concrete, which also completely surrounds the ducts and keeps them firmly in position. A type of conduit with four ducts is shown in Fig. 1, which represents the hand-hole by which connection is made with the wires leading to the lamp-post at the curb. The construction adopted where more conduits are required is shown in Fig 2. Here the conduits are composed of four units of four conduits, each set in concrete as before. The joints between the consecutive lengths are effected by bracket-shaped pieces, D, Figs. 2 and 3, which clasp the conduits, and which are held firmly in position by the concrete as it is rammed about them. The system has also been thoroughly provided with the various hand-holes and manholes necessary for getting at the wires.

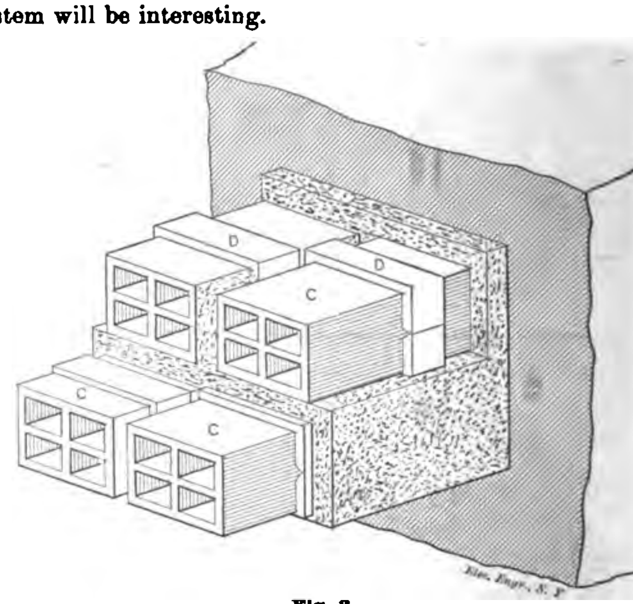

Fig. 2.

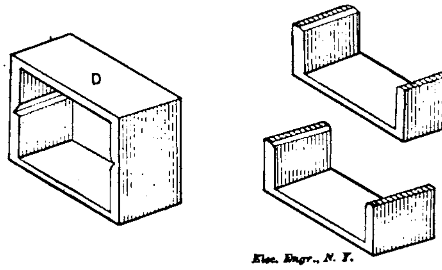

Fig. 3.

The **LYNCH AND LAKE SYSTEM** has proved equally successful whether used for electric lighting or for telephony—the two extremes of electrical work with heavy and delicate currents. It has been tried for years in Washington, and is coming into extensive use in Baltimore, St. Paul, Chicago, Minneapolis, Cleveland, Louisville, San Francisco and Milwaukee. It is very cheap, entirely efficient, easily laid, easy to operate, and is absolutely imperishable.

TRADE-MARK.

CHICAGO, November 16, 1891.

To Our Customers:

We have just completed arrangements with the Swan Lamp Manufacturing Company to handle their lamps, and will, in future, sell this company's lamps in preference to any others. We have heretofore been selling the Packard Lamp, and in making the change we do not wish to be understood as retracting any of our claims for that lamp. We are simply keeping pace with the wishes of our patrons, who demand a lamp of high efficiency and good average life rather than one of low efficiency and extra long life.

As the electric lighting industry becomes one of the stable dividend-paying interests of the world, station managers are obliged to pay more attention to every source of waste, and there has hereretofore been none more prolific than that of low efficiency lamps, especially when the capacity of the station is full.

The Swan Lamp is one of high efficiency and good average life—say, from 600 to 1,000 burning hours—while it does not blacken to any appreciable degree, even when it is nearly burned out. These lamps are made to fit any socket, and, as we will carry a stock of all ordinary candle powers and voltages, orders can be promptly filled.

CENTRAL ELECTRIC COMPANY

THE

Electrical Engineer.

VOL. XII. DECEMBER 9, 1891. No. 188.

THE EVOLUTION OF THE EICKEMEYER-FIELD STREET CAR MOTOR.

DURING the Summer of the year 1883 an exhibition of railroad appliances was held in the city of Chicago, one of the chief features of which was an electric railroad, the first ever constructed and operated in the United States for business purposes. Application was made by the board of managers to Mr. Stephen D. Field, one of the principal contestants in the Patent Office for the basic patents on electric railroads, requesting him to construct and operate an electric railroad at that exposition. But a few weeks were available for the construction of such a system. While the apparatus employed was necessarily crude and hastily thrown together, the success of the installation was complete. Thousands of passengers were carried and the whole organization of an electric railroad, financial and mechanical, was exemplified.

The motor employed on this occasion is shown in Fig. 1. It was of about 15 horse-power nominally, but was eventually worked far in excess of this figure. At the conclusion of the Chicago Exposition the motor was removed to the State Fair at Louisville, where many passengers were carried.

FIG. 2.—ELECTRIC LOCOMOTIVE EMPLOYED ON N.Y. ELEVATED RAILROAD, 1887.

The operation of this road suggested many points of importance in electric railways to Mr. Stephen D. Field, which have been incorporated with other features suggested by Mr. Rudolf Eickemeyer, and these gentlemen have joined forces under the name of the Eickemeyer-Field Company.

The first installations of electric motors on street railroads were made upon horse street railways, the roadways of which consisted of light centre-bearing rails resting upon longitudinal wooden sleepers. The motors were mounted on one or both axles of the street cars, rigidly supported at one end on the axle, the other end being supported on springs of more or less resilience. It was soon found that the tracks showed signs of wear greatly in excess of that formerly experienced in horse traction, this result being in some cases wrongly ascribed to the extra load caused by the weight of the motors. As has been stated, one end, or at least half the weight of the motors, was borne directly by the axles without the intervention of springs to relieve the blow due to the inertia of the motor when passing from the end of one rail to that of the next. This blow was of greater or less impact, varying directly as the weight of the motor and the speed at which it was driven. As a natural result, the rails soon became dented and bent down at their ends, forming a depression into which the car wheels dropped in passing, the rebound from such a drop resulting in another blow to the rail a short distance along in the direction of travel, this in time, forming a cause for a third and fourth depression, until finally the tracks became unfit for traction purposes and heavier rails were substituted. Now, the rail being of exceptional rigidity, the destructive action of the jar was transferred to the motors, causing destruction of gears, springing of axles, burning out of armatures, etc.

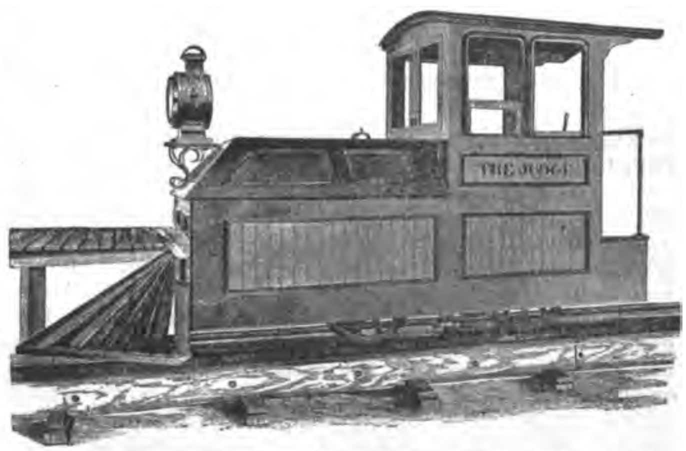

FIG. 1.—FIELD'S ELECTRIC LOCOMOTIVE "THE JUDGE," 1883.

To eliminate this bad effect, in the Eickemeyer-Field apparatus all the weight of both motor and car is supported on springs, the motor forming part of the car body and moving with it, so that the wear of the motor on the track is no greater than that caused by a loaded horse car, while the motor in turn is so cushioned on springs that the passage over irregularities of track or ordinary street obstructions results in no perceptible jar to the mechanism, the motor being absolutely rigid in the direction of travel and cushioned on springs vertically.

The first demonstration of this combination of mechanism was shown in some experiments conducted on the Thirty-fourth street branch of the New York Elevated Railroad during the summer of 1887. This motor is shown

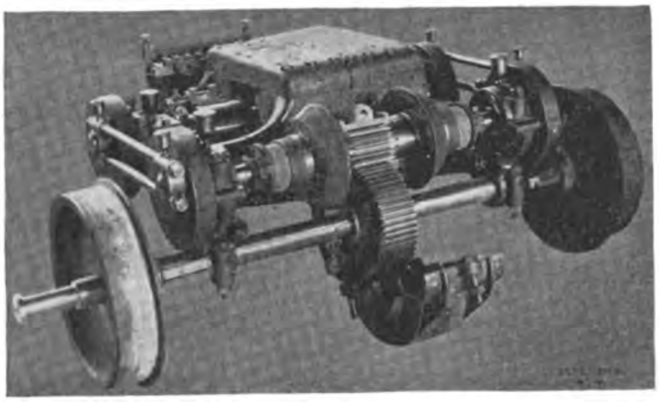

FIG. 3.—EICKEMEYER-FIELD SINGLE REDUCTION MOTOR.

in Fig. 2. Fearing that it would be impossible to design a motor of slow speed which should at the same time be of such small dimensions that it could be chambered under an ordinary street car, the motor Fig. 3 was constructed. This, it is claimed, was the first successful introduction of what is now termed "single-reduction gearing." It will be seen that in this design a gear-wheel was rigidly bolted to the car axle, this meshing into a cut steel pinion, both gear and pinion being enclosed in a dust-proof oil box, one-half of which is shown in the illustration as detached and on the ground.

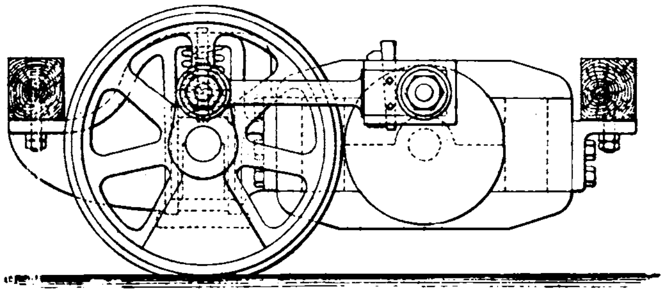

FIG. 5.—EICKEMEYER-FIELD DIRECT CONNECTED MOTOR.

Connection between the pinion and armature shaft was obtained by parallel rods between either end of the armature shaft and the pinion; these rods terminated in crank arms which were set at an angle with each other at either end of the respective shafts. The armature had a speed of 644 revolutions per minute. The parallel bars transmitted this speed of revolution to the pinion without vibration or other indication of reciprocating action. Three of these motors were run during three successive seasons a distance of from 8,000 to 10,000 miles each without any perceptible wear on the gearing or other moving part.

The excellent results obtained by these single-reduction motors showed the possibility of the suppression of all gearing on street car work and led to the construction of the motor shown in Fig. 4, wherein the motor is coupled to parallel rods and by them direct to the driving axle of the car without the intervention of any gearing. In this motor the good features of the Eickemeyer-Field apparatus were prominently brought out, and its operation was all that could be desired. It will be observed that in this motor

FIG. 4.—EICKEMEYER-FIELD DIRECT CONNECTED MOTOR.

the driving wheels were of smaller diameter than those supporting the other end of the car. As such a feature would, in some cases, be objectionable, the design shown in Figs. 5 and 6 was constructed, with wheels of uniform diameter throughout, to a single pair of which the motor armature is coupled by parallel rods, as shown in Fig. 4.

Several months' operation with motors of this type upon a road having at one place a grade of 11¼ per cent., showed that even on a grade of this amount but a single coupled axle was necessary to obtain sufficient tractive adhesion for a single car. Fig. 7 shows an instantaneous photograph recently taken at Lynchburg, Va., of a car of this type ascending an 11¼ per cent. grade.

To provide for still heavier grades and to utilize all the attached weight for tractive adhesion, the motor shown in Fig. 8 was constructed and adopted as the standard Eicke-

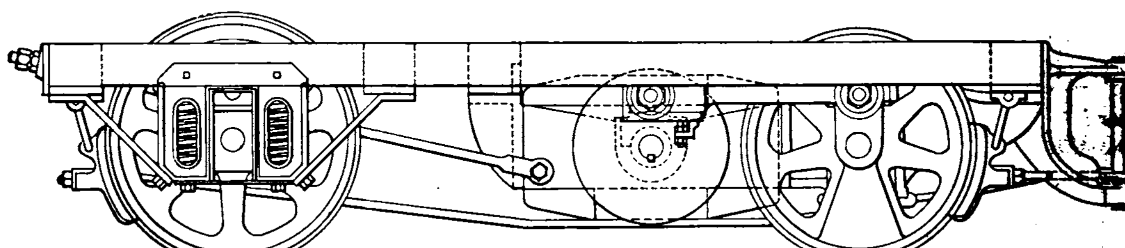

FIG. 6.—EICKEMEYER-FIELD DIRECT CONNECTED MOTOR.

meyer-Field car motor. This motor has nominally 35 horse power; the wheels are 26 inches in diameter; armature speed, 150 revolutions per minute; weight, including wheels, axles and fittings, 9,000 pounds.

for use on elevated railroads or on surface roads where great speed of train movement is desired.

There are many advantages derived in the use of this type of motor. All the wheels moving in unison renders

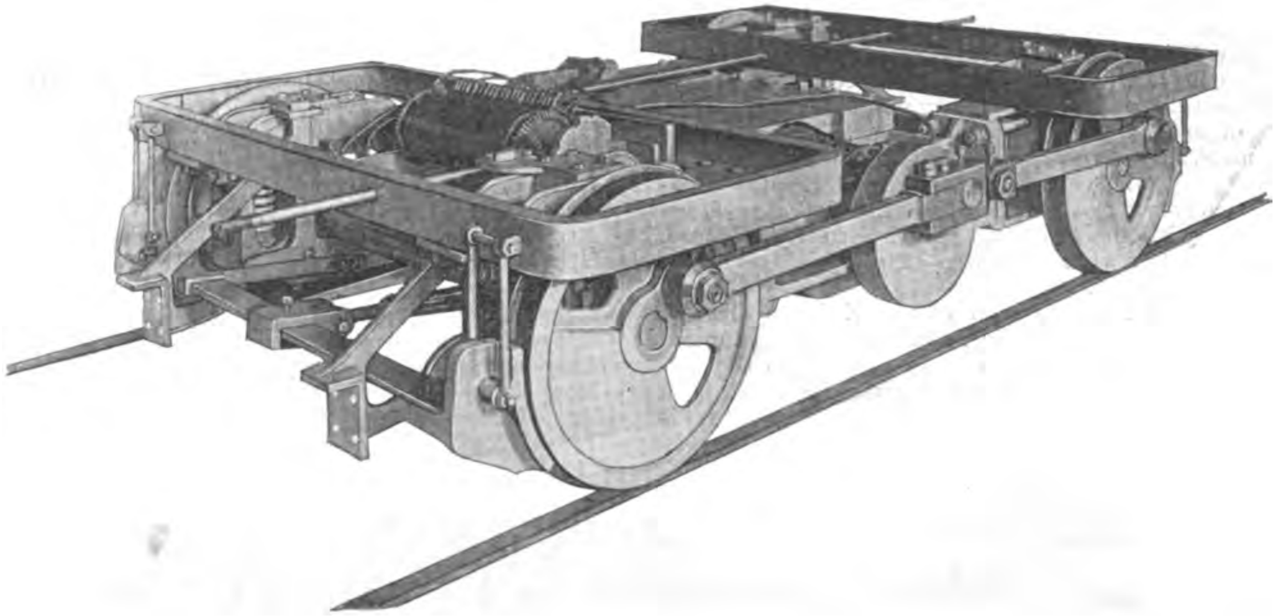

FIG. 8.—STANDARD EICKEMEYER-FIELD CAR MOTOR.

FIG. 7.—EICKEMEYER-FIELD CAR, ASCENDING 11¼ PER CENT. GRADE, LYNCHBURG, VA.

It is an interesting feature of the Eickemeyer-Field designs that they impose no limitations as to size or power of motor. Consequently, this mechanism is peculiarly adapted

a slipping on grades or wet rails almost an impossibility. Again, more power for a given weight can be had from one large motor than from two small ones, while on long vestibule cars two of these motors mounted as bogie or swivel trucks give an installation of great power and flexibility.

The feature of parallel rods as a connecting medium between the motor armature and driven wheels, while producing the same beneficial results of shock insulation, is materially different from the connecting rods as used on a steam locomotive. In the latter the connecting rods have a reciprocating, as well as a rotary, motion. The impossibility of balancing the reciprocating motion is a feature which materially decreases the speed at which a steam locomotive can be driven. Not so, however, with the parallel rods, every point of which, when in motion, describes a true circle, with the centrifugal force perfectly balanced, so that, no matter what the speed of rotation, no jarring action is experienced.

The mechanical construction of the Eickemeyer-Field apparatus is exceedingly simple. Fig. 9 shows an armature complete with crank discs ready to place in the machine. The frame supporting the armature shaft is a single, nearly square, casting within which the armature is mounted; its bearings, being bored at a single operation, are necessarily in exact alignment with the pole faces. This frame is entirely closed underneath, so that no mud or moisture from the street can penetrate. At either end of the motor frame are bolted the pedestals carrying the springs and axle bearings upon which the whole motor and car body are supported. The motor is entirely governed by a detachable crank-arm or wheel, located, preferably, on the dashboard at either end of the car. It is very easily controlled, speed and direction being governed by a single lever, and as the diameter of commutation in this machine is at an exact right angle with the pole faces, it follows that movement of the armature in either direction is accomplished without change in the brush position.

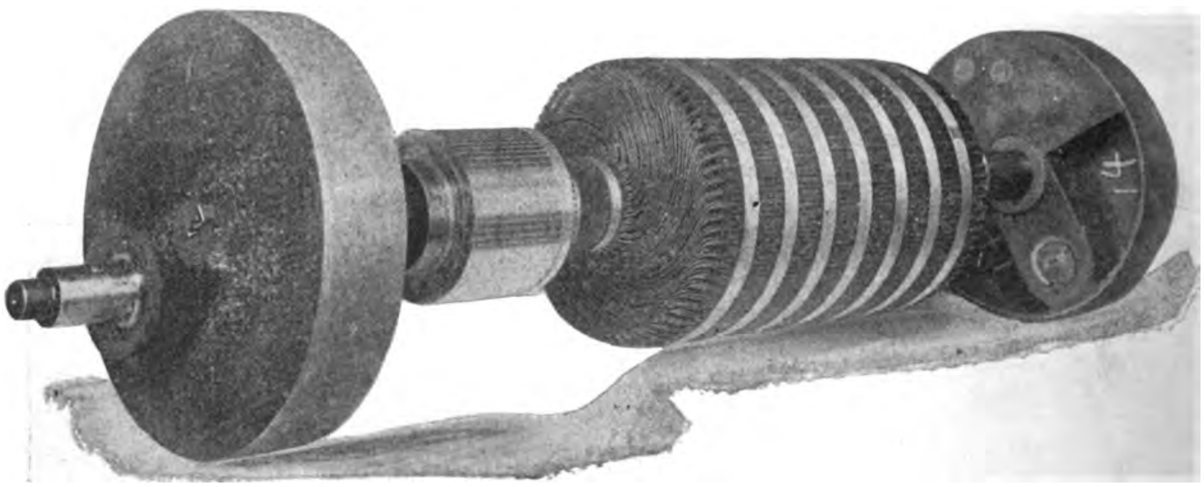

Fig. 9.—Eickemeyer-Field Armature with Crank Discs.

LINEFF TRAMWAY.

Mr. Lineff, the designer of the magnetic continuous closed-conduit system, has lately been engaged in an interesting investigation with regard to the insulating properties of various kinds of combinations of asphalt under extreme climatic conditions of wet, cold and heat. This is comparatively fresh ground for experiment, as until the present only the mechanical properties of asphalt have been studied. It will be remembered that Mr. G. Kapp a short time ago made a test of the Lineff system, which gave very satisfactory results.

AN ARGUMENT FOR ELECTRIC HEATERS.

BY

W. R. Mason

St. Joseph, Mo., Nov. 30.—[Special.]—Last night one of the cars on the street railway was run into the barn with a fire still burning in the stove. The stove became overheated and set fire to the car, which in turn fired the barn. Thirty-two cars, all the cars on the line, were consumed, together with the repair shops and storage house. Loss, $60,000; insurance, $30,000.—*Chicago Tribune.*

All people regret misfortunes which from time to time befall worthy corporations. Such misfortunes, however, may convey seasonable and emphatic warnings to those at the time more fortunate. Street railway managers may well consider the above item a "special" to themselves, and seriously contemplate replacing older methods of car heating by those more modern and, at the same time, safer and more efficient. For two years past electrical heating, especially for street cars, has been growing in popularity, and that because of its intrinsic merit. More than eighty-five roads have put electric heaters upon their cars because they are absolutely safe, absolutely clean and absolutely reliable. Doubtless many roads are using stoves for the simple reason that they have them and believe it extravagant to equip their cars with electric heaters while their stoves are at all serviceable. Such economy is practiced at a risk. An expense of several thousand dollars due to a previous saving of a few hundred dollars is hardly profitable.

It is not held that the use of stoves is inevitably followed by such disastrous results, but it is a fact that it is at the weakest points of a machine or organization that misfortune will strike. Because of their triteness, we are prone to forget certain little sayings, as for instance, "An ounce of prevention is worth a pound of cure," which contain much good advice.

But it is encouraging to mark the rapid progress in electrical heating. It must certainly satisfy the most exacting mortal. The same comment also might well be made in regard to the operation of electrical heaters now in use. But electrical heaters are not to be considered merely as a safeguard against some great loss as that recorded in the *Chicago Tribune.* As now operated upon street cars, they are economical. They remove the necessity of new stoves every two or three years and of new parts oftener, while the cars, due to the absence of smoke and dirt, retain for a longer time their cleanly appearance and, consequently, their utility.

THE PLANT OF THE EASTERN ELECTRIC CO., LTD., ST. JOHN, N. B.

During the present year The Electrical Engineer has had the pleasure of drawing attention to a number of American electric light and power plants installed in Central

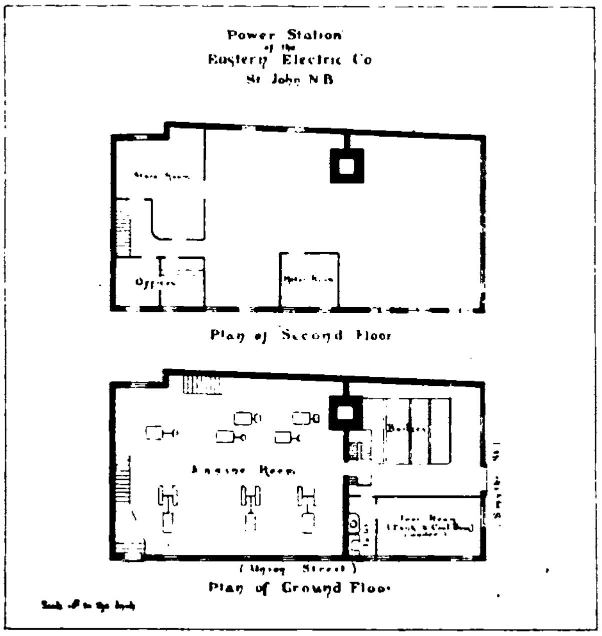

Fig. 1.—Plan of Eastern Electric Light Co.'s Station, St. John, N. B.

and South America and the West Indies. Readers of this paper will remember the fine Westinghouse plant at Havana, Cuba; the Thomson-Houston plant at Kingston, Jamaica, and the Fort Wayne plant at Barranquilla, U. S. C., all of which have recently been illustrated and described in our pages. But American enterprise has been not less active to the north of our border than in the tropics, and it is gratifying to know that apparatus of American make, or embodying American ideas and inventions, is becoming

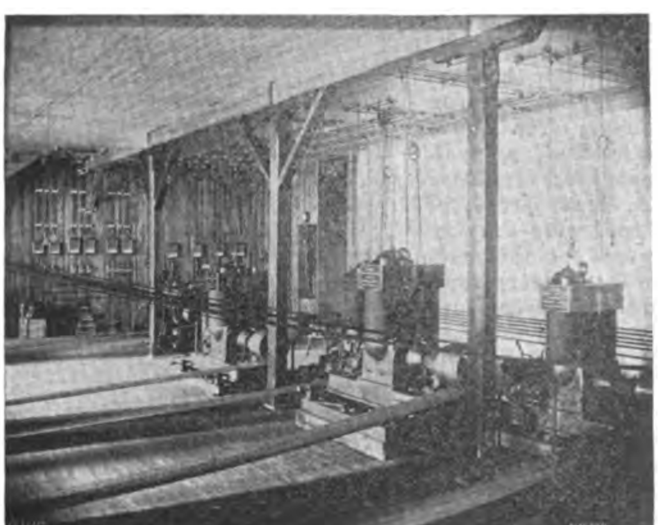

Fig. 2.—Dynamo Room, St. John, N. B., Station.

widely known through the Dominion of Canada. Some of the best examples are probably to be found in the Eastern and maritime provinces, and among these may fairly be placed the plants at St. John, New Brunswick. The development of electric light and power there is peculiarly due to American initiative, seconded, of course, by the genuine love of improvement and progress on the part of the Brunswickers. In 1889, thanks to the zeal of Mr. A. A. Knudson, a New York electrical engineer, who had done much to develop the telephone in Canada, St. John had an electrical exhibition, one of the earliest, if not the first, to be held in a British colony. It was the good fortune of the present writer to visit that beautiful exhibition and to be able to do something in cultivating popular local interest in it. The results of the display were very soon seen, and certainly one could not well wish for a more conspicuous proof of them than in the plant illustrated in this article.

The Eastern Electric Co., Ltd., of St. John, was most lucky in its choice of a site for its station, (Figs. 1, 2, 3 and 4), for the location combines many advantages, including two great essentials to economical construction and successful operation—a solid rock foundation and nearness to tidewater. As Mr. Fred. S. Pearson, the engineer of the Boston West End Road, put it, after a recent visit: "Had the city of St. John been laid waste and all its property placed at the disposal of the Eastern Electric Co., a better site for an electric light plant could not have been chosen." The site, at the corner of Union and Smyth streets, has a frontage of 136 feet and 50 feet. Of the 136 feet, a space 102 by 50 is taken up by the power station, while the remainder is now covered by a shed used as a warehouse, and

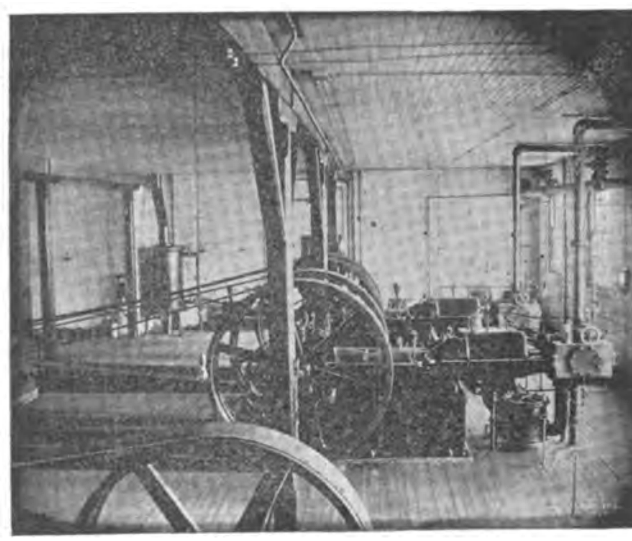

Fig. 3.—Steam Plant, St. John, N. B., Station.

held in reserve for coming extensions. The boiler house is 36 feet long by 50 deep, and the engine and dynamo room is 66 feet by 50. Under the entire property extends a firm, dry slate ledge, affording the best possible foundation for an electric plant. A few yards from the station are wharves fronting upon the harbor of St. John, where the coal used by the company is landed; while from the deep waters of the harbor itself can be obtained for the mere cost of laying the pipe an inexhaustible supply of water for condensing. Moreover, the station is peculiarly well situated for the exploitation of the Edison system. It stands right in the heart of the business portion of the city, and within a radius of one mile is contained the profitable lighting area of the snug, compactly built city.

The building itself is substantial, and even massive, being built of brick with stone trimmings. It has a gravel roof. The lower floor is occupied by the boiler, engine and dynamo rooms, ample cellarage being found underneath. The upper floor is used for offices, storeroom, meter-room, etc. The chimney is also of brick, square built, 5 feet in diameter and 100 feet high. The foundations are all of block granite, built up from the sheer bed rock in such a manner that any settling of the structure is utterly impossible. A novel feature worthy the attention of power station architects in moist climates, is the arrangement for the drainage of rainwater from the roof. It is built sloping to a centre, thus forming a catch-basin, whence leads an iron pipe, to a tank situated in the boiler-room. This iron pipe from its contiguity to the brick chimney and exhaust, is not liable to be frozen up even in the coldest weather. The evident advantages are a material saving in galvanized iron for gutters and drain-pipe and the utilization of the rainwater for boiler purposes.

The boiler house, 36 by 50 feet, is excavated about 18 feet below the street level and that of the engine beds, thus making the distance between the floor and the roof nearly 40 feet. This more than ordinary height in a medium sized station is a great help to the boiler-room, and is duly appreciated by the workmen therein. The steam-generating equipment consists of four Heine safety steel water-tube boilers, in all 500 h. p. These are provided with patent rocker grates and Jarvis boiler setting. A noticeable thing in connection with these boilers is the thickness of their steel plates, being nearly seven-eighths of an inch, thus insuring long and reliable service. In this boiler-room and immediately facing the furnace doors are situated the coal vaults, which have a storage capacity of about 250 tons. These are accessible from the rear by means of shutes extending from the sidewalk, so placed

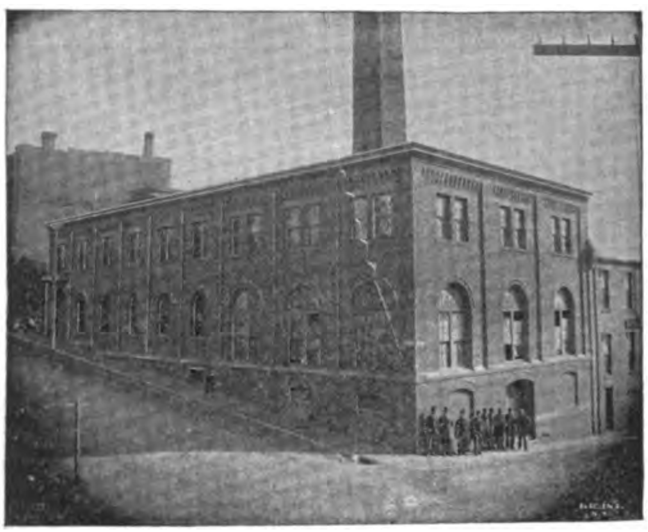

Fig. 4.—Exterior New Eastern Electric Light Co.'s Station.

that the contents of a coal cart can easily be deposited therein. Directly over the coal vaults, and supported by iron pillars passing through them, is the tank mentioned above; this is made of wood with the seams thoroughly caulked, and its capacity is 15,526 gallons. The purpose of this tank is a double one; first, to serve as a receptacle for the rain-water passing from the roof through the iron pipe already mentioned, and second, as a reservoir for a reserve supply of water in the event of the city water being shut off through an accident to the mains. It is estimated that at the present capacity of the station this tank will supply water for boiler evaporation for a space of 10 hours, which should be time enough to effect any ordinary repairs to the street mains. Above the tank and extending the whole length along the top of it, which serves as their flooring, are an engineer's work-room and a toilet-room. All parts of the boiler house are light, airy and cheerful, which materially conduces to the health and comfort of the employees.

Passing from the boiler house up a flight of iron steps, leading over the top of the boilers, and so placed as to allow an easy inspection thereof, we approach the door of the engine and dynamo room, which opens upon a platform made to overlook the boiler fronts, and enter the engine and dynamo room. Here are two engines of 138 nominal h. p. each, made by McIntosh, Seymour & Co., furnishing power to run four Edison No. 16 incandescent dynamos with current capacity for 3,000 incandescent lamps, while a 100 h. p. Armington & Sims does similar duty for a Wood arc dynamo, operating 61 street lights for the city of St. John. A No. 14 National feed water heater is used and two Knowles No. 5 feed pumps, one of which is held as a reserve. Economy in oil is secured by the aid of a "Common Sense" oil filter. The station incandescent electrical apparatus is of the standard Edison type, and the arc apparatus is of the well-known manufacture of the Fort Wayne Electric Co.

John F. Zebley.

The engines are placed upon beds of brick and cement and are fastened by anchor bolts to a ledge of slate rock three feet below the engine-room floor. Beds of solid masonry, built up from the rock, furnish a foundation for the dynamos.

At the present time the dynamos are belted direct to the engines with link and endless leather belting.

A flight of stairs leads from the main entrance of the building to the second floor. Adjoining the main building and facing Union street is the shed at present used for storing the company's heavy supplies, and under which is a coal cellar of about 400 tons capacity, now being made to contain a reserve supply of coal for use during the winter months, when the navigation of the Bay of Fundy—the water route for fuel—is uncertain. From the rear of this coal cellar a slight decline admits of the easy carriage of coal to the boiler house, by way of the cellar under the dynamo-room.

A. A. Knudson.

The station was constructed from the plans and under the superintendence of G. Ernest Fairweather, a well-known local architect. J. A. Grant & Co., of Boston, were the contractors for the erection of the steam plant, and the electrical work was done by the Edison General Electric Co. The construction of building and designing of the plant generally was done under the supervision of Mr. A. A. Knudson, the company's electrician. The executive officers of the company are: John F. Zebley, of New York, president; H. B. Zebley, New York, vice-president; A. A. Knudson, electrical manager; Charles D. Jones, business manager.

The plant started in January last, and up to the present time the company has confined its attention to high and low-tension arc lighting and incandescent work. The St. John City Railway Co., with whom the Eastern Co. has entered into a contract to furnish power for the operation of its motor cars, is now engaged in wiring its track, preparatory to the introduction of an electric service under the Edison system. This, in connection with stationary motor work for which there is a growing demand, will add a profitable increase to the revennes.

Thus far the income from lighting has exceeded the most sanguine expectations, and an early increase of the plant is now being considered. Any desired increase in the plant can be secured at a comparatively small additional outlay, as in the acquisition of the real estate as well as in the construction of the building a careful eye has been had to future requirements.

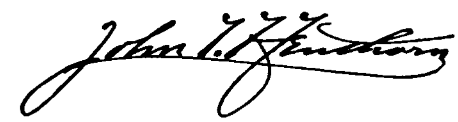
It will have been clear from the above description that the company enjoys a number of advantages making for economy and success, and tending to render the property a very handsome investment and one of the standard institutions of St. John. But with a keen perception of its opportunities in a new and growing field for electrical work, the Eastern Company is adding to its other earning departments a somewhat novel one. It has been customary for local companies to do their own repairs and not a little new construction, but in this instance the corporation is going in for the manufacture of insulated wire, under Canadian patents recently acquired by purchase from the inventors of the process of insulation, Mr. A. A. Knudson (one of the inventors of K. K. wire) and Mr. C. Cuttriss, the well-known electrician of the Commercial Cable Co. These patents cover new principles and methods in the art of insulation, and while thus giving St. John a new industry, will utilize many special advantages by being under the same roof as a large steam and electric plant. It will thus be seen that the Eastern Electric Co. bases its operations very broadly and will derive revenue from a variety of sources, any one of which has often been found productive of large dividends. We understand that steps will be taken later for the manufacture of this wire in the United States. We are glad to bring this development of electric light and power in New Brunswick to public notice, not simply because American apparatus plays so large a part in it, but because it is largely due to the intelligent work of two Americans, Mr. Zebley, a New York banker, and Mr. Knudson, whose faith in the growth and enterprise of the maritime provinces has led to this promising investment of capital there.

FRENCH ELECTRICAL INSTALLATION RULES.

The French "Union" Fire Insurance Company has procured from MM. Bunel and Picou a full report as to the precautions which in their opinion should be taken in the use of electricity. The principal recommendations of the report are as follows: The current density is not to exceed 2 amperes per sq. mm. (1,300 amperes per sq. in.) in wires of 10 sq. mm. (No. 9 B.W.G.) section and above, and 3 amperes in the case of smaller wires. Bare conductors are to be prohibited in buildings, and only allowed in exceptional cases in workshops. The protection of the conductors must be double, electrical and mechanical. The current leakage must not exceed one-thousandth of the total flow. The use of earth, or of gas or water pipes, or metallic girders, for return currents, is forbidden. The fuses must be double, and must melt with not more than a three-fold current. Resistance-coils must not be heated more than 100° C. Glow lamps must not be put on gas-fittings unless the gas is definitely cut off. Every place containing accumulators to be classified as dangerous, and to be subject to special precautions. Places where gas and electric fittings coexist to be classified as dangerous or very dangerous. The fire risk of gas lighting being represented by 4, the report concludes by estimating the risk as 3, when the electric lighting stands alone and the above regulations are strictly carried out, and as 3 to 5, if there be any imperfection in the fittings.

THE ECONOMIC LIMITS OF LARGE POWER UNITS IN ELECTRIC WORK.

BY



An article under the above caption in your issue of November 4, p. 500, by "Carleton," appears to require a little attention from the fact of the many broad statements, both made and implied, as to the alleged superiority of the high-speed engine for electrical service over that of the slow or more rational speed engine. These statements, appearing as they do in such a prominent publication of wide circulation, make it the more necessary that they should not stand uncontroverted, even though the article in question has the appearance of emanating from a source interested in this class of engine, if not prompted by business motives.

I fully agree with "Carleton" that it is proper and desirable to divide power up into proper units, but our differences at once develop when the amount of power is suggested that shall constitute such units, and as illustrating the folly of putting all the eggs in one basket the gas-holder problem is used by him. This is all right, but the unit, I contend, must be in proportion to the population and demands, and not insist that, because East Greenwich, say, has two holders, the city of Philadelphia shall have twenty holders, each of like capacity, when five could be made of equivalent capacity for the work at much less cost for maintenance.

If I were to build an electric light plant for 100 arc lights I should, no doubt, if money was scarce, couple these two machines to a moderately high-speed engine, the same as many of our now large stations were first started with. But as the growth of the station developed, a time would come where the multiple in power first selected would be entirely out of proportion to the magnitude of the station's business, thus making it imperative from a financial, as well as from a practical, standpoint that the motive power should be consolidated and engines of a power more in keeping with our resources used; this policy, I am aware, is foreign to the placing of eight engines of 150 h. p. each for a load of 1,200 h. p. The comparison in the cost of maintenance (which of course includes fuel, repairs, supplies, etc., and floor space occupied) between eight engines of the high-speed type and a modern slow-speed engine is obvious, and decidedly, in my mind, in favor of the slow-speed cut-off type.

It has been urged that variableness in the load precluded the satisfactory use of a compound or triple-expansion engine, but this is merely a theory of a would-be authority, which the actual facts of many cases about the country do not confirm, for the reason that if a station requires a multiple in power of 1,000 h. p. the demands of that city are such as to naturally provide a constant and uniform load, for at least ten hours, at from 900 to 1,100 h. p. and often for a much longer period. If we take an extreme case and suppose, for the sake of argument, that the engine must run a portion of its time at 50 per cent. of its rated capacity, even under these conditions it is far superior both in point of regulation and economy to the high-speed class, as it has been proven that a triple-expansion engine, working at half load, will develop a horse power with 14½ pounds of steam, and at its rated load less that 13 pounds. This certainly is a good record for an engine working under extreme conditions.

"Economy in floor space" and absence of a "multiplicity of parts," which tend to "increase the liability of disaster," are urged in favor of the high-speed type. This fact is true in the first item where two engines of like capacity, say, 150 h. p., but of different types, are placed alongside of one another, and constitute a multiple adapted to the requirements of a town of small proportions. If we fix upon this size of engine as the multiple for a station in a thickly settled city of five hundred thousand inhabitants, the question of real estate and the multiplicity of parts would assume a financial proportion not pleasant to contemplate, to say nothing of the men and boys required to keep them in repair, furnish the oil and look tolerably shipshape to receive company occasionally. Implied broad statements that nothing short of a high-speed engine can turn an armature at a satisfactory rotative speed and do this in the only known economical method, when all points are considered as to first cost, fuel, supplies, etc., is going beyond the bounds of engineering propriety; and facts do not warrant this belief, notwitstanding "many electric engineers have in no way changed their views from the first concerning the size and style of engines for electric requirements."

Business interests sometimes allow a man to admit that his neighbor builds the next best engine to his, as a prominent Corliss cut-off engine manufacturer once admitted to me. But I have yet to learn of a case where an admission was made of equality. The fact is that the type of machinery selected has more influence upon the question of dividends than the mere theories and pet engines of office experts.

Taking up that portion of the article touching on electric railway service, the statement regarding the severity of such work we all know; but it is a new problem to me that such variation produces a blow on the piston, and the consequent probability to disintegration of the machine as a whole. Up to this time I had assumed that the maximum pressure communicated to the cross-head and crank-pin, main bearing, etc., was the product of boiler pressure multiplied by the area of the piston, and that it was immaterial whether this pressure was maintained during 1 inch or 36 inches of the piston's travel, as regards any blow or dangerous element. Of course, if the steam is allowed to follow 36 inches on the stroke before cutting off much more power will be generated, but the maximum initial pressure upon the piston will be precisely the same as though the steam followed 1 inch or 100 inches, and I cannot, therefore, realize the cause for alarm that a long-stroke engine is going to pieces if coupled to an electric generator. Such engines are in successful operation, and, I surmise, will continue to so run with a very small fraction of cost for repairs as compared with that of the high-speed type.

If "Carleton" is familiar with rolling-mill practice he must have seen engines of 2,000 h. p. run from a friction load up to full stroke and all within one stroke of the piston's travel. The rolling of hard steel billets is quite rough work and about as severe as other service.

In speaking of the alleged blow on the piston from a variation in load, the absence of compression was pointed out as a serious objection to the automatic cut-off engine of the slow-running type. I am free to say that any Corliss engine can be made to run smoothly with a very small amount of compression, as its successful operation does not depend upon such an extreme compression pressure, as is so essential to the existence of the high-speed type, and which may be classed as a necessary evil; it is quite common to find a high-speed engine with compression exceeding that of the boilers; this loss of power and its resultant additional friction requires no comment or argument save that it is essential to the safety of the engine and inherent in that construction.

Reference was made to the fallacy of running a non-condensing compound engine, and in support of that theory the Corliss Steam Engine Co. and the Armington & Sims Engine Co. were quoted as declining to build engines of that class. This declination does not seriously affect well-known laws regarding the mechanical application of steam, for the principle of dividing the ratio of expansion between two or more cylinders for a given cut-off has been proven too often beneficial to be now ignored because a manufacturer did not take kindly to the proposition of a client. "Comment" in this case, also, may be said to be "unnecessary.

It is a well-recognized fact among flour-mill men that if a non-condensing engine with steam at 100 pounds will turn out a barrel of flour for 32 pounds of coal it is considered as a "crack" equipped mill; yet I have figures, whose accuracy can be vouched for, where a mill of precisely the same class of machinery and capacity is doing the same work on a consumption of 24 pounds of coal per barrel of flour with a non-condensing compound engine of the slow-running type. Both of these cases include wheat-cleaning machinery and elevators; and I will go still further and say that the duty of this class of engine of the slow-moving type has an economy about equal to an ordinary non-steam-jacketed condensing engine.

Following the article along we find that "Carleton" "regretted that numerous electrical engineers are for the sake of personal advancement constantly bringing forward, at the expense of the shareholder, new and untried experiments in special engines." This, I should think, indicated a line of progress and a desire to improve upon existing methods, and should be commended, rather than regretted, even though the engineers may obtain new light upon this branch of engineering and possibly contrary to existing theories of the upholders of the high-speed class. I recall cases where such dissenting engineers have reduced the item of fuel alone 66 per cent., which the stockholders fully appreciated.

It is true that the measure of economy of the steam engine is determined by the consumption of steam per horse-power per hour, and it is for this very reason that many of the principal electric lighting stations of this country, whose officials have fully considered the cost of fuel, maintenance, etc., are substituting compound engines for the high-speed type. I would not be understood for a moment as intimating that the high-speed engine is nearing its end; far from it, as it has a mission which it can, and does, perform successfully, and I draw the line only where the cost of coal would preclude its unconditional adoption.

Triple-expansion engines were suggested by "Carleton" as possibly admissible if the load could be steady and uniform, and reference is made to a well-appointed central station where a triple-expansion engine was officially tested and the report thereon was, as he states, 12.5 pounds of water per indicated horse-power. For the information of this gentleman I would say that this engine of 500 nominal h. p. (assuming that he refers to an engine running at Providence) was connected to water-tube boilers and an 18-inch steam pipe, which latter was designed for 4,000 h. p., and the amount of condensation in a pipe of this size and length (about 125 feet) was, as can be readily imagined, considerable, in addition to that carried over by the boilers, and was the cause of the allowance of 7.39 per cent. of entrainment or moisture. The report gives the result as 12.9 pounds of water per indicated horse-power. This amount of condensation and moisture was one of circumstances and not chargeable to the engine, which our friend would recognize if he were to test a high-speed engine under like circumstances and conditions. There have since been added two engines, one of 1,200 h. p., also of the triple-expansion type.

This explanation is made in the hope that it will be plain to our friend and his colleagues, and, as the official report is very clear as to details, I should be pleased to furnish a copy for his and his friends' perusal if his address is made known to the editors of THE ELECTRICAL ENGINEER or myself. And he will upon perusal see that a marked improvement has been made in steam engineering which cannot be controverted. And further, I would say that the test of this same engine was made on its every-day duty without any preparation whatever, as its daily duty was such as to make it imperative that it should be started at 3 P. M. and run until 6 A. M., which would necessarily preclude any preparation to favor the result. This had been the daily running condition from its first starting up, on November 27, 18~9, until the test, July 13 and 14, 1890 ; therefore I can very well say that this test faithfully represents the average daily running duty of this engine, and up to this time has not been equaled, to my knowledge, either by a two-cylinder compound or a high-speed type.

The record of this triple-expansion engine has since been excelled by one of the same type, but of the upright pattern, at the Harrison Street Pumping Station, Chicago, where well-authenticated figures show an indicated horse-power for a consumption of less than 12.7 pounds of water pumped into the boiler, and without any allowance whatever for leakage or moisture. When the duty of an engine is reduced to coal or water per indicated horse-power per hour, it is of course immaterial whether the load is generating an electric current or pumping water.

Reference is made to triple-expansion marine engines as a step in the wrong direction, which is about on a par with other statements made by the same authority. It is true that a triple-expansion marine engine does not reach the same degree of economy as a three-cylinder shore engine, for the reason that the ratio of expansion is not carried to such an extent, as it is imperative that all cylinders should develop their maximum power, with a result that their economy is about equal to that of the two-cylinder land compound ; at least such is my conclusion after a careful comparison of many records.

In order to still further reduce the coal consumption, there have been a number of quadruple-expansion engines built this past year, and it is not considered to be business principles to invest such large sums of money for machines of this class by steamship officials without an adequate ground for immediate return on the investment. The economy of the engines of the steamship referred to in the article as being made by the "professor" was evidently of the two-cylinder type, as the duty realized for this class of compound marine engines compares very closely with a single-cylinder steam-jacketed shore engine for the reason above referred to, and is clearly set forth by the writer in a paper read before the New England Cotton Manufacturers' Association at their meeting held in Boston.

To Mr. Thos. A. Edison justly belongs the honor of practically solving the problem of commercial electricity, but I cannot concede to our friend the claim that the high-speed engine was the pioneer engine that gave commercial electricity its first start, thereby enabling it to get a foothold, in the broad sense which our friend intended to convey to his readers ; neither do I believe that he could conscientiously say that, if it had not been for the Armington & Sims and other allied engines, commercial electric lighting would not have reached its now vast proportions.

The connection of the high-speed engine type with electric lighting was in its infancy ; the problem was to impart a rotary motion to the dynamo with a minimum of floor space, first cost and the ease with which it could be put in service, and the matter of economy was of secondary consideration, and, in fact, I surmise, left out entirely. Therefore, I think our friend must have a very high opinion of his pet type of engine and theory when he states that the high-speed engine has been the stepping stone to civilization and a "means of improving the standing of mechanics, materials and engineers." For engines were built many years ago which were fine examples of engineering and with a record of producing an indicated horse-power for about one-half the fuel that is commercially required for our friend's type of engine. I will admit that a high-speed engine requires good materials and workmanship to be run successfully ; so does a sewing machine, a rational speed engine, a lathe or a milling machine ; they all have a mission to perform which can only be successfully accomplished by the adaptation of each to the duty required of it.

Our friend appears to be laboring under the impression that, because the triple-expansion engine has from necessity come to the front (and it is to remain) with its three cylinders and connected parts, it must of necessity be dangerous, as he don't know which end is to kick first and cause the trouble ; and to ease his mind, and for his information, I may record an instance of a Corliss engine which had been run constantly, a short distance from New York, where no repairs had been made to the valve-seats of the engine for twenty years, and at the time it was reported, the valve faces were as smooth as a mirror and apparently as steam-tight as two iron surfaces could be made. This is but one example, and I should like to learn of a like case of a piston-valve that would remain reasonably tight for a period of two years.

There is one portion of the article which is quite right, namely, that the armature of the coming dynamo or generator will be connected direct to the engine shaft ; but the engine of the future for running the dynamo will be of the automatic cut-off type and will not exceed 100 revolutions per minute, thus admitting of a first-class economical engine, not exceeding in duty 14 pounds of steam per indicated horse-power and not, as our friend hopes, 200 revolutions and 18 inch to 20 inch stroke. Such a type of engine as indicated by our friend would preclude the highest degree of economy, which is so desirable at this time. Therefore I hope that the friends of the one gas-holder principle will look twice before they install ten or fifteen engines of the high-speed type, with their little army of attendants and "multiplicity of parts," into their station, when two slower engines may do the same work more satisfactorily and with far less fuel, supplies, attendance, etc.; for we can better afford with far less risk to place our dependence upon the mechanical disaster of a slow-moving engine, which so troubles our friend, rather than suffer a financial disaster, often met with in the high-speed type station.

Proceeding still further, we are advised that if we cannot put in a compound condensing engine of 200 revolutions we should, if water of condensation cannot easily be obtained at small expense, put in a direct-acting engine. This gratuitous advice is possibly offered with the belief that it costs a large proportion of the operating expenses to get that water into the condenser and an equal amount to get it out again, so that, take it all in all, you might better buy one of my high-speed engines, and save all of this useless expense and trouble, and pay the bills as they come in.

Take the article from beginning to end I cannot conceive of a more laborious endeavor to prove that "Carleton's" engine (the high-speed type) is the missing link between the most hopeless case of bankruptcy and a 10 per cent. dividend, and it certainly must be very pleasant musing upon one's return to the family fireside after a laborious day's duty to believe that such a mission has been so admirably fulfilled; and possibly it is equally pleasant to those who have the slow-speed compound type to know that their arc lights cost for fuel less than one-half those of our high-speed friend's.

If a man's mind is satisfied in this world, the road to happiness and comfort is smooth; and it is only when he gets away from home and compares notes with others that he realizes that other people are in better shape than he, and thus starts to thinking, that his trouble commences.

"ONE YEAR'S READING."

J. P. M., of North Adams, Mass., writes us under date of Dec. 3, "Enclosed please find money order for subscription for coming year. For some time past I have been an eager student of electricity, and deem it but just to say that never during any experience in my search for electrical knowledge have I progressed so well as I have during one year's reading of THE ELECTRICAL ENGINEER."

Everything is possible with wave motion.—Nikola Tesla.

GOVERNMENT CONTROL OF THE TELEGRAPHS AND TELEPHONES.

TO some people this may seem to be a far-away subject, not likely to come within the range of practical politics for another ten years. Our own impression is that its appearance on one or other of the political platforms will take place at an early date. There is a growing volume of discussion on the matter, not over-intelligent, perhaps, but still very forcible when it comes to an expression in favor of governmental control; and at each widening of the area of interest and controversy, the day when a national vote will be taken to settle the question is brought nearer. At the present moment, we have a Postmaster General who makes Government Telegraphs the burden of his song; and while the public is given to understand that Mr. Gould opposes the proposition, there are some cynical people cruel enough to say that he and Mr. Wanamaker are *au fond* affectionately in accord even to the extent of a new scheme of addition, division and silence. Mr. Wanamaker has talked loudly about Government competition, but he knows that the American nation is honest and would not allow spoliation and confiscation. Mr. Gould says he prefers private management, but is that any reason why the Western Union would not sell out for $200,000,000? After all it is quickly narrowing down to a question of price, and that the price for all the telegraphs and telephones will reach $400,000,000 will soon be seen to be near the truth.

Under these circumstances, it is fortunate that the status of the Government telegraphs of Europe should have come up for such thorough and lively discussion as it did at the Electric Club last week, when Mr. E. Rosewater, editor of the *Omaha Bee,* lectured on his recent investigations abroad. There was little of the argumentative about the admirable and public-spirited lecture, Mr. Rosewater assuming wisely that his hearers were familiar with what may be termed the constitutional and political aspects of the matter. The pith of Mr. Rosewater's contention will be found in his statistics, and we imagine that he is willing to stand or fall by them. In other words, if we can get 20-word messages for 10 cents and have a telegraph office in every hamlet in the country, he believes that the old fears as to the development of paternalism will go for naught. He is probably right, but we are among those who regard that fear as very wholesome and something to be cultivated.

Coincidentally with the publication of the report of Mr. Rosewater's lecture in the daily papers came the annual report of Postmaster General Wanamaker, who has now gone so far on the road to the realization of his hopes that he actually sees 10-cent telegrams and 3-cent "telephons" among the near possibilities. One passage of his report is very striking:—

> "A year from next March," he says, "the telephone patent expires, and, unless Congress acts promptly to authorize its adoption for communication among the people, it requires no stretch of the imagination to believe that in the next two years one immense syndicate will unite and control all the hundreds of telephone plants of the country as the telegraph is now controlled, or the two will be united, and then for the next 20 years the most astute attorneys will be legitimately earning large salaries in indignantly opposing the so-called attacks of future Postmasters General upon defenseless vested rights."

This is pretty plain speech, but as we have intimated Mr. Gardiner Hubbard and Mr. Jay Gould—like any other men with such property—will be quite willing to turn over their holdings to the Government—for a consideration.

But before we get Government telegraphs and telephones, what a blessing it would be to have a half-way decent postal service. The report of Postmaster General Wanamaker devotes considerable attention to the condition of affairs in the postal service in and about the city of New York. His observations but serve to emphasize the pressing need which is well known to exist, of a radical reorganization both of the local and general service. We are glad that the wretched condition of affairs which now obtains, has at last received official recognition, but we cannot agree with the Postmaster General as to the most effectual remedy. The present post-office is in the right locality, although the edifice is grievously ill adapted to its present purposes, or for that matter, to any other purpose. Postal experts are substantially agreed that what is required to place the service on a proper basis is a metroplitan organization, embracing New York and its suburbs, to be placed under a single responsible official with as many subsidiary officers as may be necessary, the different points in the system to be united, not by a costly and undesirable system of "pneumatic tubes," as suggested by the Postmaster General, but by a modern electric dispatch of the portelectric or some equivalent type, the practicability and maximum cost of which have been thoroughly demonstrated. With such a system, for example, a carrier containing 10,000 letters could be dispatched to Brooklyn once in ten minutes if required, occupying less than three minutes in transit, and requiring the services of nothing more than a little 10 h. p. steam engine and one or two attendants to run it. The same plant might in the intervals send a carrier to the Grand Central Depot in four minutes and to Jersey City in half that time. This, be it remembered, is not a remote possibility, but an accomplished fact. In view of what has actually been done in electric rapid transit, the proposal to make use of pneumatic tubes for postal work, at this late day, seems little less than absurd, and ought not to be entertained for a moment.

THE EICKEMEYER-FIELD RAILWAY SYSTEM.

THE history of an art is no less interesting and valuable to the student than its current progress and this is especially the case just now with the electric railway. For those who have followed the successive changes which have marked the late advances of this rapidly extending application, the history of the Eickemeyer-Field system, as described in another column, will be of more than ordinary interest. Eickemeyer and Field evidently recognized very early the necessity of reducing as much as possible the gear between the armature shaft and the car axle, and the development from the belt transmission employed at the Chicago exhibition in 1883 on "The Judge," to the present type of direct-connected motor, marks the important stages through which the electric railway has passed since its first practical application, scarcely ten years ago. As one of the pioneers of the electric railway, Mr. Stephen D. Field certainly deserves credit for having so early discerned the necessity for the reduction of gearing.

THE USE OF SMALL MOTORS.

"OF course the prospectus tells us about America, and we are always glad to receive any scientific information from that country and to pick up practical hints, but when we come to commercial matters and prices, we may be thankful that our conditions of life are so widely different that no useful comparison can be drawn." We quote the above remarkable sentence as embodying one of the arguments which the London *Electrician* brings forward in a recent editorial to prove that any motors running nine hours a day and yielding more than 4 h. p. cannot be used unless under very exceptional circumstances. Our contemporary goes even so far as to say that "if a shop were opened in, say, Queen Victoria street, for the free presentation of motors to any one who would undertake to make regular use of them in their business, we doubt if the demand would be so great." It would be needless to go over all the well-known arguments which have been proved correct to demonstrate the advantage, in every way, of the electric motor for powers far exceeding 4 h. p., which our contemporary places as a limit, but the reason why American practice should be no guide to the English engineer in this respect is beyond our comprehension. So far from placing the limit at 4 h. p., we know of more than one instance where 30 and 40 h. p. in motors is being economically applied. As time passes, we note a steady increase in the size of motors employed in isolated installations deriving current from central stations, and this is so well recognized by central station managers that they are continually pushing for this very business. As the economy of station operation is becoming greater and greater, with a consequent reduction in the cost of current to consumers, the motor finds a larger field of employment, and we believe we are not deceiving ourselves, and, in fact, base our opinion upon authentic data, when we assert that within a comparatively short time the electric motor of any size will be more economical to operate for ordinary isolated power uses than any means of power located on the premises.

ELECTRIC LIGHTING AT ST. JOHN, N. B.

WHILE the many opportunities presented in this country might well be expected to occupy the energies of those engaged in electrical pursuits, it is natural that as time goes on, the field for American enterprise and apparatus abroad will enlarge. A few weeks ago we described the successful operation of an American electric road in Italy, and now comes the news of the successful starting of another at Leeds, England. In the same way, our recent articles on American electric lighting plants at Havana, Cuba; Kingston, Jamaica, and Barranquilla, U. S. C., are now followed up in this issue by a very full illustrated description of the fine plant at St. John, New Brunswick. In this instance, again, it is American capital and American apparatus that have been employed, and the results are already of the most hopeful and promising nature. Messrs. Zebley and Knudson are to be felicitated upon their intelligent enterprise, which we would be glad to see imitated elsewhere. There are many other places where this success could be repeated, and where in conferring an enormous benefit on the community, the promoters put themselves in a position to reap a rich reward from their foresight and courage.

The Æsthetic Side of Gerricide.

IT is expected that another New York criminal will soon be escorted to the chair of electrical execution, or as it might more strictly be called "the electrical spit." One of our recent correspondents has not unnaturally been reminded by gerricide and by the experiments attending it, of what he read as a boy in *Fox's Book of Martyrs*, as to the broiling of heretics, and the other sports of that nature with which they who were sound in the faith were wont to relieve the monotony of dull afternoons in the Middle Ages. Mr. Dodge took the ground against gerricide that, while it may not make a mess in the prison, it is *uncertain*. We still think it is open to both objections. The very fact that Dr. Southwick proposes to conduct experiments as to the behavior of raw meat when violently shocked, shows that gerricide does not leave its *corpus vile* in an æsthetically pleasing condition. As to its uncertainty, we have not simply the medieval practice of broiling, but the primeval practice of killing half-a-dozen innocent victims, who may perhaps serve as escort to the gerricided criminal, but are really intended as proofs that the apparatus for the main tragedy is in running order.

THE LAW OF MAXIMUM EFFICIENCY OF ELECTRIC MOTORS.

BY

C. O. Mailloux.

In the very interesting article on his new method of operating motors, published in the ENGINEER of Nov. 25, Mr. H. Ward Leonard enunciates a so-called new law of efficiency which is, unfortunately, not free from objections.

Mr. Leonard states his "law" as follows:

> "Vary the voltage as the speed desired,"
> "Vary the amperes as the torque required."

The now classical researches and historic experiments of Marcel Deprez have long since consecrated these two statements, which are to be found, more or less amplified and elaborated, in the writings of Du Moncel, Froelich, Ayrton and Perry, Silvanus Thompson, and others. The claim to novelty evidently rests upon the "combination", or rather, the opposition of the two statements to make a law. It so happens, however, that the combination does not formulate *a* law, but merely states, somewhat awkwardly, some of the conditions favorable to *the* law—Siemens' law of efficiency. The awkwardness and vagueness of diction is made readily apparent by the fact that a good illustration of the "law," as worded, obtains in the now common practice of regulating street car motors by means of a variable resistance in the circuit. The manipulation of this resistance at the time of starting, or afterwards, *causes the amperes to vary as the torque* required. It also causes the *voltage* (available at motor terminals) *to be varied as the speed desired.* This example strictly conforms to the *letter* of Mr. Leonard's law of efficiency. That it does not conform to its *spirit* as well is shown by the deprecatory manner in which Mr. Leonard himself refers to the efficiency obtained and obtainable in such cases.

While the law is evidently more general and far reaching, in certain directions, than its author intended, in other directions it does not reach as far as might be desired or expected. Mr. Leonard furnishes a good illustration of this deficiency, though apparently without noticing that he has, in so doing, wandered from the territory "covered" by his rule. He says:

"If we have a train of, say, three cars, so that we have six motors, we can start from rest with sufficient smoothness by placing all six armatures in series, which will give us something less than one-sixth speed as the first step. Then we can place three in series with two multiples, which gives us one-third speed. Next, two in series with three multiples, which gives us full speed. Under such conditions we can dispense with the small converting plant altogether."

It is scarcely necessary to point out that in this case the torque and speed are both varied or regulated, not by following Mr. Leonard's "law," but by varying the *counter-electromotive force.* The circuit-potential available to the motors may remain constant. The current, on the contrary, will not remain quite constant for all groupings. It is apparent, therefore, that Mr. Leonard's law would be most useful when supplemented by a key to, or list of, its exceptions.

The present writer sees no necessity for discovering new laws to replace the one law of efficiency (Siemens') which we already have, so long as this law is found sufficiently comprehensive and general to include and cover, satisfactorily, all cases yet referred to it. According to this well-known law, the efficiency (K) of an electric motor is the ratio of its counter E. M. F. (e) to the direct E. M. F. (E) of the current supplied to it, or, algebraically,

$$K = \frac{e}{E}.$$

A mere glance at this equation suffices to show three ways in which the efficiency (K) can be enhanced in any given case. 1. By lowering E. 2. By raising e. 3. By doing both simultaneously. These might be called the three *conditions* which influence efficiency, and might be embodied in the following rule which is a corollary from Siemens' law.

"Vary either the direct or counter-electromotive forces, or both, so as to keep them at all times as close to each other in value as possible."

Mr. Leonard's apparatus and his "law" conform to this rule by taking advantage of the *first* condition. The case quoted of the six motors variously grouped corresponds to the *second* condition. He gives no instance of methods corresponding to the *third* condition.

The present writer first realized the bearing and importance of the above "conditions" in 1886. In 1887 he operated a storage battery car in New York City in which the speed regulation was effected partly by grouping the batteries, partly by grouping the two motors, thus taking advantage of *all three* conditions. The car operated by the writer in Washington in 1890 was also regulated in a way to profit by all three conditions.

The writer has also tried the plan of regulating by using a motor whose speed is reduced by means of gearing adapted to giving widely variable speed ratios. In this case the torque is largely, or wholly, independent of the current, being governed mainly by the ratio of speeds. The regulation is effected by the counter E. M. F. lowering or rising according to the current needed for the work to be done, (condition 2). This method, though not yet reduced to the desirable simplicity or perfection of mechanical form and feature, is, nevertheless, a promising one, and likely, on the whole, to furnish us eventually the desired constant efficiency under varying loads and rates of work in a more simple and less round-about manner than is the converter method of which Mr. Leonard's is the prototype.

Without pretending to discuss here the merits of Mr. Leonard's ingenious method and arrangement, which doubtless will not be without its sphere of applicability and usefulness, it is perhaps interesting to point out that in the case of an electric car, a continuous current converter such as described by Mr. Leonard, would add some 1,500 pounds, and *two commutators* to the car. The objections to the two extra commutators would "weigh" if anything, *more* than the double machine. The writer has himself devised methods of regulation employing continuous-current converters in connection with ordinary *series-motors.* He has always been too diffident and timid, however, to broach the question of the two extra commutators either to the street railway manager or the motor-man, both of whom would more willingly entertain a proposition to reduce, instead of to increase, the number of commutators.

One of the interesting and important conclusions to which the study of the equation of efficiency leads is that there can be no efficiency unless there is a counter E. M. F. (*i. e,* when $e = 0$, then $K = 0$). Now, since we have no commercial way of causing counter E. M. F. in motors except by motion of the armature, it follows that when the motor is not in motion, we have usually $e = 0$, and the efficiency K, consequently $= 0$. This consequence is one from which no system of continuous-current motor operation is exempt. One can, it is true, reduce E to the lowest value needed to produce in the motor the current necessary for the torque desired. The energy thus spent ($E\ C$) is what Marcel Deprez designated some years ago as the "cost of the torque (prix de l'effort statique)." This "cost of the torque" always corresponds, as shown by Deprez, to the $C^2 R$ loss in a series motor. It practically does also in other motors.

The writer may take some future occasion to describe some of the methods of regulation proposed and tried by him in his endeavors to comply with the above conditions, influencing efficiency.

REACTIVE COILS.

BY

Otis K. Stuart

SINCE the sudden and comparatively recent enormous expansion of alternating electric lighting commercially, the writer has been asked by scores of persons to explain the "principle" of reactive coils. As these requests have most frequently been made by superintendents of central stations and others directly interested in the operation of alternating current apparatus, it is believed that a brief explanation of the actions of such devices will be of interest and value to not a few readers.

An alternate current transformer consists usually of a magnetizable core around which are placed two coils of conductors, having no electrical connection with each other or with the core. If now we pass a direct or continuous current of electricity through one of these coils, the appreciable effects to be noticed will be, first, the magnetization of the core, and second, the heating of the coil through which the current is passing. The lines of force will retain the same direction or polarity so long as the current is maintained in the same direction in the coil; but if the direction of the current be changed, the lines of force in the field will be found to be directed oppositely to the previous lines; and if we again change the direction of the current in the coil, the lines of force will again take the direction or polarization they had at first. If we alternate the direction of flow of the current in the coil, we thereby alternate the polarity of the magnetization of the core.

A principle enunciated by Faraday was that if a conductor be moved across or through a magnetic field, a current of electricity would be generated in the conductor; it was Prof. Elihu Thomson, I believe, who first stated the principle backwards—that if a magnetic field cut or be moved across a conductor, a current of electricity would be generated in the conductor.

In the case of the apparatus above mentioned, we have a stationary field of magnetism, except at the very start of the current, so long as a continuous current is maintained; and consequently no current is developed in the second coil except at the very instant of start of the current through the first coil. When the direction of the current is changed, there is another instant of moving field, and another impulse of current is sent through the second coil. And if these alternations are very rapid, the second coil will receive correspondingly rapid impulses of current alternating in direction, as is the case with the secondary coil of an alternate current transformer. These impulses of current in the secondary coil not only alternate with the alternation of the current in the first or primary coil, but each impulse of the former is found to be in the direction opposite to the corresponding impulse of the latter. That is, an impulse of primary current generates a magnetic field which sets up a current in the secondary, of opposite polarity to the primary current.

We are now ready for our reactive coil. In its simplest form it consists merely of one coil of a conductor wound around a magnetizable core. A direct or continuous current sent through this coil would simply magnetize the core and heat the coil itself. Reversing the direction of the current in the coil would apparently have the effect merely of reversing the polarity of the magnetism in the core. But we have here a moving field of magnetism in proximity to a conductor, and this moving field *must* act upon the coil, and in a manner opposite to the original impulse of current. The one coil serves as both primary and secondary of a transformer. The counter effect in the coil is named a counter-electromotive force, and it acts as a block to the progress of the first or primary current. The primary current in the coil generates a moving magnetic field which reacts upon the coil, setting up a counter-electromotive force, and cutting down the current in proportion. In the case of direct or continuous currents which are sent through the coil first in one direction and then in another, the counter-electromotive force is but momentary at the very start of each impulse of current; but with rapidly alternating currents the counter-electromotive force is evidently as constant as the impressed electromotive force or primary current.

A reactive coil placed directly in the circuit of an alternating system, therefore, can be made to control the amount of current going over the system, and this is its chief use. Specially designed reactive coils are used constantly by the Thomson Electric Welding Company for controlling electric welding transformers, and similar devices are familiar to all electrical engineers. But probably the most interesting application of this valuable apparatus has recently been made by Mr. Elias E. Ries in the Ries regulating socket, which is now attracting so much attention.

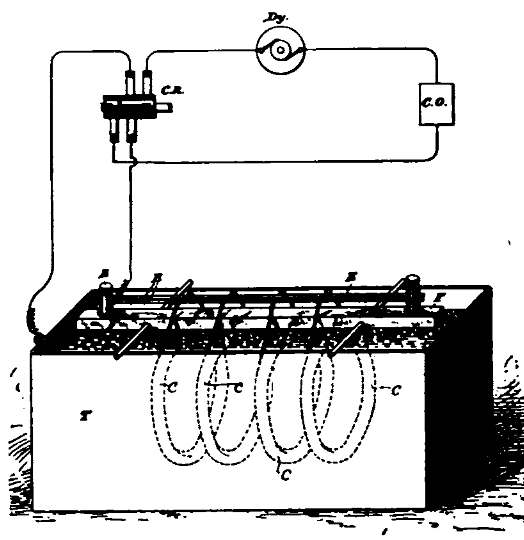
In this socket Mr. Ries has simply placed a very small reactive coil so connected to a series of contacts that, by means of a movable arm attached to an ordinary socket-key, a relatively small or large amount of current may be admitted to the filament, and the brilliancy of the light thereby governed at will. An incandescent lamp, on an alternating-current circuit, is thus placed upon an equal footing with gas, so far as the power of governing the light of individual burners is concerned. And that the method is very economical will be evident to any one who reflects that if the current does not pass through the coil, it is not used; in fact, is not generated. The total energy consumed in the lamp would be represented by the product of the voltage and the current actually supplied to the filament. And this is true in all other cases where reactive coils are employed as regulators.

VARLEY'S METHOD OF TESTING INSULATED WIRES.

IN covering electric conductors it frequently happens that particles of dust or other foreign matter lodge upon the insulating material or otherwise become incorporated within it, or that the material itself contains fine cracks or irregularities in thickness which lower its insulating power. A very large percentage of wires after being coated contain such faults, and it is a great desideratum to be able to locate them expeditiously and efficiently. Various modes of testing have been resorted to; but many of them require too much time for use where a large number of coils of wire are to be tested. Recently, however, Mr. Richard Varley, Jr., of Englewood, N. J., has devised a method, called by him the "flash test," which is based upon the fact, discovered by him, that if an insulated wire be connected to one terminal of an electric circuit the other terminal of which is placed in close relation to the insulating covering throughout its length, and the circuit charged with a current of high potential, a flash will be exhibited at such points of the conductor as are within range of disruptive discharge.

Mr. Varley's arrangement consists in charging a circuit one terminal of which is connected with the wire to be tested, and the other placed in close relation to the insulating covering with a current of sufficient electromotive force to produce a flash at points where faulty insulation exists. The terminals of the circuit are brought into the proper relation to create the flash by surrounding the insulated covering with water before charging the circuit.

As will be seen in the accompanying illustration, *Dy* represents a dynamo, in the circuit of which is interposed a series of coils of insulated wire C C C, which are to be tested. A current-reverser C R is introduced to produce periodical reversals of current. One terminal of the circuit is connected to a binding-post B and the other electrically connected with the water in the tank T. The terminals of the coils are inserted between two metallic bars E E supported in posts on the wooden beam F, supported on the tank, the bars being electrically connected with the post B. Thus the circuit between the wire forming the coils and the



VARLEY "FLASH" TEST FOR INSULATED WIRES.

water is incomplete unless leakage should exist through the insulating covering.

If now the circuit be charged with a current of from fifteen hundred to two thousand volts, and the current-reverser operated, a flash will be seen in the water at such points of any of the coils where the insulating covering is insufficient to resist such a charge. The current-reverser is operated at about sixty reversals per minute. If after a flash is developed the current be continued, the insulation would rapidly be destroyed, and in order to prevent such a result a cut-out is included in the circuit, having a lagging contact which renders it inactive except when a deficiency in insulation in the wire being tested exists. A weight on the armature is adjusted so that it normally holds the testing-circuit closed. When the armature is tilted, the weight is thrown past the centre and holds the circuit open, thus acting as a cut-out.

The coils which show a flash are removed from the tank and the operation is repeated with the others.

THE BURNET ROSETTE AND SWITCH.

BY

H. W. Burnet

EVERY one who uses suspended incandescent lamps knows how troublesome it is to light them. One has to set down anything one may have in his hands, find the lamp, then stand on tip-toe, raise both hands, use one to hold the socket and the other to turn the key; then it is lighted. Now you sit down to read or write; but you don't stay there; you must get up and stop the lamp from swinging.

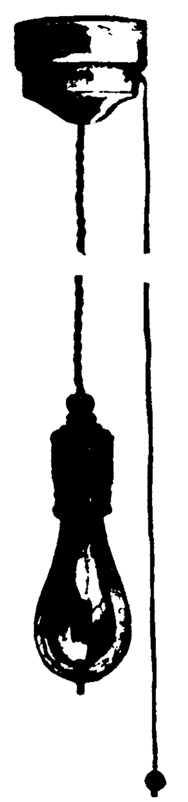
Appreciating these annoyances, the writer, some time ago, set about to design a rosette that would be as nearly perfect in design and convenience for wiring as possible, and that would be adapted to all uses to which it might be put, whether in dye-house or office, on cleat or moulding, and that would contain a switch which could be operated by a suspended cord arranged so as to hang below the lamp, where easily found and reached; or in convenient reach by seat, side of desk, near door, or anywhere else; and that could be operated by one hand. The lamp not having to be touched, would not be set swinging.

It was some time before a satisfactory switch that would answer the purpose was obtained, resulting in the simple and perfect-acting switch, illustrated in Figs. 1 and 2, and of such shape as readily to adapt itself to a rosette, socket and other uses. The switch has a quick make and a quick, long break, and after contact is once made there can be no separation until the complete break is made: a slight pull on the suspended switch-cord lights; a harder pull extinguishes, and one hand does the work.

The action of the switch is clearly shown in Fig. 3. It is composed of a double-spring arm, A, and a sector, B, made of some insulating material, with a metal-faced notch, N. A slight pull upon the cord C brings the hooked arm into this notch and completes the circuit. A harder pull brings the hook past the end of the sector and allows it to snap in the position shown by dotted lines, making an extra long, quick break. Releasing the pull allows the arm to come to the normal position, as shown, where it is ready to repeat its performance.

By arranging two sectors to face each other, Fig. 4, but with a suitable gap between, and putting a heavy cross-bar of good conducting metal on the end of the arm so as to bridge both sectors, and connecting the circuit to both sectors, thus not using the

FIG. 2.



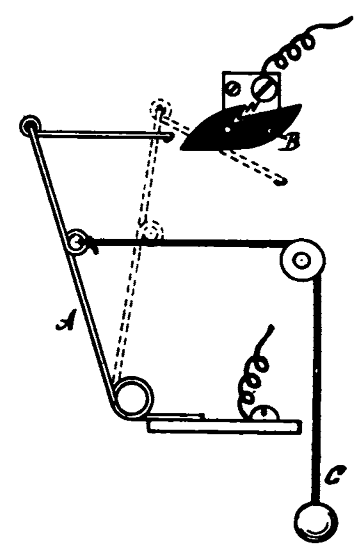


FIG. 3.

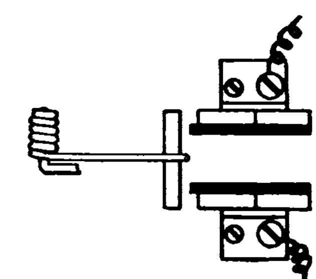

FIG. 1. FIG. 4.

BURNET ROSETTE AND SWITCH.

spring for the current, we have a switch for heavy currents on the same principle as that described above.

The complete rosette is shown in Fig. 1 and the cap and base in Fig. 2. It can be made in either wood, composition or porcelain, and can be used equally well for either moulding or cleat work. The switch may be put up either before or after wires are run and allows the wires to be drawn taut at any time after everything is in position. All connections may be made in the cap at any convenient time, and the caps afterward attached to the bases when they are in position. The switch is suitable for either damp or dry places, as it has a drip edge, and all connection are under cover. A simple method has been designed whereby the lamp-cord may be used as the pull, but this sets the lamp to swinging, which trouble it is desirable to obviate. It possesses a perfect action for a distant switch, and such switches are about to be designed for various currents. They will save the cost and trouble of running wires to convenient places for the ordinary switches.

An electrolier switch has also been designed by the writer which is enclosed in a bulb-shaped casting, threaded at both ends to receive the gas-pipe of the electrolier; a lever protrudes through a slit and a cord is attached to this. The cord has upon its lower end a ball or ring which may be pulled by the hand or with hooked pole, if out of reach. The cord may be brought over one or two pulleys to the side of room if desirable.

A SOUTHERN civil engineer writes us under date of Dec. 3: "If my humble opinion is worth anything, allow me to say that I consider THE ELECTRICAL ENGINEER a standard scientific journal that the electrical profession in this country should be proud of.

THE NEW THOMSON-HOUSTON W. P. MOTOR.

IN order to supply the demand for a compact motor equipment which should be adopted for narrow-gauge railroads, the Thomson-Houston Electric Company some time ago began the construction of a special equipment, in which particular attention was paid to the mechanical as well as electrical protection of the motor. This has resulted in what is known as the new "W. P.', (water-proof) motor, in which single-reduction gear is retained, and the construction of which is well illustrated in the accompanying engravings, Figs. 1 and 2.

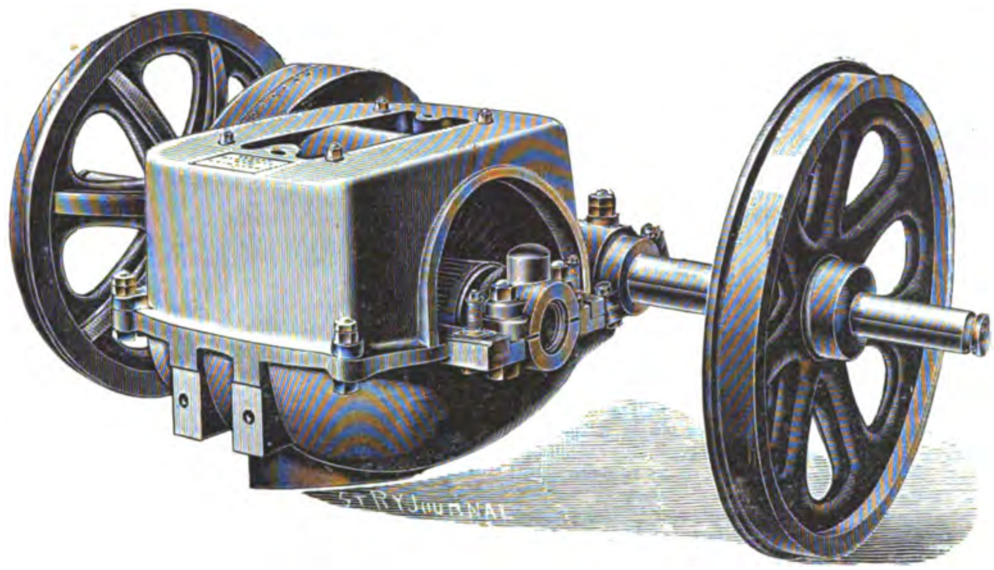

FIG. 1.—THE NEW THOMSON-HOUSTON "W. P." MOTOR.

The motor-frame consists of two castings of steel clamped together by bolts at the front and back, the axle brasses being held between the two parts. The armature bearings are cast in one piece with the lower half of the frame, and are provided with caps so that the linings may be inspected or renewed without disturbing other parts of the machine. The lower half is shaped somewhat like a bowl, rounding up from a plow-shaped bottom, which will throw aside stones or other obstructions which may be on the track. The engraving shows the upper half of the case raised. The upper half meets the lower, except upon the armature bearings, where holes are left for access to bearings and commutator and for ventilation. Only one field spool is used, which

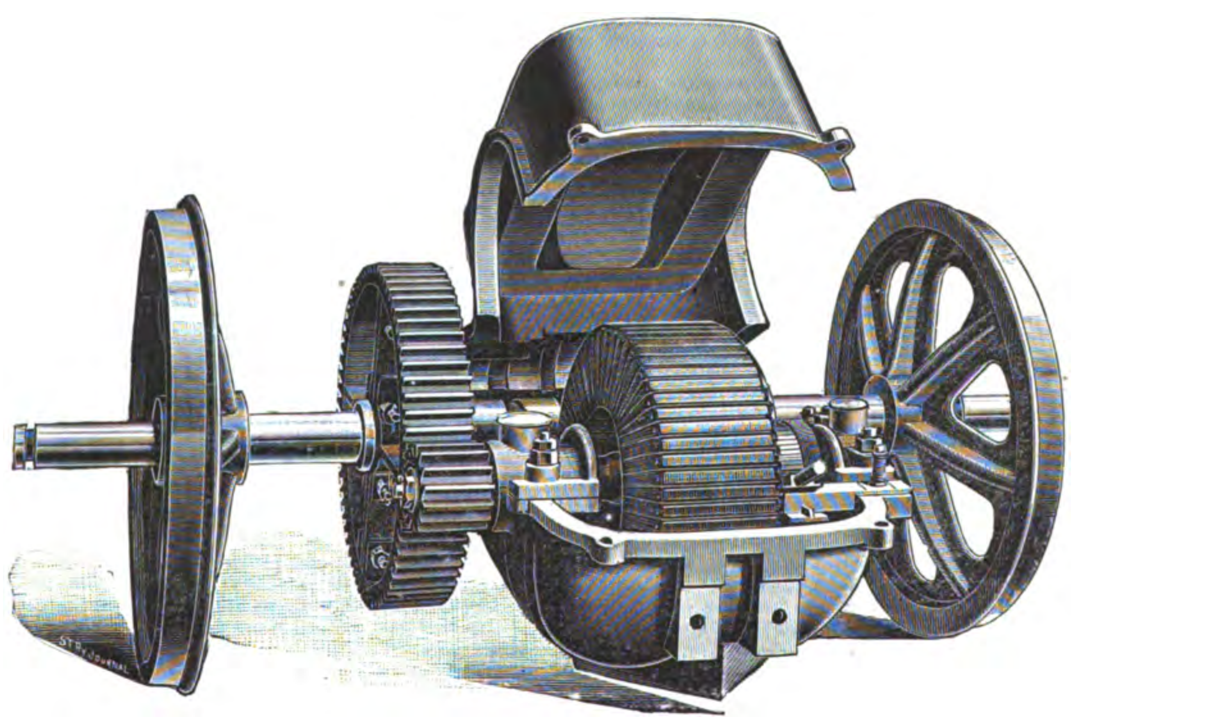

FIG. 2.—THE NEW THOMSON-HOUSTON "W. P." MOTOR.

surrounds the armature and upper pole-piece, and is itself completely covered by the frame.

A feature of this machine is the fact that it is so proportioned that at its normal load the solenoidal pull of the field is sufficient to lift the armature and relieve the bearing of its weight. There will, therefore, under ordinary conditions, be no tendency to hot bearings.

The motor can be run in water up to the axle—in fact, can be left standing in it without damage; and water dripping on it from above is shed off without gaining the interior of the motor. It will thus be seen that the armature, field spool, commutator and brushes are completely inclosed in the frame.

The parts of the frame are hinged together at the axle end. By removing four bolts, therefore, the upper half may be swung upward, or the lower half downward through a trap in the car floor or into a pit under the track, as may be convenient. The armature or field spool may then be easily removed.

Not only is the motor, as a whole, ironclad, but the armature is also ironclad. The core is a ring with projecting teeth of a peculiar form. The coils are wound between the teeth and held firmly in place by wooden wedges. No binding wire is used, and to replace a coil it is only necessary to drive out a wedge and the coil can be rewound without disturbing the rest of the winding. The winding is continuous; joints in the wire, where necessary, are electrically welded, no solder whatever being used. This construction protects the armature winding from mechanical injury as it is below the surface of the iron core. Electrically, a decided advantage is gained because the air gap can be made very small. This permits of comparatively few turns of wire being used to excite the field and consequently requires but a short magnetic circuit. It will be noticed also that practically all the metal in the machine is used in the magnetic circuit, thus making the weight of both iron and copper small.

The brush holders are mounted in a groove planed in the frame alongside of the armature bearing. By giving a quarter-turn to a handle on the brush holder, it may be taken from the motor to examine or renew a brush.

The armature shaft has been made short and heavy to avoid the possibility of springing and is fitted with steel shells, thus ensuring a proper bearing at all times. In case of wear from long use or scoring from grit, these shells can be replaced. The linings of the boxes are of punched sheet metal just thick enough to stand the wear required of them, and when thrown away waste little metal. The gears are of steel and are run in a case filled with oil. This case is split in halves and has a hinged cover through which the gears may be inspected and oil introduced. By loosening the nuts on two hinged bolts, a section of this case can be removed and the pinion on the armature shaft drawn off without taking apart the gear case proper. The small size of this motor permits two of them to be mounted on a truck of five feet wheel base and three feet gauge.

Although originally intended only for narrow-gauge roads, the "W. P." motor has performed such good service that it has been adopted by some companies as their regular service. Among others the West End Company of Boston, have tested it with the result that they have given an order for no less than 500 motors of this type to be used in the extension of their electric railway system.

ANNUAL DINNER OF THE ENGLISH ELECTRICAL ENGINEERS.

The annual dinner of the Institution of Electrical Engineers was held last week, writes our London correspondent. With the exception of the remarks of Prof. Crookes, the president of the society, the speeches were dull and pointless. I give you here a few of the sentences which the Professor uttered in proposing the toast of "Electricity in Relation to Science." He said they had happily outgrown the preposterous notion that research in any department of science was mere waste of time. It was now generally admitted that pure science, irrespective of practical applications, benefited both the investigator himself and greatly enriched the community. They knew little as yet concerning the mighty agency of electricity. "Substantialists" told them it was a kind of matter. Others viewed it, not as matter, but as a form of energy. Others again rejected both those views. High authorities not even yet agree whether we had one electricity or two opposite electricities. The only way to tackle the difficulties was to persevere in experiment and observation. The light which the study of electricity threw upon a variety of chemical phenomena could not be overlooked. The facts of electrolysis were by no means either completely detected or co-ordinated. They pointed to the great probability that electricity was atomic; that an electrical atom was as definite a quantity as a chemical atom. It had been computed that in a single cubic foot of the ether which filled all space there were locked up 10,000 foot tons of energy which had hitherto escaped notice. To unlock this boundless store and subdue it to the service of man was a task which awaited the electrician of the future. The latest researches gave well-founded hopes that this vast storehouse of power was not hopelessly inaccessible. Up to the present time they had been acquainted with only a very narrow range of ethereal vibrations. But the researches of Lodge in England and Hertz in Germany gave an almost infinite range of ethereal vibrations or electrical rays from wave-lengths of thousands of miles down to a few feet. Here was unfolded a new and astonishing universe—one which it was hard to conceive should be powerless to transmit and impart intelligence. Experimentalists were reducing the wave-lengths of the electrical rays. With every diminution in size of the apparatus the wave-lengths got shorter, and could they construct Leyden jars of molecular dimensions, the rays might fall within the narrow limits of visibility. They did not yet know how the molecule could be got to act as a Leyden jar, yet it was not improbable that the discontinuous phosphorescent light emitted from certain of the rare earths, when excited by a high-tension current in a high vacuum, was really an artificial production of electrical rays, sufficiently short to affect the organs of sight. If such a light could be produced more easily and more regularly, it would be far more economical than light from a flame or from the arc. By means of currents alternating with very high frequency, Professor Nikola Tesla had succeeded in passing by induction through the glass of a lamp energy sufficient to keep a filament in a state of incandescence without the use of connecting wires. He had even lighted a room by producing in it such a condition that an illuminating appliance might be placed anywhere and lighted without being electrically connected with anything. He suspended two sheets of metal, each connected with one of the terminals of the coil. If an exhausted tube was carried anywhere between these sheets, and placed anywhere, it remained luminous. The extent to which this method of illumination might be practically available experiment alone could decide. From Tesla's researches it appeared that a true flame could now be produced without chemical aid—a flame which yielded light and heat without the consumption of material and without any chemical process. To this end they required improved methods for producing excessively frequent alternations and enormous potentials. Would they be able to obtain these by tapping the ether? If so, they might view the prospective exhaustion of coal fields with indifference; they would at once solve the smoke question and thus dissolve all possible coal rings. Electricity seemed destined to annex the whole field not merely of optics, but probably also of thermotics.

THE GLOUCESTER, MASS., ELECTRIC STREET RAILWAY.

This road was started about five years ago with five miles of single track and five horse cars; eighty horses were used. After running with the above equipment for three years, three electric

Fig. 1.—Power House, Gloucester Mass., Electric Railway.

cars of the Daft system were added, and about a year later two more miles of track were laid; this summer another two miles of track were laid, making nine miles of track now in use.

In May last some motors of the Detroit Electrical Works' standard electric railway system, were added to the equipment, and later, enough more of the same system to make eight cars thus equipped. On Aug. 27 the formal opening of the road was made with a complete equipment of electric cars of the Detroit Electrical Works system operated by the single overhead trolley.

The power-house equipment now consists of one tubular boiler, Phœnix make, of New York; one tubular boiler, Roberts make, of Cambridge; one 125 h. p. engine, Phœnix; one 200 h. p. engine, McIntosh & Seymour; and two 80 K. W. generators, Detroit Electrical Works; a third generator of the same size and make has been ordered. The generators are belted direct from the engines.

The car equipment consists of eight 16-foot car bodies, eight 30

h. p. Detroit Electrical Works standard motors, and eight McGuire 19 B. steel trucks.

The road now runs from Rocky Neck through Gloucester to Bay View, Riverdale, Annisquam and Lanesville. During the summer months seven cars are run regularly, and on very good days all eight; during the winter, four cars are run regularly. The average mileage per car per day is 113; this is about what is averaged on most of the roads now using electricity.

In Gloucester there are probably more miles of crooked streets proportional to its size than in any other city in the Union; the view of Main street gives a fair idea of Gloucester streets in general. In the whole nine miles of track of the Gloucester railway there is only one straight stretch of one-third of a mile, and

FIG. 2. VIEW ON ELECTRIC ROAD, GLOUCESTER, MASS.

altogether there is probably not much over a mile; so there are nearly eight miles of curves. In addition to the curves there are many grades of from 3 per cent. to 9 per cent., and in four instances curves of short radius are located on steep grades.

During the last six weeks of the summer schedule seven cars were run regularly, and often eight; yet only two or three times was a car run into the car barn for repairs. It has often been said that a truck fitted with one motor geared to both axles and held rigidly would not run satisfactorily around curves. The record made in Gloucester effectually answers this statement, as the cars averaged 113 miles per day and did it in a perfectly satisfactory manner.

The current for the four cars which are now being run regularly is furnished by one 80 K. W. generator, which is driven by the 121 h. p. engine; the daily consumption of fuel is one and one-half tons of slack and one-half ton of Cumberland coal.

The number of passengers averaged daily for the four cars is 1,900; during the summer the number carried daily averaged 4,000.

The receipts per car show an "increase" for the last three months over the corresponding months of last year of twenty-five per cent.; the operating expenses, including interest at 6 per cent. on sixty thousand dollars (the cost of equipping with electricity) show a "decrease" per car of 12 per cent., allowing for the greater mileage which the electric cars make over that made by the horse cars; the operating expenses per car mile show a "decrease" of twenty-five per cent.

The above showing is certainly an excellent one, and speaks well for the "Standard" electric railway system of the Detroit Electrical Works.

ELECTRIC TRACTION IN EUROPE.

THERE can be no doubt, writes our London correspondent, that electric traction is attracting great attention in Europe at the moment, and it will be strange if some of the many schemes suggested are not executed. In addition to the proposals made in England, the Municipal Council of Paris has provisionally accepted the project of M. Berliner for an electric railway which will cross Paris at its greatest breadth. There are to be six stations, the generating machinery to be situated at the end of the line. In many respects the railway will be built after the model of the South London Railway.

While speaking of the South London Railway I might say that by an increase of the fares and the issue of season tickets the financial results at the end of the year ought to look better than they have ever done before, for the increased fare has caused little or no falling off in the number of passengers.

THE GOVERNMENT TELEGRAPHS OF EUROPE.[1]

BY E. ROSEWATER.

THE founders of our Republic conferred upon Congress the power to establish post-offices and post-roads. It is scarcely conceivable that it was their intention to limit the national legislature to the conveyance of the mails in post coaches running over wagon roads. The manifest scope of the constitution touching the exercise of the power to establish and maintain a postal system is to facilitate commercial and social intercourse between the people by the use of every device that will insure the speedy and economic transmission of intelligence. The century that has elapsed since Benjamin Franklin assumed charge of the first post office in the United States has witnessed the transition from the postal stage coach, the pony express and carrier pigeon, to the "fast mail" train drawn across the continent at the rate of a mile a minute; from the 60 days across the Atlantic" packet sail-boat to the "six days from New York to Southampton or Liverpool" twin-screw steamer. But our postal system cannot attain its full measure of usefulness and efficiency until the electric telegraph and long-distance telephone have been made an integral part of our postal facilities, with the pneumatic tube post as an auxiliary for conveying letters and messages in our great population centres.

Everybody familiar with the history of the telegraph knows that Professor Morse offered his invention to the Government for the paltry sum of $100,000, and urged the Postmaster-General to construct and operate telegraph lines as an adjunct of the mail service. It is also historic that the monumental mossback who occupied the position peremptorily declined the offer of Professor Morse, on the ground that in his judgment such a thing as transmitting messages from one point to another over a wire was preposterous and impossible. In due time, Professor Morse prevailed upon Congress to appropriate $30,000 for the construction of an experimental line of telegraph, and with this money the first wire built and operated in America was erected between Baltimore and Washington. So the telegraph at its very inception owed its successful introduction in America to the munificence of the Government, and by rights it should have been operated as a part or our postal system from the outset.

In 1862 Congress was again invoked to aid in the extension of our telegraph facilities. At that time the most rapid communication between the people east of the Mississippi and those on the Pacific Coast was by the overland stage and pony express. A bonus of $400,000, payable in ten annual instalments, was voted to the company organized to build the Pacific telegraph line. This extension of the telegraph across the continent, from the Missouri river to Sacramento, involved the construction of about 1,700 miles of pole line. The bonus of $235 per mile not only paid for the whole line, but left a very considerable margin. The promotors of the enterprise, within five years, realized three dollars for every fifteen cents they had actually invested. I have recalled these historic facts merely to disabuse the minds of many who labor under the delusion that our telegraph system, unlike that of other countries, has been built up entirely by private capital and individual enterprise. It is not my purpose at this time, to indulge in an exhaustive history of our complex system of telegraphs under corporate ownership. Suffice it to say, it is the natural outgrowth of promiscuous construction, wasteful competition, and reckless absorption. A bird's eye view of our telegraphs would present a dense jungle of poles planted and transplanted, and a bewildering network of wires strung and restrung by a succession of stock-jobbing speculators. As an inevitable consequence, the Western Union Company, which has swallowed more than sixty big and small competitors, is periodically overstocked with needless wires between great commercial centres, which usually offer the most tempting field for enterprising men who build lines to sell out, while there always has been a lamentable lack of telegraph facilities at small cities and towns that are made dependent entirely upon the congested railroad wires. Our telegraph companies never maintain an office where the receipts do not offset the expenses. Such a policy is not pursued in countries that possess postal telegraph facilities, because the Government is at no additional expense for rent, and postmasters in small towns and cities are required to perform the duties of telegraph operators.

Nothing has impressed upon me more forcibly the dangerous tendencies of telegraph inflation and over-capitalization than the comparative exhibit of the world's telegraph system submitted to Congress last winter by the president of the Western Union Telegraph Company. According to Dr. Norvin Green, this country has 185,000 miles of telegraph pole line, as against 375,000 miles possessed by all other countries of the world. There are 673,000 miles of wire in the United States, as against 1,111,968 in all other countries, and there are in America 18,000 telegraph stations, against 53,000 in all other countries. Mr. Green computes the aggregate number of telegrams handled in this country at a fraction over 60,000,000, while he credits

1. A lecture delivered before the Electric Club, N. Y., Dec. 3, 1891.

the rest of the world with handling 173,000,000 telegrams. As a matter of fact, the aggregate number of telegrams handled in European countries alone, computed officially for the year 1889, is 204,935,055. What do these figures show? With one-half of the world's telegraph line mileage, American telegraph companies should have handled one-half of the business. Instead of handling 102,000,000 telegrams, they only handled 60,000,000. With one-half of the world's telegraph lines in a country that boasts two-thirds of the railway mileage of the world, America should have her full quota of the world's telegraph stations; but out of 53,000 we only have 18,000, including railroad offices, which comprise nearly three-fourths of our telegraph stations. On the other hand, Great Britain, with less than one-third of the wire mileage of the United States, handled 63,403,399 telegrams in 1889. Do not these figures demonstrate that the periodic acquisition of lines built for speculation prevents the economic working of our system by clogging it with useless wires, and will always operate as a barrier to a material reduction of our telegraph tolls, because our telegraph companies adjust these tolls on the basis of a capitalization which at this time already includes from $40,000,000 to $50,000,000 of stocks and bonds issued for speculation plants.

Let us take a cursory survey of the Government telegraphs abroad. I trust that I violate no confidence in stating that before embarking for Europe last summer, I procured letters of introduction from Postmaster-General Wanamaker to the postmasters of England, France, Germany and Austria, coupled with a request that their respective departments extend to me the facilities for making an inquiry into the practical operation of their systems of telegraph. This investigation was a self-imposed task. I have for more than a quarter of a century been an outspoken advocate of the postal telegraph, and desired to see for myself how it worked in foreign countries. Upon presentation of my credentials, I was everywhere accorded the most courteous reception. The chiefs of the telegraph bureaus, telegraph engineers and superintendents, took pains to exhibit the operating rooms, instruments, batteries and appliances to me, explained to me the methods pursued in handling dispatches and freely answered all inquiries concerning construction of lines, subways, office regulations, number and qualifications of employés, working hours and wages. They also furnished me sample telegram blanks and official documents relating to the management, extent of plant and business done. The Hon. J. Cameron Lamb, general manager of postal telegraphs for Great Britain, favored me with an official letter to the postmasters of Manchester, Birmingham and Swansea, which enabled me to inspect the telegraph operating rooms and investigate the operation of postal telegraphs in those so-called provincial cities.

I will read you Mr. Lamb's letter which I was permitted to retain as a souvenir of British official courtesy:

To R. M. Johnson, Esq., Postmaster and Surveyor, Manchester; J. F. Wight, Esq., Postmaster and Surveyor, Birmingham; E. H. Oakden, Postmaster, Swansea.

DEAR SIRS:—The bearer of this note is Mr. Edward Rosewater, Omaha, United States. The postmaster-general desires that he may have full information regarding the telegraph work in your offices, and I am to ask that you will be good enough to allow him to see the operations actually performed and to afford him all necessary facilities. I am, dear sirs, yours very truly,

J. C. LAMB.

Similar courtesies were extended to me by the director-general of the German postal telegraphs, Dr. Haake, and Dr. Neubauer, director-general of the postal telegraphs of Austria.

The first step toward merging the telegraph system of Great Britain with the postal service was taken in 1868, when Parliament passed an act authorizing the purchase or leasing of all lines operated by private companies.

The proposition to establish a postal telegraph had been vigorously opposed by the telegraph companies at every step, and when the transfer was finally made, the government came into possession of a conglomerate system of lines which had been allowed to run down by the companies from the time Parliament had voted to take them out of their hands. The act of 1868 fixed the uniform rate of one shilling (25 cents) for a message of 20 words, exclusive of address and signature, and three pence (6 cents) for each additional five words, to all parts of the United Kingdom. This was a material decrease from then existing rates, and, as a natural consequence, the postal telegraph lines, in their wretched condition, were for a time inadequate to handle the increased business. This defect was, however, remedied as soon as the tumbled-down lines had been re-constructed and the old plant had been thoroughly overhauled.

In 1870-71 the number of messages handled by the British postal telegraph was 9,850,177. In 1874-75 the number had increased to 19,253,120. In other words, the number of telegrams handled had doubled within five years. In 1880-81 the number of telegrams handled was 29,411,982, another increase of 55 per cent. in five years, and in 1885 the number of messages handled had reached 39,146,283. By the Act of October, 1885, the rate on telegrams to all parts of Great Britain was reduced to six pence (12½ cents) for a message of 12 words, including address and signature, and one-half penny (one cent) for each additional word. This reduction was followed by an enormous increase of business. In the year 1886-87 the number of telegrams handled was 50,243,639, and in the year 1890-91, 62,403,399.

This vast volume of telegrams is handled by the British postal telegraph with promptness and marvelous accuracy, so far as I was able to observe. In London, the city messages are transmitted exclusively by postal pneumatic tube. The pneumatic tube department in the great central telegraph station handles the bulk of the letters, dispatches and cards that are delivered within the city of London. Outside of the London Exchange, which is supplied with an independent system of direct commercial wires, all communications within the city of London proper, are despatched by pneumatic tube.

Thousands of dispatches, letters and postal cards are literally shot by air pressure every hour of the day from the 20 postal tube stations located at the points most accessible into the Central Telegraph station, and there they are re-distributed and fired back to other stations, delivered by carrier or forwarded by telegraph or telephone to points outside of London. The longest of those tubes is that from the Westminster parliament building, through which the proceedings of parliament are shot to the Central Telegraph Office, and thence transmitted by wire to provincial cities or delivered to such London papers as may order duplicates.

The tubes have not only enabled the postal authorities to transmit the dispatches and city letters in London more rapidly than they could be forwarded by wire, but they have done away with the costly and inefficient local wire service and in a measure the pole and wire nuisance. But to the public, the greatest benefit of the tube system is its cheapness. In New York or Chicago a city message of ten words or less costs you 20 cents. In London you can send as many words as you can write on the blank or card, which varies from 100 to 1,000 words, for six pence (12½ cents), and, what is also important, your message will have been delivered almost before the girl who usually acts as operator in the hotels of local offices in our cities has had time to copy it. By the tube system no copying is done—the original message is delivered to the party to whom it is directed, unless it is to go by telegraph or telephone to points beyond London.

While London was the first city to utilize pneumatic tubes for the rapid transmission of mail matter and telegrams, the cities of Paris, Vienna and Berlin have for years been served by pneumatic tube post. During the year 1889 the pneumatic tube post of Vienna handled 2,692,752 letters, telegrams and postal cards. Of this number, 1,541,647 were telegrams. But the city of Berlin can truthfully boast the most perfect and best served system of postal pneumatic tubes in the world. While London has only 20 pneumatic tube stations, Berlin now has 51, distributed not merely over the entire area of the German capital, but reaching out into the suburbs. You may deposit your message in one of the pneumatic tube stations, and it will reach any point within a radius of 10 miles within six minutes, including a retransfer at the central tube station. For six cents and a half your message or letter inclosed in one of the red Rohr Post envelopes, will be fired through the tubes from Berlin to Charlottenburg, and delivered by postal carrier.

Berlin has about the same population as New York, but New York does four or five times as much business by mail or telegraph. But it takes from one hour to half a day to transmit and deliver a message by mail or wire from the City Hall to Harlem.

The Postmaster General of Great Britain was empowered by the Act of 1868, which authorized the acquisition of the telegraph lines, to facilitate the collection and transmission of dispatches by designating places for depositing telegrams in letter-boxes and other depositories, and telegrams deposited therein are, if written on stamped paper of proper value, conveyed by letter carriers to offices of transmission by wire or to the tube stations free of charge. This is a convenience that we cannot secure so long as our telegraph lines remain under corporate ownership. But the postal telegraph facilities in London, even without this special convenience, could scarcely be improved on. At the present time there are 538 stations in London from which telegrams may be forwarded. Of this number, 451 are branch post offices and 87 are railway station offices. Inasmuch as the telegraph tolls are uniform throughout Great Britain, parties simply purchase stamps covering the cost of any message and the stamped blank is rushed through the tube to the Central Station, and thence transmitted by wire to its destination. A telegram with the proper stamp attached, dropped into a post-office box in any city in Great Britain, will be wired from the nearest telegraph station just the same as if the sender had gone through the tedious formality of handing it directly to the receiving clerk at the telegraph office. For the accommodation of business men and other patrons who use the telegraph frequently, stamped telegraph blanks are supplied at a trifling extra charge for paper. Similar conveniences are enjoyed by the people of France, Germany, Austria and other countries of Europe.

It would be impossible within the scope of this lecture to describe in detail the great operating rooms of the capitals of Europe.

The largest telegraph office in the world is in the British metropolis, employing an aggregate of over 3,300 operators and clerks in one building. Of this number two-thirds are men. The female operators occupy a large and well-lighted hall in which the Morse instruments, with registers and paper reels, are used exclusively. Nobody is permitted to receive by sound; and this is also the strict regulation on all telegraph lines where Morse instruments are used in France, Austria and Germany. The main operating room in London is like a great machine shop, although not half as noisy as the main office of the Western Union in this city. All the most approved telegraph appliances are utilized. The English Wheatstone with modern improvements appears to have the preference. The Hughes printing instruments, perfected in England, are receiving greater appreciation in Europe than they do in America.

In Berlin the Hughes printing instrument has the preference, and one hundred of these are used in the central telegraph station. Delany's sextuplex, an American invention, has been in active use in London for several years and the inventor and patentee receives £2,000 or $10,000 royalty per year from the British Government. This fact affords sufficient proof that the Government telegraphs in Europe utilize all the inventions as rapidly as do the American private companies. The operating room of the Central Paris telegraph office is a rectangular hall with Gothic arch ceiling. The operating tables are placed to insure convenience for retransmission. The Morse instruments are in use on short circuits, and the Hughes printing machine operates on several lines, but the favorite instrument on the French telegraph is the Baudot. This is a printing telegraph operated by synchronic movement. The only skill required is in transmitting. The receiving is automatic, by paper roll three-fourths of an inch wide on which a message is printed. These printed slips are pasted on telegraph blanks delivered as they are received. The Baudot instrument has been perfected so as to operate duplex and quadruplex—this is, sending and receiving two or four dispatches simultaneously over one wire. The operating force in the main office at Paris consists of 550 men and 450 women. The day operators work seven hours and the night men ten hours. The night men receive larger pay and extra-ordinary pay after midnight. In France as in England the Postal Telegraph employees are allowed two weeks' vacation each year with full pay. At the central telegraph station in Vienna about 500 instruments are in use largely composed of Morse registers and Hughes printing machine. The Hughes instrument has been perfected by an ingenious Austrian electrician, and is now operated on several long wires as a quadruplex. The American plug switches supplied with wires separated into divisions, most in use in Vienna, are exceptional features. At London, Paris and Berlin the switches are altogether on a different model. At the Berlin central telegraph station no duplex or quadruplex instruments are in use, the Government having supplied an abundance of wires for the volume of business done.

One of the novelties introduced at Berlin is the use of an accumulator battery. This battery consists of 120 cells divided into three sections of forty each; only two of these sections are in use at any one time they operate. A steady current and no variation has been noted during the ten months that they have been in use. The German Government pay the Berlin Electric Lighting Company sixteen marks, or less than four dollars per month, for maintaining this battery, from which 300 wires are steadily supplied with electric current. The managers of the Berlin office pride themselves upon the fact that they have worked direct with Teheran, the Persian capital, a distance of 3,500 miles. A through line from Berlin to Rome over bronze wire works admirably and is now in constant use. The most commodious and magnificent telegraph office in all Europe at the present time may be found at Birmingham. The operating room in Birmingham is a new building recently completed by the Government. The room is a quadrangle 206 feet by 42, lighted from all sides and equipped with the most modern appliances and the finest test-board switches in all England.

This rambling survey of the great telegraph stations of the European capitals may be somewhat disappointing, but it is impossible within the limit of time at my command to enter into greater details.

The impression has prevailed in this country that the Postal Telegraph service of Europe does not afford as good facilities and cheap rates to the press as do the telegraph lines of America. This I have found to be erroneous. While the British Postal Telegraph does not permit preference in the transmission of dispatches to any patron, the press dispatches are transmitted over special wires. The efficiency of handling press dispatches in London surpasses anything I have ever seen. Reporters and correspondents file their dispatches, inclosed in special envelopes, directed to the Intelligence Bureau; they are immediately shot into the central Postal Telegraph building and transferred through a pneumatic tube into the Intelligence Bureau; there the envelope is opened, the dispatch checked, and at once transmitted by special wire, or by telephone, as the sender may direct. Press dispatches may be duplicated to any number of papers, and parliamentary proceedings and other general news is often wired simultaneously to from 200 to 300 papers. The Intelligence Bureau supplies leased wire service to leading dailies, and one may lease a wire for all night or for short periods at very reasonable rates. The London *Times*, Manchester *Guardian*, Liverpool *Courier*, and dailies in Edinburgh, Glasgow and Dublin receive the bulk of their telegrams by a leased wire. Charges for any distance in Great Britain for press messages are as follows:

For every 100 words between 6 P. M. and 9 A. M., 1s. (25 cents).
For every 75 words between 9 A. M. and 6 P. M., 1s. (25 cents).
For press dispatches sent to more than one address, 2d. (4 cents) for every 100 words in the night or 75 words in the day for each additional paper.

Computed for a service of 1,000 words a night, a special dispatch directed to one paper would cost $2.50; the same dispatch transmitted in the day to one paper would cost $3.33. But suppose that this service is to go to a press association of 10 papers, then the service would be for 1,000 words, night, $6.50 to the 10 papers; in the day to the same papers, $8.13. If the service is to go to 25 papers, then the cost of 1,000 words in the night would be $12.10, and transmitted in the day, $14.85. This is less than 1¼ cents per word night work, and 1½ cents for day work delivered to 25 papers. In other words, each paper in an association of 25 dailies would pay only 48⅖ cents for 1,000 words of night report and 59⅖ cents for 1,000 words of day report, while 10,000 words of night report would cost $4.84 and 10,000 words of day report $5.93 per day for each paper. This is certainly a lower rate than the most favorable contract any telegraph company has ever granted to the Associated Press or any other association.

The rate charged for leased wires in Great Britain is $2,500 per annum for a line extending to any distance within the United Kingdom, the service beginning at 6 P. M, and terminating at 9 A. M. for six nights in the week. The Government furnishes the operators and instruments. Leased wire messages are delivered free at newspaper offices at a distance of one mile from the main office. Special wires can be extended into newspaper buildings by the payment of additional rental computed on a distance basis which would be very trifling. In this country the wire rental is computed at $10 per mile. A line 200 miles long would rent for $2,000 a year, and the paper leasing the same would have to pay for the operators, which would incur an additional outlay of $2,000 per year. A line between New York and Cleveland, a distance about the same as that between London and Glasgow, would cost $6,000 a year for wire rental and $2,000 for operators, as against $2,500 charged for the same service in Great Britain. The press service receives special care at the Paris central office and the leased wires service is even more liberally arranged in France than in England. You can lease a wire for an hour and even for five minutes. The rate for one hour over a wire extending any distance within the Republic of France is 30 francs or $6, including operators' service at both ends, or 2½ francs, or 50 cents for five minutes. The average transmission is 2,000 words an hour, and often with very rapid printers, 300 words in five minutes. International wire service is necessarily dearer. There are, however, several international wires leased to newspapers and Press Bureaus. The *New York Herald* has a leased wire for certain hours between London and Paris, and the Reuter and Havas Correspondent Bureaus have several wires leased which are operated by them for the transmission of International Press news analogous to the Associated Press reports. The French Postal Telegraph grants a rebate to the press for the time during which a leased press wire is in use for commericial purposes. When the press has leased wires and the Government uses them in the interval when they are not in use for press dispatches the expenses are shared in proportion to the service.

In Austria the bulk of all press dispatches is transmitted by long distance telephone, which is part of the Postal Telegraph plant in that country. This is also true of Germany. All the press dispatches between Vienna to Prague, a distance of nearly 300 miles, are transmitted by telephone at rates computed according to the time consumed.

The salaries of Postal Telegraph employees in Great Britain will compare favorably with those paid for the same class of operators in this country, barring perhaps a dozen officials of the highest rank. The pay-roll of the British Postal Telegraph embodies:

	Annual salary.	Annual increase.
1 Engineer-in-chief	$6,000	$250
1 Assistant and electrician	4,750	125
1 Submarine supt. at Woolwich	3,500	125
1 Superintending engineer	3,500	125
1 Assistant supt. engineer	2,250	125
13 Supt. engineers	3,000	
31 First-class inspectors	1,400	
64 Second-class inspectors	1,050	

LONDON CENTRAL TELEGRAPH STATION.

Male Staff.

1 Controller	$5,000
1 Deputy	3,750
2 Assistants	2,500
19 Chief operators	2,000
52 Assistant chiefs	1,550
48 Second-class chiefs	1,500
170 Senior operators	950
441 First-class operators	800
1149 Second-class operators	550

Female Staff.

1	Matron	$1,150
9	Supervising operators	900
18	Assistant supervising operators	700
40	Second-class operators	550
230	First-class operators, per week	9.50
521	Second-class operators, per week	7.50
53	Pneumatic tube attendants, chiefly boys, per week	7.50

This salary list should allay the groundless fears aroused among my former associates in the telegraph service, that postal telegraph would reduce them to starvation wages. Another feature of the British telegraph management is the retirement of aged employees on an allowance that places them beyond dependence. By the telegraph purchase act of 1868, all telegraph employees who had been in the service of the companies twenty years or more prior to the purchase, and failed to secure re-employment in the Postal Telegraph service, were to receive annuities equal to two-thirds of their salary, and if less than twenty years, the annuity was to be reduced by one-twentieth for every year under twenty, but no annuity was granted to any employee who had served less than five years in the telegraph companies' employ. In 1891 there were on the Postal Telegraph pay-roll the following ex-employees of the telegraph companies:

7 Chief Officers and Superintendents,
25 Inspectors and Linemen,
37 Clerks and 1 Messenger, or in all 70 persons.

There were also the following employees retired on account of old age or disability:

1	Engineer-in-chief	$4,000.
1	Controller	2,805.
108	Male Operators, £9,672 each	445.
67	other employees including linemen, messengers and laborers.	

This is certainly liberal treatment. The same policy is pursued in France, Austria and Germany. In the latter country, Postal Telegraph employees share with all other government employees the benefits of the system of life insurance and annuities after a long term of service. But the most striking feature of the government telegraphs in its relations to employees is the impartial promotion of every person according to capacity and merit and the assurance of employment during good behavior.

The tenure of office, or rather of employment, constitutes one of the most commendable features of government telegraphs and is the most potential safeguard against political interference with persons employed in this branch of the public service. "The greatest trouble we have," said the Director General of Telegraphs for Germany, "is to get rid of a man that makes himself offensively disagreeable. We cannot discharge a man who has been placed on the permanent employment roll after two years' probationary service, until he has been convicted of a criminal offense before a court under the same process that is prescribed for violators of the criminal code. We can fine him for neglect of duty or suspend him for a short time, but he cannot be dismissed from the service." In this country operators hold their places subject to the whims and caprice of officials often their inferiors in point of ability and no redress is afforded for the most glaring injustice.

Now a word about the political influences of the postal telegraph. My investigations were confined to four countries, England, France, Austria and Germany. France is a republic like ours, and party feeling is more intense there than in America. England is a constitutional monarchy, governed by party that holds its supremacy through electoral majorities. Germany and Austria are limited monarchies. In all these countries the response to my inquiries concerning political interference with telegraph employees, or abuse of power in tampering with messages, was uniformly the same. The chief operator of the Swansea (Wales) office declared most emphatically that he was a radical and decidedly opposed to the present Conservative party in power. He said also that a number of the operators in his office were either radicals or Liberals, but "if the postmaster who has supreme control of the telegraph force dared to dictate what ticket we should vote, or undertook to interfere in any way with our rights as citizens, we should soon have a Parliamentary inquiry, and the postmaster would soon find himself dismissed in disgrace." In Paris Mons. Magne, Director General of Telegraphs, expressed great surprise at my question about political interference with Postal Telegraph men. "We all exercise our rights as citizens untrammelled," said he; "Postal Telegraph men are not allowed to take an active part in campaigns or in public meetings, but all vote as they please." Such a thing as trying to delay a political message or tamper with it, or divulge its contents, has never been heard of in France. The attempt, if made, would cause a revolt and overthrow the party that was in power at the next election. The Director General of German Telegraphs was equally emphatic. He said: "There are quite a number of social democrats in the telegraph service. These men are virtually committed against our form of government, but we cannot interfere with them so long as they do not conduct themselves treasonably." In all European countries the laws against delaying or destroying telegraphic dispatches are much more severe than they are in this country.

It gives me great pleasure to be in a position to pay a high compliment to American telegraph operators. After careful inspection of the Postal Telegraph in the British metropolis, in Paris, Berlin, Vienna, Birmingham, Manchester, Hamburg, Prague and other European cities, I can truthfully assert that the most skilful telegraphers of the world are in America. One of our first-class operators does fully as much work in a given time as is done in London, Paris or Berlin by two operators. On the other hand, the European telegraphers as a class have a higher education and are fitted not only to manipulate instruments and transmit despatches but to supervise other branches of the postal service. In Germany telegraphers are classified from the outset into two classes; the first class is made up of men who have received a high school education before entering the service. This class receives the lowest pay and can only aspire to promotion within the telegraph service. The second class is made up from graduates of universities who are paid a higher salary from the outset, and are in line of promotion, as electrical engineers, superintendents, and finally postmasters in the larger cities. This feature has made the telegraph a stepping-stone towards important positions in the civil service that are directly or indirectly connected with the postal system.

Literature.

A Practical Guide to the Testing of Insulated Wires and Cables. By HERBERT LAWS WEBB, Member American Institute of Electrical Engineers and of the Institution of Electrical Engineers, London. *New York. D. Van Nostrand Company,* 1891. 12mo, pp. 118 + 8; 38 illustrations. Price, $1.50.

THE series of articles by Mr. Webb, which originally appeared in the columns of THE ELECTRICAL ENGINEER, have met with such favor at the hands of the profession, that they have now been republished in a convenient little volume, which cannot but prove highly acceptable to the large and increasing number of electricians employed in the class of work of which it especially treats.

Mr. Webb is certainly to be congratulated upon the plain, simple and direct manner in which he has succeeded in dealing with a subject, which, while perhaps of no great intrinsic difficulty, has too often been made difficult and repellant to the young practitioner —who, in this country at least, has not infrequently to cope with such matters without other mental equipment than a limited public school education—by a useless parade of mathematical learning. Not that we have the slightest sympathy with those who are wont to ridicule and disparage all mathematical treatment of electrical subjects, but that we do appreciate the requirements of the imperfectly taught or untaught student, who has, nevertheless, the intelligence necessary to do good work within the range of ordinary attainments, but who needs a guide to point out his way in language which he can understand.

With the utmost brevity consistent with clearness, the author first lays down the general principles of testing; then proceeds to describe, one by one, the construction and use of the several instruments and appliances, and finally explains the methods of applying the apparatus to the determination of results in the problems which arise in every-day practice. The illustrations are largely reproductions of photographs of actual instruments in use at the present day, and comprise also the necessary diagrams exhibiting the organization of the testing outfit as a whole. Some of the criticisms of the author respecting the minor details of construction in modern apparatus seem to be well founded. For instance, every one who has had experience with the detestable little commutator, which is often supplied with portable testing batteries, will heartily endorse the author's anathematization of it.

The directions for the setting up, and more particularly for the care of a testing outfit are judicious and timely, and the same may be said of the observations in respect to the importance of properly recording of the results. "In making reports or entering up records of tests," says Mr. Webb, "there can be no greater error on the part of the observer than to imagine, because certain data are well known to him, that there is no necessity to write them down. . . . . The object of keeping records and making reports is to furnish other persons with full information upon the subject," a most obvious truth, but one which is not infrequently wholly lost sight of, as those of us who have had occasion to consult such records are but too well aware.

The mechanical execution of the book is not quite up to the standard which ought to prevail in such matters. The process illustrations might at least have been as well printed in a book as they were in the columns of the weekly journal in which they first appeared, which can scarcely be said to be the case, while the binding is of that peculiarly exasperating kind which cannot be made to stay open unless a ten-pound weight is placed on it; a most annoying defect in a book required for constant reference at times when both hands are fully employed otherwise.

The intrinsic merits of Mr. Webb's book can hardly fail to ensure for it a large and permanent demand among the electrical fraternity.

Society and Club Notes.

THE ELECTRIC CLUB.

THE lecture on "The Government Telegraphs of Europe" delivered at the Electric Club last week was a very great success. Mr. Rosewater's lecture, which is given in full in this issue, was followed by a most animated discussion in which Messrs. Erastus Wiman, Insull, Foote, Bryan and Leslie participated. Mr. Rosewater's brilliant rejoinders elicited frequent applause from an audience that was evidently opposed in the main to the views he set forth. Among interested listeners were President Chandler, of the Postal Telegraph Co,; George G. Ward, of the Commercial Cable Co; George Francis Train; Gen; O. E. Madden; A. S. Brown, and W. J. Dealy, of the Western Union Co. After the lecture, Mr. Rosewater held an informal reception of Old Timers, all of whom as president of their organization he invited to the next annual meeting in Omaha.

The next meeting of the club bids fair to be a most brilliant occasion. It will be held on New Year's Eve. Mr. Joseph Howard, the famous journalist and a member of the club, will deliver a lecture on his reminiscences of journalism. Only they who have had the pleasure of hearing "Howard" speak and lecture, can form any idea of the wonderful interest that he imparts to this subject; and it is safe to predict an overflowing audience for him. The second part of the entertainment will consist of a high-class musical programme under the direction of Dr. Wangemann, whose skill and taste are so well known. Promise has already been secured of some of the best musical talent in the city.

NEW YORK PRESS CLUB.

THE annual election of the Press Club was held last week, when the regular ticket was triumphantly elected by about two to one. The second name on the ticket was that of Mr. C. W. Price, editor of *The Electrical Review*, who was nominated as vice-president. The compliment thus paid to the electrical press is a high one, and it is general cause for congratulation that the honor has been so well bestowed. Mr. Price has probably as large an acquaintance in journalism as he has in the electrical field, and that his qualities are equally appreciated in both spheres of activity is seen in the fact that he is also at the present time one of the vice-presidents of the Electric Club. Mr. Price enters upon his new duties at an interesting period, as it is the intention of the Press Club to push forward vigorously in the increase of membership and in the building of a fine club house, in the vicinity of Printing House Square. It is understood that Mr. Price will continue his active and successful work as secretary of the International League of Press Clubs. The general idea of a clubman is that of a being to whom selfish indulgence in *dolce far niente* is the chief end of existence. Mr. Price may be pointed to as an exemplar of the other kind of clubman, who believes that the club may be made to play a great part in promoting intercourse and friendship, and who is willing to sacrifice his time and money freely in making the club the centre of all that is brightest and best.

NEW ENGLAND ELECTRIC CLUB.

A STRONG effort is being made in and around Boston to establish a club under the above title now that the Boston Electric Club has become defunct, and with that end in view a paper is being circulated for signature.

It is the design of the promoters that the club shall include in its membership, representatives of every branch of the art, and that a merely nominal admission fee shall be charged that all may avail themselves of the privileges which such an organization will surely give.

Recognizing the need of such a club the signatories agree to become members of the New England Electric Club, also to pay a charter admission fee of five dollars, and dues not exceeding ten dollars per annum.

Already a large number have signified their desire to cooperate in this movement. A meeting of signers will be called at an early date for completing the organization. At this writing nearly 100 representative men throughout the electrical field in New England have given their names as prospective members, and every indication warrants the belief that it is a matter of only a short time when the incorporation of the club will take place.

THE "ELECTRICAL WORKERS OF AMERICA."

A SPECIAL dispatch from St. Louis of Nov. 28, says: "The convention of electrical linemen, which has been assembled at Lightstone Hall during the last week, has completed its work by forming a national organization of electrical workers of America. This organization will immediately apply for a charter and will send a delegate to the convention of the American Federation of Labor at Birmingham, Ala., next month. The officers of the new organization. which will be known as the National Brotherhood of Electrical Workers of America, are: Henry Miller of St. Louis, grand president; E. Hartung of Indianapolis, first grand vice-president; J. T. Kelly of St. Louis, grand secretary and treasurer. The next convention will be held at Chicago on the second Saturday of November, 1892.

Letters to the Editor.

THE BERLINER AND BELL PATENTS.

IN his article on the Berliner and Bell patents, published in THE ELECTRICAL ENGINEER of December 2, Prof. Houston appears to be in error in certain of his assumptions, a circumstance which somewhat impairs the force of his argument. As you pointed out in your editorial article of November 25, Hughes' microphone was not made public until several months after Berliner's application had been filed, nor in fact had Hughes even made the discovery at that date, so that Berliner's apparatus cannot properly be said to be merely "an application of Hughes' microphone to the telephone transmitter." Nor has the extended public use which has intervened between the date of the filing of Berliner's application and the issue of his patent necessarily any legal bearing upon its validity. A notorious illustration of this proposition might be instanced in the case of *Colgate* vs. *The Western Union Telegraph Co.* decided by Justice Blatchford in 1878. This suit was brought on a patent of one Simpson for insulating electric wires with gutta-percha. Simpson's application was filed in 1849, and even then the invention had been in public use by the telegraph companies more than a year; it was pending in the patent office eighteen years, not having been issued until 1867; during which period the invention had been in extensive public use all over the world; but the court nevertheless awarded a decree to the complainant for an injunction and accounting. It may be that the Berliner patent will fail to be sustained, but it appears to me it will hardly be overthrown upon the grounds adduced by Prof. Houston.

FRANKLIN L. POPE.

December, 4, 1891.

Reports of Companies.

SUCCESS OF THE WESTINGHOUSE REORGANIZATION.

It is authentically stated that the organization of the Westinghouse Electric and Manufacturing Company has been practically completed by the covering into its treasury of $1,000,000 in cash by Messrs. August Belmont & Co., Lee, Higginson & Co., and Brayton Ives, in payment for a similar amount of preferred stock, the sale of which they had guaranteed, and by the issue of $2,000,000 of preferred stock in cancellation of a like amount of debt.

The reorganization committee will complete its work by authorizing the Mercantile Trust Company to notify the holders of its receipts given to stockholders of the Westinghouse Company, the United States Electric Lighting Company, and the Consolidated Electric Light Company, that it will issue regular certificates in exchange for such trust receipts.

A year ago the Westinghouse Company was so seriously embarrassed that few believed that there could be found a favorable solution of the difficulties. The company was hampered by heavy rental expenses, due to the control of the United States and Consolidated Electric Light Company, and its money was tied up by the deferred accounts receivable and in heavy stocks of material, so that the continuance of regular business was difficult. During the year the company has not only continued its business, but has paid interest on its debt, cash for its supplies, and, out of collections and earnings, has reduced the liabilities of itself and leased companies over $750,000.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED DECEMBER 1, 1891.

Batteries:—

Open-Circuit Battery, J. F. Wollensak and W. E. Gill, re-issue 11,207. Filed Oct. 13, 1890.
Claim 1 follows:
In open circuit batteries, the combination of a cup having holes through its sides, a carbon stick having a hole in a position and direction to be brought into a line with the holes in the cup, and a pin passing through the holes in the cup and stick.

Conductors, Conduits and Insulators:—

Splice for Electric Conductors, W. J. Hield, 464,022. Filed May 15, 1891.
Metal splice adapted for use on trolley wires.

Electric-Wire Support, R. Ellison, 464,298. Filed May 18, 1891.
An iron pole for electric wires.

Insulating Composition, S. W. Kimble, 464,367. Filed Feb. 24, 1891.
Claim:
The composition consisting essentially of pulverized mica, silicate of soda, and a mineral substance, such as talc free from lime, combined and molded under pressure.

Insulating-Support for Electrical Apparatus, S. W. Kimble, 464,368. Filed Feb. 25, 1891.
An improved method of mounting binding posts, etc., upon their non-conducting supports.

Composition of Matter for Insulating Purposes, etc., S. W. Kimble, 464,369. Filed Feb. 26, 1891.
An insulating material consisting of pulverized mica, silicate of soda, sulphur or sulphur compound, and another mineral substance, such as finely divided asbestos, molded cold under high pressure.

Joint for Electric Conductors, H. W. Fisher, 464,475. Filed Mar. 7, 1891.
Claim 1 follows:
An electric cable consisting of two or more portions of armored conductors having their ends united by a hollow cast metal joint, forming an integral part with the adjacent sections of armor.

Distribution:—

Electric Regulator, C. W. Holtzer and G. E. Cabot, 464,136. Filed Apr. 3, 1891.
A device for operating a rheostat in an electric light or power station in such a manner as to obtain a uniform electromotive force in the current on the main line by including and excluding resistances, according to the nature of the variation of the electromotive force.

Relay, R. Varley, Jr., 464,133. Filed Feb. 10, 1891.
Claim 1 follows:
A relay provided with an armature carrying a rearwardly-yielding contact mounted to lag under the influence of inertia when the armature is attracted, whereby the circuit controlled by the relay is affected only when currents of definite duration flow through the relay coils.

Dynamos and Motors:—

Transformer and Armature-Core, C. E. Kammeyer, 464,026. Filed May 7, 1891.
Claim:
An armature core consisting of a series of plates, said plates provided with permanently flexible insulating coats of varnish or the like applied permanently to the plates, which are then built together to form such core.

Field-Magnet for Dynamos or Motors, C. E. Kammeyer, 464,027. Filed May 9, 1891.
Has for its object to provide a cheap, simple and convenient device for retaining the magnetizing coils in connection with the field-magnet and to facilitate their removal and substitution if necessary.

Electric Motor, M. H. Collon, 464,063. Filed Jan. 27, 1891.
Claim 1 follows:
An electric motor comprising a solenoid and an endless core forming an electrical conductor to convey the current to and adapted to complete the circuit through the said solenoid.

Electrical Generator, V. Hirbec, 464,156. Filed Nov. 6, 1890.
Two forms of electric generators, the one designed for the teaching of physics and the other for industrial use.

Armature for Dynamos and Electric Motors, St. J. V. Day, 464,216. Filed May 1, 1890.
Claim:
The combination, with a shaft of an armature mounted thereon and means for securing one end of the said armature to the shaft, the opposite end thereof being free to expand and contract longitudinally.

Electric Motor, H. A. Florian, 464,299. Filed Jan. 6, 1891.
Has for its object a standard electric motor which shall be durable, compact and efficient and not liable to get out of order.

Electric Motor, J. R. Robinson, 464,231. Filed Feb. 3, 1891.
Claim 1 follows:
The combination of a stand or support with a swinging electric motor suspended by a gimbal joint from said stand.

Heating:—

Electric Heating Apparatus, M. W. Dewey, 464,247. Filed March 9, 1891.
Consists of the combination of a plurality of cases, an electric heat-developing conductor within each of said cases and a frame to hold or support them.

Electric Heater, P. Wright, 464,055. Filed March 21, 1890.
Claim 1 follows:
The combination, in an electric heater, of the base and cap constructed of conducting material, an intervening inclosure constructed of non-conducting material, and an enclosed medium of high electrical resistance.

Lamps and Appurtenances:—

Treating Filaments for Incandescent Electric Lamps, J. Bradley, 464,005. Filed June 6, 1891.
Provides means whereby a carbonized filament may be freed from loose or partially detached particles of carbon.

Electric Arc Lamp, W. A. Nicholson, 464,132. Filed June 12, 1891.
Relates to improvements in that class of arc lamps using a carbon disc in place of the upper carbon pencil.

Electromagnet, O. E. Lundstedt, 464,198. Filed Feb. 2, 1891.
An electromagnet for use in connection with the controlling mechanism of an arc lamp.

Metallurgical:—

Process of and Apparatus for Manufacturing Copper Tubes, A. S. Elmore, 464,351. Filed Dec. 1890.
Method of manufacturing copper tubes by means of electro-deposition.

Measurement:—

Potential Indicator, C. E Kammeyer, 464,025. Filed May 7, 1891.
Claim 1 follows:
The combination of an electric generator with translating devices in series with each other, a circuit closer, and connections whereby either one of them may be short circuited, said circuit closer responsive to changes in the current delivered.

Method of Testing Insulated Wires, R. Varley, Jr., 464,135. Filed Feb. 10, 1891.
Claim 4 follows:
The method of testing an insulated wire which consists in surrounding the insulated covering with a fluid conductor connecting the wire and such fluid conductor with the terminals of an electric circuit carrying an alternating or reverse current and interrupting the circuit when a flash is developed at a point of defective insulation.

Miscellaneous:—

Lineman's Vise, J. McIsaac, 464,034. Filed July 6, 1891.
An improved form of vice for lineman's use.

Electric Circuit Closer, R. Varley, Jr., 464,134. Filed Feb. 10, 1891.
A high-tension circuit closer by which a very brief closure of the circuit or a prolonged closure may be made at will.

Watchman's Electric Recorder, H. Redding, 464,256. Filed Apr. 16, 1889.
An electric recorder and registering system for the use of watchmen.

Phonograph, G. H. Herrington, 464,476. Filed Sept. 11, 1886.

Electric Elevator, W. Baxter, Jr., 464,470 Filed Dec. 8, 1890.
Has for its main object to provide means of closely connecting an electric motor with a hoisting pulley and gearing without injuriously affecting the action of the magnetic field of the motor.

Magneto-Electric Ignitor for Combustible Vapor Engines, L. G. Wooley, 464,347. Filed Sept. 26, 1890.
Claim 4 follows:
In combination with a combustible vapor engine, an electric machine adapted to produce a pulsating current and a current breaker located within the combustion chamber of said engine, rotating synchronously with the armature of said electric machine and adjusted to break the circuit only at the point of highest tension of said current.

Railways and Appliances:—

Electric Brake, LaM. C. Atwood, 464,002. Filed Feb. 27, 1891.
A brake for street cars operated electrically by means of solenoids.

Electric Apparatus for Use on Railway Trains, R. A. Wilder, 464,090. Filed Jan. 9, 1891.
Has for its object the utilization of the potential energy of railway trains by means of electric apparatus.

Method of and Apparatus for the Propulsion of Trains, J. B. Mahana, 464,342. Filed Jan. 24, 1891.
Has for its object to utilize the full energy of an electric locomotive, when not needed to move the train, in storing up surplus power for use in cases of emergency.

Trolley-Wheel for Electric Railways, S. W. Kimble, 464,370. Filed May 29, 1891.
Claim 3 follows:
A trolley-wheel provided with rubber tires on the flanges between which the trolley-wire groove is formed.

Trolley Wire Hanger, S. W. Kimble, 464,371. Filed May 29, 1891.
Has for its object to produce a hermetically sealed insulated trolley hanger and analogous appliances.

Hanger for Trolley Wires, T. E. Adams, 464,411. Filed July 17, 1890.
Claim 13 follows:
In an insulator, the combination, with a metallic shell, of a shank and insulating material therein, and flanges on said shank imbedded in the insulating material, so that said insulatidg material will form more than one canopy around said shank.

Crossing for Trolley Wires, R. M. Jones, 464,129. Filed April 16, 1891.
Has for its object to provide a crossing which shall insure a perfect insulation of the wires of the respective systems.

Telegraphs and Telephones:—

Telegraph Repeater, R. L. Atkinson, 464,001. Filed Mar. 27, 1891.
Relates to improvements in telegraphic repeaters and is especially designed to remedy a fault in the operation of Brownson & Shull's repeater, described in Patent No. 66,945.

Electric Transmitting Telephone, R. Eickemeyer, 464,152. Filed May 23, 1891.
Has for its object to equalize the vibrations of the transmitting diaphragm so that the greatest vibration possibly resulting from the human voice will be incapable of breaking connections at the contact points and will be as readily distinguishable as those produced by ordinary conversation.

Vehicles:—

Electric Fire Engine, M. W. Dewey, 464,244. Filed Feb. 9, 1891.
An electric fire engine electrically propelled.

Electric Hose Carriage, M. W. Dewey, 464,245. Filed Feb. 24, 1891.
An electrically propelled hose carriage, the hose reel of which is also operated electrically.

Electrically Propelled Vehicle, M. W. Dewey, 464,246. Filed Mar. 2. 1891.
Has for its object to electrically guide a self-propelled wheeled vehicle.

Electrically Propelled Vehicle, M. W. Dewey, 464,248. Filed Mar. 23, 1891.
Relates to mechanism for electrically propelled vehicles having wheels on opposite sides adapted to turn relatively to each other in order to facilitate the turning of corners.

MR. GARDINER C. SIMS, of the Armington & Sims Engine Co., has, we note, acted as one of the expert valuers of the property acquired by the Rhode Island Perkins Horse Shoe Co., one of the largest industrial properties put on the financial market this year. His associates were Mr. William Corliss and ex-U. S. Senator Chace. The business reported on has been earning a profit of over $260,000 a year for a long time and the authorized capital of the new company is $2,750,000. Mr. Sims has served several times in such a responsible capacity, and is much sought after when questions arise as to the value of manufacturing plants and processes.

THE THOMSON-VAN DEPOELE NEW "ARC" COAL UNDERCUTTING MACHINE.

THE undercutting of coal by machinery is an important problem for the mining fraternity. The undercut may be made by hand, but this method not only adds largely to the expense of mining coal, but also makes a large quantity of fine coal or slack which is comparatively a waste product except in certain cases. To avoid this difficulty and to furnish a machine which shall be easy to manipulate, the Thomson-Van Depoele Electric Mining Co., of Boston, have designed their new "arc" machine, which is illustrated in the accompanying engraving.

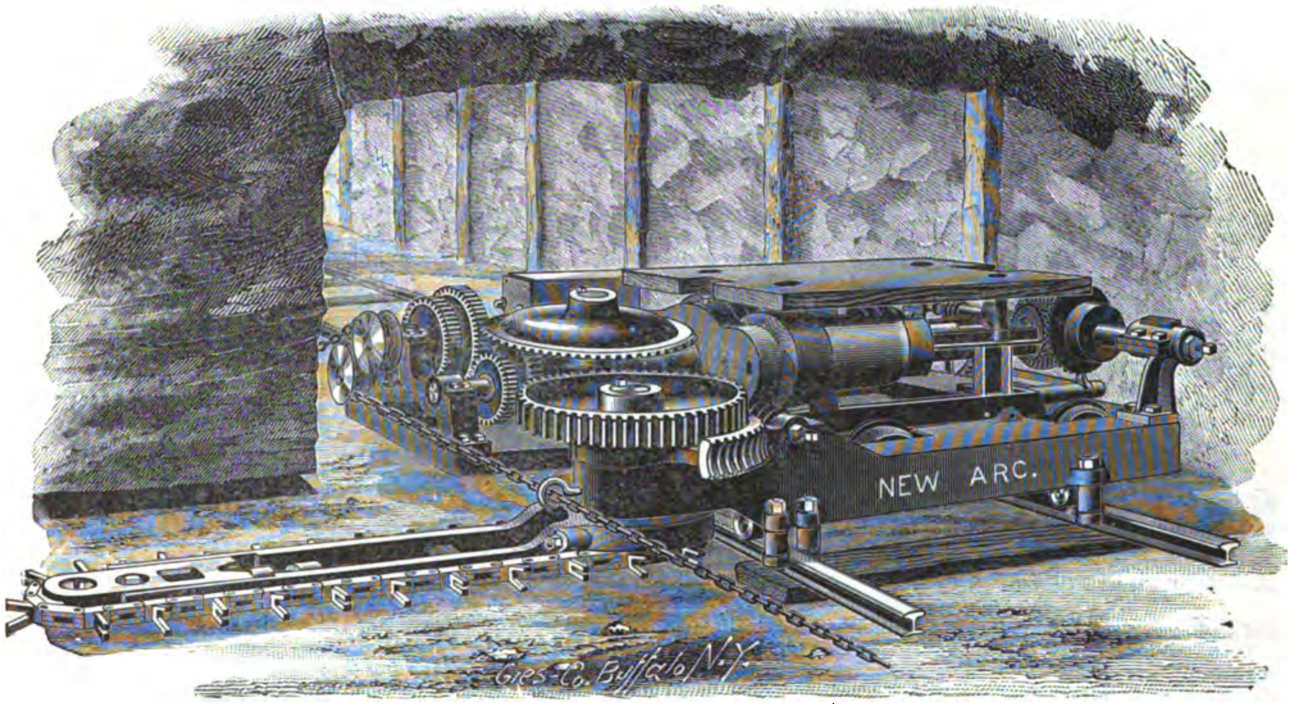
As will be seen, it consists of a heavy iron base cast in one piece which serves as a foundation for all the parts, carrying two pairs of axles, one at right angles with the other. The gauge of one pair is fixed to suit the regular track gauge of the mine wherein the cutter is to work, and these axles carry small flanged wheels upon which the cutter is easily moved about the mine and in and out of the rooms. The second pair of axles carry small wheels for supporting the cutter when in actual operation and carrying it along the face of the wall being cut. They are not flanged, but are kept upon the track by two pairs of single and two pairs of double guides. The support of the machine is easily changed from one pair of axles to the other by means of a cam worked by screws, the larger flanged wheels being raised out of the way when the cutter is in actual operation, as shown in the illustration.

The motive power is furnished by a 15 h. p. motor, which in the latest machine is somewhat changed from that shown, the motor being perfectly water-tight and thoroughly protected from all danger of mechanical injury. The armature shaft carries a beveled pinion at each end. That nearest the commutator is made to engage, by means of a controlling arm, either one of the two beveled gears shown in the illustration, thereby giving the shaft on the right a right-handed or left-handed rotation. By means of the chain of gears and an ingenious mechanical device, this shaft operates the feed chain at practically any desired speed. The feed chain is made fast to a post ahead of the machine and in this way the cutter is drawn forward at a speed under control of the operator, and which can be varied with the hardness of the coal. The same gearing by means of another controlling lever is made to move the arm from a position alongside the machine at the beginning of the cut to the position shown in the illustration, where it is held rigidly during the remainder of the cut. The second pinion on the armature shaft operates the endless chain carrying the cutting knives about the arm.

The controlling devices are such that the cutter may be held stationary while the knives are in operation, an important point in cutting through particularly hard formations. The length of the arm carrying the endless chain is made to suit the requirements of the mine in which it is to operate, the undercut usually being made of a depth equal to the thickness of the vein.

The length of the arm is adjustable within certain limits in order to take up the stretching of the chain due to wear. The chain and knives are drop forged and of a strength to withstand the hardest usage. The knives are easily detachable from the chain so that a new set of sharp knives may be substituted for the old set in a very short time. The track along the face of the work consists simply of two rails with an iron cross-tie, and may be laid and removed in a very short time and with a small amount of labor. By the use of this track and this type of machine, the necessity for removing a heavy piece of apparatus by hand, oftentimes in a very low room, is avoided—a very important point and one which will be appreciated by those who have had experience in these matters. For its operation the cutter requires two men, one of whom is at the machine itself controlling the rheostat and operating devices; the other keeps the track laid ahead and sets posts for anchoring the feed chain. All trouble with the slack clogging up the cut is obviated as the knives themselves bring nearly all the slack outside the cut, leaving a clean space.

The machine is thus seen to possess very important advantages in all kinds of working and for large room working, or along wall system these advantages become all the more prominent. It is operated on a 220 volt circuit, making it entirely harmless electrically.



THOMSON-VAN DEPOELE NEW "ARC" COAL-CUTTER.

THE PITTSBURGH WESTINGHOUSE WORKS.

PART of the plant of the Westinghouse Electric Company will likely be moved. The officials are considering the change in location of the street railway motor department, which is about one-half of the plant, to the recent site of the Air Brake Works, on Robinson street, Allegheny. Superintendent Schmid, says:

"We are running night and day and taxed to our utmost capacity in turning out orders for gearless railway motors, and cannot begin to fill the orders which are coming from all parts of the country. The demand for more room is imperative, and we could utilize as much more as we now have. Mr. Westinghouse and the other officials of the company are considering the advisability of moving this department to Allegheny, but have arrived at no definite conclusion in the matter."

THE DONALDSON-McRAE ELECTRIC CO.

PROF. OWENS, of the University of Nebraska, has just given the Donaldson-McRae Electric Company, of Baltimore, an order for 50 of their new design of storage batteries, and an order for a dynamo and motor for the laboratory of the University. The Donaldson-McRae Electric Company make a specialty of winding motors for storage and primary battery currents and are doing a brisk business. They are also introducing a storage battery of their own which is giving great satisfaction in phonograph and other work of a similar nature, where absolute reliability and a great number of ampere hours are desired.

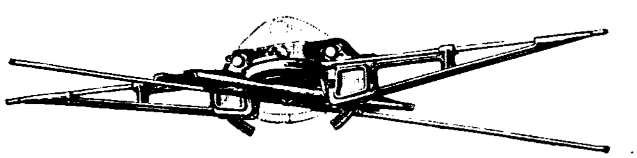
TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

The cost of advertising is a small percentage of the larger profit.

NEW FORM OF BAGNALL LIVE TROLLEY CROSSING.

THE Emerson Electric Co., of St. Louis, have lately introduced the improved form of Bagnall live trolley crossing shown in the accompanying illustration. The new form is so constructed as to operate in either direction, and is therefore applicable to either double or single track service. This is effected by using two bridge levers so jointed together as to meet at the centre of the crossing gap when actuated by a trolley wheel. In the normal position the two levers are separated from each other by the action of gravity on their counterweighted parts.



NEW BAGNALL LIVE TROLLEY CROSSING.

By means of a trough-shaped inclined plane attached to the under trolley wire the height of the cross-over has been reduced. The size has also been reduced about one-half, but all the parts are constructed more substantially than ever before. An insulated hood protects the working parts from sleet and also prevents a cross-connection between the two trolley wires.

This new form of trolley crossing is being placed upon the market at a lower price than the old form, and has already met with a very favorable reception.

THE TRIUMPH COMPOUND ENGINE CO.

THE Triumph Compound Engine Co., of Cincinnati, O., recently received the following letter:

ROCHESTER, N. Y., Nov. 21st. 1891.

TRIUMPH COMPOUND ENGINE CO.,
Cincinnati, O.

GENTLEMEN: The engine that you furnished us a few months ago has been doing good service and we are well pleased with the performance of the same. We have been trying same under most adverse circumstances, unsuitable boilers and connections, being compelled to use temporary boilers while putting in new. The test made October 28th by Mr. Caudle and our Mr. Lauer was highly satisfactory as well as surprising, the fact as shown by cards Nos. 6 and 8 that the engine was carrying a load of 115 and 117 h. p., taking steam through a 2 inch pipe instead of a 4 inch, carrying the steam over 100 feet to the engine.

You will remember that you would not guarantee to me a horse-power over 90, although you thought it might show 100. We will be pleased to show this engine and its performance to any one who is desirous of seeing a novel and unique machine get around at the rate of 350 revolutions per minute.

Yours truly,
A. DOLBEER,
Superintendent Motive Power,
Buffalo, Rochester, and Pittsburgh Railway Co.

THE CLARK ELECTRIC SEARCH LIGHT.

A special silver medal was awarded the Clark Electric Company, 192 Broadway, New York, by the American Institute, at the close of the Sixtieth Annual Exhibition, November 28th, 1891, for the Clark electric search light. The new and novel features of this light created great interest and it was one of the attractive features of the exhibition.

To see an arc lamp turned in every possible position and burning perfectly at every possible angle was something new; it elicited many inquiries.

The light was thrown in every nook and corner of the building and upon the floor directly under the lamp and then to the ceiling, searching out all the imperfections of the old Institute; and sometimes in the eyes of the visitors

The Clark Company are constantly bringing out new and valuable improvements in arc lighting, of which they make a specialty. They have established a high reputation for the apparatus of various kinds which they manufacture, the merits of which are proven by the rapidly increasing demand from their former customers as well as from many new sources.

DAY'S KERITE.

THE many friends of Kerite and of Mr. W. H. Eckert, will be glad to learn that the gentleman named has succeeded to the general management of Day's Kerite, vice G. B. Prescott, Jr., resigned. Mr. Eckert has had a long and valuable experience in the electrical field, and particularly in those lines where Kerite has made its greatest successes. The following announcement has been made by the firm.

NEW YORK, December 1, 1891.

The undersigned desires to announce to the electrical industries that he has assumed the management of the long established and celebrated insulated wire and cable business of A. G. Day (S. A. Day, successor), and that he is prepared to supply their wants in the line of high grade insulation.

It is unnecessary to refer to the character of the goods, as it is a well-known fact that the Kerite insulation is the best, having been used for the greatest number of years and sold to the largest extent of any insulation in the market.

Trusting that the users of Kerite will continue to approve its qualities, and all others who desire a first-class insulation, that has been successfully employed for aerial, subterranean and submarine purposes for more than 25 years, will test its merits, I am

Very truly yours,
W. H. ECKERT,
General Agent.

DALLETT & CO. DYNAMOS AND MOTORS.

MR. NEWTON L. SCHLOSS, 126 Liberty street, reports the following recent orders: 1 one h. p. motor, Charles Vogt & Co., printers, 132 Church street; 1 five h. p. motor, Montague & Fuller, bookbinders' machinery, 28 Reade street; 1 five h. p. motor, Smith & Seward, coin makers, 92 Fulton street; 1 ten h. p. motor, Charles Hirsch, electrotyper, 113 Nassau street; 1 fifteen h. p. motor for elevator work, R. C. Williams, grocer, Thomas and Hudson streets; 1 90 kilowatt generator, 1 100 h. p. motor, 1 125 h. p. Triumph valveless compound engine, wiring for 1,000 lights, and two Hunter clutches, for N. Y. Biscuit Company, Tenth avenue and Fifteenth street, city. The plant for the New York Biscuit Co. will be coupled direct.

These are the Billberg motors and dynamos made by Thos. H. Dallett & Co., of Philadelphia, of which firm Mr. Schloss is New York agent. The engine is the valveless Triumph compound engine which is represented solely in the East by Mr. Schloss.

THE WESTON STANDARD VOLTMETER IN GERMANY.

W. LE CONTE STEVENS writing to Mr. Edward Weston, vice-president of the Weston Electrical Instrument Company, Newark, N. J., says that the Weston Standard Voltmeter is held in very high esteem in Germany. At a lecture recently attended by him at the Polytechnic School in Zurich, the lecturer, who was a member of the Testing Commission at the recent Frankfort Electrical Exhibition, said he had subjected the Weston voltmeter to various tests and found it in the highest degree satisfactory—the best thing from America that was exhibited at Frankfort. As an illustration of the excellence of the magnet employed, he stated that an instrument having fallen accidentally upon the floor, its subsequent indications were not affected more than ⅛ of 1 per cent. by the mishap. The Weston Electrical Instrument Company are very busy.

THE GERMANIA ELECTRIC CO.

THE following letter speaks well both for the Germania shade-holder as a desirable article of manufacture and THE ELECTRICAL ENGINEER as an advertising medium:

HELSINGFORS, Nov. 7, 1891.

GERMANIA ELECTRIC CO,
505 Exchange Building,
Boston, Mass.

DEAR SIRS: Enclosed please find draft on New York for $7, in exchange for which please send us one gross of your Germania shade-holders as advertised in THE ELECTRICAL ENGINEER.

The best way to send them is via Hull, and we should like to receive same as early as possible.

We are, dear sirs,
Yours faithfully,
HELSINGFORS ELEKTRISKA BELYSNINGS AKTIEBOLAG.

AN ELECTRIC EXCHANGE FORMED AT ST. LOUIS.

A NUMBER of electrical supply companies and contractors of St. Louis have got together and formed an association and named it the St. Louis Electric Exchange. The officers elected are: R. C. Wolfram, president; Ed. E. Cook, vice-president; R. V. Scudder, secretary, and R. Dodsworth, treasurer. The regulations provide that no member of the association shall buy from, or sell to, any company or contractor who does not come up to the regulations of the association. They will begin operations at once, and a lively fight is expected from those who are opposed to being forced to comply with these regulations.

PASS & SEYMOUR INSULATORS.

THE accompanying illustrations, Figs. 1 and 2, show two novel forms of insulators recently introduced by Pass & Seymour, of Syracuse, N. Y. Fig. 1 is a circuit-break insulator, in which the distance between the wires is very great. This may also be used equally well as a tree insulator. It is made in two sizes, and is sufficiently strong to stand the breaking strain of any wire that may be fastened to it.

The cleat, shown in Fig. 2, is intended to take the place of those of wood, now in general use. It is so made that the wire may be held in position loosely until properly adjusted, when, by tightening the screws, it is bent in the rounded jaws of the cleat and held very firmly. This insulator holds any size wire from the smallest used to No. 6.

Both of these articles are made of Syracuse china, fully glazed. The cleat, however, is furnished in the unglazed state for concealed work.

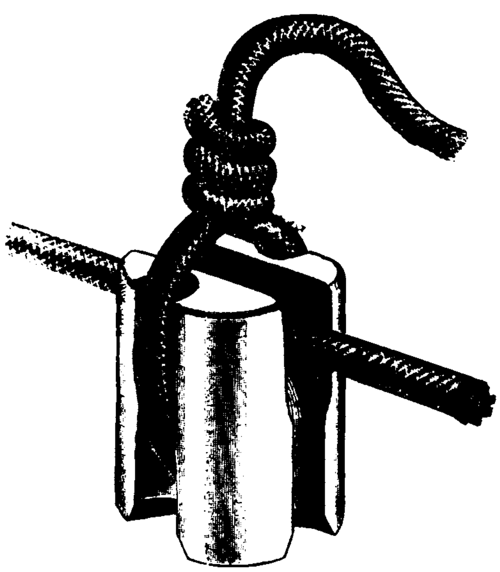


FIG. 1.—PASS & SEYMOUR'S CIRCUIT BREAK INSULATOR.

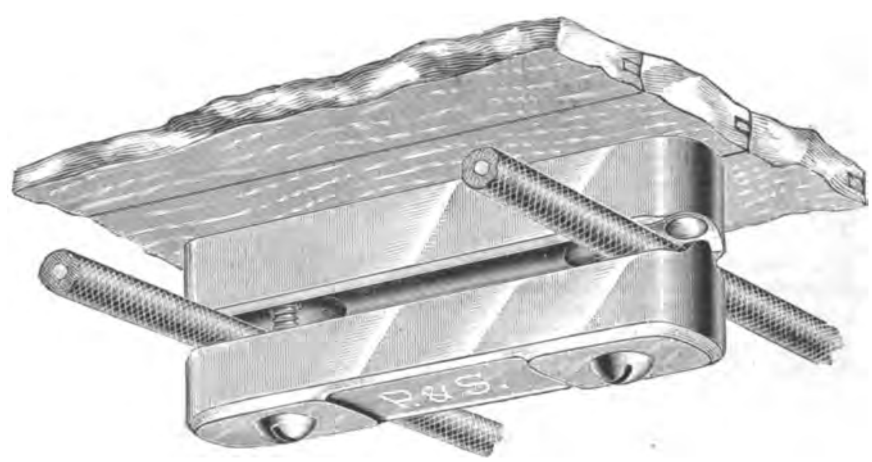

FIG. 2.—PASS & SEYMOUR'S CHINA CLEAT.

THE D. M. STEWARD MANUFACTURING CO.

THE above concern is in itself one of the most remarkable instances of the wonderful development of the new South. Its principal now has his factory established literally on the very spot where he once bivouacked as a Union soldier, and he transferred his business to Chattanooga from Ohio because of the greater advantages to be found in Tennessee. Lava insulators, one of the many special products of this progressive concern, have now become a "household word" in the electrical industry, a fact pretty clearly brought out by orders running up to 200,000 pieces in a single week.

CENTRAL ELECTRIC CO.

The Central Electric Company has just received a large importation of all-steel pliers of standard sizes. These goods are guaranteed to be all steel and superior to any on the market, and are being offered at very attractive prices. The company has also received, direct from Germany, an importation of sal ammoniac, which is guaranteed to be the pure article, and on which they make low prices on large quantity orders.

FIRES IN CHICAGO CENTRAL STATIONS.

Our Chicago correspondent writes us as follows, with regard to the two recent fires in that city:

CHICAGO ELECTRIC LIGHT AND POWER CO: I saw Mr. Wilmerding, secretary and treasurer. He says that the loss is not nearly as great as at first expected. It is chiefly in the building, fixtures, and dynamos. The engines, boilers and most of the shafting are in good shape and will be able to be used very shortly. The dynamos are chiefly damaged by water, and a large portion of them can be fixed up. They are making arrangements for temporary power in various points and have already made arrangements to take care of about a quarter of their load, and in a week expect to have all their lamps running. They will immediately commence reconstructing the plant. The loss is almost fully covered by insurance. The amount of loss has not yet been accurately determined.

CENTRAL ELECTRIC LIGHT CO: This plant is an entire wreck. Perhaps the engine may be saved, but that is not yet certain. They expect to be able to take care of all their lights from the 3d Avenue plant.

CENTRAL ELECTRIC COMPANY, CHICAGO.

THE Central Electric Company have again added to their quarters, being obliged to secure increased storage capacity for their stock. The large line this company handles, which includes appliances for all classes of electrical work, necessitates carrying a very large stock, and the business has increased very handsomely during "dull times." This company, who are always in the front rank of progress, have recently put in a large stock of electric light carbons that will enable them to furnish carbons to consumers in Chicago at factory prices. The sales of Okonite wire have been larger than ever before, evidencing advancement in the use of high-grade materials throughout the electrical fraternity. The Swan incandescent lamp, for which this company are general Western agents, has obtained a popularity in their hands that is also deserving of mention. The branch houses of this company, viz., Southern Electrical Supply Company of St. Louis; Gate City Electric Company of Kansas City; Western Electric Supply Company of Omaha, and the Electric Power Transmission Company of Denver, are doing a thriving business and in this connection, the Central Electric Company can be said to lead the van in the West. The company carry the Swan lamps in all voltages and candle powers, and will fill the largest orders promptly. The lamp is said to show a very small watt consumption to the candle-power.

MEETING OF SUPPLY MANUFACTURERS.

AT the call of a number of gentlemen interested, a meeting of electrical supply manufacturers was held at the Hotel Metropole in this city last week, at which a number of questions of importance to the trade were discussed. Principal among them were the prices to be charged for switches and sockets to various classes of concerns. As a result, it was decided to allow a sliding scale of discounts to concerns which were classified as follows: A, Large firms that do no construction work; B, Supply houses that do no construction; C, Construction companies that do not deal in supplies.

The sessions were held with closed doors and the meeting adjourned subject to the call of the chair.

GERMANIA ELECTRIC CO.

THE Germania Electric Co. has recently installed electric lighting plants in the following places: Hermann Bonitz, Lodi, N. J., one 50-light machine; De La Vergne Refrigerating Machine Co., New York, one 500-light machine; J. S. Mundy, Newark, N. J., one 400-light machine; the Newichawanick Co., South Berwick, Me., one 300-light machine; the Pabst Brewing Co., South Boston, complete steam and electric plant for 100 lights. This is an exceedingly good showing for a company who have but recently commenced to give the dynamo business any special attention.

THE NEW ENGLAND SWITCH.

IN the accompanying illustration is shown the "New England Switch," the general Western agency for which has been secured by the Electric Appliance Co., of Chicago. It is constructed on correct mechanical and electrical principles, the best of material being used throughout, and is strong, neat in appearance, and at the same time remarkably simple in construction and very durable and reliable. The contact pieces consist of copper brushes, giving high conductivity, backed up by German silver springs, and are forced down and held firmly between the contact lugs by

THE "NEW ENGLAND" SWITCH.

a "cam," making an excellent contact, which it is impossible to break without turning the handle.

These switches, it is stated, are in great favor among electrical engineers throughout the country and giving the best of satisfaction. They are made in sizes of from ten to fifty amperes on porcelain bases, and 75 and 100 amperes on slate bases.

INTERIOR CONDUIT AND INSULATION CO.

THIS company, of 42 and 44 Broad street, has just issued a new batch of circulars relative to its brass-armored tube, elbows, tees, &c.; standard elbows and tees; twisted wire clips for conduit tubes, and attaching plug and receptacles. The clip is made of iron wire in two sizes. The plug is of hard rubber, and the receptacles are mounted on porcelain base or in the regular branch box. With regard to the elbows, we note that the company is prepared to supply them in future with the couplings attached. The new price list for the brass-armored tube shows an extremely low cost for this useful article.

ELECTRIC APPLIANCE CO.

THE ELECTRIC APPLIANCE COMPANY report having closed arrangements for the exclusive Western agency for the New England switch, which is described elsewhere in this issue, and also for the entire line of specialties manufactured by the Consolidated Electric Manufacturing Company, of Boston, some of which are the C. E. M. jack-knife switches, C. E. M. sockets, Wade dynamo register, O. R. W. oil filter, S. & W. speed indicator, "telescope" switchboard plug, Davis arc cut-out and Corthell lamp adjuster, which, with the addition of Paranite wires, "swinging ball" lightning arrester and Walker ammeter, mention of which has already been made, gives them a most desirable line of specialties and one that will undoubtedly enable them to command a large trade from the very start.

A THRIVING YOUNGSTER.

JUST two years ago George Cutter brought out a street hood which embodied a number of new features. Last week an order for 250 brought the number in use up to ten thousand, and yet the stern owl in the cut says "Still there's more to follow."

IN the description of the new Thomson-Houston freight locomotive described in our last issue we omitted to mention that the designing of this locomotive was done by Mr. C. H. Veeder, under the supervision of Mr. J. P. B. Fiske, who has charge also at the Lynn factory of all the motor work now being done by the company except the railway work and long-distance transmission.

THE DETROIT ELECTRICAL WORKS have closed a contract with the Kokomo City Electric Railway Co., of Kokomo, Ind., for an 80,000 watt generator and five 30 h. p. motor equipments, to be delivered on or before Dec. 15.

PHILADELPHIA NOTES.

THE LA ROCHE ELECTRIC WORKS have received an order from James W. Queen & Co., of this city, to build a direct-current dynamo, an alternating dynamo and a motor to run them, all of which are to be specially made and of the best of material that the market affords, and will be highly finished with all the latest improvements. Inasmuch as Queen & Co. demand the best machinery that can be produced for the use of calibrating instruments in their new laboratory at 1010 Chestnut street, the La Roche Company feel highly complimented for receiving this order.

THE HEISLER ELECTRIC CO. is installing plants for their long-distance incandescent lighting in the towns of Matteawan, N. Y., Homer and Chelsea, Mich., and an additional plant at Union City.

THE CRESCENT INSULATED WIRE CO., of Trenton, N. J., have found a ready market for their rubber-covered wire as fast as they have been able to turn it out. They will be compelled to increase their facilities for manufacturing shortly.

THE IMPERIAL PORCELAIN WORKS, of Trenton, N. J., have created such an enviable reputation for making fine porcelain for electrical purposes that they are scarcely able to fill their orders. Mr. F. A. Duggan, the proprietor, with long years of experience fully appreciates what the electric trade demands. This with his personal supervision and promptness in filling orders has built up for him a most successful business.

MR. T. L. TOWNSEND, of the Partrick & Carter Co., has just returned from a three month business trip through the West and South. Although Mr. Townsend has been over the same territory many times, representing the same company, which is one of the oldest in the country, he says there never before was such a demand for their goods.

WESTERN NOTES.

THE ILLINOIS ELECTRIC MATERIAL CO. report business as flourishing and the demand for "Canvas Jacket" line wire and Bishop india-rubber covering wires and cables as being exceedingly good.

THE ELECTRIC APPLIANCE CO., of Madison street, Chicago, are beginning to take some nice orders for Paranite rubber insulated wires and cables and also for other general electrical supplies. Mr. W. W. Low, of the company, has just returned from the East, where he has been making arrangements to take the agency for various good specialties.

MR. C. E. OLDACRE has been in Chicago during the past week attending to important business for his company.

MR. WM. HOOD, 239 La Salle street, Chicago, says that he is receiving some very nice repeat orders for Jewel incandescent lamps. In places where he has taken orders for from ten to fifty he is now receiving orders for from 200 to 500 and upwards, which is a very convincing proof of the general satisfaction that the lamps are giving. The Mosher arc lamp, for which he is general agent, is also meeting with good success, the Mosher Co. having recently started out a new style of lamp containing important improvements, and the sales of which are expected to be very large.

THE GREAT WESTERN ELECTRIC SUPPLY CO. are doing their share of business, filling orders for all kinds of general electric lighting, power and railway supplies from all parts of the country.

THE ELECTRIC MERCHANDISE CO. are meeting with the most excellent success in the introduction of their Burton electric heaters. Parties who have used the heaters are continually sending in orders for more sets and expressing in gratifying language their appreciation of the work their heaters are doing.

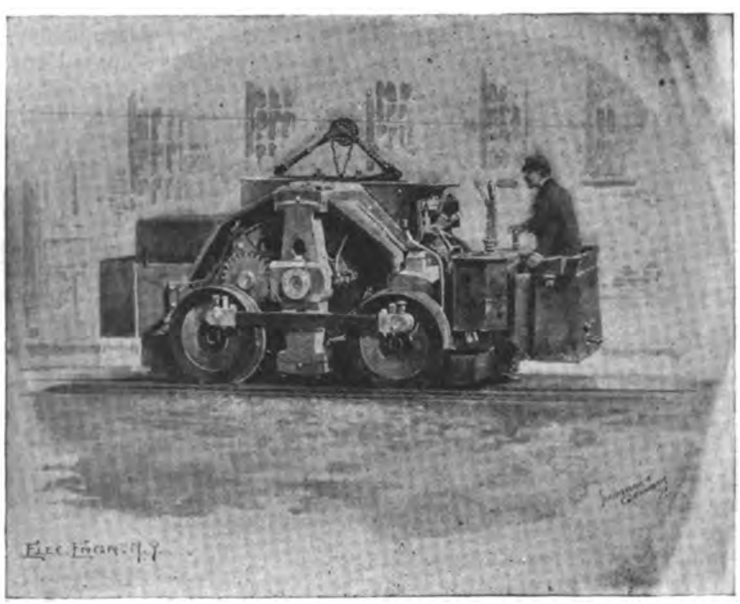
THE

Electrical Engineer.

VOL. XII. DECEMBER 16, 1891. No. 189.

THE EDISON ELECTRIC LOCOMOTIVE FOR MINE WORK.

DURING the past year a number of articles have appeared in THE ELECTRICAL ENGINEER, descriptive and illustrative of electrical mining apparatus; and it must have been evident to all that the work was entering upon a further stage of magnitude and importance. Some idea of the scale upon which operations are now conducted may be formed from the sketch here given of the new mining locomotive recently built by the Edison General Electric Co. for the Loyalhanna Coal Co., of Philadelphia. It is, we believe, by far the largest electric mining locomotive ever built. The contract with the Loyalhanna Co. called for a locomotive able to deliver 360 tons of coal every hour at the bottom of the shaft. To do this necessitates hauling a train of 30 coal cars over an average distance of 4,000 feet every 15 minutes. Each car weighs about one ton and contains three tons of coal; the total weight of each train is, therefore, about 120 tons. As there are numerous sharp curves and grades varying in steepness up to four and five per cent., some idea can be formed of the power necessary to do the required work. The usual speed with a train of 120 tons will be about 7½ miles per hour, but during the test made two weeks ago a speed of 12 miles per hour was attained, and the heavy trains were handled with ease and facility, the capacity of the locomotive being found to be far in excess of the requirements. The motor is of the four-pole type, and built in the most substantial manner. The magnets and the armature are protected from injury by iron casings. The power is transmitted from the armature to one axle by heavy gears, and the wheels on this axle are connected to the others by connecting rods, as on a steam locomotive. The full tractive effect of both pairs of wheels is thus obtained with the least amount of gearing. The track gauge is three feet eight inches, and the distance from centre to centre of the axles is the same. The speed of the locomotive is governed by a special controlling switch and the seat of the driver is so arranged that he can easily look in either direction, according as he is running one way or the other.



THE NEW EDISON MINING LOCOMOTIVE.

Sand-boxes are provided for sanding the rails in case of the wheels slipping. These are controlled by two handles placed within easy reach of the driver. The track is of T rail, thoroughly "bonded." About one mile of track has already been laid, and the length in the main entry alone is expected to reach nearly two miles. Several branches turn off from the main line into workings on either side. The trolley-wire, which extends along the track overhead, and from which the current is taken, is carefully supported on insulators especially designed for damp locations, and is also protected by an inverted wooden trough supported above it upon cross timbers. A heavily insulated copper feeder wire runs the entire length of the track, and is connected to the trolley-wire every hundred feet or so by branch wires. The feed-wires and trolley-wires running off on the branch lines are connected to the main wires through cut-out boxes, or switches, by means of which the electric current can be shut off whenever desired.

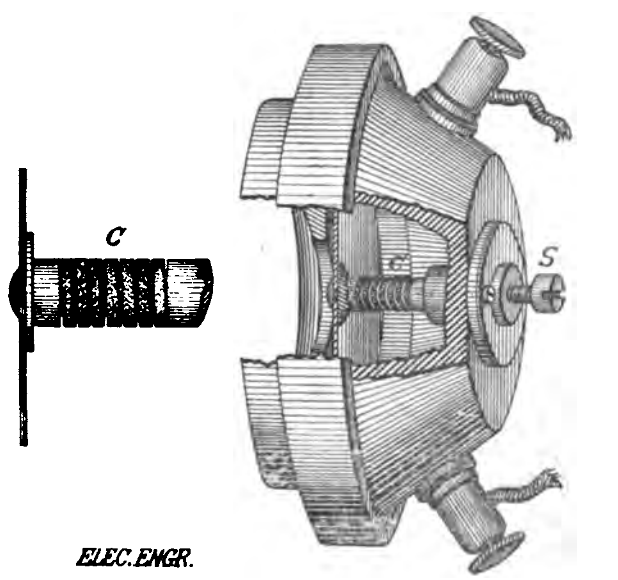
The generating dynamos which furnish the electric current are located in the same room as the hoisting-engines. They are two in number, compound-wound, of the most improved type manufactured by the Edison Company, and are driven by a high-speed steam engine of 150 horse-power. The wires are carried from the dynamos to a switchboard on the wall, where are placed the controlling devices, switches and other apparatus, all within easy sight and convenient of access for the engineer in charge. From the switchboard the heavy conducting wires are carried down the air-shaft into the mine, a vertical distance of 200 feet. Great care has been paid to all essentials, and in every respect this may be considered a model installation. The results already obtained will lead to increased application of such locomotives in the near future.

A TELEPHONE TRANSMITTER WITHOUT ELECTRODES.

BY

Chas Cuttriss

WHILE it would appear that the field of telephone transmitters had been pretty thoroughly gleaned, still among the stubble there has remained one that promises to be of considerable importance both for long and short distance transmission. As is often the case, the present invention is the result of research in a new direction. Upwards of a year ago I was experimenting with some carbon contact points with a view to getting data of their action under different pressures and with various strengths of current. In one set of experiments I was surprised to observe a steady movement of the galvanometer, indicating a gradual increase of resistance in the circuit, and as the opposite effect was expected I was led to examine closely into the cause of this action. Arranging the contact points in such a manner that they could be examined by a powerful



FIGS. 1 AND 2.—CUTTRISS' TELEPHONE TRANSMITTER, WITHOUT ELECTRODES.

magnifying glass, it was observed that on the first application of the battery there was a good surface contact between the carbons, but that as they expanded under the heat the surface gradually became raised until, at last, the contact was so exceedingly small that it became incandescent for an instant. At the moment of incandescence the contact points fell together again, and the action was repeated, the whole cycle taking about 30 seconds, and in some cases it would keep on repeating with great regularity for 20 minutes, or more, before the points became so much changed as to stop the action. While it was interesting to observe this action it was on the other hand very disappointing, as it showed the impossibility of using the contacts for the purpose intended.

I was then led to try a number of contact discs, but here I was met by the difficulty that with the light pressure I was using—only from 2 to 10 grains—the various discs would never resume their former condition after the removal of the pressure. It was at this time that I realized that the only way to get around the two difficulties would be to make such an arrangement that each contact should have a tendency to spring open and at the same time preserve continuity of circuit. After trying numerous devices without success it occurred to me that a helical carbon spring, if such a thing could be made, would offer the best solution of the difficulty.

For upwards of a month I had a maker of incandescent lamps trying to produce some of these helices, but without success. I then determined to try it myself; so, with an Edison fan motor geared direct to a fan rigged up out of a tin can, an improvised Fletcher's blow-pipe and a small circular crucible furnace, I went to work, and in a few hours had got my first helix. But, as may be imagined, it was too ethereal for the rough and tumble of this world.

Nevertheless, it showed that I was on the right track and after a few days' practice, little trouble was experienced in turning out about anything I desired. I now have the carbon helices of such resistances that when closed in their natural condition they have a resistance of about 10 ohms; but when fully distended the resistance is upwards of 500 ohms, and a movement of .01 of an inch tending to open the convolutions makes a variation of from one to two hundred ohms. Their action on the instrument for which they were designed was perfect and no sparking could be observed between the convolutions until the battery was increased to such an extent that the whole helix was heated to some 300 or 400 degrees Fahrenheit.

This absence of sparking under heavy battery at once struck me as a valuable feature in a telephone transmitter and as the battery circuit could never, under any circumstances, be interrupted, there should be an absence of those ear-breaking kicks which are so often experienced when impatience is expressed at the distant end.

As a result I devised the simple arrangement shown in the accompanying engravings. As will be noted in Fig. 1, the helical carbon spring C is permanently cemented to the diaphragm and presses against the end of a screw S, to which it is also permanently connected and by which its tension can be regulated and the convolutions of the helix brought nearer together, or separated, as desired. The carbon helix is shown enlarged in Fig. 2.

Experiments proved the correctness of my theory and not only does the instrument transmit speech loudly, but the enunciation is so remarkably clear that I have been led to look for some particular reason why this should be so. I think it will be found to be owing to the extreme lightness of the helix (generally less than one grain); to the absolute continuity of the circuit—that is to say, the elimination of electrodes—and also to the fact that as each part of the spiral is tending to open itself it absolutely precludes any tendency for the surfaces to jam or lock together.

"CONDUIT WIRING."

BY

Augustus Noll

THE methods, heretofore employed, in fitting buildings for electric lighting for future service, were at once costly and unsatisfactory. The wires, were brought to all the outlets, and connected to the main and feeder wires by means of cut-outs or safety devices, grouped in central points; the main feeders were brought to a point in the front of the cellar, and the wires were usually imbedded in the plaster.

After a few years, a lighting company having been organized to supply electricity, in any city, the owner applies for connection of his building with their system under the impression that the only requirement and expense is the small cable which connects the street mains with the main wires in the cellar. He usually receives a report, after his premises have been inspected, that: *The* *wires are not large enough; or it is wired on the two-wire system, and we require three; or vice versa; or the lines are grounded, due to the deterioration of the insulation, and numerous other faults.* To remedy these defects, usually, is as expensive and more troublesome than the original work, and the work at best then is "botched." The building, as noted above, was "wired" for so-called "future use," and as shown, it is usually a gamble, as far as satisfactory results are concerned. The character of the work is neither permanent nor finished.

By the use of conduits, these defects can be overcome. Instead of "wiring" a building for future use, "conduit it."

The cost is less than one-half; the work is permanent, and can be installed in such a way, that in future, any system of lighting can be used. The wires need not be installed until there is immediate use for them, and then only in the parts of the building it is intended to light. The insertion of the wire in the conduit, can be made quickly and without cutting or defacing the plaster or wood-work in the building.

The conduits should be installed in such manner that the channels will be continuous from the outlets to the cut-out or distributing boxes, thence to the main floor-box, and the next end to the front of the cellar. They should be of ample size, and a sufficient number provided to allow placing only one wire in a tube. One or more receptacles, according to the size of the building, should be provided in the walls, and should extend the whole height of the building. The location of these should be central as far as possible.

Angle and fishing boxes should be inserted liberally, for purposes of access, location of cut-outs, and to simplify and make easy the insertion of the wires.

At least two large tubes should be run to each floor in each recess, and in large structures an extra pair should be run in each recess, extending to the top floor. At each floor, and fitted in the recess, should be placed the main floor fishing box, fitted with sockets for the entrance and departure of the tubes, and also fitted with a cover, the surface of which should be flush with the surface of the plastered wall; the smaller boxes being finished in like manner, gives a finished appearance to the work.

In buildings, where the lamps or "points of lighting" are subject to continual changes, such as office buildings, etc., due to subdivision of offices, erection of partitions, etc., a good plan would be to provide a separate feeder for each office, placing the main box on the side-wall, in the corridor, and from that box, carry two or more conduits, according to the size or number of lights, on all side-walls of the office, locating the tubes either behind or directly under the cornice, and at certain intervals, insert a box. In these boxes can be located the cut-outs, and all branch or tap connections can be made therein. This will obviate the necessity of defacing the side-walls and ceilings, will simplify the system, and add to its appearance. Should the present tenant vacate the office, the changes in the location of lights, to meet the requirements of the next, can be made quickly, cheaply, and without annoyance, either to the owner or tenant, also without interruption to the lighting system installed in the other offices or public part of the building.

A conduit system installed in this manner will meet the requirements of either the two or the three wire systems, direct or alternating current, and the electromotive force used can be either 50, 100 or 200 volts; and at the same time, it gives the owner his choice, and does not limit him to the use of any one system, to which his building is fitted, as in the previous methods.

The work if properly installed, and good materials are used, will be permanent, safe and cheap.

It is conceded by all experienced in the art of artificial illumination, that the method employed in obtaining it by means of electricity is the safest. It is the aim of all interested in the art, to provide safeguards. The fire underwriters have received our hearty co-operation, and the result of our combined efforts have been such, that at the present time, a building can be fitted for an electric lighting system, which is safe and permanent, and which affords few chances for interruption to a steady light.

The Board of Fire Underwriters insist upon the use of a system of wiring which includes all possible safeguards, but the consumer insists not only upon the use of a system which is free from dangers of fire, shocks, and large bills due to leakage; but also, upon a system that will afford steady and uninterrupted light at all times, and for which he is willing to pay.

Every improvement in installation work, either in materials, method or appurtenances, has increased the cost, yet the work increases in volume every year; electric light is gradually covering the field, to the exclusion of all other artificial illuminants.

Being willing to pay for the best system of "installation work," the consumer is entitled to that which experience has taught us gives the best results in matters of safety, permanence and reliability, and which is in the end the cheapest. This experience will compel us to adopt the "conduit wiring" system, which is conceded by all electrical engineers to be the best; but, do we give the consumers the best, even when we adopt the conduit system, and place two wires of different polarity in one tube? Is it the safest, most permanent and reliable?

The conduit manufacturer, when exhibiting his product, inserts wires of different polarity in the tube and in turn, arcs, short circuits, and overloads them; but forgets that the consumer is principally in need of a good lighting system. *It is light, and such light that won't go out,* he wants, and it is reasonable to suppose that if each wire is provided with a separate conduit, the desired result is obtained.

The consumers not only want a safe system, but one that affords very limited chances for short circuits, arcs, etc., and when two wires of different polarity are placed in one tube, these elements of danger and interruption are invited. Two wires placed in a tube and exhibited in a show-room may be safe enough, but would any one be rash enough to do so, when installing a plant in a brewery, or in a building where gases are generated? Excessive moisture in the brewery, and explosive gases in the other building, would from experience, teach us to provide a conduit for each wire, and in addition to this, to use only such wire, having an insulation of the very highest grade.

The conditions, under which the work is placed, comparing the first with the last two noted, are, I admit, extreme, but, comparing the last two with those under which conduit wiring is installed, in general practice, are the conditions so dissimilar? In the first, we are confronted by moisture; safeguards are provided against this, not on account of the danger of fire, so much as excessive interruptions to the lighting system. In the other, the danger lies in the gases which are generated, and in case of a short circuit, though the metal strip may fuse and break the connection, still an explosion may occur, due to the spark or flash created at the time of short circuiting.

Are not these same conditions met with, to a greater or lesser degree, in every installation? Is there a building, where it can with safety be assumed that the conduits will, at all times, be absolutely free from moisture and gas?

This can best be answered by the fact that some of the most careful and experienced contractors and electrical engineers throughout the country, now insist upon figuring on placing only one wire in a tube, when asked to submit proposals for installation work. The general results obtained, by placing two wires in one tube, have been very unsatisfactory, and the experience costly. While the first cost is greater, when inserting only one wire in a tube, still, the annoyance and cost of repairs will in a few years, more than offset the difference in first cost between the two methods.

Time has shown, that two wires placed in a tube invite short circuits; that the work is unsatisfactory; that the interruptions are of such frequency, that no dependence can be placed on the light; that the work is, to say the least, temporary, and in many cases where the service has been unsatisfactory, a separate conduit for each wire would have obviated the causes thereof.

The gas and water pipes, placed in buildings are not supposed to leak, nor is such leakage supposed to enter the conduits used for electric light wires, but it does, and to a very great extent. The moisture which enters may be only a source of annoyance and expense, but the presence of gas is dangerous.

One of the strongest claims that is advanced by the manufacturers of interior conduits in favor of the conduit system, is the simplicity, cheapness, and absence of annoyance, when making changes in lighting system or increasing the number of lights on the various circuits.

With the twin-conductor system, the increase of lights is limited to a great extent. The Board of Fire Underwriters limit the amount of current to be carried on duplex wires inserted in conduits, and should a consumer change from a 100 volt system to a 50 volt system, and at the same time increase his lights, his margin will be very small unless the tubes are unusually large.

That the National Board of Fire Underwriters had misgivings as to the use of twin conductors in a tube, is evidenced from the fact that in their rules (June 10th, 1890) they limit the carrying capacity to five amperes. The committee on wiring appointed by the National Electric Light Association, submitted their report at the last meeting (Montreal, Sept., 1891) and recommended that "Conduits must not be supplied with a twin conductor in a single tube, where a current of more than 10 amperes is expected." From data, which is daily accumulating, I believe it is a matter of only a short time, when its use will be prohibited entirely, and that the "single-conduit, twin-conductor system," will follow in the wake of "undertakers," and other low-grade insulated wires.

A system of conduit wiring can be installed, that will equal gas piping in permanence, but it can only be done, by using the best conduit, and the highest grade of insulated wire, and providing a separate duct for each wire.

Experience has taught us, that for electric lighting purposes, no place is dry enough to permit the use of inferior insulated conductors, and that the best is the cheapest; this applies equally as well to conduits. The conduits are installed under the same conditions as wire, and the same care must be taken.

Some years ago, the writer was consulted, regarding a large wiring contract, by the officer of a lighting company, on the matter of insulated wire; the writer suggested the use of a certain insulation, which in his opinion has no superior; an electrical engineer who was present, suggested the use of inferior grades in such places as small stores, etc., in side streets, claiming that in these cheap places a cheaper wire can be used, and so save money for the company.

The writer answered that it was just in the cheap places, that the best wire should be used, the dangers being greater than in the better constructed buildings on the main thoroughfares. That the officer of that company appreciated the importance of using the best grade wire, and that the position then taken by the writer was a strong one, is attested by the fact that to the writer was awarded the contract, in a clause of which it stated "that the contractor was to guarantee the work for a period of one year, from the time of turning on the current," and although several years have elapsed, there has not been one cent expended in repairs, due to the insulation on the wires. The contract covered all kinds of work, and in all parts of New York City, and included residences, theatres, stables, bakeries, etc.

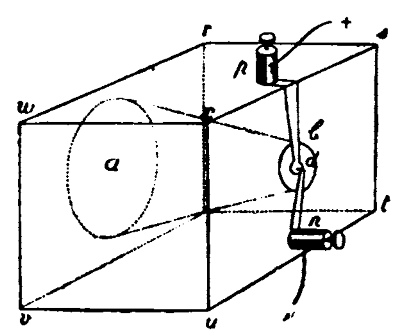
This officer, while not an electrician, possessed a large business experience, which no doubt taught him that, by protecting his customer, he was protecting his company. Had inferior wire been used, no doubt the loss to the company, in decreased monthly receipts, due to the interrupted service, and the employment of a repair gang, would have more than offset the difference in first cost.

TELEPHONE TRANSMITTER PATENTS.

BY THALES VOLTA BLACKSTONE.

In the opinion of many persons who may be presumed to be competent authorities, the fuss which has been made over the recent issue of the Berliner microphone patent seems out of all proportion to its real importance. The hysterical editorials which have appeared, not only in the daily newspapers, but even in technical journals whose editors might be expected to know better, betray a phenomenal ignorance of the subject which is occasionally highly diverting. As a matter of fact, Mr. Park Benjamin, in his letter recently printed in the *Evening Post*, came very near making a centre shot, in the following felicitious observation, which is quite too good not to be quoted:—

> If Reis invented Berliner's structure and Bell taught the world how to use it long before Mr. Berliner applied for his patent, an anxious public will wait somewhat breathlessly to hear the Bell Company's explanation of what there was left for Mr. Berliner to invent.



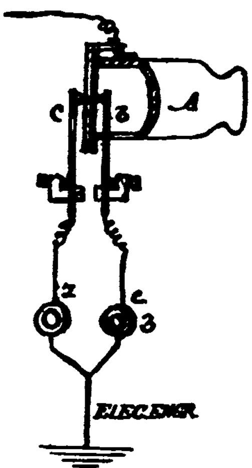


FIG. 1.—REIS TRANSMITTER. FIG. 2.—EDISON TRANSMITTER.

One anwer to this conundrum may be found in the testimony of Thomas A. Edison, given by him while being cross-examined by Mr. Betts in the telephone interference cases some years ago. Referring to an experiment which had been made by him with the Reis-Legat transmitter about July, 1876, Mr. Edison was asked:

> *Q.*—Did you succeed in transmitting any words with it at that time?
>
> *A.*—I can't say; *we generally knew what was coming*, and knowing what was coming, even a Reis transmitter pure and simple, transmits and reproduces sounds which sound almost like that which was being transmitted, but when it was attemped to transmit something which the receiver did not know, *it was very seldom that any word was recognized.*

Those who have tried it will recognize this as a faithful description of the performance of the "Reis transmitter pure and simple."

The testimony of Mr. Edison, however, is scarcely needed to establish the fact that the Reis instrument "pure and simple" is one which is absolutely worthless for any commercial purpose, notwithstanding that more than one learned university professor has hopelessly stultified himself by giving sworn evidence to the contrary. *It has never yet been demonstrated in the presence of a court of justice that the Reis apparatus "pure and simple" is capable of transmitting a single intelligible sentence,* notwithstanding that such a demonstration, if it could have been made, must have conclusively disposed of the celebrated "method claim" of the Bell patent.

Mr. Edison was further asked, in the course of the same examination:

Q.—What specific addition or modification of the Reis instrument, as described in those publications, is necessary to adapt it to transmit articulate speech?

A.—I have found that carbon placed between the electrodes makes it a very good transmitter.

Q.—If one of the electrodes of the Reis transmitter, as described in those publications, was made of carbon, would it then be adapted to the transmission of articulate speech?

A.—Yes, sir.

Now, what was the Reis apparatus, "pure and simple?" In the Annual Report (Jahresbericht) of the Physical Society of Frankfort-on-the-Main, for 1860-61, Philip Reis published an article "On Telephony by the Galvanic Current." A translation of a portion of this with a fac-simile of the accompanying illustration will show exactly what he had done at that time:

From the standpoint of the preceding principles, I have succeeded in constructing an apparatus by means of which I can reproduce the tones of different instruments; yes, and even to a certain degree, the human voice.

In a cubical block of wood, Fig. 1, *r s t u v w x*, is a conical aperture *a*, closed at one end by the membrane *b* (made of the lesser intestine of the pig), in the centre of which a little piece of platinum is cemented as a conductor of the current. This is united to the binding-screw *p*. From the binding-screw *n* there proceeds also a thin strip of metal over the middle of the membrane and terminates in *a little platinum wire which stands at right angles to the length and breadth of the strip*. From the binding-screw *p* a conducting wire leads through the battery and to the distant station, terminating in a helix of copper wire overspun with silk, which in turn connects with a return wire that leads to the binding-screw *n*.

Now we may see, as Mr. Benjamin puts it, exactly "what remained to be invented." Substitute for the little platinum wire which stands at right angles to the length and breadth of the strip," a *carbon point*, and we have the precise structure which Mr. Edison said he had found to be "a very good transmitter."

It therefore becomes an interesting subject of inquiry as to *who* invented that "which remained to be invented." The particular thing does not appear to be visible in the claims of the recently-issued Berliner patent. On the contrary, the indications are that the much-sought-for Ethiopian is concealed in an entirely different part of the woodpile; a part which has hitherto apparently escaped the attention of searchers.

On July 20, 1877, Mr. Edison filed an application in the Patent Office for an "Improvement in Speaking Telegraphs." He says in his specification, referring to the drawing, a copy of which is given herewith, Fig. 2:

The object of this invention is to transmit the human voice over telegraphic wires for conversational purposes. . . . . A is the resonant chamber over the end of which the diaphragm is stretched, . . . *b c* are two contact-springs, having points made of compressed plumbago, mixed preferably with gum-rubber, but any substance not liable to rapid decomposition may be used; these points face each other on the opposite sides of the diaphragm, and make contact with platina disks secured to the diaphragm. . . . . As plumbago decreases and increases its resistance enormously under slight changes of pressure, it follows that the strength of the electric waves will be in proportion as the speaker's voice is strong or weak. . . . The point *b* may be dispensed with on very short lines.

This structure is also shown, in practically identical form, in Fig. 10 of Edison's British Patent of 1877.

This application was put into interference with an application of Berliner filed June 4, 1877, the following being the point in issue, as officially formulated:

In a telegraphic apparatus operated by sound, the combination with the diaphragm, of one or more contact points of *plumbago or similar inferior conductor* in the electric circuit, whereby the rise and fall of electric tension is proportionate to the pressure exerted upon the said point or points by the diaphragm.

It will be seen that this issue involves precisely the thing which, in the words of Mr. Benjamin, "remained to be invented" to convert the apparatus of Reis into a commercial instrument.

What has become of this interference? The writer is not in the secrets of the Patent Office nor of the Bell Telephone Company, but he has made diligent inquiry respecting this matter among those who might be expected to know, without eliciting any very definite information. He has searched the archives of the Patent Office in vain for any record of the decision of this interference, and the obvious inference is that it must be still pending.

If this be the fact, and priority of invention should ultimately be awarded to Mr. Berliner, we shall have the answer of the Bell Company to Mr. Benjamin's conundrum. To conclude, therefore, the following propositions are submitted:

1. The Reis transmitter, "pure and simple," is not a commercial instrument.

2. The Reis transmitter, plus Edison's (or Berliner's) carbon electrode, is a commercial instrument.

THE LIGHTING OF RESIDENCE DISTRICTS.

BY

W. S. Barstow

In the history of every company, electrical or otherwise, there comes a time when it is necessary to extend its business; and this extension is often unprofitable for some time after its start. When a corporation is already showing net earnings it is a source of displeasure to the stockholders to be obliged to relinquish any portion of the present earnings for the prospect of increased earnings at a future time.

Electric light companies, in order to prove that the claim of "light and power for the public" is a just one, find it necessary to enter residence districts and supply current on the same basis as gas. It is an unfortunate undertaking for any dividend-earning company to erect and endeavor to maintain a central station in a residence district, with the expectation of net earnings therefrom during the first or second year. The business man is willing to pay for commercial lighting a sum which he would never think of paying for the lighting of his residence. He will, however, install 10 lights in his dwelling to one in his place of business, although he may only use one out of the 10. Thus the lights burning in a residence district are only a small percentage of the lamps installed. The maximum load of a station in a residence district is actually about 25 per cent. of the lamps installed or connected, while that of a station situated in a business section of a city is never less than 50 per cent. This means, that in a residence district we must connect twice as many lights as in a business district to get the same income. Another unfortunate thing in residence lighting is the fact that during four months of the year the dwellings are closed, and during the months they are occupied the light is only used about five hours out of the 24. The company, like the winter-hotel manager, is obliged, at the start at least, to make up the interest on its investment for the summer months out of the earnings of the other seven.

It therefore follows that a company operating in a residence district must endeavor to either increase its earnings as much as possible during the winter months in order to offset the loss during the summer, or so reduce the cost of current that the receipts balance the expenses during the summer months. As the former depends on the popularity of the light, and the popularity depends to a considerable extent on the cost, it is evident that every effort must be made to reduce the cost of operation so that receipts balance expenses during unprofitable months.

The fact that current can be supplied more economically from a station already in paying operation than from a station having heavy operating expenses to start with, needs no emphasis, as current generated in quantity with large units working efficiently is more economical than current generated in a number of small units. Thus it only remains to be ascertained what we can afford to lose in conductors. And in order that this point may not be considered entirely theoretically it might be of value to those interested in this subject to know what has been actually done in this direction from a practical standpoint.

The second district system of Brooklyn is laid out similar to any ordinary Edison three-wire central station system of underground conductors; each feeder is brought to a central point of distribution situated on land owned by the company, so that in the event of the load warranting the operating of a station in after years no change in the feeders will be caused by its erection. From this central point of distribution a large feeder is laid to the First District station, a distance of about two miles. The question arose before the work was begun, At what load would the economy of transmission on this feeder be overbalanced by the loss in the conductors and interest on any special apparatus required? To answer this question, the cost of labor, interest on investment, and deterioration of a new isolated station must be balanced against increased cost of

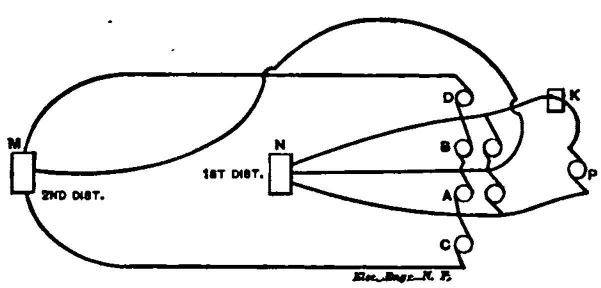

FIG. 1.—METHOD OF DETERMINING LOSS IN TRANSMISSION.

labor in old station, interest on investment, deterioration, and the loss in transmission—the cost of fuel, water, etc., remaining the same in either case.

The following equations may present this more clearly:

$$\overbrace{\text{Cost of labor} + \text{Interest on investment} + \text{Deterioration}}^{\text{Separate Station}} = \overbrace{\text{Increased cost of labor in old station} + \text{Interest on investment} + \text{Deterioration} + \text{Loss of transmission.}}^{\text{Feeder Transmission.}}$$

In the above equation the interest on investment + deterioration is generally equal by both methods, so that we have:

$$\frac{\text{Separate Station}}{\text{Cost of labor}} = \frac{\text{Feeder Transmission}}{\text{Increased cost of labor + loss of transmission}};$$

or, cost of labor (in separate station), *minus* increased cost of labor (in old station), *equals* loss in transmission.

By substituting the figures for the items in the last equation it will readily be seen when the loss in transmission becomes greater than the cost of operation of a new station. For example, the cost of labor in a separate station for 24 hours would ordinarily be

2 engineers	$6.00
2 firemen	5.00
2 dynamo men	5.00
	$16.00

While the increased cost of labor in an old station (one already in operation) for 24 hours would ordinarily be

1 engineer	$3.00
1 dynamo man	2.50
	$5.50

Therefore, $16.00 *minus* $5.00, *equals* loss of transmission, or, $10.50 *equals* loss in transmission. That is, until the loss in transmission for 24 hours a day throughout the year exceeds $10.50 (in current only), it is preferable to transmit current rather than to generate a separate supply.

In order that we may reckon the loss in transmission in dollars and cents it is obvious that we must have some way of securing a tangible record of this loss. An exact, recorded measurement of the loss can only be obtained by separating the current supplied into two distinct parts—one, the current actually consumed at the lamp; the other, the watts lost in transmission. When divided in this way we can easily meter the loss and thus keep an exact account.

After a year's successful operation by the Brooklyn Company in its new district, described by the writer in THE ELECTRICAL ENGINEER of May 6, 1891, the following plant has been devised whereby it is possible to correctly record the loss of power in transmission to the new district. The arrangement is as follows:

In the diagram Fig. 1, M and N denote the centres of distribution of the two districts, in which N is practically the location of one station, and M is about two miles distant from this point. A and B are the two pairs of machines (more or less) on ordinary three-wire system, supplying current at 115 volts to N, to supply current to M (at the same voltage at lamps). Dynamos C and D are placed as shown in the diagram. The armatures of these machines C and D are wound for the maximum current supplied to M, the voltage being the maximum economical drop in transmission in feeder. These two machines are belted to a 230 volt motor P which is run from the main station bus. As may be seen in Fig. 1, C and D will generate whatever watts are lost in transmission in conductor to M, the watts furnished to the lamp at M being generated at A and B. In fact, in action, C and D are nothing more than electrical (hydraulic) rams raising the pressure of the current delivered by A and B. By making C D series machines they become entirely automatic in regard to the regulation of the pressure necessary to counter-balance the drop in the feeder.

In the motor circuit a meter is placed at K, and this gives us the total loss in transmission + the inefficiency of the transforming device, and by subtracting the latter from the total reading the actual loss in the conductor may be obtained. In transmitting 300 amperes to M, the average day load in the residence district, the pressure of C or D is 10 volts. The actual cost of a year's loss in transmission is as follows:

Winter (7 months)	*Week-day loss.*	
	11 P. M. to 4 P. M. =	1.52
	4 P. M. to 11 P. M. =	2.80
	Total,	$4.32
	Sunday and holiday loss.	
	11 P. M. to 4 P. M. =	.48
	4 P. M. to 11 P. M. =	.98
	Total,	$1.46
Summer (5 months)	*Week-day loss.*	
	11 P. M. to 4 P. M. =	1.56
	4 P. M. to 11 P. M. =	1.40
	Total,	$2.96
	Sunday and holiday loss.	
	11 P. M. to 4 P. M. =	.32
	4 P. M. to 11 P. M. =	.42
	Total,	$0.74

Average loss per day during the year.........	$3.36
Total loss per year...........................	$1,227.68
Total loss allowed (efficient loss)............	$3,832.50

By calculation of total number of lamp-hours (of 8,000 lamps connected) and receipts, the cost per lamp-hour at the centre of distribution in the new district two miles from the generating centre is 10 per cent. more than at the generating centre.

The above figures need no explanation as to the financial efficiency of low-tension transmission. Of the 8,000 lamps connected 5,000 are located 2,500 feet from the distributing point of this district, or about two and a half miles from the generating point; 1,000 lamps and 60 h. p. in motors are connected 5,000 feet from the distributing point, or three miles from the generating point!

Fig. 2 is a diagram of an average daily pressure at the main station-end of the transmitting feeder. The constant for this diagram is 7.82 amperes = 1 volt drop (each volt above 117). This gives one-half the load of the feeder at 117 volts.

In the manner above shown, new districts may be entered without serious loss in earnings, and whenever the district becomes so loaded as to pass the point of economy by transmission, a station can be erected which from the very start will have a good paying load. The feeder may then be turned into new territory or left as a tie-line between the two stations. The advantages of this system for residence lighting will be appreciated by all companies who have struggled along turning over the net earnings of one station to make good the deficit of another.

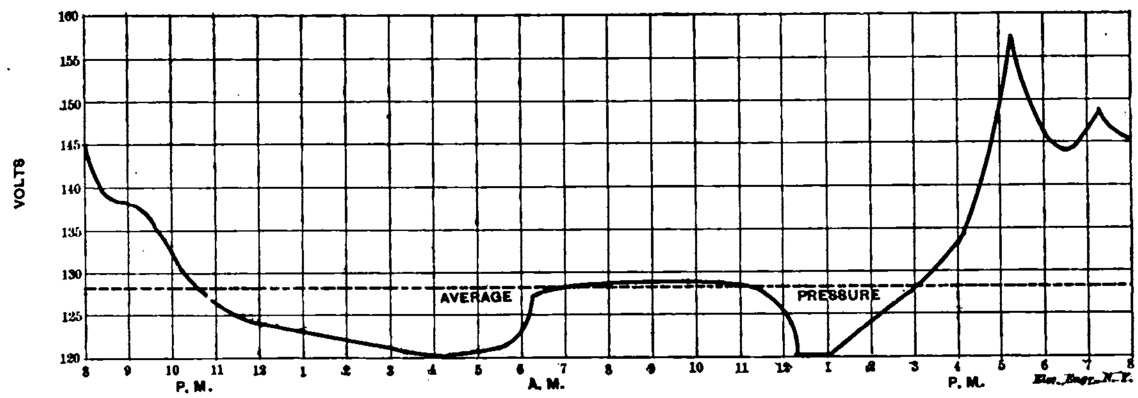

FIG. 2.—CURVE SHOWING AVERAGE PRESSURE OF TRANSMITTING FEEDER AT MAIN STATION.

THE HUM OF MOTORS.

BY

Chas J. Hayes.

As to the cause of the humming of motors, I would offer the following explanation: We know that all sound is produced by vibration, hence there must be produced somewhere in the motor, sufficient vibration to cause sound. The question is, How and where is the vibration produced?

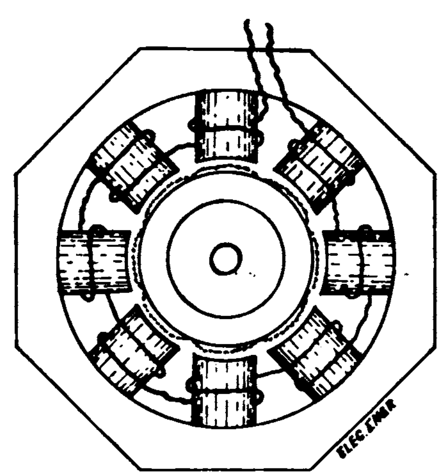
Take for illustration an eight-pole motor with Gramme ring armature, with armature winding removed. The humming action would be the same with winding on or off, as demonstrated by Mr. Huff in his experiments,[1] but for clearness in the accompanying figure I take it with the winding off.

Now, if a strong current be passed through the coils of the field-magnets, the armature being at rest, that portion of the iron of the armature core lying directly in front of the poles, will be strongly attracted and slightly raised, against the resistance of the iron of the core, above those portions lying in front of the spaces between the poles, as shown, magnified, by the undulating dotted line in the figure.

The distance to which the surface of the iron will be raised is, of course, imperceptible without the use of very delicate and exact measuring instruments, the amplitude of vibration necessary to produce sound being very small.

Now, by revolving the armature, it will be seen that every part of its circumference will be brought in succession in front of each of the poles and consequently attracted and slightly raised as it passes, producing a progressive undulatory movement of the iron of the ring, like waves on a body of water. And if the speed of the armature be sufficient, this movement, or vibration, will become audible, producing a musical tone, depending for its pitch upon the speed, and for its intensity upon the degree of magnetization of the field. This appears to be the action that takes place in all motors that hum, but, of course, the more poles a motor has, the less speed required to produce a given pitch.

The quality of iron used in the armature, particularly its



HUMMING ACTION IN MOTORS.

degree of elasticity, would somewhat affect the tone produced. The movement of the molecules of iron upon each other, necessary to produce this vibratory movement, is one of the probable causes of the heating of armatures.

I would suggest wrapping the armature loosely with a piece of unshellacked cloth before winding, as being likely to somewhat deaden the vibration or at least muffle it. Can any one suggest some other remedy?

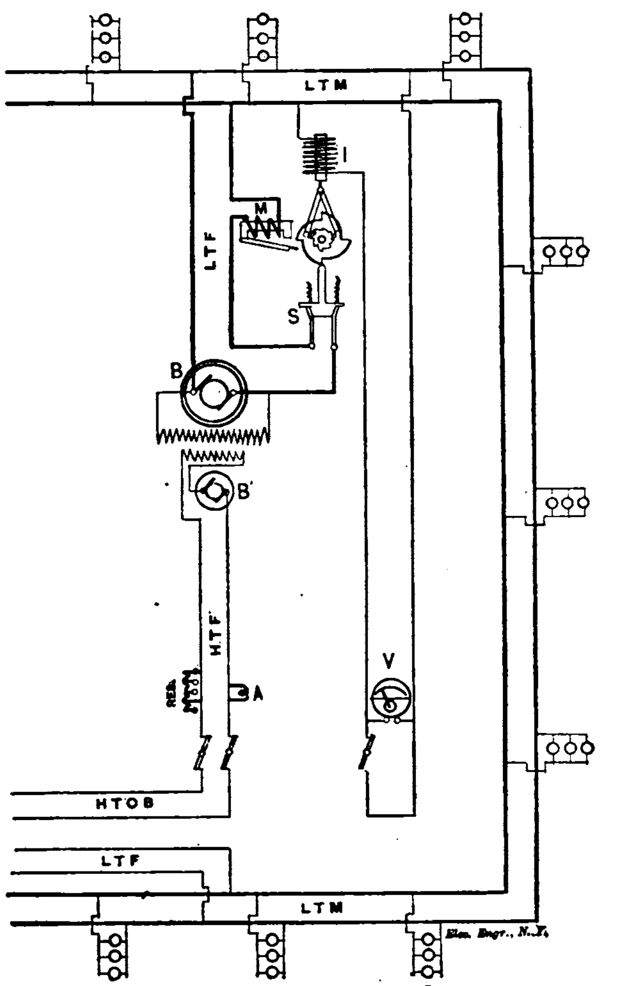
1. THE ELECTRICAL ENGINEER.

DISTRIBUTION OF ELECTRICITY AT OXFORD.[1]

The system of electrical distribution that is being adopted by the Oxford Electric Supply Company will be watched with interest by electrical engineers, having been designed with the object of placing the continuous-current motor-generator on an equality with the alternating-current transformer in the matter of manipulation and control.

The local authorities, stipulated that continuous currents should be employed, and as the generating station is situated at a distance of about 1,200 yards from the centre of the area to be supplied, a high-tension converter system became necessary, and 1,000-volt continuous-current generators with continuous-current transformers to convert to 100 volts and feed into a network of secondary mains, were adopted.

The main feature of the system is the arrangement



Distribution by Motor Dynamos at Oxford.

whereby all the transformers in a district to be supplied can be completely controlled, stopped, or started, from one switchboard situated in the middle of the district; the high-tension current being supplied from dynamos running in parallel at the distant generating station to omnibus bars on the switchboard from which it is distributed through separate switches to the high-tension armature of each transformer. A voltmeter above each switch is connected by pilot wires to the point in the secondary network at which the low-tension armatures supply current, and the high-tension and low-tension armatures of the transformers are connected and disconnected from the high-tension omnibus bars and low tension network, respectively, according to the number of lights in use at one time, varying the number of transformers running with the conditions of the load during each part of the day. In this manner it is never necessary to run any transformer with less than 50 per cent. of its full load, and as the machines as constructed yield an efficiency of 84 per cent. at half load and 90 per cent. at full load, it is expected that the total efficiency of distribution will be very high.

As the number of lights in use increases, the transformer, situated at the switch station, is connected to the high-tension omnibus bars and its low-tension armature to the nearest point in the secondary network. Separate voltmeters are connected to the low-tension mains at the points at which the distant transformers feed into the network. When these voltmeters show that the E. M. F. on the low-tension mains is below the normal, the transformers are started up one by one, as shown in the accompanying illustration, which gives one distant transformer, and the switches at the switch station for controlling it.

The high-tension feeders, as shown in the accompanying diagram, are connected to the omnibus bars by means of the double-pole switches, the regulating resistance preventing a momentary excess of current. The current is supplied to the armature through a few turns of highly insulated wire wound round the magnets of the transformers, which partly magnetizes the field, and passing through the high-tension armature causes the transformer to rotate when the low-tension armature generates an E. M. F., and the main magnetizing coils, being connected as a shunt across the low-tension armature energizes the field to the full extent. The resistance is now cut out of the high-tension circuit until the E. M. F. on the secondary armature is equal to the E. M. F. on the low-tension mains, as indicated on the voltmeter, V. The low-tension armature is then switched on to the mains as follows:

One of the voltmeter wires is connected to the mains through the winding of a magnetic switch, shown diagrammatically at S, the small current constantly passing through the voltmeter being insufficient to affect the switch. A switch is arranged at the switch station to short circuit the voltmeter, which allows the full current required by the magnetic switch to pass through the wires and cause the magnet, I, to ascend, when the circuit is again broken at the voltmeter switch, allowing the magnet, I, to descend again. The double movement rotates the cam wheel through $\frac{1}{8}$th of a revolution, and pressing the contact piece into the brushes of the switch, S, thus connects the low-tension armature to the low-tension mains. The voltmeter, only being momentarily short circuited, reads, as before, across the mains. The E. M. F. on the voltmeter is kept constant by means of the regulating resistance in the high-tension feeders, and the transformer is disconnected from the mains when the amount of current being supplied, as indicated on the ammeter, A, falls below a certain amount.

On disconnecting the transformer again, the resistance is once more inserted until the current falls to zero, indicating that the E. M. F. on the secondary armature is too low to supply any current to the mains; the switch S, is then broken by again short circuiting the voltmeter, rotating the cam wheel through another $\frac{1}{8}$th of a revolution and allowing the springs to pull the contact piece from the brushes. Thus there is no sparking at the brushes of the switch, S, as under ordinary circumstances the circuit through it is never broken while any current is flowing. The magnet, M, is connected to the low-tension feeders in such a manner that should the low-tension armature be switched on to the mains before the high-tension armature or before the low-tension armature is giving sufficient E. M. F., the excess of current flowing back from the low-tension mains will cause the armature of the magnet, M, to be attracted, knocking round the cam wheel slightly and breaking the circuit at S, again, but leaving the switch ready to be "made" again when necessary from the switch station.

By the above means each distant transformer is as completely under the control of the attendant at the switch

1. London *Electrical Review*.

station as the transformer fixed at that station, and as the oiling is automatic by means of oil pumps on the armature shaft, the transformers themselves will only require inspection every three or four days.

The plant to be first installed at Oxford will be capable of supplying 7,500 running lights of 32 watts each. The buildings for the generating station are making good progress, and the current will be supplied early in the new year.

The details of the circuits, &c., are due to Mr. Thomas Parker, works director of the Electric Construction Corporation, and J. H. Woodward and E. and G. Rees.

A SIMPLE METHOD OF LOCATING ARMATURE DEFECTS.

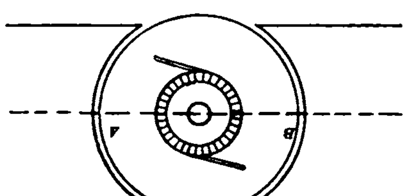
BY

Osborn P. Loomis

All electricians are aware of the many trials of searching for an armature "short-circuit." One method is to run the armature by the usual belting and excite the field; then by observing the heated parts some idea may be obtained where to commence searching for the trouble. It will be understood that the above will only apply to the short-circuiting of a few coils, for when the whole, or nearly the whole, armature is closed on itself by the two adjacent wires touching, running in an excited field will warm all of the wires and, of course, no locating is possible. To add to the trouble, the machine must be belted up and run, which takes time, and repeated trials become very annoying.

I will now describe a method, devised by the writer, which at times has been very convenient. No arrangement for belting need be made; it is only necessary to fasten a monkey-wrench to the rim of the pulley, or, better still, a crank to the end of the shaft. Now excite the fields and, to make the effects more marked, connect the coils in parallel as the excessive current will only be used for a moment. When this has been done the strongest man will scarcely be able to rotate the armature, and then only with extreme slowness, except at one position. When this position has been found, mark the armature at points in the centre of the pole-pieces A, B, as shown in the accompanying diagram, and at both ends of the armature.

The explanation is that both halves of the armature op-



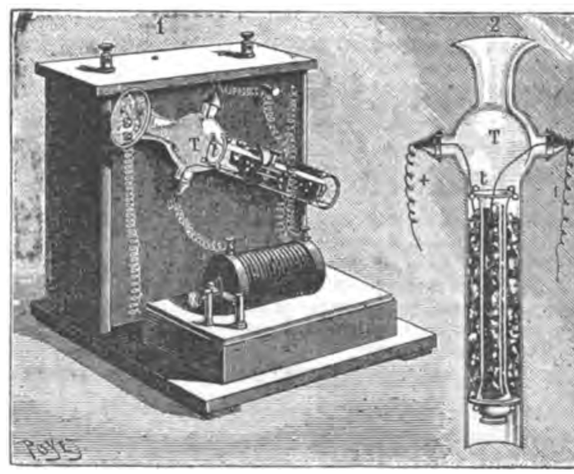
LOCATING ARMATURE DEFECTS.

pose one another at this position; but when not at these points a continuous circuit is formed and the resultant magnetic effect is enormous. As the "cross" will be found at one of these four marked points it becomes desirable to know in which one it is most likely to be found. Experience has shown that it is nearly always on the commutator end in the last half of the winding where the wires pass down through the first half terminals. In armatures where the windings are equal, I suppose it would be as liable to be at one point as at another.

With this method a defect can be found and remedied in a few moments, for it has always been a simple matter to repair it when discovered. These results can be observed in a perfect armature by connecting the opposite sections of the commutator. When only one coil is short-circuited, the magnetic effect is much less and the points must be marked 90° from the ones shown, but these cases are few and are soon discovered in other ways. The above will be understood to apply to armatures of the drum type with Siemens winding.

THE GIRERD ELECTRICAL APPARATUS FOR GENERATING OZONE.[1]

The valuable properties of ozone as a disinfectant are so well recognized that a simple apparatus for generating it will tend to increase the application of this valuable



GIRERD'S OZONE GENERATOR.

agent, which has now become a recognized factor in the destruction of disease germs. A simple and compact apparatus of this sort has recently been constructed by Dr. Girerd and is illustrated in the accompanying engravings. The apparatus is so constructed as to furnish air not only with ozone, but also with a metallic vapor. Starting with the principle that the quantity of ozone generated is directly proportional to the air acted upon, that is, to the surface of the electrodes and also to the current, the inventor employs gold or aluminum foil. These fine sheets are loosely packed and present an enormous surface in a small space. As shown in Fig. 1, the apparatus consists of two perfectly cylindrical and concentric tubes. The metal foil contained in the central tube *t*, Fig. 2, is connected to the wire and constitutes one of the poles; the other pole is formed by the arrangement of the metallic foil placed in the annular space between the tubes T *t*. The apparatus is operated by means of a small Ruhmkorff coil, giving a quarter-inch spark, and fed by three sal-ammoniac cells. The apparatus occupies a space only 8 inches square and is thus quite portable and very practical.

THE ELECTRIC LIGHT AND COMPRESSED AIR IN MUNICH.

It it stated that a German company has submitted a project for a compressed air installation in Munich, which in addition to supplying motive power is intended to provide for the electric lighting of the city. The total installation capital has been fixed at 4,200,000 marks, the total annual expenditure at 550,000 marks; the total length of the conductors will amount to 65,000 metres.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

LIGHTING RESIDENCE DISTRICTS.

THE first efforts of every electric light corporation have been bent on securing what appeared to them at the time as the most profitable class of customers, and as a result we find stations started largely for the furnishing of current in business districts where the hours of lighting are long and the load from which is fairly constant over an extended part of the day. Hence, even at the present time there are comparatively few cities in which any systematic attempt has been made to introduce current for incandescent lighting into the purely residence districts. That the stand taken on this question by station managers in general is one hardly warranted by facts, indeed, that residence lighting can, on the contrary, be made a paying business, is thoroughly demonstrated by the excellent article of Mr. W. S. Barstow, appearing on another page. As pointed out by Mr. Barstow, the question resolves itself into determining the point at which the economy of transmission in a feeder running a considerable distance is overbalanced by the loss in the conductors and the interest on any apparatus acquired. This, of course, will vary with the amount of load at the distant point, and he shows by actual figures an example in which it is evidently more profitable to operate a long feeder, though involving considerable loss in transmission, than to operate a station at the distant point. The experience gained by the Brooklyn Company shows that the cost per lamp hour at the centre of distribution in a district two miles from the generating centre is only 10 per cent. more than that at the generating centre itself, due to the excellent method of operation adopted by Mr. Barstow. For those who have placed the limiting distance of successful low-tension distribution at a fraction of a mile, the operation of lamps and motors three miles from the low-tension generating point will appear somewhat in the light of a revelation. Mr. Barstow has certainly proved that station managers need not fear to open up new districts even though for the time being the location of a station in such districts may be unprofitable. Aside from this, however, the introduction of circuits into such districts cannot fail to create such a demand that the erection and operation of a generating station will be called for within comparatively short periods of time.

A LEGAL CONTEST OVER THE HYDROCARBON TREATMENT FOR INCANDESCENT LAMP BURNERS.

THE suit of the United States Electric Lighting Company against the Edison Lamp Company, which has been pending for more than three years and was heard last week before Judge Acheson in Philadelphia, is perhaps second only in importance in its relation to the incandescent lamp industry to the filament case recently decided by Judge Wallace in favor of the Edison Company. The complainant alleges an infringement by the Edison Lamp Co. of a patent granted to it in 1884, as assignee of Edward Weston, covering the process of the hydrocarbon treatment, or "flashing" of the carbon conductors of incandescent lamps, the process which Justice Butt, of the British High Court of Chancery characterized, in his opinion sustaining the Cheesbrough patent as "one of singular beauty and efficacy." The history of this patent is somewhat unusual. In 1878 Sawyer and Man and Hiram S. Maxim filed nearly contemporaneous applications for patents more or less fully describing this process. An interference was instituted, which was terminated in December of that year by an adjudication of the Commissioner of Patents as against Maxim in favor of Sawyer and Man, to whom a patent was accordingly issued, covering the process referred to. In May, 1881, somewhat more than two years after the issue of the Sawyer-Man patent, Weston made application for a patent for the same invention. After a vigorously contested interference, the Commissioner of Patents decided Weston to be the prior inventor as against Sawyer and Man and a patent was accordingly granted to him; being the one on which the present suit is based. Considerable difficulty was experienced by the complainant in its efforts to procure evidence of infringement, resort being finally had to the heroic expedient of summoning certain workmen from the Edison Company's lamp factory and compelling them to testify. The principal points relied upon by the defense were the insufficiency of the evidence in behalf of Weston to establish the fact of the completion of his invention at a date anterior to that of Sawyer and Man; an allegation of public use for two years by Sawyer and Man before the date of Weston's application, and finally that there had been no actual infringement on the part of the defendant;

it being contended that the limited use proven by the witnesses called by the complainant, was merely an experimental and not a commercial use. The case was argued with much ability on both sides, the arguments occupying a greater portion of three days. An abstract of the proceedings is given elsewhere in this issue. It is thought that a decision will be reached within a few weeks.

MEASURING ALTERNATING CURRENTS.

BESIDES the variety of apparatus necessary for its operation, the introduction of the alternating-current system of distribution at once made it necessary to provide instruments for its measurement—not only instruments required for metering the current, but also such as are necessary to obtain instantaneous indications of the condition of the circuits carrying the currents. To produce an instrument of small compass and unvarying accuracy that should indicate currents of all ranges of frequency, and at the same time be capable of indicating equally well for continuous currents, naturally involved such conditions that it is not to be wondered at that considerable time has elapsed before such an instrument can be said to have made its appearance. It is true that instruments of this nature, such as the Cardew, have been employed and not without some degree of success, but we think that a close analysis of this form of instrument will show wherein it possesses points of weakness that make it inferior in action to those instruments embodying the electro-dynamometer principle. The instruments of the latter type, as heretofore constructed, have also had their shortcomings, but we believe that on perusal of the description of the new alternating and continuous current voltmeter of Mr. Weston to be found in another column, our readers will admit that the difficulties have been overcome. The degree to which Mr. Weston has succeeded by the light construction adopted in reducing the current required may rightly be considered a triumph of electrical and mechanical skill, and it is not difficult to discern for his new type of instrument a success even greater than that which his magnetic instruments have attained.

THE WIRING OF BUILDINGS.

ONE of the greatest improvements in electric lighting of late years has been the introduction, through the efforts of Mr. E. H. Johnson, of methods of carrying the wires through buildings in conduits or ducts. This plan seems to us correct and proper from every point of view, and we believe the time is near at hand when all interior wires will have to be run through conduits. Laws, ordinances and insurance regulations are all tending to this end, and the rapid extension of incandescent lighting in residences and office buildings has already won over public approval to methods that save the plaster or decorations and that leave the wires accessible. It is this state of affairs that gives importance to the plainspoken discussion of the subject in our columns this week by Mr. Augustus Noll, who was one of the first men in the country to do wiring work, and who is to-day a warm advocate of "piping the wires." It will be seen that Mr. Noll offers some sharp criticisms on devices and apparatus now very popular in the market, and makes some rather surprising statements in support of his claims.

DEALING WITH THE "MUNICIPAL PLANT" CRAZE.

EVERY now and then a town gets the idea that it wants an electric lighting plant of its own. Sometimes the idea is carried out at the expense of the taxpayers, and generally the local company has a hard time of it. An incident that has recently come under our notice shows that, when it will, the local company can protect itself very effectually against these attacks. In a New England city a few followers of Bellamy wanted to adopt municipal lighting, and gained the public ear. The president of the company did all he could to stem the tide of "opinion," but of course he was "prejudiced." He then bethought himself of the papers and articles prepared by Mr. Allen R. Foote and others, showing the true figures of municipal lighting, and had copies sent to 40 or 50 of the citizens. The result was gratifying. To use the language of the president: "We educated the gentlemen in question to such an extent that they made it unanimous. * * * At any rate, some of our National brethren are laid on the shelf for three years." We would recommend a similar line of procedure to others among our electric lighting friends who are passing through this kind of ordeal. The pamphlets cost very little, and can be readily obtained from Mr. Foote and the National Electric Light Association. The results will be very gratifying in any intelligent community.

Underground Rapid Transit.

THE public interest in underground rapid transit for this city was remarkably shown at the dinner of the Commonwealth Club last week, when Mr. Simon Sterne, supported by Mr. Frank J. Sprague and others, made a cogent and forcible exposition of the merits of the Greathead system and of the manner in which heavy electric locomotives had succeeded in London. A large gathering of business and professional men not only heard the arguments with interest but greeted every point with significant applause. Nothing could have been more vigorous than the approval that accompanied Mr. Sprague's statement as to the ability of electric motors to haul the heaviest loads, and his characterization of the criticisms on their assumed inadequacy as puerile and beneath serious consideration. They who know what electric motors are doing will agree with him. The range of the electric motor is greater than that of the steam locomotive, and it certainly does not lose in efficiency as it gains in size.

A New Departure in Telephone Transmitters.

THE recent issue of the Berliner microphone patent, the long-pending application for which has been the occasion of so much curiosity, speculation and criticism, lends peculiar interest to new developments in telephone invention. Mr. Charles Cuttriss's description of his new transmitter, printed elsewhere in this issue, will be found suggestive. A very interesting feature is the absence of electrodes; a characteristic which would seem to differentiate the instrument materially from the usual types.

THE WESTON DIRECT READING ALTERNATING AND CONTINUOUS CURRENT VOLTMETER.

The modern applications of electricity have called for the invention and perfection of many auxiliary devices as safeguards to the circuits carrying the current and also of apparatus for ascertaining the condition of the circuit at all times. Among the latter, the various types of measuring instruments, such as ammeters and voltmeters, have deservedly been the object of much study by many eminent electricians, with the result that the forms which have been devised are only limited by the number of phenomena which may be employed to indicate the presence of an electric current. But apparatus intended for the purpose of affording indications of the condition of electrical circuits, in order to possess value, must be so designed and constructed and embody such principles of action as will permit its indications to be practically constant under all conditions of fair use, and continue so for an indefinite period.

Realizing these important factors, Mr. Edward Weston several years ago invented a type of measuring instrument which embodied in its construction a permanent magnet and a movable coil, which moved in the gap included between the poles of the field magnet and a soft-iron core. This combination formed practically a closed magnetic circuit, which experience has proven to be practically absolutely permanent in its nature. In proof of this we need only cite an experiment which we saw performed and which was as follows: A continuous current voltmeter of the Weston type was attached to a circuit reading 100 volts, and by bringing a magnet in contact with the poles of the magnet of the instrument itself, so that the *N* and *S* poles respectively came in contact, the reading of the instrument was changed from 100 to 22. The magnets were then struck repeated blows with a hammer in order to facilitate any change which might take place in the condition of the magnet of the instrument. The auxiliary magnet was then withdrawn, whereupon the needle resumed its original indication of 100 volts within one-tenth of a division, proving practically that no sensible change had taken place in the condition of the magnet.

The experiment was then tried of increasing the strength of the instrument magnet by placing the *N* pole of the auxiliary magnet in contact with the *N* pole of the instrument magnet, both *S* poles also being in contact. The increase in the field thus brought about served to throw the index off the scale. The shocking of the magnets was then repeated, but, upon withdrawal of the disturbing magnet, the index resumed its first position within less than one-tenth of a division. A more crucial test could not be devised to show the permanency of the magnets employed by Mr. Weston in his well-known type of instrument. Indeed, Mr. Weston goes even so far as to place greater reliance in his instruments than in the tangent galvanometer, owing to the fact that the latter changes its indications with every change in the intensity of the earth's magnetism; whereas his instruments, when standardized, have proved their stability, entirely independent, of course, of all except the most powerful external magnetic influences.

With this success gained in the field of continuous-current instruments, Mr. Weston proposed to himself the problem of constructing an instrument of like accuracy and permanency which could be used equally well on circuits carrying either alternating or continuous currents. Those who have had experience in the measurement of alternating currents, will readily concede that the task undertaken by Mr. Weston was one of no mean proportions, but that, on the contrary, its successful solution might well demand the highest ingenuity, not only in the application of electrical principles, but also in the exercise of mechanical skill, in order to make such an instrument an everday working tool for electricians.

In casting about for the best principle upon which to construct such an instrument, Mr. Weston, after much thought, turned to the application of the principle embodied in the electro-dynamometer, that is, a fixed coil acting on a movable coil; but the mere selection of this principle by no means gave the solution of the problem. It must be evident that in order to be equally applicable to both continuous and alternating currents, the instrument must have practically no self-induction. How to obtain this condition with coils carrying alternating currents may be said to have been the problem solved by Mr. Weston. Starting with the fact that the self-induction of such a system depends primarily upon the strength of the current and the number of turns in the coils, Mr. Weston at once set himself the task of reducing the current required to operate the instrument to the smallest possible amount. The corollary to this was, to construct the instrument so that its moving parts should have the least possible weight, and that the friction should be reduced so as to make the instrument as sensitive as possible. To what degree Mr. Weston has succeeded in fulfilling these conditions will be apparent when we state that the moving coil, pointer, springs and pivots of the new instrument weigh together only 31 grains, that is, less than one-fourteenth of an ounce.

The new instrument is shown in two types in the accompanying engravings, Figs. 1 and 2, which represent, respectively, the double and single scale instruments.

FIG. 1.—WESTON DOUBLE SCALE ALTERNATING AND CONTINUOUS CURRENT VOLTMETER.

The most essential part of the instrument, of course, is the system of fixed and movable coils, the latter being shown enlarged in Fig. 3. The movable coil consists of copper wire .002 inch in diameter, the fineness of which can be judged from the fact that the average human hair is .00225 inch. The diameter of the coil is 1¼ inch, and it is wound so that it presents a ⅛ inch square section, consisting of 525 turns. As the proximity of any considerable quantity of metal near the coils would introduce disturbing factors, it became necessary to avoid the use of a supporting spool for the wire of the movable coil, which upon trial, was found to be quite stiff enough without a spool. The pivots upon which the coil turns are attached to it by means of small aluminum plates, which are first cemented to the coil and then wound with silk thread. The pivots consist of hardened steel, which are ground to gauge and polished. The entire movable system, as stated above, does not exceed 31 grains in weight.

It might be urged that the weight of the coil could have been still further reduced by the employment of aluminum wire, and this, as a matter of course, also suggested itself to Mr. Weston. Indeed his first instruments actually embodied aluminum wire coils, but it was found that aluminum could not be drawn practically below .005 or .006 of an inch, although Mr. Weston himself has, with great care, succeeded in drawing it down to .00325 ; but as a still finer wire was needed in order to meet the requirements of the case, Mr. Weston was obliged to fall back upon copper, aluminum being employed wherever possible in the other parts of the movable system. It will be noted that the coil is balanced practically for all positions, in the same manner as a watch balance, and, as in the magnet type of Mr. Weston's instruments, acts against the force of very delicate springs which also serve to carry the current to and from the coil.

It will also be noticed that the coil is provided at its lower end with a disc which constitutes part of the friction device provided for the purpose of damping the instrument. It will be evident that, as above stated, the placing of any metal near the coils to effect damping would cause injurious reactions. In the same manner magnetic damping was not permissible as it would cause the indications to differ with the rate of frequency of the alternating current ; hence it became necessary to control the instrument by mechanical means in order to bring the parts quickly to rest. The brake in the instrument illustrated is combined with the contact-key shown as the hard rubber knob in Figs. 1 and 2. The brake normally presses against the disc and holds the moving parts rigid. When the key is depressed the current is first turned on and then the friction is gradually reduced just sufficiently to allow the coil to gradually move along until, by the time the key is fully depressed, it has reached the position due to the action of the current and indicates the proper reading on the scale. Thus while the instrument in itself is not dead-beat, the means provided by the brake allow readings to be taken nearly as quickly as with a dead-beat instrument.

The stationary coil which surrounds the movable one just described, consists of wire .003 inch in diameter, the number of turns of which is as small as possible compatible with securing the necessary field of force, the coil being wound on a very thin, hard rubber shell. The amount of current needed to move the index across the entire scale differs somewhat in the various ranges made, varying from .02 to .056 of an ampere in the two-scale instrument, with the lower scale reading to 60 volts and the upper to 120. The resistance of the instruments averages for 60 volts about 1,100 ohms, and for 120 volts about 2,200 ohms.

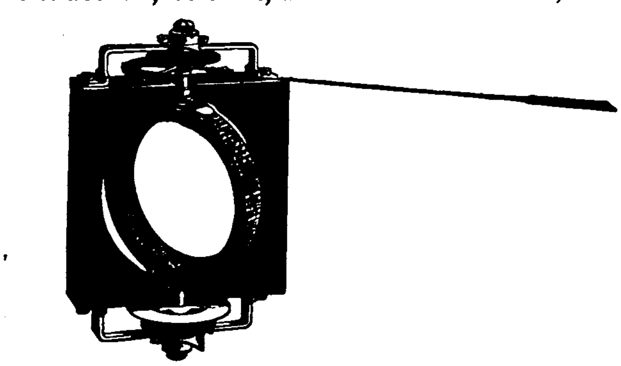

FIG. 3—MOVABLE SYSTEM OF WESTON ALTERNATING AND CONTINUOUS CURRENT VOLTMETER.

In single-scale instruments the resistance is generally much higher and the current lower. The principal resistance is in the form of a non-inductive resistance coil outside of the operative system, which is placed in series with the latter, the movable and fixed coils also being in series.

Not the least important part of the instrument is the means afforded by it, of obtaining correct readings at all ranges of working temperature. It is a common practice of instrument makers to attach to their instruments a table, giving the temperature corrections, based merely on the changes in the resistance of the copper coils in the instruments ; but it by no means follows, as will be presently shown, that such corrections will give accurate results, and, that, indeed, the indications may vary very largely from the truth when so corrected. While it is true that an increase in temperature of 5 degrees F., for instance, increases the resistance of copper by about 1 per cent., a like change of temperature in the magnetic system of an instrument, may cause changes which may be either positive or negative in their nature, according to the type of in-

FIG. 2.—WESTON SINGLE SCALE ALTERNATING AND CONTINUOUS CURRENT VOLTMETER.

strument. In Mr. Weston's magnetic voltmeters the relationship is such that the increased resistance due to increased temperature in the wire, is almost exactly counterbalanced by an increase in the magnetic system, due to elevation of temperature. Consequently the instrument itself compensates almost perfectly for the change in resistance of its coil, due to changes in temperature. The new alternating current instrument has decided the fact that it was impracticable to compensate directly for both of these sources of error; but there is added a thermometer, the bulb of which extends over and comes in contact with the coils and is so flattened and contains such a small amount of mercury so as to give quick response to the slight changes in temperature of the coil. The stem of the thermometer is placed below the glass cover and can be easily read.

The compensation for changes in temperature is provided for by means of a minute rheostat shown at the right-hand corner of the instrument, which has a dial graduated into 20 parts, each indicating a change of 2½ degrees F., and the whole extending between 60 and 100 degrees F. This provides for a change in temperature of 50 degrees, which is sufficient for all practical purposes. To compensate for temperature, therefore, it is only necessary to note the reading on the thermometer and to turn the pointer of the rheostat to the mark corresponding to the temperature indicated by the thermometer. The actual changes in the resistance due to temperature are small, as a large proportion of the resistance is German silver, less than $\frac{1}{10}$ of it being of copper.

A question which many will ask regarding the instrument is, Will the indications vary with currents of different number of alternations? The practical elimination of the effects of self-induction, as described above, is the best answer to this question. Experiment has shown that no difference can be detected in the readings of this instrument between a perfectly continuous current and one varying from that up to 300 alternations per second, a range covering all practical systems of electrical distribution in use at the present time, and proving the instrument to be practically without self-induction.

It is interesting, as showing the marvelous delicacy and accuracy of the instrument, to note that a weight of .4 of a gram, about six grains, acting on the movable system at a radius of half an inch, will cause the index to move entirely across the scale, and, as the instrument is sufficiently sensitive to indicate $\frac{1}{1000}$ of the whole scale, it will indicate to the $\frac{1}{1000}$ part of .4 gramme, that is, .4 of a milligramme, or about $\frac{6}{1000}$ of a grain. Indeed it has been suggested that the instrument might be used as a delicate balance. Of course such a result can only be obtained by the reduction of all the moving parts to the smallest possible mass and by very excellent workmanship. As Mr. Weston correctly argues, lightness is necessary not only for accuracy in an instrument, but its very life is dependent on it, as lightness means reduced friction and wear on the pivots under ordinary use as well as that from shocks to which portable instruments are inevitably subjected. In the type of instrument shown in Fig. 1, it will be noted two scales are provided, the upper reading up to 120 volts and the lower to 60. In this way accurate readings can be obtained over both ranges. Instruments are now made which have a range as low as 20 volts with full-scale deflection, and others requiring 5,000 volts for the full-scale deflection. A large variety of intermediate ranges are also made.

It is almost needless to remark that the instrument is characterized by that beauty of design and fineness of work common to all Mr. Weston's work. No detail seems to have escaped his attention and the whole instrument evidently has had every care and attention given to it, to make it eminently suited for the work to be done. The instrument has been under close examination and test for several years, and as now constructed may be considered standard in type and free from all elements tending to introduce error.

IS ACTINISM A SPECIES OF ELECTROLYSIS?[1]

BY PROF. E. J. HOUSTON.

I DESIRE in the present paper briefly to call attention to another probable source of difference of electric potential, that may still further mask or render difficult of detection the differences of potential existing naturally in growing plants. Before doing this, however, I will briefly review some of the more important causes which produce differences of potential in growing plants. The principal of these are as follows, namely:

(1) Various chemical processes that occur in the cell walls of the growing plant. (2) Molecular movements of liquids throughout the plant, which result in the production of diaphragm currents. These molecular movements may either be those caused during the growth of the plant, or may be caused by the mere bending of the plant by the wind, or other cause external to the plant. (3) Differences of potential developed in plants which would result in currents of the general character of the demarcation currents observed in animals; that is currents due to the chemical action of the various liquid materials exuded at the surfaces of injured or abnormal plant tissue. (4) Differences of potential due to the evaporation of moisture from the surfaces of the leaves, derived either from the rain or dew, or from the evaporation of liquid substances given off from the body of the plant. (5) Differences of potential arising from the electrolytic decomposition of carbonic acid, or the various forms which carbonic acid derivatives assume during assimilation.

The causes above enumerated refer to the differences of potential that have their seat in the structure of the plant itself. Another source of differences of potential is to be found in the differences of electric potential that generally exist between the atmosphere that surrounds the plant and the earth or soil in which it grows. These differences of potential being neutralized in the various parts of the plant itself, would, of course, result in the production of electrical currents.

I desire to call special attention to the fifth head under which I have classed differences of electric potential in plants, viz., those arising from the electrolytic decomposition of the various oxygenated carbon compounds derived mainly, if not entirely, from the carbonic acid of the atmosphere. The decomposition in the leaf under the action of sunlight, and the carbonic acid, or its derivative compounds, probably partakes of the nature of electrolytic decomposition. In this direction I would suggest the following lines of investigation, namely:

(1) To ascertain experimentally whether there exists on the opposite faces of a growing leaf, when exposed to the full action of sunshine, a difference of electric potential resulting from the polarization which always accompanies electrolytic decomposition; and if it be so, what is the nature of such polarization. If such differences of potential actually exist, it would of course follow that the illumined face of such leaves, under polarization, would be mainly electro-negative, since it is at or near this face that the carbon and less highly oxidized carbon compounds appear, while the dark or less illumined face would be electro-positive, since it it is here, for the greater part, that the oxygen is liberated. (2) Whether electrodes suitably connected to the opposite faces of a growing leaf in the presence of sunshine will show the presence of an electric current arising from an equalization of the difference of electric potential. (3) Whether a suitable leaf-battery could not be devised by connecting, in alternate succession, the opposite faces of a series of leaves on a plant-stalk. (4) A comparison of the effects of sunlight and artificial light, such as the electric light, on such electrolytic decompositions. (5) Whether any differences exist in the case of the light produced by an alternating-current arc light and that produced by a constant-current arc light. (6) Supposing the presence of the differences of electric potential due to the electrolytic decomposition to be established, and the direction of the electric currents so produced, known, to ascertain whether an electric current led through the plant in the same direction as the current produced by actinism would not tend to increase the assimilation and the subsequent growth of the plant; and, whether, on the contrary, an electric current sent in the opposite direction through the growing leaf would not tend to check such assimilation of growth. (7) To ascertain experimentally whether the converse of the proposition is true, namely, whether an electric current of approximately the same strength as that produced by actinism, when sent through the leaf in the opposite direction, would not result in the production of luminous phenomena in the leaf.

The following facts, well recognized in botany, would seem to show, to some extent, at least, the presence of a species of polarization in certain plants during active growth in sunshine. In the case of those plants which bend or become concave on the side the most exposed to light: This curvature is due to the fact that a smaller growth occurs on the illumined than on the dark side. This is well recognized in botany, and such plants are called in general *heliotropic* plants.

In the case of plants that turn toward the sun: It is a well-known fact that some plants turn toward the light. It is possible that this motion is in some manner the result of the polarization effected during growth by the sunlight. In a series of experiments concerning the effects of the electric light on plant growth made at the Experimental Station of Agriculture of the Cornell University, some important facts were discovered concerning electric plant-culture.[1] These experiments seem to show that electric light promotes plant assimilation, and sometimes hastens plant growth and therefore maturity.

The Cornell experiments made during 1889 and 1890 were with the light of a constant-current Brush arc lamp. Those made during 1891 were with the light of a Westinghouse alternating current arc lamp. It would seem to be a matter of considerable interest in the case of these experiments to ascertain definitely whether any marked differences exist between the action of the light produced by a steady current and that produced by an alternating current. In the line of investigations here suggested it would of course seem as if the electric decomposition would be less marked in the case of the light produced by an alternating current than that produced by a steady current. And that therefore in those cases where the electric light of the steady current had proved to be injurious to the growth and assimilation of the plants, that with the alternating-current light such injurious effects should be less marked.

MR. GEORGE PORTER has entered upon the duties of secretary of the National Electric Light Association, vice Mr. Beane, resigned. The new secretary has already done good work for the association in bygone years, showing himself unsurpassed as chairman of the transportation committee.

1. Abstract of a paper read before the Electrical Section of the Franklin Institute.

1. See THE ELECTRICAL ENGINEER, Oct. 14, 1891.

THE DISCUSSION OF GOVERNMENT TELEGRAPHS AT THE ELECTRIC CLUB.

THE lecture on the "Government Telegraphs of Europe," by Mr. E. Rosewater, editor of the *Omaha Bee*, printed in THE ELECTRICAL ENGINEER last week, was followed up by a very brisk discussion.

MR. ROSEWATER added the following: Before concluding I want to say that in advocating the transformation of our system of telegraph to the postal system, I have no personal interest whatever beyond that of a citizen of the United States. I have no grievance against any telegraph official. I am on the very best of terms with all the Western Union officials so far as I know, and with the Postal Telegraph officials. I have always been on good terms with them. The paper of which I own the greater part is a member of the Associated Press. We have leased wires and pay the Western Union probably from fifteen to twenty thousand dollars a year for special service; so that I have no grievance whatever, personal or political. I have nothing to redress. But for more than twenty-five years I have been convinced that sooner or later the Government, as a matter of military necessity and as a matter of commercial necessity and in the interest of the social intercourse of the common people of the United States must own the telegraph and operate it; and this conclusion all disinterested parties must reach when they examine impartially the figures and the records that are presented by the reports of the Western Union Telegraph Company and other companies of this country, and the reports that have been made abroad by the different governmental postal telegraph officials. There is no doubt whatever that our wire system is enormously overloaded. We have more wires than we need, and we have them in the wrong place, and we do not serve one-half the people with telegraphic facilities that ought to have them and at a lower price than they now are; and we cannot lower the prices so long as the present system prevails. Competition is always followed by combinations, and one company springs up and declares, like all the newspapers that spring up, that they are here to stay, but in a short time they are swallowed by the great American anaconda. I do not blame the anaconda for swallowing them, but they are not very desirable morsels. As a matter of fact they have congested the anaconda very badly. (Laughter). But it is one of those laws of necessity. Now, how much longer is this to continue? The present telegraphic system of this country is stocked for about $100,000,000—a little more than that. Upon that the people of the United States, the patrons of these telegraphs are paying, independent of the excessive cost of maintaining and operating six million or more dollars as dividends. Now six million dollars on the British basis or upon the basis that we can establish, for our credit is just as good as that of Great Britain, represents a capitalization of $200,000,000, and we could better afford to-day to pay $200,000,000 for the American telegraph systems and place them under the control of the Government, than we can to continue this system and keep on like a snowball, rolling and rolling and enlarging and making it utterly impossible in the future to deal with the problem that must sooner or later meet us again.

I speak specially of the problem of handling telegraph dispatches during time of war. It is all well in time of peace. But those who have been where I was during the Rebellion, realize, perhaps as fully as any one can, that a Government that does not control the arteries of communication and the system which is equivalent to the nervous system of the body cannot possibly sustain itself in time of war without serious disaster and without an enormous increase of expenses and a prolongation of the war costing millions of dollars and many hundreds of thousands of lives. I have said it and I can repeat it to-night that I am fully convinced if the Government of the United States had owned the wires at the outbreak of the Rebellion in 1861, the war would not have lasted more than two years. But I cannot digress in this way now, and I will leave it to other gentlemen, for I would like to have this matter thoroughly discussed. There are two sides to it, as has been said before, and I would be pleased to hear from those who differ with me on this question.

MR. ERASTUS WIMAN, who presided, while complimenting Mr. Rosewater on his address, failed to see much of an argument in it for government telegraphs. He said: "It has always been a matter of surprise to me that those who say that the Government should go into any business should want to have it go into electricity. It seems to me it would be better to go into oil. If the Government wants to do the people good and exercise paternalism over them, oil would be very much more adapted to its purpose. The objection against the present system of telegraphy is that it is a monopoly. It is not nearly the monopoly that oil is. There is a great deal more monopoly to-day in the Standard Oil Company than there is in the Western Union Company. There is only one oil company and there are 40 telegraph companies. A man can go to Wall street and buy a share at about 80 or 83 in the Western Union Company. To save his soul he cannot buy a share in the Standard Oil Company. Any man for $80 can know everything about the Western Union Company—exactly what the officers receive and every other detail. But I defy anybody under the sun, except the syndicate of the Standard Oil Company, to discover the details of the operations of that company. How many per cent. of the people do you suppose are affected by the telegraph? It is a fact that not three per cent. of the population of the United States use the telegraph; while I believe 97 per cent. use oil."

Mr. Wiman then called attention to the shortcomings of various government departments, and drew the inference that telegraphs would fare no better. Moreover, so long as the principle "To the victors, the spoils," prevailed, there would not be any safety in government service during times of great political excitement.

MR. A. R. FOOTE—Mr. Chairman and gentlemen, I think Mr. Rosewater and Mr. Wiman have both lost sight of the fact that whoever operates the telegraph, whether it is a private corporation or the government, people must be employed to do the work. Those people in this country are bound to be politicians. Members of the different political parties have operated the telegraph for a long time but there has never been a complaint from any political party that it was badly treated under the present system. How they will get along under government ownership I do not know.

Mr. Rosewater closed his paper with a statement that it is necessary for the safety of this country that the Government shall own the telegraph. We have supposed that it was necessary for the safety of this country that the Government should own its army. When the civil war broke out in 1861, the men who were loyal handled the telegraph keys loyally. The men who were disloyal did the other thing. We had in our government men whom we had educated at West Point, and one of them became the President of the Southern Confederacy. The Government owned West Point then and owns it yet. If government ownership were a security against disloyalty, there should have been no disloyal men in the Southern army who were educated at West Point. Will Mr. Rosewater say to this audience or to the Association of Old Time Telegraphers, or to the Military Telegraphers' Association that the service was not safe in their hands during the war? Was not that service well and loyally done?

Mr. Rosewater paid a compliment to the operators in America by saying that one American operator does about twice the work that an English operator will do—two to one. My observation of the way clerks work in the city of Washington and the way they work in your private business offices leads me to believe that the clerks employed in private business do twice the work of clerks employed by the Government in Washington—two to one. I do not see in this any reason why the Government should own the telegraph.

I understood Mr. Rosewater to say that the countries in Europe where the government owns the telegraph are as quick to take up inventions and utilize them as they are in this country. I understood him also to say that in three out of the four countries he visited, messages are received by the recording Morse instrument; that the only exception was England were they work by sound.

If Mr. Rosewater stated to the audience how many post offices there are in England and how many telegraph offices there are I did not hear him.

MR. ROSEWATER—If you will allow me to answer you and give me a little time after you have concluded, I will give you all the information you want.

MR. FOOTE—The public are under the impression that a postal telegraph system means a telegraph office at each post office. That is the impression given out. According to the best statistics I can get, such is not the case in England. In England in 1889 there were 17,829 post offices and 7,021 telegraph offices, being one telegraph office for every two and-a-half post offices. In the United States for 1891—these statistics are from the *World* Almanac—there are 66,000 post offices and 25,591 telegraph offices, being one telegraph office to every two and one-twelfth post offices. The percentage of telegraph offices to post offices in this country is a little greater than it is in England.

In England the increase in the number of telegraph offices for two years from 1887 to 1889 was 517. There were 6,514 offices in 1887 and 7,031 in 1889. In the United States the increase in telegraph offices for the same time was 3,116. There were 15,876 offices in 1887 and 18,992 in 1889. The increase for England on 6,514 offices is but 8 per cent., while the increase for the United States on 15,876 offices is about 20 per cent. The increase for the United States, 3,116 offices, on the number of offices in England is nearly 48 per cent. against the English increase of but 8 per cent.

Mr. Rosewater did say that we have too many wires and that the country is doing about one-half the business it ought to do. We may look for an explanation in a comparison of telegraph offices with population and area. In England, taking the census of 1881 and adding 10 per cent. to it, to bring it up to date, there is one telegraph office for every 5,500 population. In the United States there is one telegraph office for every 2,400 population. I wonder why Mr. Rosewater did not stay in England and get the people to extend the benefits of the telegraph so that they might be served in equal proportion to population with the United States.

The size of the country has something to do with the problem.

In England there is one telegraph office to 17.27 square miles. In the United States there is one telegraph office to 131 square miles.

The population to the square mile has something to do with the problem. In England the population is 320 to one square mile. In the United States 17.93 to one square mile.

The area and population to telegraph offices compare as follows:

England, area 17.27 square miles, population 5,526.

United States, area 131 square miles, population 2,349.

A short time ago it became my duty to formulate a schedule for collecting the statistics of telegraph companies for the Eleventh Census of the United States. In a certain report which I called for, the telegraph companies wanted to enter commercial news messages, press messages, etc., I said no; what I want is a report that will show what the farmers and wage-workers of this country are paying for the service you are rendering in comparison with what the same class of people pay for the service rendered them by governments that own and operate the telegraph systems in foreign countries. For this reason I would admit to the report full rate, night-rate and money transfer messages only, and at the rate now being paid over the counter by any one who may have occasion to use the telegraph. I have made up the figures for 8,358 full-rate messages, 614 night-rate messages, and 6 money transfer messages. I find that these messages contained 195,914 words, counting all words in the address, body and signature of the message, making an average of 21.82 words per message. The reason for counting the words in this way is that the governments owning and operating telegraphs count and charge for every word transmitted. The tolls paid for these messages average 41¼ cents each. The English rate would be 21 cents each. On the face of the showing thus far made it appears that the rate in this country is double that of England. I find, however, that the average mileage of these messages was 540 miles, and the average distance from New York to the places to which they were sent is 603 miles. On account of distance the office transmitting 8,978 messages repeated over 11,000 messages in the same period of time. As the greatest distance in England is not over 600 miles it is reasonable to assume that the average mileage of 8,978 messages sent out from London will not exceed one-half the average mileage of the messages sent out from New York. Therefore, messages from New York averaging 540 miles at 41¼ cents each are as cheap as messages from London averaging one-half the distance at 21 cents each. This, however, is not the whole story. These messages were sent at the rate given in any direction desired from New York. England is not large enough to make a comparison with the United States. We are compelled to take Europe for such a purpose. If a citizen of London wishes to send a message five or six hundred miles in any direction it must go into other countries, as the American citizen's message goes, from State to State. Let this be tried and then make a comparison of European rates with United States rates.

Rate from New York on 8,978 messages averaging 21.82 words and 540 miles is 41¼ cents each.

Rate from London for a message of 21.82 words, distance 600 miles:

To Sweden	$1.74.	U. S. rate same distance	41¼c.
" Norway	1.52.	" " " "	41¼c.
" Germany	1.30.	" " " "	41¼c.
" Austria	1.52.	" " " "	41¼c.
" Corsica Isles	.87.	" " " "	41¼c.
" Spain	1.74.	" " " "	41¼c.

I suppose this explains why so many people come to this country. It must be to enjoy the privilege of telegraphing a long distance at the low price charged by our grinding monopolies. (Applause and laughter.)

I do not know whether Mr. Rosewater can be said to be the representative of the Postmaster General or not; but I do know that we can judge of the kind of advice that the Postmaster-General has received on telegraph matters by his official utterances. Here is an official circular dated June 15th, 1891, fixing the rate for Government messages, 10 words exclusive of place from, date, address and signature, at 10 cents to all distances up to 400 miles. As the message actually counts 20 words, this is 10 cents for 20 words for 400 miles. Half a cent a word is allowed for each additional word. I would like to have Mr. Rosewater state, if he will, whether he believes that a charge of one-half a cent a word will pay the expense of doing the business over a distance of 400 miles? On June 29th, 1889, the Postmaster General issued an order fixing the rate at one mill a word irrespective of distance for all messages day and night. If one mill a word for all distances day and night, was a fair and honest compensation in 1889, I would like to know what has increased the cost of telegraph service to bring it up to half a cent a word for 400 miles in 1891?

I am somewhat disappointed that Mr. Rosewater told us so much about the detail of the mechanism of the telegraph and so little of the argument in favor of government ownership. I am not clear from what he has stated whether he meant to advocate government ownership or government control. There is a broad difference between the two. Not knowing what Mr. Rosewater was to say this evening I have brought here a reported interview with him. I do not know whether he will object to my commenting on what is in that interview or not.

Mr. Rosewater—I never heard of the interview. If they have an interview with me; that is all right. I will say that about three weeks ago Miss Kate Field called on me and wanted to have an interview for her paper. I stated that my time was too much occupied in the commission in which we were engaged and advised her to read the testimony that I had given before the Post Office Committee, and said that whatever other matter she wanted she could ask me for. She never came back but she carried off the little pamphlet and copied it *verbatim et literatim* into the paper. If that is the matter, why it is a very stale piece of news.

Mr. Foote—I suppose it is correct?

Mr. Rosewater—Oh, it is correct. If it is what I testified before the committee.

Mr Foote—That is the main point. We do not care how old it is if it is true. Truth never dies.

There is one point in this Kate Field article to which I wish to refer and Mr. Rosewater can easily set himself right if he is wrongly reported. He says here: "I would buy out all the telegraph lines in America and then advertise for proposals and have them operated by private companies under the control of the Government, fixing the rates and requiring them to report their earnings from time to time to the Government. When the receipts exceeded 10 per cent. upon the invested capital, their investment being rather small, I should insist upon their reducing the rate." I suppose he means dividends instead of receipts. To give an idea of what Mr. Rosewater considers a small capital, he is reported here as saying that when the Government turned over the military lines to private companies, Feb. 27, 1866, it owned 41,211 miles of land line and 178 miles of submarine cable. I understand that to mean miles of wire instead of miles of line. He is reported to have said that the property was worth $2,000,000 to $3,000,000. Was it miles of line or miles of wire?

Mr. Rosewater—I presume it is miles of wire.

Mr. Foote—Assuming that Mr. Rosewater means miles of wire and that he will probably agree that the true valuation would be the average between his extremes, the statement may be construed to mean that the Government owned 14,389 miles of wire worth $2,500,000 or about $174 per mile. At this rate the present valuation of the combined mileage of the Western Union and Postal Telegraph Companies is $138,332,834. Now if the military telegraph lines were worth $174 a mile it is fair to presume that the lines that are now working commercially are worth as much. The capitalization of these companies, however, does not begin to reach the value given by Mr. Rosewater. This may be where the watered stock is to come in. I am of the opinion that if Mr. Rosewater can induce the Government so to fix rates that the companies can earn 10 per cent. on this valuation that they will give him an exclusive contract to attend to their stock-watering hereafter. Government ownership is advocated by Mr. Rosewater as a principle. In my opinion the principle is radically wrong. It is opposed, as I understand the matter, to the underlying fundamental natural laws that govern all human actions. When you separate a man from any direct interest in his work or any hope of having any direct interest in his work, you separate that man from the most active elements that can induce him to be thrifty, saving, progressive, observing and careful in every thing he does. I do not suppose that any of you gentlemen will admit for one moment that there has ever been a work undertaken by government that has been executed at anything like the cost it could have been by private parties. A gentleman with whom I was conversing in Boston not long ago—a very competent engineer—observing the work on Government buildings, forts and arsenals, etc., said that he did not believe that, with two or three exceptions, in these United States there had been one single instance where a Government building had been put up at any thing like the cost it would have been erected by private parties. He estimated that the excess of cost was at least 100 per cent. In other words that it cost the Government twice as much to do the work as it would private parties. Assuming for the sake of the argument that the capitalization of these telegraph companies can be agreed upon; they have accepted a law passed by Congress in 1866 which defines the way in which the Government can acquire possession of their property. If the capitalization is agreed upon and the interest on the capital is fixed at the same rate that the Government pays on its bonds the capital question will be out of the way. Then comes the question of maintenance and operating expenses. I do not think that any one will suppose for an instant that such expenses, operating under government ownership in this country would come anywhere within the limits that they do under private management. I do not think that 20 per cent. difference would be too large a margin to allow for the difference in effective management. Therefore, I assume that the telegraphs of this country, operated under private management, doing a business at the same rate that it would cost the Government to do the business could pay at least a 10 per cent. dividend and at the same time be furnishing the service at what the ordinary politician calls cost—which is what it would cost the Government.

The absence of statistics for all these details is the weak point in the argument. When we do not have statistics which both sides can agree upon as being true and accurate we cannot follow our arguments to their legitimate conclusions. I have under my hands the work of obtaining these statistics from the telegraph companies in the United States. That work will be accomplished in the course of time provided the Government will furnish the funds to do the work. It is now practically at a standstill. Those of you who want to have the statistics will have to assist in getting the appropriation. (Applause).

PRESIDENT INSULL thought that Mr. Wiman must be drawing his political conclusions from Canadian experience. As to the work in England, he would draw attention to the fact that the government authorities there had put their telegraph wires underground while the American companies were saying that it could not be done. Moreover, the high rates that prevailed in this country were not such as to help in building up new sections, such as the Northwest, where a pioneer would be taxed not 12 cents for 12 words, but 13 cents for a single word. "The great advantage of the government administration of telegraphs more especially in England, where I have had some experience, is that if you are in the smallest village where there is transmitted but one message a day, you pay exactly the same rate as you would in a larger city, and the business man there has the same opportunity to develop his business that the man has who lives in a large centre of population." Mr. Insull pointed out that Mr. Foote's figures as to the number of American offices overlooked the fact that many of the offices he counted were useless and unnecessary duplicates, provided by competing systems. He had no very decided views on the subject, but saw no reason that the same control could not be exercised over the telegraphs that was exercised over the railroads. Such control would undoubtedly inure to the advantage of those who sent telegrams. As to the difference in speed of operating, Mr. Insull thought that atmospheric conditions had a good deal to do with the lower efficiency in England and Europe.

MR. ROSEWATER.—I happen to have with me a few figures that I made up to-day from the official book in the German language, by the Austrian Government, giving a full account of all European postal facilities and telegraphic facilities, and I find this to be the fact that in Great Britain the number of post offices by the last report of the Postmaster General was 18,359, the number of telegraph stations 7,627. That is for the year 1890. I have a report with estimates for 1892.

MR. INSULL—Would not those figures include the stations they have for the reception of packages?

MR. ROSEWATER—I want to show you the reason why they do not have so many telegraph stations; inasmuch as they receive telegrams at all post offices, they do not require so many telegraph stations. They have only 5,912 postal telegraph offices and 1,715 railroad telegraph offices in Great Britain. France is the only country in Europe probably, and perhaps in the world, that has more telegraph offices than post offices. She has 7,026 post offices, and 9,498 telegraph offices, of which 6,086 are postal and 3,412 are railroad. Austria has 18,017 post offices and 10,806 telegraph offices, of which 5,311 are postal and 5,495 are railroad. Germany has the largest postal telegraph system in Europe; she has 21,212 post offices and 16,408 telegraph offices, of which 12,431 are postal and 3,977 railroad. Now computing the whole thing what do we see? In all these four great countries the total number of post offices is 64,614 and the number of telegraph stations 44,339. You notice that there are nearly two-thirds as many telegraph stations as post offices, and notwithstanding Mr. Foote's statistics I would venture to say that he is entirely mistaken, unless Dr. Green gave wrong figures to the Government last winter. According to Dr. Green there are eighteen thousand some six hundred telegraph stations in America, including all the railroad offices, and to the best of my knowledge the number of post offices is about 60,000 or 61,000. Now we have over sixty thousand post offices and only 18,600 and some odd telegraph offices, and of these you find that the telegraph companies have got less than 5,000. All the telegraph companies have got less than 5,000 telegraph offices and the balance are all railroad offices. Now just compare those countries and see what an absurdity. This is a striking argument it seems to me in favor of postal telegraphy because it enables the people in the smaller towns and villages to get the facilities of the telegraph, and while my friend here says that there are only a few clodhoppers out in the West that are entirely cut-off, it seems to me that every citizen of the United States is as good as every other citizen and it doesn't matter whether he is on a farm or in a work-shop. The object of the postal system is to facilitate the intercommunication of intelligence. If that had been established, no matter what disparaging statements have been made here to day as regards the mismanagement of different branches of governments, I defy any man here to come forward and show where there is a better system under corporate control than the post office system of the United States to-day. (Applause). I defy—

MR. S. BRYAN—I accept that challenge with very great pleasure.

MR. ROSEWATER added that if the telegraphs were turned over to the Government, all the good men would be better employed and better paid than they were before, and that they certainly would not lose their personal integrity and rectitude. As to the value of the telegraph lines turned over to the Western Union Company at the end of the war, he would say that his figure of $2,000,000 was made for a period when gold was worth 180 cents, and everything was in proportion. That peculiar transaction was still unexplained. There were 44,000 miles of wire and 160 or 200 miles of cable, and it was all turned over for nothing. With regard to Mr. Foote's figures of distances in America and Europe, he would point out that right in New York the Western Union Co. charged $1 for a message, and even then would not allow the steamship company to make a bulletin of the intelligence. As a matter of fact the people of the United States had paid the Western Union $250,000,000 since the war, and had that money been paid to the Government they would have a better and cheaper system. As to safety of messages, he believed they would be much securer with a national service than they now are in private hands. All these imaginary dangers were bugbears, and moreover it was not true that government telegraphs did not pay. In England last year, the telegraphs earned a very fair dividend in spite of many heavy charges assessed on them and many expensive additions and improvements. It was certain that England would never return to private telegraphs. Prof. James Bryce, who wrote the *American Commonwealth*, had told him it was absurd and impossible.

MR. BRYAN, who was once connected with the postal service in this country and prominently engaged in developing the postal system of Japan, attacked postal administration very strongly, and drew the inference from its badness that government telegraph administration would be as bad. He spoke also of his personal experience with the telegraph in England and on the Continent, and considered the service very inferior to the American.

MR. E. A. LESLIE, as an old personal friend of Mr. Rosewater in the days when they both were operators, said that the great idea of the lecturer was to promote the welfare of the operator and that was the noble thought underlying all his arguments on the subject.

College Notes.

A FOUR YEARS' COURSE IN ELECTRICAL ENGINEERING AT COLUMBIA COLLEGE.

AN undergraduate course of four years in electrical engineering has been established in the School of Mines, Columbia College, in addition to the present two-year post-graduate course which has been in successful operation for several years. Thus there will be two complete courses in electrical engineering in New York City. The latter course is for graduates of scientific schools and colleges and is entirely devoted to electrical engineering proper, the students having already passed the necessary preparatory studies in mathematics, physics, chemistry, mechanics, drawing, etc. This course is found to give the most excellent results by reason of the maturer years and better training of post-graduate students.

In addition to such graduate students there are, of course, a much greater number of younger men who desire to enter a course of electrical engineering immediately on leaving school without going through a previous collegiate course. A new four-year course has therefore been established parallel to the well-known courses in mining engineering, civil engineering, chemistry, architecture, etc., at the School of Mines, with the same requirements for admission, which are equal to the regular entrance examinations at first-class scientific schools. The first two years of the new course will cover the preparatory work in mathematics, physics, chemistry, mechanics, drawing, etc., required for admission to the post-graduate course. The last two years will be devoted to a thorough course in electrical engineering proper and will be equivalent to the present post-graduate course, hence there will be no lowering of standard.

As a preparation for the study of electrical engineering the first two years of this course are equivalent to four years in any course other than electrical engineering, thereby saving much time without sacrificing any electrical engineering subjects.

The instruction in electrical engineering will be conducted as heretofore by Prof. Crocker and Dr. Pupin. The mathematics, physics, etc., will be taught by the respective professors of those subjects.

The degree given to those who satisfactorily complete the course will be that of electrical engineer. The new course will regularly begin October, 1892. Examinations for entrance are held June and September. The one-year partial, or special course, will be abolished next year to make room for the students in the regular courses.

SAFETY DEVICES.[1]

BY C. C. HASKINS.

VARIOUS metals having different electrical carrying capacity, must necessarily be variously affected thermally; and as some of these fuse at a much lower temperature than others it is readily seen that protection from abnormal heat in an electrical conductor is readily arrived at by the use of the fusible strip, which, placed in direct line with the passing current, will, before undue heating of the conductor proper takes place, melt, and thus break the continuity of the conductor.

Such, briefly stated, is the usual method of protection from abnormal currents. Let us look at this subject for a brief time, and see if in practice this is as reliable as theory would indicate.

The material from which these devices are constructed may be either a simple metal or an alloy of two or more metals in combination. A curious fact in this connection is that an alloy may be made of two metals which has a lower melting point than either of the metals of which it is made.

The metals which are more commonly used are tin, bismuth and lead.

The melting point of tin is	451°, F.
" " " of bismuth is	512°, F.
" " " of lead is	620°, F.

Now, different combinations of these metals will give us widely different results. Equal parts of tin which fuses at 451° and lead, which fuses at 620°, will give us an alloy which will fuse at 385°. Tin and bismuth in similar proportions will fuse at 250°. One of tin, one of lead and four of bismuth will melt at 200°. Lead 5, tin 8 and bismuth 8 form a combination which melts at 212°. Other combinations will give us an upward range far above the necessities of the case, and the admixture of other metals will give any desired melting point.

W. H. Preece has furnished us with the results of a long list of experiments, in his fuse table. This table gives the sizes of pure wire which will fuse by a current of from 1 to 5 amperes up to 50, by steps of 10 amperes to 100, and by steps of 20 amperes to 200 amperes. These figures are given for tin, lead, copper and iron.

In the matter of safe carrying capacity of copper wire there seems to be considerable diversity of opinion. We are told that a No. 0000 wire B. & S. gauge is good for 312 amperes by one authority, a second says 229 amperes, while a third says 300 amperes, and the last speaker says 175 amperes. Number 6 is given 65.2, 43, 80 and 35 amperes. Number 14 is given 16.2, 11, 22 and 10. These various figures come now from the Board of Trade of England, from Boston, from New York and from Montreal. With such a broad field for selection it would certainly seem possible that a perfectly reliable fuse should be readily accomplished for any known requirement, and yet with such a disagreement of authorities as given above it is not very strange if the fuse manufacturer should occasionally err in the capacity of the wares he offers.

Mr. Lee L. Summers, assistant electrician of the Western Union Telegraph Company at Chicago, has very kindly furnished me from his note-book some facts which are interesting in this connection. Called to devise some means of protection for conductors carrying small currents, such as are used for telegraphy, his experiments with alloys of tin and lead were mostly confined to those of quite small capacity. He says in substance, the smallest fuse placed upon the market was variously stated by different makers. One claimed them to be of one-half, others of one, and still others of one and one-half to two amperes' capacity. These fuses were either lead alone, or lead and tin. As a rule the lead fused at a lower temperature than the alloy. The exact gauge of these fuses was difficult to ascertain because of their irregular diameter, and the softness of the metal. This lot was samples of so-called one-lamp wire. It melted with between 2¼ and 3 amperes. Attempts were made to reduce the cross-section of these samples, but its feeble tensile strength prevented, for the wire became quite brittle when drawn through the die. His experiments led him to believe that the fuse wire known as of one-light capacity would require an average of about 2¼ amperes to rupture the circuit. German silver was tried by Mr. Summers, the wire being drawn down to 36 and 38 B. & S. gauge. This wire fused with from ¾ to 1 ampere and proved quite constant. But the fineness and delicacy of wire of that diameter unfitted it for general use.

Other parties besides Mr. Summers have given this matter much thought and time, and some of the results are even more remarkable. Among these are the recorded experiments of one investigator with a lot of fuses marked 15, which stood up nobly until melted by 30 amperes. This mark 15 may have meant 15 lamps, but it is charitable to believe it should read amperes.

Not only is the moderately expert electrician allowed abundant choice in the selection and dimensions of his so-called safety strips, but the deplorably ignorant operator can, and sometimes does, impose upon himself, even to the substitution of 97 per cent. copper in place of fusible metal, as he says "because they last better," rather than remove the difficulty which renders the better conductor necessary.

In close proximity to the safety strip matter is another to which I call your attention because of the possible danger which may at any time be drawn from its lurking place through the ignorance of the general public of electrical laws. The electric motor switch, as often constructed, has now and then the uncomfortable habit of stopping at an intermediate point between off and on, thus leaving a portion of the resistance in circuit, and of course a part of the current flowing through it. This current may or may not be sufficient to move the machine, and the switch may be left in that position intentionally or accidentally. When the quitting time arrives there are few employees in many an establishment who are not ready to rush for the door. It is very easy to stop a machine by throwing the switch lever part way over in the haste of quitting time, and had we nothing better than theory to base the statement upon, it might be hard to prove that such an act of carelessness was ever committed.

Let me give you two dissimilar cases which I assure you are authentic. A fan in a restaurant was run by a motor, and doing excellent work during extremely hot weather. The weather changed suddenly and the economical proprietor thought to save some current, and run his motor slower by turning in part of the rheostat. He knew just enough of electricity for that, and his little learning proved a dangerous thing. You have anticipated the result. It didn't melt out the safety plug, but it heated the fire department and warmed the underwriters. In another case a small motor was used to run a light piece of experimental machinery, in a dark corner of one of Chicago's sky-scraper buildings. It required all the current to run the fake, whatever it was, and when the schemer left the room at night he turned the switch just far enough to stop the motor, locked up and went home. The department extinguished the blaze about two o'clock the next morning, and the fuse was not injured.

Now mark, these two cases show that under some circumstances the best of soft strips may be thoroughly valueless.

This state of things has existed, and does exist to some extent to-day, and yet the remedy for this class of danger seems to me simple and easy of accomplishment. If the stationary motor switch is so made that it can never be left between full on and full off, it can never be so left.

But the soft strip conundrum is not so readily answered. There are several points to be considered.

1. When the ordinary dynamo man requires a wire or strip of a certain capacity he must perforce take on trust the article given him. He has no means of verifying the purchased article, and may, or may not get what he requires. And more than that. High authority has advised that all soft strips should be made of sufficient carrying capacity to allow a surplus of 25, 50, or even a larger per cent. excess over the marked capacity. As in many instances there is no mark on the fuse it is not beyond the range of possibilities that the salesman may err in supplying the purchaser, or that the latter may mistake in replacing a fuse.

2. The fuse wire may change its carrying capacity by exposure. Oxidation has that effect. If it is firmly fixed when first placed, unless it has a hard metal terminal the constant pressure tends to flatten the contact, and thus loosen the connection—possibly setting up an arc at that point. The constant vibration of a building tends to loosen any but the most firmly set screws, so that here are two evils to be avoided.

3. There is no means at hand for effectually preventing the user from endangering not only his own, but his neighbor's property, by substituting other than fusible metal in the cut-outs.

For these several difficulties there should, it seems to me, be found reasonable and simple remedies It was once customary to designate the limit permitted upon a wire by the number of lamps. This is no longer practical. There is such a variety of lamps, so many different voltages, and hence so many differing rates of current absorption, that our only standard of allowance is the ampere. It seems to me that the device, whatever shape it may assume, should be so arranged that its actual capacity at a certain temperature can be known at a glance. The cut-out block should be so construced that only the strip for which it is marked can be used with it. A 10 ampere block should not be made capable of holding a 20 or 40 ampere strip. With a given alloy the manufacturer would be able to make his strips uniform, so that the carrying capacity would be easily verified by a wire gauge or micrometer. So many millimetres wide, so many thick—so many amperes capacity, and no more.

I make these suggestions as a possible solution of a difficulty which is growing formidable, and in the hope that by drawing attention to the existing necessity, the matter may be thoroughly sifted and proper remedies applied.

DISCUSSION.

MR. FORÉE BAIN drew attention to experiments made by him which proved that the rupture of fuses is dependent largely upon the suddenness with which the current is applied, a 10-ampere fuse

1. Abstract of a paper read before the Chicago Electric Club, December 7th, 1891.

carrying 42 amperes with a gradual application, while a sudden rush of 10 amperes ruptured it. To remedy this he suggested the employment of a spring or weight which acts to agitate and stretch the metal when the temperature rises; this reduces the cross-section and augments the effect of the overload, even though it comes on gradually. Mr. Bain also preferred a pure metal, such as tin to an alloy, the slightest difference in the composition of which makes a large difference in its character. Tin has a lower melting point than any other pure cheap metal, except lead; does not oxidize so readily, and does not crush like alloys. Mr. Bain also described a battery cut-out embodying a thermostat operated by the heat generated in a fine German silver coil. He was not in favor of electromagnetic cut-outs as they offered mechanical resistance and they did not afford good electrical contacts especially when used for heavy currents.

Legal Notes.

INCANDESCENT LAMP LITIGATION—THE UNITED STATES ELECTRIC LIGHTING CO. vs. THE EDISON LAMP CO.

THE action brought in the spring of 1889 by the United States Electric Lighting Company against the Edison Lamp Company, in the United States Circuit for the district of New Jersey, alleging in fringement of a patent granted to it in 1884, as assignee of Edward Weston, for an improved process of manufacturing conductors for incandescent lamps, came up for final hearing in Philadelphia, on December 9th, before Hon. Marcus W. Acheson, circuit judge; Hon. Edward T. Green, who was also to have participated in the hearing of the case being indisposed and unable to sit. Kerr & Curtis, solicitors for the complainant company were represented by Thomas B. Kerr of New York and George H. Christy of Pittsburgh, of counsel. Eaton & Lewis, solicitors for the defendant were represented by Sherburne B. Eaton and Frederic H. Betts of New York, of counsel. The opening argument in behalf of the complainant was begun at 10 o'clock by Thomas B. Kerr.

ARGUMENT OF MR. KERR FOR THE UNITED STATES COMPANY.

Mr. Kerr said that the bill in this case was filed by the complainant as assignee of Edward Weston, for the infringement of Letters Patent No. 306,980, granted October 21, 1884 for a process of manufacturing conductors for incandescent electric lamps. He said that this is the case which showed a strong equity on the part of the complainant. The invention was one of peculiar and striking novelty as well as utility in its relation to the electric lighting industries. The light of the incandescent lamp was produced by the resistance of the conductor in the lamp to the passage of the current, the lamp conductor being of a material of less conducting capacity than the wires which convey the currents to and from the lamp. The illuminating conductor must have the capacity of withstanding the intense heat thus produced, through the more or less protracted periods, and the more or less frequent occasions when a lamp is required in the ordinary uses of daily life. Ordinary carbon was early recognized by experimenters as a material possessing certain properties peculiarly adapting it for this purpose, but at the same time combining other characteristics which put its valuable properties beyond reach. One of these impediments was the affinity of oxygen for carbon; when oxygen was present it attacked the carbon as soon as brought to incandescence, and destroyed the conductor; hence experimenters had sought to make a lamp in which oxygen would be excluded from contact with the carbon, and for this purpose they had tried filling the lamp-chamber with a preservative atmosphere, such as nitrogen, and they had also tried to exhaust the air from the chamber. Earnest and unremitting efforts had been made to overcome all these difficulties, but it was not until the latter part of 1880 that they had resulted in the production of a commercial lamp. Another impediment had been the lack of homogeneity in the structure of the carbon. This characteristic produced unequal heating, the weak or defective places offering the most resistance and producing the greatest heat. The result had been that the conductor had soon broken down at these points and the lamp had been destroyed. The solution of the problem of making the resistance of an incandescent carbon conductor uniform throughout its length was of vital commercial importance, for if all other difficulties were removed but this, upon this alone depended the production of a durable incandescent lamp, The problem had been attacked in different ways by different inventors but it had remained to Weston to solve it by the discovery and application of a scientfiic law of singular beauty and of striking utility.

Weston's discovery was that if an electric current be passed through a carbon conductor so as to heat it to a visible heat while immersed in a hydrocarbon liquid or surrounded by a hydrocarbon vapor, the heat would decompose the adjacent hydrocarbon, and would cause the particles of carbon dissociated therefrom to be deposited within the pores and upon the heated surface of the conductor; he had found that the deposit would be greatest at the point of greatest heat, and proportionately less at other places, so that if the operation was continued long enough, the resistance and consequently the conducting power of the carbon would become absolutely uniform throughout its length. By this process the mechanical strength and elasticity of the conductor were at the same time increased, and it also became possible, by the same means, to bring the conductor to any desired standard of resistance so that all the carbons for a particular type of lamp could be made of absolutely uniform conducting power, and capable of rendering a uniform and definite illuminating service.

Mr. Kerr then read passages from the specification of the patent in which these advantages were pointed out, and also from the testimony of Mr. F. L. Pope, the complainants' expert, in which the matter was further elaborated.

The claim of the patent was as follows:

"The improvement in the art of making carbon conductors for incandescent lamps, which consists in first forming a carbon core or base, and then building up said core with carbon obtained and deposited upon the same, by and during the operation of electrically heating said core while surrounded by, or saturated with, a carbonaceous substances, substantially as hereinbefore set forth."

He thought it superfluous to discuss this claim. It was clear, concise and comprehensive, exactly describing and broadly covering the invention. That invention if novel, was of a character which left no question as to its patentable qualities. The very defect of the carbon was made the means of its cure. The relation between current resistance, heat and deposition was sympathetically responsive and exact. It was an automatic process; a law of nature working untrammelled and unimpeded to its natural and perfect end. Human agency set the apparatus in operation and nature brought out the results as certainly as it caused a weight to fall to the ground or water to expand with cold.

The defendant in its answer had denied that it had ever infringed at all, or in any way, the Letters Patent or any rights of the complainant thereunder, but the testimony of the witnesses Whitehead, Clifton, Latus, Marshal and Clarke, was to the effect that the defendant company had treated at least 20,000 carbons in accordance with the invention, for use in the manufacture of incandescent lamps. These men were employees of the defendant company and their testimony was wholly uncontradicted. It was not alleged that Mr. Edison was personally responsible for the infringement, but he would show that the Edison Lamp Company did resort to this process and did make use of it.

He would next consider the defenses relied upon. First, as to Sawyer and Man, it was contended by defendant that Weston had surreptitiously and unjustly obtained a patent for that which was in fact first invented by Sawyer and Man, who were using reasonable diligence in adapting and perfecting the same. The same parties were alleged to have had the invention in public use for more than two years before the application of Weston. This defense of prior invention had already been adjudicated by the Patent Office in Weston's favor. He had filed his application for this patent on May 27, 1881. It had been put into interference Oct. 1, 1881, with the patent of Sawyer and Man of January 7, 1879 (No. 211,262). The issue was that of priority of invention. Both parties had taken testimony in regard to their respective dates, their efforts in reducing to practice and other points pertinent to the issue. That interference record had been stipulated into the present case. Mr. Kerr then read from the the testimony in the interference proceedings showing that Weston had made use of the process he had afterwards patented in preparing carbons, in 1876 and 1877, and had employed these carbons to produce electric light by incandescence. In connection with his testimony Weston had produced certain exhibits, among which were a piece of apparatus used by him in 1876 and 1877, in treating carbons; a sketch of his first apparatus in which the carbon was treated in oil, and of his second apparatus in which the carbon was treated in gas. Several other exhibits of pieces of apparatus had also been put in. These exhibits, although somewhat crude in character, as was usual with the early embodiments of nearly all valuable inventions, were practical and effective in operation, and tended strongly to corroborate the testimony of the independent witnesses as to the experiments which had been made by Weston in 1877 and 1878. Mr. Quimby a well-known solicitor of patents and expert had testified that he first became acquainted with Weston in the spring of 1877; that Weston showed him the operation of treating a carbon by the process of the patent within six months from the date of his first acquaintance with him. Broadbent, foreman of the machine room of the Weston Dynamo Electric Company, testified to having seen Weston treating carbons by placing them in a globe filled with oil and running a current of electricity through them. Havell, although a business man having no special interest in the subject of electricity and called as an adverse witness, yet corroborates Weston in several important particulars. Theberath, another adverse witness was an ordinary workman, whose testimony was wholly negative and worthless. He merely says he was employed by Weston; that he was often in his laboratory, but that he does not recollect seeing him make any experiments in incandescent lamps either in the laboratory or in the shop. His testimony had been contradicted in several important particulars and had been shown to be wholly untrustworthy. Mr. Kerr then proceeded to consider the adjudications in the interference case in the Patent Office, which was decided in favor of Weston by the Examiner of Interferences; by the Board of Examiners-in-Chief, and by the Commissioner of Patents; the three tribunals concurring in the finding. The Commissioner held:

"It suffices to say that after a careful consideration of the evidence I am convinced that Weston made and completed the invention, in a legal sense, prior to Sawyer and Man, and the decisions of the legal Examiner of Interferences and the Examiner-in-Chief that the former is the prior inventor is approved and affirmed."

No new testimony had been brought on the subject of priority of invention, and he would therefore respectfully submit that the concurrent decisions of the three tribunals of the Patent Office in favor of Weston, if not *res adjudicata*, were at least entitled to great respect, and should not be overruled by the Court in the absence of controlling evidence to the contrary.

Referring next to the testimony of Weston that no commercially incandescent lamp had been made until the latter part of 1880, Mr. Kerr read from the testimony of Hebard, from which it appeared that the complainant was at work on incandescent lamps in 1880, first in Bridgeport and afterwards in New York: that in the spring of 1881 complainant having secured all the stock of the Weston Electric Light Company took possession of its factory in Newark; that Weston was made electrician of the complainant company, and that the manufacture of lamps using his hydrocarbon process, became a commercial enterprise during the late spring or summer of 1881. It also appeared that prior to Hebard's official connection with the complainant, it was the owner of patents of Maxim, several of which were for improvements upon the Weston process, but as they contained no claim for the fundamental invention, there was no conflict between them and the patent in suit. It was not until the latter part of 1880 that the incandescent lamp reached a condition of practical utility, so that Weston could adapt his invention to public use, and consequently he could not before that time have made a contract with the public for the 17 years' beneficial use of the invention, which the law provided as a reward to the meritorious inventor. Within a short time after the lamp was perfected Weston had filed his application and in due course had obtained his patent. Hebard had testified that since September, 1890 he had been an officer of the Sawyer-Man Company, and had had the general management of its business. The production had been, a large part of the time, as many as 10,000 or 12,000 lamps per day, all having carbons which had been subjected to the hydrocarbon treatment.

The defendant had produced three witnesses, Hubel, Beers and Bradley, who had testified that they had worked for Weston at various periods between 1876 and 1880; that they never saw him experimenting with lamps or treating carbons, and that they thought if such operations had been performed they were in a position to know it. Such testimony was purely negative in character, and could have but little weight in the face of the positive testimony of witnesses who say that they have actual knowledge of such events. He knew of no case where evidence of this character had been successfully cited against a patent. There were, however, many cases, in which the doctrine had been laid down that such evidence could not be received to overcome the positive testimony of witnesses having actual knowledge of the facts.

Coming now to the allegation of the insufficiency of Weston's specification, Mr. Kerr said that the specification had been criticised by defendant's expert, Clarke, as erroneous and defective, and as embodying information not possessed by Weston or others in 1877 and 1878. Mr. Clarke had testified that he had had an extensive experience in reference to the manufacture of incandescent lamps in connection with Mr. Edison, and with the defendant company, which, however, did not qualify him as an expert in reference to the particular subject matter of the patent in suit. It appeared from Mr. Edison's affidavit and otherwise that defendant companies did not use the hydrocarbon treatment process in its general manufacture, the reason, as stated by Mr. Edison, being that he did not resort to the hydrocarbon process because it was patented in this country and he did not steal patents. Clarke himself says he has had no practical experience in treating carbon conductors except as to certain experiments made in connection with this case. His statements are therefore to be received with allowance. He had been asked as to whether, in his opinion, the information acquired by the witnesses Quimby and Broadbent in the years 1877 and 1878 was sufficient to enable a person skilled in the art to practice the invention. Neither the statute nor the rules of evidence required that the deposition of a witness as to facts within his knowledge, under an issue of priority, should be in the nature of a patent specification.

Mr. Vandergrift, who had been engaged in the manufacture of incandescent lamps ever since January, 1880, when he had first been employed by Maxim, at Bridgeport, and who from 1885 to 1889 had been superintendent of the lamp factory of the complainant company, tried several experiments with the apparatus shown in his sketch, a reproduction of that testified to by Weston, and had shown many of Clarke's statements to be erroneous. Clarke had admitted that the apparatus described in the patent was the same as that which had been used by Weston in his experiments. Vandergrift's testimony had shown that Weston's specification complied fully with the law, and in the best possible way. Indeed the specification went beyond the ordinary requirements of the law, which assumed the specification to be addressed to a person skilled in the art. Any laborer employed about the establishment, by simply making the physical structure described, would inevitably produce the result. Nothing was left to judgment, to skill, or to science; it was only necessary to follow the plain directions of the specification. The invention was not limited to the use of any particular form of hydrocarbon; it might be oil, it might be gas; but it must contain carbon as a constituent element. The evidence is that defendant used kerosene oil; Weston commenced with kerosene and went on to gas, finding that the less the specific gravity of the hydrocarbon used, the finer the result. The only condition was that carbon must be a constituent.

The defendant had taken the ground that the grant to Weston had been barred by two years' public use. Mr. Broadnax had instituted proceedings after the grant; he wanted the Commissioner of Patents to have the goodness to tell him why Weston's patent had been issued. They had his statement that one main object of the testimony taken in the interference proceedings had been to prove prior public use. Mr. Kerr said he had called attention to this, because it appeared to be one of the main defences in the case. There had been a constant effort to make a public use appear, which upon careful scrutiny did not appear at all.

The cross-examination of Weston showed the diligent efforts which he had made to secure an incandescent lamp. There was the long story of his troubles in obtaining a vacuum; his experiments with chemicals, and so on, but though he worked persistently in 1878, '79, '80, no incandescent lamp had been produced until the fall of 1880. All that time Weston had been trying to utilize carbon, but there was no place he could use it, and no way in which he could make it useful to the public. The testimony in this case is uncontradicted, that in the latter part of 1880, the complainant company first succeeded in bringing before the public a commercially successful incandescent lamp. If any question should arise as to whether Weston had been showing due diligence, they should look at his cross-examination. He would ask his Honor to read the whole 40 pages; not a line could be left out. Weston's statement is corroborated by the evidence of Quimby. Quimby's deposition in fact might almost serve as a specification; he had witnessed the operation with an intelligent mind; he had seen this operation of "building up the carbon" going on under his very eyes. Havell, a witness called by Sawyer and Man, had confirmed Weston as to the treating of carbons in oil. These witnesses had clearly established the fact that in 1877 Weston had been treating carbons for the purposes of this invention. He had been experimenting in incandescent lamps. It had been conclusively proven that in 1877 he had had this invention.

The testimony of Sawyer and Man, shows that on March 8, 1878, they first treated carbon for incandescent lamps by the dydrocarbon process. They had made a great many lamps of the pattern illustrated in the *Scientific American;* Man says, hundreds of them. But the evidence was, that though the lamps were tried, *not one of them was ever sold;* Sawyer and Man could accomplish nothing, and in 1879 they closed up; granted a license to Thomas Wallace, and the entire business was transferred to Ansonia. The whole thing had thereafter sunk into oblivion. Prior to September, 1879, the testimony was that not one lamp of all these was successful; not one. They had made no public use of the lamps; they had merely been exhibited to induce people to take stock. There had been no place in that lamp for Sawyer and Man or for Weston to utilize this invention.

In 1879, patents had been issued to Sawyer and Man, both here and in England; meanwhile Weston was still diligently at work upon the problem of the lamp, upon which the beneficial use to the public depended. Beautiful as the first invention was, it was practically useless without the second; and this never came until the latter part of 1880, and then by the complainant company giving to the public the first commercially incandescent lamp. If Weston had been thus diligent, it could not make any difference what others might have done. Now this was not all that had occurred in the Patent Office. Maxim had also filed an application, had been put into interference with Sawyer and Man, and Sawyer and Man had beaten him. Maxim had given a deposition in that case. He had made an experiment which had been spoken of as a public use. It was a lamp, not a treating apparatus; there had not been gas enough in the lamp-chamber to build-up the carbon. Then Maxim had told the real truth, but in his present deposition he has attempted, without much success, to explain away and modify his original statements. This experiment was the only thing he had done prior to 1880. One hundred incandescent lamps had been made under his direction at Bridgeport; 800 more in New York; none of them were sold; they had put up, in the fall of 1880, an advertising plant of 60 incandescent lamps with treated carbons—the very first commercial incandescent plant in public use. Mr. Curtis had testified that it was not until November or December that lamps were made that could be sold. In February, 1881, the complainant company secured a majority of the stock of the Weston Company; Weston in April became the electrician of the United States Company. Mr. Curtis had then consulted him about the machines and processes of manufacture; Weston said to him, "I invented that process of hydrocarbon treatment." Investigation had showed the truth of his statement, and his application for a patent followed; so that the skill came together with the legal title, to the United States Company, and then, as we find by the testimony of Curtis and Hebard, the United States Company had embarked in the manufacture and sale of incandescent lamps. Mr. Hebard says that 10,000 lamps per day were now made with treated carbons, an enormous industry which had been started and built up under the Weston patent.

In reference to the question of infringement, the testimony of complainant's expert, Mr. Pope, had not been questioned, rebutted or touched. It would seem, that with the ability possessed by Mr. Edison, of making lamp conductors of pure vegetable carbon, his company might have refrained from the use of complainant's patented invention.

The complainant, said Mr. Kerr, had supported every allegation in the bill. They felt that Mr. Weston had brought to the knowledge of mankind, one of the most useful as well as one of the most beautiful discoveries ever made; a discovery which had in truth unlocked the secret storehouse of nature. No carbon could be made a perfect conductor except in this way, and in this way any carbon could be made useful. A great, vast, useful territory had been conquered and opened up by this discovery. In 1877 Weston had made this invention, but his work was not done; he had no place in which to use it. Day by day, month by month, year by year, he had patiently wrought to solve the further problem of making that beautiful discovery useful to the public, but not until the fall of 1880 could the place be found in which his incandescent carbon could be made useful. Then, and not until then, did he go to the Patent Office and ask for the well earned reward of his labors. Nobody had been harmed by his delay; nobody had any means of using the invention. The moment a contract could be made with the Government by which he could get the 17 years' beneficial use to which he was entitled, he had applied for his patent. The only defence to that patent was a purely technical defence—a defence wholly without merit. Common justice and common sense required that this patent should be sustained, for this inventor had contributed more to the real benefit and welfare of the public, than had one in ten thousand of those who apply for the protection of the Government for their discoveries and inventions.

STORAGE BATTERY LITIGATION—AN INJUNCTION AGAINST THE ELECTRCAL ACCUMULATOR COMPANY.

On the 2d of December an injunction was issued by the Circuit Court of the United States for the Second Circuit of the Southern District of New York, against the Electrical Accumulator Company, Theodore N. Vail and O. E. Madden, forbidding them from infringing the patents of Chas. F. Brush, March 2, 1886, No. 337,299, and October 17, 1882, No. 266,090, for secondary batteries. The injunction specifies claims 1, 2, 3, 6, 7 and 12 of the first-named patent, and claims 7 and 14 of the second patent. The Consolidated Electric Storage Co. is the licensee of Mr. Brush under his storage battery patents.

STORAGE BATTERY LITIGATION—PERPETUAL INJUNCTION GRANTED BRUSH.

A perpetual injunction was issued in the United States Circuit Court, Trenton, N. J., on Dec. 7, restraining the Accumulator Company from making storage batteries in infringement of the patents of Charles F. Brush, now owned by the Consolidated Electric Storage Company, the successors of the Julien Electric Company.

THE ADAMS ELECTRIC RAILWAY SUITS.

A beginning was made last week in St. Louis, in the suits for infringements of the Adams electric railway patents. Prof. F. E. Nipher was put on the stand by the Adams Railway Co., and testified in support of the Adams side of the litigation, which is directed against the Edison, Thomson-Houston and other electric railway sytems.

Mr. R. Varley, Jr., has lately been appointed superintendent of the large Okonite works at Passaic. In spite of the responsible nature of his duties, Mr. Varley finds time to do a good deal of inventing. Reference was made to another of his patents in the last issue of The Electrical Engineer.

Letters to the Editor.

REACTIVE COILS AND THEIR EFFICIENCY.

In your issue of December 9th, Mr. Otis K. Stuart in a short article on Reactive Coils, accredits me with having first stated that if a magnetic field cut or moved across a conductor a current of electricity would be generated in the conductor. This may be Mr. Stuart's opinion, but of course any one who is familiar with the work of Faraday and others will understand that the principle was known many years before I was born, and is a fact so self-evident that no statement of it would be required, the relation of a conductor to a magnetic field, whether the field or the conductor moves, being perfectly well understood from Faraday's investigations.

Mr. Stuart also says that probably the most interesting application of reactive coils has recently been made by Mr. Elias E. Ries in the Ries regulating socket. If he will refer to my patent No. 428,647, he will see that nothing more is needed than to put that apparatus in practice to obtain the results that Mr. Ries has obtained in the same way. In fact in my house in Lynn, I had several such regulating arrangements for my incandescent lamps, and they were put in operation as far back as 1886. As to the economy of such an arrangement for turning up and down incandescent lamps, that is more problematical, as it is well known that to dim an incandescent lamp by lowering the potential between its terminals reduces its efficiency at so rapid a rate that when it is burning at dull redness and giving scarcely any illumination a very large percentage of the energy is still being expended in producing radiant heat. A Ries regulating socket which I have seen does not even cut out all the reactive coil at the point of maximum brilliancy, though it substantially does so. In so far as it fails to cut out the coil it lowers the brilliancy of the lamp and therefore lowers its efficiency. It is very questionable indeed whether the size of the reactive coil is by any means sufficient for the work which it has to do.

Elihu Thomson.

Lynn, Mass., Dec. 10, 1891.

REACTIVE COILS.

What could Mr. Stuart possibly have had in mind, in making the extraordinary statement which appears in his recent article on "Reactive Coils," to the effect that Professor Elihu Thomson was the first to state the principle "that if a magnetic field cut or is moved across a conductor, a current of electricity would be generated in the conductor"?

Faraday, *Experimental Researches*, vol. i, p. 11 (November, 1831)—introduced one end of a cylindrical magnet, three-quarters of an inch in diameter, and eight and a half inches long, into the axis of a helix, whose terminals were united to a galvanometer, and then "the galvanometer needle being stationary, the magnet was suddenly thrust in; immediately the needle was deflected. * * * * Being left in, the needle resumed its first position, and then the magnet being withdrawn, the needle was deflected in the opposite direction." Again, in vol. i, p. 548, he says:

"A single flat helix was connected with a galvanometer, and a magnetic pole placed near to it; then by moving the magnet to and from the helix, or the helix to and from the magnet, currents were produced indicated by the galvanometer."

New York City.

MR. LEONARD'S LAW OF MOTOR EFFICIENCY.

In the issue of The Electrical Engineer of Dec. 9, Mr. C. O. Mailloux, in discussing the law I stated as governing the operation of motors of perfect efficiency, makes some statements which seem to be incorrect and to which I therefore wish to call attention.

In my article I discussed a motor whose speed and torque must both be varied to meet the conditions of practical work, and stated that to operate efficiently we must

"Vary the voltage as the speed desired,
Vary the amperes as the torque required;"

and I then described a method by which this result should be accomplished.

Mr. Mailloux finds nothing new in this law and mentions a host of electricians in whose writings it can be found "more or less amplified." I think, however, that it will be difficult to find a motor whose speed and torque are both variable which follows the law as stated. In the shunt motor, the amperes are varied as the torque, but the speed is constant; hence, it is not an example. When a rheostat is inserted in the armature-circuit of a shunt motor, it is true that that portion of the energy which is utilized in the armature follows the law; but the total energy used does not follow the law at all, for the volts are constant from the line under varying speeds, and the efficiency, instead of being a constant, is directly proportional to the speed.

Mr. Mailloux is, I think, in error in stating that in the street-car motors commonly in use the amperes vary as the torque. Such a condition could only be realized in a constant field and with the series fields commonly in use as a constant field is not realized under varying torques, although the commutation of the field is, of course, an endeavor to approximate to it.

In commenting on my suggestion as to the grouping of six motor armatures in various relations from series to multiple while in constant fields, Mr. Mailloux says: "It is scarcely necessary to point out that in this case the torque and speed are both varied and regulated, not by following Mr. Leonard's 'law,' but by varying the counter-electromotive force. The circuit-potential available to the motors may remain constant. The current, on the contrary, will not remain quite constant for all groupings. It is apparent, therefore, that Mr. Leonard's law would be most useful when supplemented by a key to, or list of, its exceptions."

It seems to me that in dividing the total initial electromotive force between the six armatures in series and securing one-sixth speed we certainly "vary the volts as the speed desired;" and I look upon the counter-electromotive force as the *result* of the impressed electromotive force and consequent speed, and not as the *cause* of the speed. Also, there is no question that the current *will* be constant for all groupings, neglecting, of course, the slight effect of the losses in heat, as we do when we speak of a shunt motor as having a constant speed, and a current proportional to the torque.

Mr. Mailloux says: "It is perhaps interesting to point out that in the case of an electric car, a continuous current converter, such as described by Mr. Leonard, would add some 1,500 pounds and two commutators to the car. The objections to the two extra commutators would 'weigh' if anything *more* than the double machine." Although "interesting," Mr. Mailloux's statement is far from correct, as the additional weight will be between 400 and 500 pounds instead of 1,500. The abhorrence of commutators shown by Mr. Mailloux is explained by his statement: "The writer has himself devised methods of regulation employing continuous-current converters in connection with ordinary *series-motors*."

When a commutator is subjected to the severe inductive reactions of a series field, and especially with a rheostat also in circuit, it is not to be classed with a commutator on an armature having no rheostat in series and running in a constant shunt field. A commutator which, in the former case, would spark viciously and continuously, will, in the latter case, run absolutely sparklessly and require no more attention than a well-lubricated bearing.

Mr. Mailloux has been kind enough to grant that my method of operating a motor "will not be without its sphere of applicability and usefulness," which practice has already demonstrated in its commercial application to traveling cranes, where the use of series motors with rheostat control of speed has been attended by such serious drawbacks as to cause certain manufacturers of traveling cranes to quickly appreciate the value of a current and torque automatically proportional to the load and a speed perfectly controllable in either direction from zero to the maximum, and also automatically constant at any desired speed regardless of the load.

H. WARD LEONARD.

NEW YORK.

Society and Club Notes.

THE CANADIAN ELECTRICAL ASSOCIATION.

THE Canadian Electrical Association has been organized at Hamilton, Ont., with the following officers: President, J. J. Wright; first vice-president, H. J. Dunstan; second vice-president; John Carroll; secretary and treasurer, C. H. Mortimer; executive committee, E. S. Edmonson, H. O. Fisk, W. A. Johnson, S. J. Parker, A. B. Smith, D. Thomson, Thos. H. Wadland, A. A. Wright and John Yule.

THE AMERICAN INSTITUTE.

AN electrical section of the American Institute has recently been organized with the following officers: E. T. Birdsall, president; Dr. L. H. Laudy, vice-president; J. W. Hull, secretary. The section will meet on the second Wednesday of each month at the rooms of the Institute, 115 West 38th street. This section will be similar to the polytechnic, photographic and other sections of the Institute. We must confess that this step seems to us unnecessary and inadvisable. There are now three active electrical bodies in New York, which between them cover the field very thoroughly. Moreover, the New York Electrical Society for some years tried to act as an electrical section of the moribund American Institute and at last retired in disgust under Prof. Crocker's leadership. It has not since had any occasion to regret its action.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

The 62d meeting of the Institute will be held at 12 West 31st street on Wednesday evening, December 16th, at 8 o'clock. A paper will be read by M. I. Pupin, Ph. D., on "Polyphasal Generators." Postponed discussions on Prof. Harris J. Ryan's paper and the Report of the Committee on Units and Standards will be in order, if time permits.

Literature.

CASSELL'S RECORD OF SCIENTIFIC PROGRESS.

THIS time-honored publication is now in course of preparation, covering the year 1891, under the able charge of Mr. Robert Grimshaw, No. 21 Park Row, New York. We are requested to inform our readers that Mr. Grimshaw will be glad to receive the details of their work in scientific lines for insertion in the Record.

AN EDISON CONFERENCE.

DURING the past week an important conference of the Edison district managers and heads of departments was held. A preliminary meeting was held in Chicago on Monday, and the business was resumed later in the week in the East, part of the time being given up to visits to Schenectady, the New York Works and the Lamp Works at Harrison, N. J. It is understood that a number of leading matters were discussed at the conference, which lasted several hours daily, and that the officers of the company are very much pleased at the results, both in the interchange of ideas and facts and in the showing made as to the stability and progressiveness of the Edison business throughout the country. No details of the topics touched upon are obtainable, however.

The conference was closed on Saturday evening, by a banquet at Delmonico's given by the second vice-president, Mr. Insull, in honor of Mr. Edison, when 29 gentlemen sat down at table. Mr. Insull had Mr. Edison on his right and Mr. Villard on his left. There were also present First Vice-President Herrick; District Managers Shain, Mitchell, Beggs and Reece; Mr. E. H. Johnson; Mr. C. Batchelor; Mr. John Kruesi and Mr. E. Gilmore, managers of the Schenectady Works; Mr. Francis R. Upton, manager of the Lamp Works; Mr. John Langton, manager of the Canadian Works; Mr. Hutchinson, manager of the New York Works; Mr. Henderson, chief engineer of the Edison General Co; Mr. Kennelly, electrician of the Edison laboratory; Mr. Hastings, treasurer of the Edison General Co.; Mr. Muir, manager of the electric railway department; Mr. Dana Greene, manager of the light and power department; Mr. J. Kelly, manager of the wire department; Mr. Lemaire, manager of the fixture department; Mr. Ord, comptroller of the Edison General Co.; Messrs. Tate and Butler, of the executive department; Mr. Arango, of the Spanish Edison Co.; Messrs. Eaton and Lewis, of the legal department; and Mr. H. W. Darling, special agent. Among those who participated in the conference but were unable to attend the banquet were Messrs. Coster, Barr, Paine and Glass, of the District offices.

The toast of the evening—that of Mr. Edison—was appropriately proposed by President Villard, and acknowledged by Mr. Batchelor, as one of Mr. Edison's oldest associates. The "District Managers" toast was responded to by "Oregon" Mitchell. Major Eaton then gave some interesting reminiscences of the early days, as the first president of the original Edison Co.; and he was naturally followed and, in the same vein, by Mr. E. H. Johnson, who was never more eloquent and felicitous, and who took occasion to express feelingly his great pleasure at the success now being achieved by his old protégé and associate, Mr. Insull. This graceful tribute of esteem and friendship, coupled with a toast, was neatly and sympathetically replied to by its recipient; and speeches were also made by Messrs. Herrick, Ord, Henderson, Beggs, Kennelly, Kruesi and Upton.

ELECTRICAL EXECUTION.

A MURDERER named Loppy was executed at Sing Sing last week. The execution was "instantaneous" and "successful" of course. It required four contacts extending over a period of six minutes. Loppy was killed by the first contact, it is said, and the other three were "thrown in," simply to make sure.

A NEW ENGINEERING FIRM—SPRAGUE, DUNCAN & HUTCHINSON, LTD.

A CORPORATION under the above name has just been formed in this city and has opened its offices at 15 Wall street, under the business managership of Mr. Alfred Bishop Mason. It is no exaggeration to say that this is one of the most important happenings of a very eventful year in the field of electrical engineering. Mr. Frank J. Sprague is justly recognized as one of the foremost men in the profession, while his work in electric railroading at once lifts him into the category of historical pioneers. The record of electrical triumphs in America will be incomplete if it does not give large space to his inventions and achievements in electric railways. Mr. Sprague has of late made a special study of rapid transit problems. In order to devote his time to the new firm he has resigned as consulting engineer of the Edison General Electric Co. The second member of the firm is Dr. Louis Duncan of Johns Hopkins University, who has been constantly before the electrical public since the memorable lamp tests at the Franklin Institute in 1884, and whose contributions to electrical science and its literature have been neither few nor mean. It is understood that Dr. Duncan is shortly to drop his important professional duties at Johns Hopkins, (where he created the Electrical Laboratory,) and give himself up to this work; toward which he has always had strong inclination. Dr. Cary T. Hutchinson, also a Johns Hopkins man, has served as electrical engineer with the old Sprague and new Edison General Companies, and was for a time assistant to the chief engineer of the latter corporation. More recently he has been engaged on the mathematical and experimental work connected with some of the later Sprague inventions.

Frank J. Sprague.

Dr. Louis Duncan.

This firm, with its high personal reputation and many influential connections, is destined to play a conspicuous part in electrical engineering, and may be counted upon to help raise the standard of a rapidly advancing profession. It will make a specialty of consultation work, whether for bankers and investors, cities dealing with electrical questions, mines or mills desiring to utilize electric power, street railroad companies, or steam railroads proposing to handle suburban traffic by electricity. As we have said before, to employ the services of a first-class engineer in regard to new schemes, or the status of existing enterprises, is never an expense but an economy. With the return of business prosperity, now so close at hand, electricity will be the great and favored field for investment, and more than at any time before will the consulting electrical engineer act in a responsible and useful capacity. The sentiment of the electrical community as a whole is voiced in the hope that this newly formed company may enjoy a large measure of public patronage and support.

Dr. Cary T. Hutchinson.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED DECEMBER 8, 1891.

Accumulators:—

Secondary Battery, I. L. Roberts, 464,665. Filed Dec. 31, 1890.
A secondary battery having an electrolyte composed of the salt of iron capable of absorbing an acid radical, and a non-porous electrolytic diaphragm interposed between the electrodes.

Electrode for Secondary Batteries, W. Morrison, 464,676. Filed Oct. 27, 1890.
Provides means by which the materials composing the plate are confined and at the same time allow afree circulation of the gases or solution to and from the plates in charging and discharging.

Clocks:—

Electric Programme-Clock, C. Lester, 464,730. Filed Apr. 10, 1891.

Distribution:—

System of Distributing Electricity, T. A. Edison, 464,822. Filed June 26, 1882.
Has for its object the utilization of high-tension currents on the main conductors of an electric lighting system having incandescent lamps, motors, etc., arranged in multiple arc and requiring a current of lower tension.

Dynamos and Motors:—

Armature Winding for Dynamo-Electric Machines, C. R. Arnold, 464,547. Filed Mar. 14, 1885.
Has for its object to avoid the inequality in the length and resistance of the various armature coils as well as to secure other advantages.

Electro-Magnetic Motor, N. Tesla, 464,666. Filed July 13, 1891.
Has for its object to secure artificially a difference of a quarter of a phase between the currents in the two energizing circuits of an alternating motor.

Transformer-Motor, O. T. Blathy, 464,671. Filed Nov. 8, 1889.
Consists of an electric motor for alternate currents dispensing with the introduction of the current by commutator and brushes.

Automatic Cut-Out for Electric Motors, S. S. Wheeler, 464,948. Filed July 16, 1887.
Consists of a cut-out controlling the connection of a motor and adapted to automatically disconnect the motor from the circuit upon the occurrence of any undesirable condition of running.

Lamps and Appurtenances:—

Electric Arc Lamp, A. G. Waterhouse, 464,682. Filed April 1, 1891.
Method of simplifying the operation and construction of arc lamps.

Incandescent Lamp Filament, L. K. Böhm, 464,719. Filed Jan. 2, 1890.
A filament consisting of carbonizable material impregnated with carbonates of calcium or magnesium.

Measurement:—

Time-Registering Device for Electrical Currents, W. D. Wilder and W. Cobb, Jr., 464,540. Filed Nov. 18, 1889.
Registers automatically the length of time an electric lamp or motor is being used.

Electric Meter, A. G. Waterhouse, 464,683. Filed April 10, 1891.
Electro-chemical meter whereby the current is measured by the electrical decomposition of a fluid.

Metallurgical:—

Ore Separator, W. G. Conkling, 464,816. Filed Sept. 19, 1889.
A magnetic ore separator.

Process of Obtaining Metals from their Ores or Compounds by Electrolysis, C. S. Bradley, 464,933. Filed Feb. 23, 1883.
Claim 1 follows:
Process of obtaining metals from their ores of compounds, consisting of passing an electric current through a fused portion of the ore or compound contained in an unfused body or heap of said ore or compound.

Miscellaneous:—

Electric Fare-Recording System, B. S. Molyneux, 464,518. Filed Feb. 28, 1891.
Has for its object to record fares taken on an electric railway car at points distant from the car itself.

Cut-Out, C. R. Arnold, 464,548. Filed June 11, 1891.
Claim 1 follows:
A fusible cut-out consisting of an open glass tube having metal ferules at the ends and a fusible strip within fastened to said ferules.

Lightning Arrester, E. Thomson, 464,595. Filed Oct. 11, 1890.
Consists of a continuous conductor connected to ground and so arranged as to form a series of disruptive insulation spaces of a total resistance sufficient to prevent the passage of much of the line current to earth.

Electrical Condenser, N. Tesla, 464,667. Filed Aug. 1, 1891.
An electric condenser composed of plates or armatures immersed in oil and adjustable in respect to one another.

Drill for Electric Railways, H. P. Bradford, 464,678. Filed July 27, 1891.

Electrical Transformer, A. Poleschko, 464,677. Filed April 17, 1891.
Consists of a core of spaced iron plates having a vertical slot containing the primary coils and another slot at right angles to the first containing the secondary coils.

Electric Body-Wear, L. Anderson, 464,691. Filed Mar. 16, 1891.
An electric belt.

Clamp for Electric Wires, J. J. Green and G. C. Brown, 464,770. Filed Oct 30, 1890.
An insulating clamp adapted to hold firmly various sizes of insulated wires. (See THE ELECTRICAL ENGINEER of Dec. 2).

Railways and Appliances:—

Electric Railway-Signal, C. E. Buzzell, 464,490. Filed June 20, 1891.
An arrangement for automatically indicating the positions of semaphores, etc., at any desired point.

Conduit-Conductor for Electric Railways, W. H. Knight, 464,505. Filed Aug. 4, 1888.
Claim 4 follows:
In an electric railway the combination of a sectional supply conductor with safety devices normally included in circuit between succeeding sections thereof.

Electric-Railway System, L. O. Dion, 464,557. Filed Dec. 5, 1890.
An arrangement by which in a storage-battery system of electric traction the battery may be charged while the cars are in motion.

Carriage-Actuating Mechanism, W. H. Phillips, 464,587. Filed Feb. 2, 1891.
Relates to automatically controlling the movements of vehicles.

Electric Track Signal, H. A. Parrish, 464,655. Filed Mar. 9, 1891.
A railway signal actuated by the passage of the wheels of the locomotive over a tead-bar which completes an electric circuit.

Transmitting Mechanism for Motor Cars, C. W. Thomas, 464,640. Filed Jan. 23, 1891.
Claim 2 follows:
A combination with the track wheels and with the transmitting mechanism of the motor car of the four systems of optionally applied normally inactive brakes whereby the car can be started at the desired speed or brought to rest.

Trolley for Electric Railways, J. W. Schlosser, 464,780. Filed Aug. 10, 1891.
A jointed trolley arm the two parts of which are connected by a lash automatically tripped.

Telegraphs:

Automatic Fire-Alarm Telegraph, M. Martin, 464,510. Filed Feb. 21, 1887.

Telegraph Key, L. F. Robare, 464,897. Filed June 4, 1891.
A simple legless telegraph key from which the regular binding posts are omitted.

Telephones and Apparatus:—

Spring Jack Switch, W. R. Patterson, 464,519. Filed May 27, 1890.
A switch for use on telephone exchange boards obviating damage to the electrical connection resulting from accumulation of dust.

Means for Preventing the Interference with Speech on Telephone Circuits by Induced or other Currents, W. Stanley, Jr., J. F. Kelly, 464,529. Filed May 22, 1891.
Has for its object the elimination of induced currents by means of placing a receiving instrument in a portion of the circuit adapted by the adjustment of its self induction and capacity to oppose the passage of current waves below a certain frequency.

Protector for Telephones, J. L. W. Zietlow, 464,643. Filed March 31, 1891.
Relates to a method of protecting telephone and telegraph wires from the damaging influence of powerful currents.

Patent Notes.

AN EDISON PATENT FOR CONNECTING "TENSION REDUCING" DEVICES IN MULTIPLE ARC.

On December 8, a patent was issued to Mr. T. A. Edison, entitled "System of Distribution," No. 464,822, which will attract considerable attention owing to the broadness of the claims embodied in it. The patent was filed June 26, 1882, and describes the method of employing a high-tension main circuit extending to a distant point and "tension-reducers" located at a distance from the point of supply and connected with the high-tension circuit in multiple arc so as to be independent of one another, the lamps or motors on the derived low-tension circuit also being connected in multiple arc.

One method of accomplishing this object is described, consisting of secondary batteries or condensers which are charged in series from the high-tension circuit and discharged in multiple into the low-tension circuit, this being accomplished by means of a revolving commutator.

The patent was the subject of prolonged interference proceedings; its claims are as follows:

1. In a system of electrical distribution, the combination of a main circuit extending to a distance from the source of electrical energy and having a current of high tension, a constantly-acting tension-reducer connected with such main circuit by a multiple-arc or cross circuit, so as to be independent of other similarly-connected tension-reducers, and a translation-circuit supplied by such tension-reducer with a current of lower tension, substantially as set forth.

2. In a system of electrical distribution, the combination of a main circuit extending to a distance from the source of electrical energy and having a current of high tension, a translation-circuit, translating devices arranged in multiple arc in such translation-circuit, and a constantly-acting tension-reducer connected with such main circuit by a multiple-arc or cross circuit and also connected with said translation-circuit, said tension-reducer being charged from such main circuit and discharging a current of lower tension in said translation-circuit, substantially as set forth.

3. In a system of electrical distribution, the combination of a main circuit extending to a distance from the source of electrical energy and having a current of high tension and a translation circuit with an intermediate secondary battery or condenser, and a continuously-working commutator throwing all the elements of such secondary battery or condenser together and at the same time rapidly form a series connection with the main circuit to multiple-arc connection with the translation-circuit, and back again, substantially as set forth.

4. In a system of electrical distribution, the combination of a main circuit extending to a distance from the source of electrical energy and having a current of high tension, and a translation-circuit with an intermediate secondary battery or condenser, a commutator throwing all the elements of such secondary battery or condenser together and at the same time rapidly form a series connection with the main circuit to a multiple-arc connection with the translation-circuit, and an electric motor working such commutator, substantially as set forth.

The Edison Company claims that the patent covers the placing of converters or transformers in multiple arc.

ELECTRIC RAILWAYS—HUNTER vs. POPE.

Commissioner Simonds, on November 28, decided an interference of long standing between Rudolph M. Hunter and Franklin L. Pope, involving an important invention in circuits for electric railways in favor of Pope, reversing the previous decisions of the Examiner of Interferences and the Board of Examiners-in-Chief in favor of Hunter. The points involved were similar to those in the recently decided interference of Hunter *vs.* Jenkin.

CENTRAL ELECTRIC CO.

There have been a great many switches placed upon the market during the past year, but for quality and satisfactory results in every day use, the Bryant switch, it is claimed, has not been surpassed. The Central Electric Company, who are the general Western agents for this switch, have no reason to be afraid of a waning popularity, as some recent handsome orders attest.

The Central Electric Company's Chicago city trade has become of such importance and consideration, that they have been obliged to put on a special delivery wagon. In doing so, they have selected a wagon of original design and artistic appearance, which excites comment wherever it goes.

The Central Electric Company report a splendid business in their Improved Candee weather-proof wire, and Special Candee feed wire, for electric railways. These wires are the product of the Okonite Company, and are up to the high grade of this well-known company's products.

The method of giving away goods as a business policy to secure orders, is a novel one in the electrical business, and the Central Electric Company are entitled to the credit of this departure, which, they say, has been happily received by the trade, and has netted good results thus far.

"THEY COVER THE GROUND."

To the Toronto Construction and Electrical Supply Co., Toronto, belongs the credit of being the first wholesale electrical supply house in Canada to canvas the entire Dominion by means of capable traveling representatives, who each carry with them several sample trunks filled with the latest and best novelties for electrical uses. At the present time, one representative is in British Columbia, another in Halifax, N. S., and four others are at various points between the two first mentioned, which are nearly 4,000 miles apart, and as a result of such a progressive policy, the business of the company has increased with great rapidity. All purchases made by the Toronto Co. are for prompt cash, and consequently they buy to the best advantage.

ELECTRIC LIGHTING IN THE MARITIME PROVINCES.

The Moncton Sugar Refining Co., of Moncton, New Brunswick, are now equipping their buildings with an electric light plant, which is being installed by John Starr, of Halifax, who has also contracted to light the Pyrites Mining Company's property at Pilley's Island, Notre Dame Bay, Newfoundland; and the plant is now being installed under the superintendence of his electrician, Mr. C. A. Hoyt. The offices, stores, dwelling houses, wharves and tramway, besides the shafts and underground workings of the mine, will all be lighted by incandescent lamps of 16 c. p. each.

Mr. Starr, who is one of the pioneers of electric lighting in Canada, is general agent in Canada for the "Lahmeyer" system of dynamos, which are giving entire satisfaction in several factories which have lately been equipped.

Mr. B. Frank Johnson, of the Interior Conduit and Insulation Co., has removed from the Provident Building, Phila., to the office of Walker & Kepler, 531 Chestnut street, with which firm he is now associated in the Conduit Company's interest. This change was made necessary owing to the increasing demand for the more prompt delivery of the conduits and other products from the company's factory. Mr. Johnson reports having recently closed several large contracts in which metal-covered tubes will be exclusively used, and that the leading architects and builders are enthusiastic in their advocacy of this new conduit, as well as of the many other improved devices recently designed for the simplification and efficiency of the Interior Conduit Co.'s system of electric wiring.

Mr. W. S. Ford, long time superintendent of the Colorado Telephone Co. has been given the post of superintendent of Bell telephone underground work, with headquarters in Boston.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT

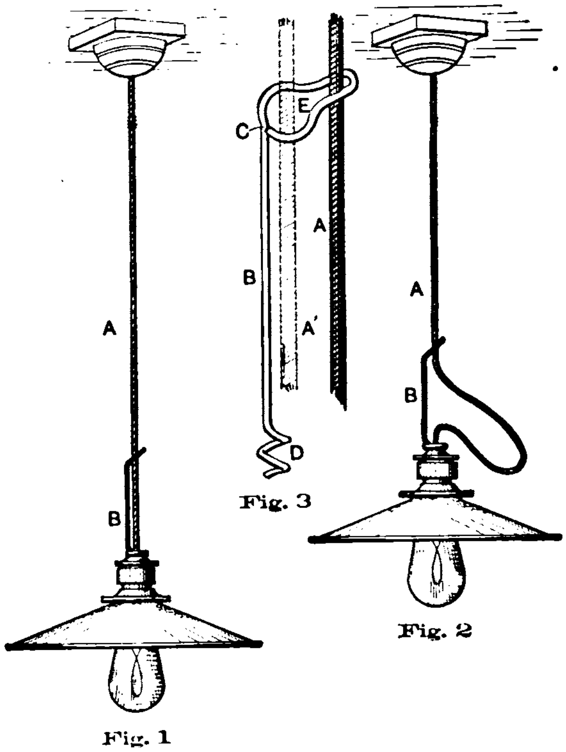
Choose your advertising mediums as you would your friends.

THE SCHENCK CORD ADJUSTER FOR SUSPENDED LAMPS.

THE necessity of a simple and effective cord adjuster by means of which an incandescent lamp when not in use may be readily and quickly moved out of harm's way, has led Mr. Unico H. W. Schenck, of Brooklyn, to devise the arrangement shown in the accompanying illustrations.

As will be seen, Figs. 1, 2 and 3 represent the adjuster in operation. It consists of a wire rod one end of which is rigidly attached to the lamp socket, and the other fashioned into a goose-necked loop, through which the flexible cord passes.

The device is attachable to any make of socket without discon-



SCHENCK LAMP-CORD ADJUSTER.

necting the cord. In Fig. 3, A represents the cord caught in the neck of the loop, and A', when the lamp is at its lowest point as in Fig. 1. Here B is the stem; C shows the end of the loop disjointed that the cord may be sprung into position without disconnecting it. The spiral end D around the cord fits into the hole in the socket used when the latter is attached to a bracket, and is held in place by the set-screw. The raising of the lamp is effected by simply allowing the cord to run through the large end of the loop in the rod and when the proper height is reached, catching it in the narrowed end. It can be operated by one hand.

This device is manufactured by the National Speciality Co., 720 Fourth avenue, Brooklyn, N. Y.

THE AKRON ELECTRICAL MANUFACTURING COMPANY.

THE above concern of Akron, O., has just closed contracts for the following machinery and apparatus: Four 40,000 watt incandescent dynamos, one 15-light arc dynamo, ½ h. p. motor and one 5 h. p, motor, to be placed in the new fireproof Lexington Hotel, at Chicago, Ill.; one ½ h. p. motor for Stanley & Co.'s coffee house, Akron, O.; one 50 light incandescent plant for the Akron Machine Co.'s works, Akron, O They have also sold five of their well-known Loomis fire-alarm boxes to be placed in various manufacturing establishments in Akron, and two to be included in the fire-alarm system of the city of Zanesville, O. Mr. W. D. Chapman, the general manager of the company, erports the outlook for new business as quite flattering.

MR. CHAS. E. CHAPIN.

MR. CHAS. E. CHAPIN, Electrical Exchange Building, New York, Rooms 417 and 418, announces his readiness to serve as buyer for all or any electric companies requiring machinery, material or supplies.

Mr. Chapin has had a large experience as an official in electric companies, and was for a long time the purchaser for the Sawyer-Man Electric Co., of New York. For the past year he has done the buying for Alexander, Barney & Chapin, of this city, but has recently resigned his position with that company.

Mr. Chapin's long and wide experience in the market for electrical goods would seem to guarantee careful and expert attention to any business entrusted to his hands. His character for probity and energy is well known to the electrical fraternity.

BALL & WOOD CO.

THE new plant of the Ball & Wood Co., builders of the Improved Ball automatic engines, is so far completed that shipments of engines have commenced, and the works have been running night and day since October first to clear up their order books. During the recent meeting of the Society of Mechanical Engineers in New York, the Ball & Wood Company had the pleasure of entertaining many of the members who took advantage of the proximity of the works to run out and inspect them and extend their congratulations. Orders for the Improved Ball engines have already been executed as follows: 150 h. p. for the State House, Trenton, N. J.; two 150 h. p. for the Edison Electric Illuminating Co., of Paterson, N. J.; 75 h. p. for the Saugerties Electric Light Co , Saugerties, N. Y.; 100 h. p. for the Meriden Electric Light Co., Meriden, Conn.; 75 h. p. for the Edison General Electric Co., Rockledge, Fla,; 100 h. p. for the Leominster Worsted Co., Leominster, Mass.; 150 h. p. for R. H. Macy & Co., New York; two 75 h. p. for the Four Seasons Hotel, Cumberland Gap, Tenn.; 150 h. p. for the Electric Light Co., Madison, N. J.; 150 h. p. for the Laconia Car Co., Laconia, N. H.; 300 h. p. cross-compound for the Edison Co., of Paterson, for street railway service.

WESTON ELECTRICAL INSTRUMENT CO.

THE WESTON ELECTRICAL INSTRUMENT COMPANY, Newark, N. J., has taken a contract to build a 5,000-ampere ammeter for the Wilson Aluminum Company, of Leaksville, N. C. This instrument is to be a very large form of the well-known Weston type of ammeter, with some important modifications to meet the peculiar requirements of the case. It will have a scale about 14 inches long, which will be divided into 250 parts. Each division will equal 20 amperes, and the divisions will be large enough to be easily read to tenths or 2 amperes, and with care to 1 ampere. The scale will be laid out by actual calibration to the full current to be measured by the instrument in practical work, namely 5,000 amperes. This may seem a somewhat astonishing thing for the Weston Company to do, especially when we consider the work which is commonly done by the use of a current of 5,000 amperes. Thus in incandescent lighting with the direct current, each 16 c. p. lamp requires about .5 ampere. The current required to standardize this instrument would therefore run 10,000 incandescent lamps. Notwithstanding the enormous strength of the current required, it is not beyond the facilities of the Weston Electrical Instrument Company to handle it in the regular course of their work, without a single change in their appliances or any special preparation.

The appliances of the company for standardizing work are generally known to be excellent, but we imagine it will be news to our readers to learn that any instrument-making firm in the world was in a position to command in its laboratory such enormous currents as those referred to. It is a fact, however, that this concern is already equipped to do this gigantic work.

Some idea of the perfection of the Weston Electrical Instrument Company's plant in this respect can be formed when we state that the copper conductors in the laboratory for handling ammeter work weigh about 4 tons and that some of the mains have a sectional area of 5 square inches, and that they are capable of carrying a current of 10,000 amperes without inconvenient heating.

THE SCHULTZ BELTING CO., of St. Louis, Mo., have just sold two "Woven Leather" link belts to the Citizen's Electric Railway Co., of Decatur, Ill.; fifteen in the State of Montana; five in the State of Washington; one flat belt, 48 inches wide, heavy double, to the Municipal Electric Light and Power Co., of St. Louis, who have been using one of their 48-inch double belts for 19 months. Also one double belt to Clinton, Mass., 30 inches wide and 175 inches long, and one 36 inches wide and 210 inches long.

H. WARD LEONARD & CO.

H. WARD LEONARD & Co. have secured the contract for wiring the *Mail and Express* Building for 3,500 incandescent lamps, acting as sub-contractors under the Waddell-Entz Electric Company.

They have also received an order from Wm. Sellers & Co., of Philadelphia, for two 40 h. p. motors for use upon traveling cranes. The motors are to be supplied under rigid specifications, as to dimensions and performance; but the decision as to the particular make of motors to be used is left with H. Ward Leonard & Co.

Mr. Leonard is now licensing various manufacturing and construction concerns under his recently patented system of motor regulation. The basis of the license is a charge $2.50 per K. W. (roughly per horse-power) in the motor. The royalty charge is not an annual charge, but is paid once for all in each case. Wm. Sellers & Co., have taken a license under Mr. Leonard's patent on this basis, they agreeing to use the method upon all electric cranes they build in the future during the life of the patent. The royalty is so small that the method will probably be rapidly introduced wherever it is applicable.

NEW HEISLER INSTALLATIONS.

THE HEISLER ELECTRIC LIGHT Co., of Philadelphia, report the following business:

Carroll Electric Light Works, Matteawan, N. Y. (increase of plant) 600 32 c. p. lights capacity. Messrs. Rheubottom & Bond, Union City, Mich. (increase of plant) 200 32 c. p. Merced Gas and Electric Light Co., Merced, Cal. (increase of plant) 400 32 c. p. Glazier-Strong Oil Stove Co., Chelsea, Mich., 200 32 c. p. Messrs. Cortright & Son, Homer, Mich., 160 32 c. p. Kingman Water and Light Co. (increase) 200 32 c. p.

The municipal plant now being installed by this company at West Toronto Junction, Ont., Can., is nearing completion, and the lights will be in operation very shortly.

The company also report a large and constantly increasing demand for their series lamps for use on arc light circuits.

PHILADELPHIA NOTES.

GEO. CAMPBELL & Co., who were recently burnt out at Washington Ave., have leased and are fitting up the mill at Clifton of the Longstreth estate. As part of the new equipment they have ordered of Messrs. M. R. Muckle, Jr., & Co., a 9-inch Westinghouse compound engine and a 300-light dynamo. Messrs. Muckle & Co. have also sold to the Onderdonk Heating and Ventilating Co. a 25 h. p. Jr. Westinghouse engine to drive the electric light plant and other machinery in the building of the Scott Paper Co., of Philadelphia.

MR. W. A. STADELMAN, of the Equitable Engineering & Construction Co., has closed a contract with the Curtis Bay Railway Co. of Baltimore, Md., for a complete electric outfit for their road. Mr. A. H. Rutherford and Mr. W. C. Sedden, the proprietors of the road, have, it is said, secured large blocks of stock in the new Edison lighting station which will soon be in operation.

THE PARTRICK & CARTER Co. have achieved a world-wide reputation on their King annunciators, and during the past year they have shipped these annunciators to nearly all parts of the civilized world. Last week they received orders from Moscow, Russia, and Constantinople, Turkey.

THE SPELLIER ELECTRIC TIME Co. held its annual meeting of stockholders last week, and elected Mr. H. B. Cutter president and general manager, and Mr. E. M. Dobelbower secretary and treasurer. The treasurer's report showed the company to be in a prosperous condition.

MR. L. K. PEROT, of the Equitable Engineering & Construction Co., is a benedict, having married last week Miss Jessie Hannis, daughter of one of our most prominent lawyers, Mr. William C. Hannis. They are spending their honeymoon in the South.

MR. J. W. PARKER has sold a 150 h. p. cross compound condensing engine to the Rock Creek Electric Railway Co., of Washington, D. C., and 150 h. p. standard engine to the Lynchburg, Va., Electric Railway Co.

THE AJAX METAL Co. are installing an incandescent plant in their factory on Richmond street, and have let the contract to the Pennsylvania Electric Engineering Co.

MR. GEORGE B. SHAW, general manager for the National Electric Manufacturing Co., Eau Claire, Wis., paid a flying visit to Philadelphia last Monday.

THE BINGHAM HOUSE are about to put in their own plant which will comprise two 500-light incandescent dynamos.

THE PENNSYLVANIA ELECTRIC ENGINEERING Co. have secured the agency for New Jersey, Pennsylvania and Delaware for the Ries regulating sockets.

QUEEN & Co. say that the demand for their new Wagner-Queen voltmeter has been away beyond their expectation.

NEW ENGLAND NOTES.

CAPT. A. DE KHOTINSKY, accompanied by his family, arrived this week in Boston, and will now be permanently attached to the staff of the Germania Electric Company, of Boston, as electrician of the company. Capt. De Khotinsky has for years been manufacturing incandescent lamps at Rotterdam and Frankfort, but will now devote the whole of his time to their manufacture in the States. The lamp which bears his name, and which was invented by him, has become very favorably known in Europe, and is remarkable for its enormous range as regards voltage, candle power and efficiency, running from 5 to 200 volts, from 4 to 300 candle-power, and from 1¼ to 5 watts efficiency.

THE REDDING ELECTRIC COMPANY, of Boston, are rapidly developing a very large trade in the East for the aluminium carbons, for which they are the sole New England agents, and which are becoming very popular. Their business in the well-known Redding watchman's clock is also increasing, and the company are on the outlook for live agents in all parts of the country to whom they would give exclusive territorial rights.

WESTERN NOTES.

THE ELECTRIC MERCHANDISE Co. have the Burton electric heaters in daily operation on 90 roads. This shows a remarkable appreciation of their advantages and commercial practicability. The number in use is rapidly and continually increasing. It is needless to say that in every case they are giving entire satisfaction. These heaters are also in use for house heating and in office buildings and are a great success. Those who are still skeptical as to the economy and practicability of this means of heating should write the above company, who will be glad to furnish full details.

THE POND ENGINE Co., through their Chicago office, have closed a contract to replace the 60 h. p. Armington & Sims engine in the American Express Company's building on Monroe street with an engine of the same make of 120 h. p. The present engine will be moved to the express stables on Sebor street to operate the lighting plant in that building. For the past nine years the American Express Company's plant has been operated by an Armington & Sims engine, which has given such good satisfaction that the present order was secured in spite of unusually sharp competition.

MR. F. DAY VOORHEES, the popular general agent of the Norwich Insulating Wire Co., of New York, was a visitor to Chicago last week looking after the sale of his paper wire for underground and interior use. Mr. Voorhees reports that he has got a large amount of cable working on underground arc lighting circuits here, and that it is giving the most eminent satisfaction. In fact, no trouble at all has ever been occasioned by it, which speaks highly for the insulating qualities and manufacture of the cable.

MR. W. J. PILICY, well known in Eastern and Western electrical circles, has united himself with the Illinois Electric Material Co. as their selling representative. Mr. Pilicy is popular among the electrical fraternity in the West and will no doubt command his full share of the trade.

MR. WM. HOOD is the only customer of the Chicago Arc Light & Power Co. who can look on their recent burn-out with smiling complacency, as he throws on his "Jewel" incandescents just the same as ever. This is one of the cases where the storage battery comes to the front.

MR. E. C. OLDACRE, general agent of the Jenney Motor Co., was a caller at the Western office of THE ELECTRICAL ENGINEER last week. He has been spending some time in Chicago looking after some important deals, and his many friends in this city are always glad to see him.

MR. CHARLES B. COON, of Hill clutch fame and the manager of the Chicago office of that firm, has returned from some recent business trips, upon which he succeded in placing a large amount of their well-known clutch and shafting work.

☞ Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Miscellaneous, etc., will be found in the advertising pages.

THE
Electrical Engineer.

VOL. XII. DECEMBER 23, 1891. No. 190.

THE NICHOLSON ELECTRIC HOISTING AND CONVEYING MACHINE.

THE application of the electric motor to the many forms of hoisting devices has engaged the attention of electrical and mechanical engineers within the past few years to an extent that has perhaps not been fully appreciated by those not directly connected with the development of this department of electro-mechanics. Of this class of apparatus the machine recently produced by the Nicholson Electric Hoist Company, of Cleveland, Ohio, is entitled to consideration as occupying a field not hitherto invaded by the electric motor—that of unloading ore and coal from vessels at docks, and hoisting and conveying the material to stock piles or freight cars convenient for future movement.

The Nicholson machine is the invention of Mr. Ezra Nicholson, of Cleveland, and is shown in the accompanying engravings made from photographs taken of the first plant installed on the docks of the Cleveland Rolling Mill Company. The apparatus consists of a drum hoist, electric motor and controlling devices mounted upon a tram-car constructed of light steel I beams.

The gauge of the car is five feet, wide enough to admit of hoisting the loaded bucket between the girders and up into the tower of the car. In operation the tram-car is run out on the boom directly over the hatch of the vessel and the bucket lowered by gravity, being controlled by a brake on the hoisting drum. The motor is disengaged from the gearing on the axles of the car and thrown into gear with the hoist by a single movement of a clutch lever. The controlling-switch is moved to turn on the current, and the loaded bucket is hoisted at the rate of 5 feet per second vertically to the frame of the car. When the sheave-block reaches the top frame it is locked automatically, and at the same time the power is transferred to the car axles, and the car moves along the tramway at the rate of 20 feet per second to any desired point, where it is stopped by the operator.

The loaded bucket is then tripped by the operator and the contents are dumped on the stock pile, or the bucket lowered to a freight car and there dumped by the operator, who hoists the bucket to the tram-car and returns for a new load. The time occupied in actual work in hoisting a loaded bucket of ore weighing 3,000 lbs. and carrying the load 200 feet, dumping and returning for a new load, is 55 seconds. The time occupied in accomplishing the same work by the steam automatic cable systems is 70 seconds.

The tramway upon which the machine moves is elevated 35 feet above the surface of the dock, and is so arranged mechanically as to admit of lateral movement along the dock, the front and rear frames resting upon tracks for that purpose. The front boom of the tramway is run out over the vessel's hatchway, being supported by guys, as shown in the photograph, and in order to allow the vessel to leave the dock, the boom is folded up and rests against the front frame.

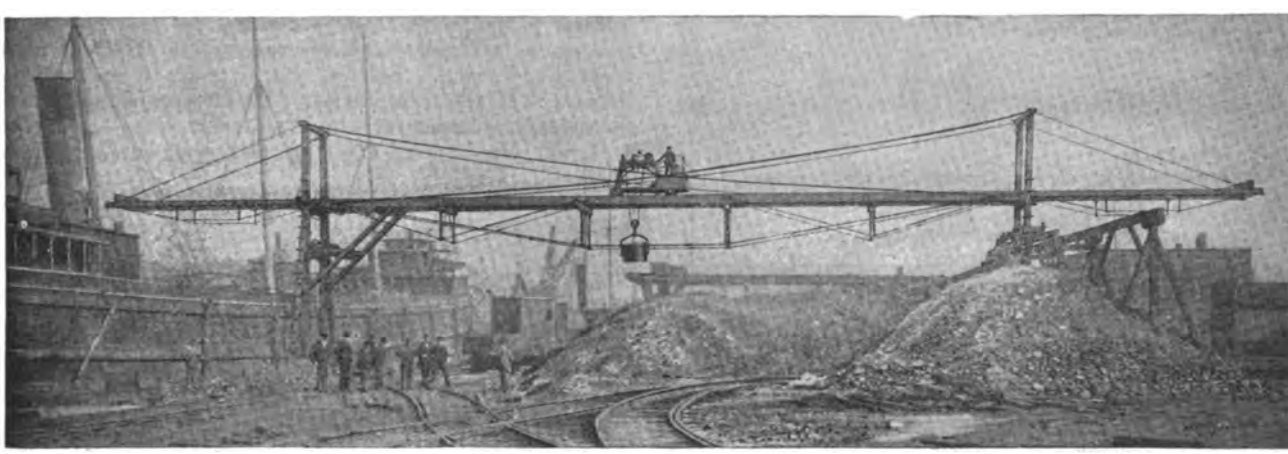


FIG. 1.—THE NICHOLSON ELECTRIC HOIST AT WORK ON THE ORE DOCKS, CLEVELAND, O.

Power for the motor is obtained from a station located near by, and a trolley wire is located upon the top of one of the girders. The trolley-wheel, by a downward contact, feeds the motor. The motor is perfectly insulated from the frame of the car, as is also the hoisting drum and wire rope. A ground wire is connected to the wheels of the car, and the rails are all bonded and grounded to water pipes adjacent.

The carrying out of the mechanical details of this electrical hoisting and conveying system, has been very carefully accomplished by W. P. Williams, engineer of the company and member American Society Civil Engineers, before whom the plan of operation was recently explained. Mr. Williams' plans for the operation of a large plant are very complete. By taking advantage of the intermittent character of the work, the power plant may be much smaller than the total combined power of the hoists, so that great economy of room as well as of power is had; or the station may be away from the docks entirely. Mr. Williams also proposes to utilize the power plant for lights to facilitate work at night, and has devised some special apparatus for safely lighting the interior of the vessels while being unloaded, as well as the docks. The motor employed by the company is the single-magnet type of 30 h. p. and together with the controlling devices was designed for this special work by Mr. Frank B. Rae, of Detroit.

One great advantage of the Nicholson system is the presence on the tram-car of the operator, who is at all times over the scene of work, and has perfect control of the movements of the car. This obviates the necessity of the signal men used in the steam cable systems. The mechanical parts subject to wear and tear are reduced to a minimum in the electric hoist, and the absence of the boiler and engine plant of the steam systems occupying room valuable for storage of ore, is an important feature. The first cost of construction, the cost of maintenance and the expenditure for labor are all much less with the electric system than where steam cables are used.

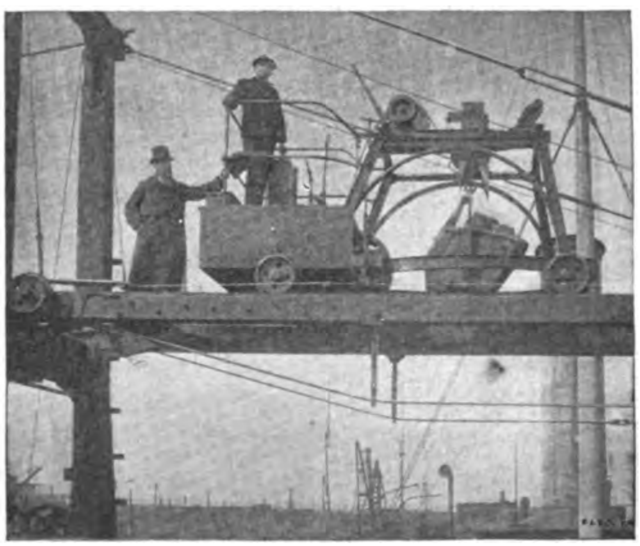

Fig. 2.—The Nicholson Electric Hoisting and Conveying Machine for Handling Freight on Docks, etc.

A few figures concerning the iron and coal interests of the great lakes may show to what a magnitude the work of loading and unloading vessels has reached on those inland waters.

During six months of navigation in 1890, nine million tons of iron ore was transported by vessels from the mines on Lake Michigan and Lake Superior to ports on Lake Erie, where it was unloaded. At Cleveland alone last year, two million tons of ore were unloaded at the docks, and one million tons of coal were shipped to the upper lake ports. In order to accomplish this amount of work, many of the docks have been equipped with steam systems of hoisting and conveying, at a great expense. The average cost of the ore tramways or "bridges" equipped is $10,000, and oftentimes six of these bridges are placed opposite one vessel for unloading.

These steam hoists only work in the day-time, while the Nicholson system is designed to work at night as well as during the day, thereby reducing the length of time necessary for vessels to remain at the discharging port. In these days of radical changes, time is the most important element to the vessels of lake marine, and with the advent of the "Whaleback" barges and steamers of greater speed and carrying capacity, the terminal companies must equip their docks with hoisting plant giving the greatest dispatch.

The Nicholson system appears to supply this want and not only will many of the docks at the lake ports recognize this and equip with electric hoisting and conveying machines, but other ports where it is desirable to unload merchandise from steamers, such as boxes, casks, bales, etc., and remove the goods to some point for storage more cheaply than by using 'longshoremen, will adopt this economical system.

The Nicholson Electric Hoist Company has been organized by Mr. Williams in Cleveland, and the directors are men largely identified with the shipping and iron mining interests of that region. Mr. C. W. Foote, formerly agent of the Sprague and Thomson-Houston Companies at Cleveland, is the general manager of the company. The mechanical work and bridges will be constructed by the Cleveland Ship Building Company, while the electrical equipment will for some time to come be purchased in the open market.

COMPENSATING RESISTANCES FOR GALVANOMETER SHUNTS.

BY

Charles P. Frey

The ordinary operation of connecting a resistance commonly called a shunt in multiple with the coils of a galvanometer, and thereby decreasing the current flowing through the instrument, and consequently confining the swing of the needle to an observable range, is too well known to require description. In order to reduce the deflections to known proportions, it is necessary to use coils in both galvanometer and shunt, the resistances of which have an ascertained value. Briefly, the formula for shunts is as follows: If the total current (C) divides between two resistances, the lesser resistance will carry the greater current and vice versa. The proportion of current traveling through the galvanometer will be $C\frac{S}{G+S}$, and the current flowing through the shunt will be $C\frac{G}{G+S}$.

For convenience in calculation, the resistances of shunt coils are usually proportionately adjusted so as to reduce the galvanometric sensitiveness to its $\frac{1}{10}$, $\frac{1}{100}$ and $\frac{1}{1000}$ part.

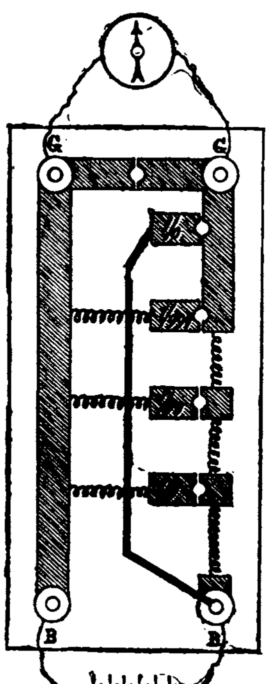
Shunt coils form an important adjunct to a galvanometer, especially when the latter is of the reflecting type, and is to be employed in connection with other apparatus for determining the value of high resistances. When the conditions of lines or the insulating qualities of materials used for covering wires are to be tested, shunts are almost indispensable. In high-resistance measurements, the usual method of employing shunts is to determine the "constant" of a galvanometer by means of the $\frac{1}{1000}$ shunt, and noting the deflection.

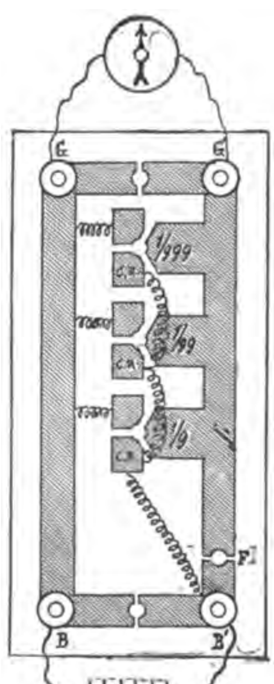
The "constant" once determined, the insulation of the line, etc., is generally measured by cutting out the shunt and any resistance that may have been introduced in the circuit, and taking readings with the galvanometer at maximum sensitiveness. An error in the degree of deflection obtained when the shunt is used will hence introduce an error in the basis for calculation. It is therefore evident that it is of intrinsic importance to secure shunts upon the correct adjustment of which dependence can be placed. When purchased from reliable manufacturers, there is usually no cause for apprehension on this score, but nevertheless there is a source of error involved in the use of ordinary shunt coils which, as one writer has it, "introduces an element of vagueness in the result." The fact is, a shunt having a resistance of, for instance, exactly $\frac{1}{9}$ the resistance of the galvanometer, will *not* reduce the deflection to precisely $\frac{1}{10}$, although the formula previously referred to seems to proclaim that such will be the case.

Disproportionate deflections are sometimes correctly attributed to lack of proper adjustment in the position of the scale. Obviously it is essential to adjust the scale so that it will be perpendicular to the reflected beam when the latter is not moving, but even this precaution will not eliminate the discrepancy.

Several prominent writers on the subject of electrical "testing," among others, Sprague, Ayrton, Gordon and Kempe, have mentioned the peculiar characteristic of shunts referred to, but only one author (Kempe, as far as the writer of this article can discover) has treated the subject exhaustively. In his excellent handbook on Testing, Kempe explains as follows :

. . . . "When a shunt is introduced between the terminals of a galvanometer which reduces its sensitiveness to one-half, or a shunt equal to the resistance of the galvanometer, it will not exactly halve the current passing through the instrument. If we used a tangent galvanometer, we would find, if the deflection without the shunt was 40 divisions on the tangent scale, the introduction of the shunt would not bring the deflection down to 20, but some deflection greater than 20. The reason of this is that the introduction of the shunt reduces the total resistance in the battery circuit, and consequently increases the strength of the current passing out of the battery. It is this increased current, then, which splits between the galvanometer and shunt, and not the original current. To make up for this decreased resistance caused by the introduction of the shunt, it is necessary to add in the battery-circuit a *compensating resistance* equal in value to the amount by which the original resistance was reduced."





KEMPE'S ARRANGEMENT. FREY'S ARRANGEMENT.

FIGS. 1 AND 2.—COMPENSATING SHUNTS.

In addition to the above extract, Kempe devotes several pages of his work to mathematical considerations of the subject, and also describes and illustrates a compensating shunt-box of his own invention, a highly ingenious contrivance, which will be explained in this article.

The value of a compensating resistance (if introduced in the battery-circuit) must, in order to maintain a uniform current, be equivalent to the difference between the resistance of galvanometer and shunt in multiple, and that of the galvanometer only. When the resistance of the galvanometer is, for instance, 5494.5 ohms, and its sensitiveness is to be reduced to its $\frac{1}{10}$ part, the value of the shunt will be $5494.5 \times \frac{1}{10-1} = 610.5.$

The resistance of the divided circuit (galv. and shunt) will be $\frac{G\,S}{G+S} = 549.45.$ The compensating resistance will be

$$5494.5 \times \frac{10-1}{10} = 4945.05$$

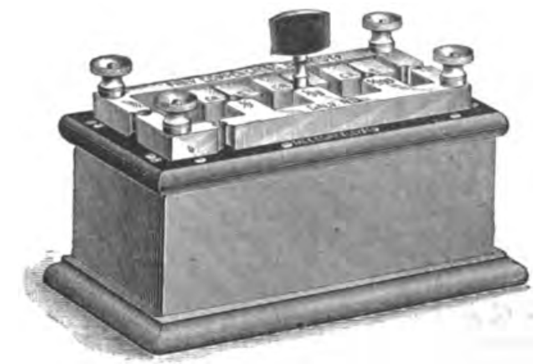


FIG. 3.—FREY COMPENSATING SHUNT.

Or, the compensating resistance (C) may be determined as follows : $C = G - \frac{G\,S}{G+S}$. In simple arithmetic the compensator equals, in this case, $5494.5 - 549.45 = 4945.05$. Kempe's device for combining shunts and compensating resistance so that both may be thrown in circuit by means of one plug, is illustrated by Fig. 1. By following the path of the connections it will be seen that by placing a plug in the hole marked $\frac{1}{2}$ the shunt is cut out. Now removing the plug to the $\frac{1}{1000}$ position will throw in circuit a shunt equal to $\frac{1}{999}$ of G and also introduce in the battery circuit a compensator consisting of three branches connected together in series, which jointly equal $\frac{999}{1000}$ of G.

Placing the plug in the $\frac{1}{10}$ position will, however, necessitate a change in the ratio of the corresponding shunt coil, since that part of the compensating coil which is between the $\frac{1}{10}$ and $\frac{1}{100}$ contact blocks, is now added to the *galvanometer circuit*. Hence this resistance becomes an inconvenient factor which must be taken into consideration in determining the value of the $\frac{1}{10}$ shunt. When the $\frac{1}{2}$ shunt is to be used, matters are still further complicated, as will be seen by referring to the diagram. The formula for determining the value of shunts and compensators of this type may be found in Kempe's treatise. The instrument itself has not however come into general use, owing probably to the intricate adjustment required, and the difficulty involved in testing the various requisite resistances. Figs. 2 and 3 illustrate a shunt box with compensating resistances which (the writer believes) embodies all of the essential features of Kempe's arrangement without the attendant complications already referred to. Its construction is exceedingly simple, and can be at once understood by tracing the path of connections on Fig. 2. It consists primarily of three shunt coils of usual proportionate resistances. These can be successively thrown in circuit together with suitable compensating coils, by means of a single plug, which, when inserted, connects in each case two independent blocks with a common conductor. The battery wires are connected at B and B' as shown and the galvanometer at G and G'. Now if one of the shunt coils is in use and an extra plug (not required for actual tests) be inserted at F, the compensating coils will be short-circuited, and since the principle of adjusting the shunt coils to $\frac{1}{10}$, $\frac{1}{100}$, and $\frac{1}{1000}$ (or any other preferred fraction) of the galvanometric resistance is maintained throughout, the box will not, under the given conditions, differ from one of conventional pattern as far as the shunt coils are concerned. When, however, the extra plug at F is removed, the path of the current from the battery will be from the insulated block at B' *through the compensating resistance* to the nearest block marked $C\ R$. If the plug is inserted at $\frac{1}{10}$, the current will then split between the $\frac{1}{10}$ shunt and galvanometer coil. Between the first block $C\ R$ and the second is another compensator connected in series with the first one, and between the second and last block is a third coil connected in series with the two others.

Since each block will be insulated when unplugged, the wire used for the $\frac{1}{10}$ compensator may form part of the compensator for the $\frac{1}{100}$, etc.

The resistance of the three parts of the compensating coils is determined as follows: Let G (the galvanometric resistance) be 5494.5 ohms. The $\frac{1}{10}$ shunt compensator will then be 4945.05 ohms (see preceding formula). The total resistance of the $\frac{1}{100}$ compensator will be 5439.555; but since part of this resistance is furnished by the $\frac{1}{10}$ compensator, the resistance of the coil between the first and second blocks marked $C\ R$ will be $5439.555 - 4945.05 = 494.505$, while the resistance between the second and third block marked $C\ R$ will be: $5489.0055 - 5439.555 = 49.4505$. Hence it is obvious that the resistance of the entire circuit will remain uniform, whether shunt coils are used or not. When it is desired to use the galvanometer at maximum sensitiveness, the plug is removed from the shunt coils and inserted at F. This simultaneously cuts out both shunt and compensating resistance and permits the current to travel directly to the galvanometer, through the brass bars.

Removing the plug entirely leaves the circuit open. To short circuit the battery and leave the galvanometer open, the plug is placed between B and B' and finally when experiments are concluded, the galvanometer can be short circuited and the battery circuit left open by placing the plug between G and G'.

In addition to general ease of manipulation, this form of compensating shunt has the advantage of being easily and quickly tested for accuracy with the aid of a rheostat and bridge. The resistances of the shunts only can of course be tested by connecting G and G' and shifting the plug. By connecting at B' and G' the compensating coils can be measured in the same manner.

Greeley Laboratory, Greenbush, N. Y.

THE POLESCHKO TRANSFORMER.

All existing transformers may be classed in two groups; in the one, such as the Ruhmkorff coil, the Gaulard & Gibbs and the Swinburne "hedgehog" transformer, the iron core is in the form of a cylinder; in the other the iron core is in the form of a closed geometrical figure, annular as in the Zipernowski, Deri and Blathy, or otherwise, as in the Westinghouse, Ferranti, &c. In transformers of the first group, the lines of force generated in the iron core by the action of the primary helix are given off as a bundle from the north pole and proceed to the south pole across the outer space, where they form closed curves of all possible radii. The secondary coil in this case is in the intermediate space between the iron core and the exterior system of the lines of force. In transformers of the second group, all the lines of force generated in the iron core by the action of the primary coil remain entirely in the core itself without appearing at the exterior. These lines of force remaining in the iron core can only pass in the interior of the spirals of the secondary coil or they may encircle the outer secondary coil. In both cases the lines of force never touch the secondary helix itself.

In transformers of the first group, as well as the other, the secondary coil is not traversed by all the lines of force which circulate in the iron. It is only a small portion of the lines of force which detach themselves, so to speak, from the general magnetic flow which reaches the secondary coil in closing along short elementary curves.

Recently however, Mr. Arcadius Poleschko, of St. Petersburg, Russia, has devised an arrangement, shown in the accompanying illustrations, by which the magnetic

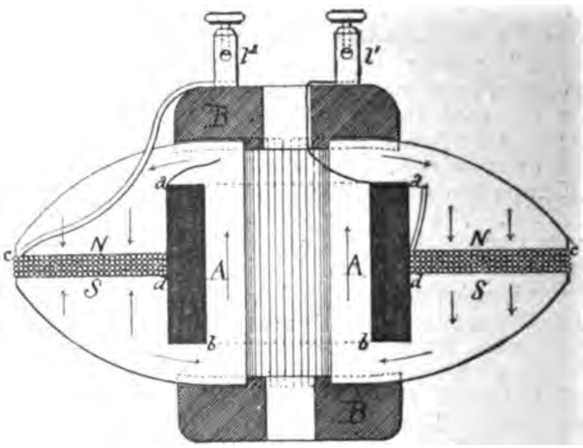

Fig. 1.—The Poleschko Transformer.

flux in the iron is all made to pass entirely across the secondary coil. In this apparatus the secondary helix $\pm l_2 \mp l_2$ is influenced in the first place by the current in the primary helix $\pm l_1 \mp l_1$, and in addition by the whole of the magnetic flux which is developed in the iron core A A by the action of the primary coil upon this core.

The core consists of blades or thin plates of sheet iron. The plates A A, the shape of which is shown in Fig. 1, are arranged in the form of a ring and inserted at the top and bottom into two insulating hubs B B. The primary coil $\pm l_1 \mp l_1$ is arranged in the vertical cavity *ab* within the interior of the core, Fig. 1, and the secondary coil $\pm l_2 \mp l_2$ is arranged outside the first in the form of a flat ring of small height, but of great breadth, in the direction of the diameter of the ring. The secondary coil of this shape is placed in a narrow channel *cd* in the core, extending substantially at right angles to the slot *ab*. The ends of the two coils are led to corresponding terminals on the insulating hub.

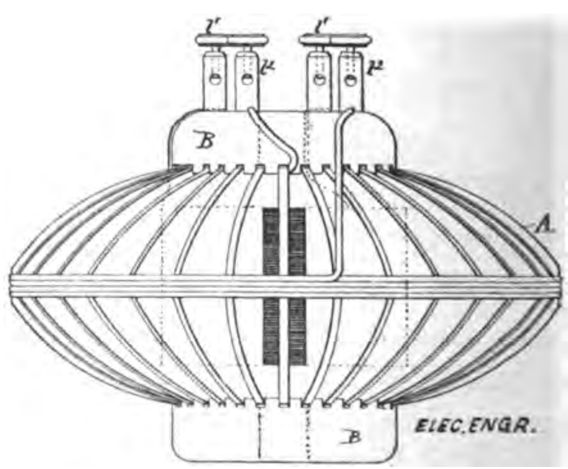

Fig. 2.—The Poleschko Transformer.

The channel which cuts the mass of the core across the direction of the lines of magnetic force increases very considerably the rapidity of demagnetization and diminishes the hysteresis. The thin iron plates of the core are insulated one from another by air. This arrangement of core has the double advantage of avoiding Foucault currents and of increasing the cooling surface.

THE ELECTRICAL USES OF EUREKA TEMPERED COPPER.

Among the numerous improvements in detail which have aided in raising the electrical arts to their present high standard, those relating to the manipulation of cop-

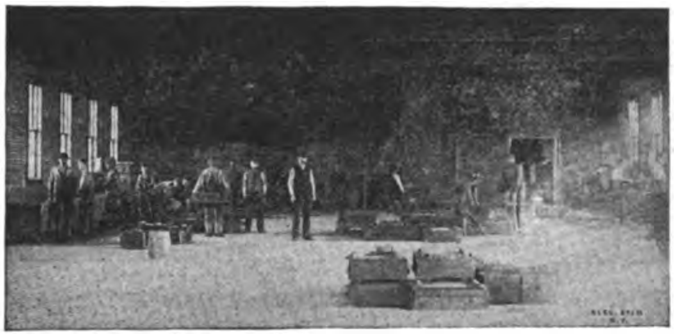

Fig. 1.—Moulding Room, Eureka Tempered Copper Co.'s Factory, North East, Pa.

per itself may well claim a prominent position. As copper in its various forms constitutes a vital material of all electrical apparatus, and especially that of dynamo-electric machinery, a process by which its life could be prolonged was, therefore, a problem, the solution of which might well occupy the time of investigators. It was already known that copper had been tempered by the ancients, as borne witness to by specimens of copper edge-tools in many museums; but the tempering of copper was a lost art, until within a few years, when Mr. Almer Thomas discovered the process as the result of a prolonged attempt to overcome a seemingly insurmountable difficulty. The history of the discovery is well worth recording here. It would seem that trouble with a wrist-pin box in the oil regions of Pennsylvania, while drilling an oil well, led

Fig. 2.—"Gate" Room.

him to experiment with all the remedies and mixtures of metal, and, finding none that would keep cool where he had to use the box, he tried copper, but with no better results. He then, with true Yankee grit, determined to try a scheme of making the box do the work and, after days of patient labor, he succeeded.

From this successful start many annoying wrist-pins in all the surrounding country were repaired and engineers felt that their days of trouble were fast disappearing. Mr. Thomas had in effect discovered, first, a method of casting pure copper without alloys of any kind and free from blow-holes; and, second, a method by which the copper so cast could be hardened sufficiently for all mechanical uses and imparted a strength equal to that of ordinary steel, or, if desired, made as malleable as wrought-iron and capable of being welded or forged into any desired shape by any blacksmith.

The marvelous success met with at once enlisted the attention of capitalists, and the Hon. W. L. Scott and Messrs. Alfred Short and Luzern Merket were associated with Mr. Thomas in the advancement of the new art. This resulted in the formation of the Eureka Tempered Copper Co.

Mr. Alfred Short, who has been a conspicuous figure in all enterprises of a mechanical nature in North East, Pa., was made president and general manager of the company, and in less than two years the company was enabled to construct a building devoted entirely to its own uses. This building is constructed of brick with slate roof, a model in design, furnishing free ventilation, and the moulding-room, shown in the engraving, Fig. 1, is 150 feet by 50 feet and 16 feet in the clear, being probably without ex-

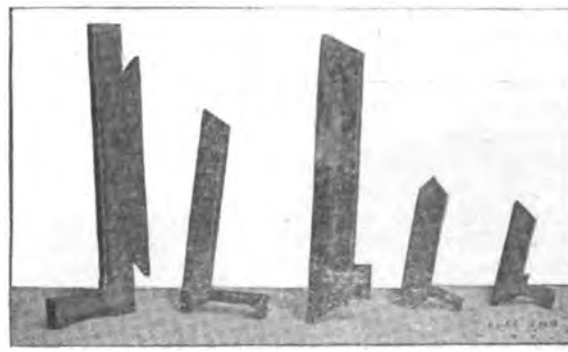

Fig. 3.—Various Forms of Commutator Segments.

ception the largest copper foundry in the world. It is designed to accommodate 12 massive copper furnaces.

The gate-room, Fig. 2, adjoins the moulding-room, where are located many workmen cutting off gates and grinding the surplus from castings. The gate-room was formerly the old moulding-room and is 50 feet by 50 feet.

With a material of this character at their command, and knowing the difficulties encountered with commutators and brushes, it is not to be wondered at that the company devoted the first eighteen months of their existence entirely to the manufacture of commutator segments and brushes.

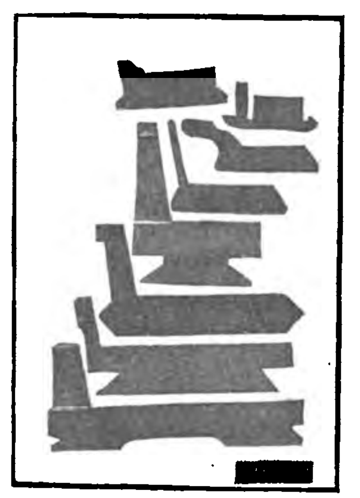

Fig. 4.—Various Forms of Commutator Segments.

For, in spite of the many attempts which have been made to supersede the employment of copper subjected to wear in electrical apparatus, the fact remains that at the present time, no substitute is available which can be said to compare with copper for such purposes. This quest for a substitute was early inaugurated in the present electrical era, and as a result we may note the employment at various times of commutator bars of brass and various alloys, and, in one instance even, of iron, but they all lack the essential qualities of conductivity and toughness which copper alone possesses, and which is brought out in a marked degree in the tempered copper manufactured by the Eureka Tempered Copper Company. This metal combines those peculiar qualities which enable the commutator bar to withstand the peculiar action to which all surfaces transmitting heavy electric currents are subjected. This quality, once pointed out, was quickly appreciated by the manufacturers of electrical apparatus with the result that at present scarcely a single part of electrical machinery subject to rubbing contact and wear is now employed in which the Eureka tempered copper is not in use. Thus, in the accompanying engraving Fig. 3, are illustrated a variety of commutator segments employed in various types of machines which in themselves form an interesting study of methods of construction of this particular and important part of all direct current dynamos. Still other forms of commutator

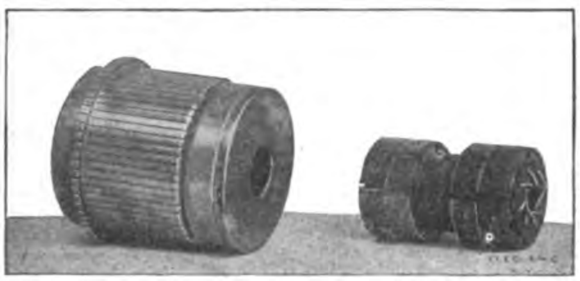

Fig. 5.—Low and High Potential Commutator.

segments are shown in Fig. 4, each having its peculiar individuality. Fig. 5 shows two well-known types of commutators, that to the left being the usual type employed with the Gramme and Siemens type of armature; and that to the right, a Brush commutator.

But there are still other important surfaces subject to wear on the dynamo, namely, the brushes, and in this direction, also, the Eureka Company has applied its metal with eminent success. Fig. 6 shows the various types of brushes, from those with fine slits up to the type embodying almost a solid construction, adapted to various types of machines. These brushes partake of the same nature as the commutator segments in their wearing qualities, in toughness, as well as in their conductivity, and, as a con-

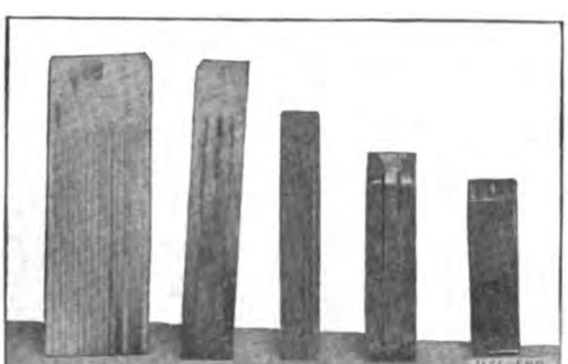

Fig. 6.—Types of Tempered Copper Brushes.

sequence, where both are used the sparking at the commutator is reduced to a minimum.

The large wear met with in some of the practical details of electric railway work has also developed several important applications for tempered copper there. Among these we may mention its employment in the gears employed to transmit the power from the motor to the car axle, and also for trolley wheels to take the current from the overhead wire, examples of which are shown in Fig. 7. In the case of the gear wheel, its peculiar toughness gives it not only a long life, but the anomalous structure of tempered copper largely reduces the noise, which is so noticeable and disagreeable a feature in steel pinions. In the case of

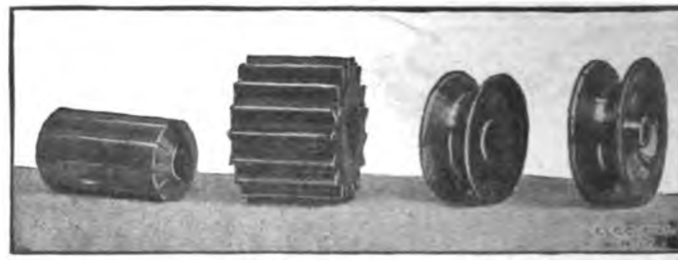

Fig. 7.—Railway Gears and Trolley Wheels, Tempered Copper.

the Eureka tempered copper trolley wheels, its wearing qualities have also largely reduced the difficulties encountered by this necessary adjunct to electric railway work. That important *vade mecum* of the electrical worker, the soldering iron, has also brought out the admirable qualities of tempered copper, and our illustration, Fig. 8, shows two forms of such soldering irons, which are very little liable to "burn." This illustration also shows a segment of a Thomson-Houston commutator, for which this copper has been largely employed.

Numerous tests have shown tempered copper to consist

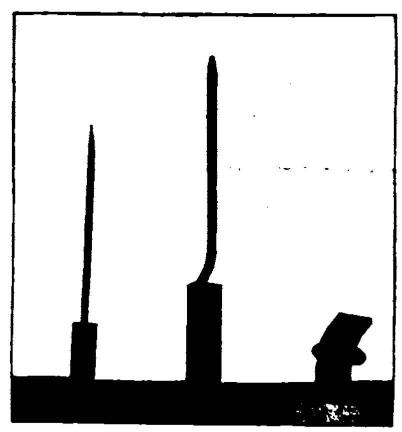

Fig. 8.—Tempered Copper Soldering Tools.

of copper 99.981 per cent. pure, with a tensile strength of 64,000 lbs. per square inch and a compression strength of 189,000 lbs. to the square inch. A test made a short while ago by the Austrian Government Industrial Department at Vienna, showed a higher tensile strength than many of the steels which had been tested there.

Wire made from tempered copper is being largely used for all purposes where great strength is desired, and its purity renders its conductivity far greater than copper alloys. Besides this, its fibrous nature makes it an excellent metal for bearings, to which purpose it is now being largely applied.

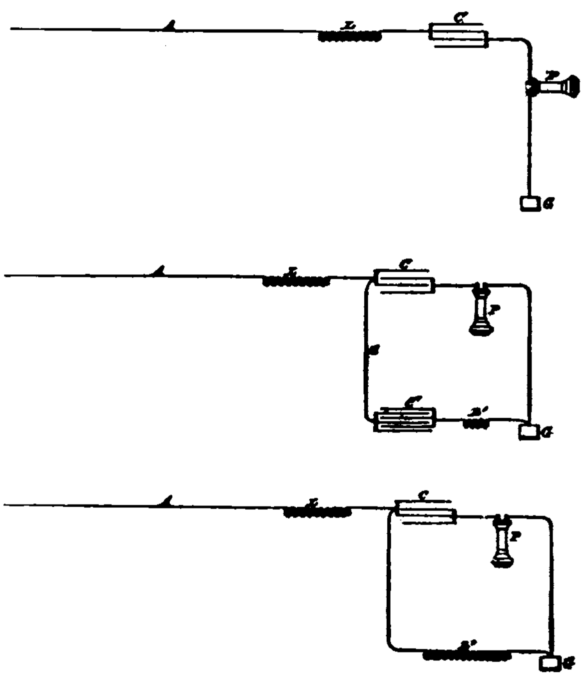
We may note here also that in recognition of the remarkable and valuable properties of Eureka tempered copper, the company has been awarded the John Scott Medal of the Franklin Institute.

Besides the shops illustrated, the works of the company embrace a large store and packing room. The products here assembled include everything made of copper, from the smallest contact buttons or spiral springs, to bearings weighing half a ton each. The machine shop and pattern-room are also extensive and all buildings are equipped with machinery of most modern construction and latest improvement.

The situation on the line of the Lake Shore Railroad, and the New York, Chicago and St. Louis Railroad, with branch tracks running into the works, gives them unexcelled shipping facilities. Each department of the immense works is under the direct charge of a foreman of thorough training and experience, and only skilled workmen find employment in the works. With these advantages the company are enabled to produce the best quality of work, which is attested by the fact that there is scarcely an electrical manufacturing concern in the country that does not use tempered copper in one form or another. The growth and success of this important enterprise is a most striking instance of the manner in which electricity stimulates work in other fields; and the subject has seemed to us specially worthy of extended treatment in our columns.

STANLEY AND KELLY'S INDUCTION PREVENTER FOR TELEPHONE LINES.

It is a well-known fact that the self-induction and capacity of an electric circuit over which a current of a given periodicity is flowing may be adjusted relatively to



Figs. 1, 2 and 3.—Stanley & Kelly's Telephone Induction Killer.

each other and to the current so that only the dead resistance of the circuit will be opposed to the passage of such current. In general, if n be used to denote the number of complete waves of the current per second, L, the coefficient of self-induction of the circuit, and M, its capacity in microfarads, then any line that possesses the necessary values of L and M in the equation

$$n = \frac{10^3}{2\pi\sqrt{LM}}$$

will offer no other opposition to a current of n waves than that of ohmic resistance. It is obvious, however, that for all other frequencies an opposition other than that of ohmic resistance will appear, for higher frequencies, due to an unbalanced self-induction, for lower, to an unbalanced capacity. It is clear, moreover, that as the capacity introduced continues to neutralize the self-induction to some extent for all frequencies, that all rates above the normal will get through more readily than if no capacity were present, although the farther they are from the normal the less will they be helped. It is otherwise with lower frequencies. Here the opposition is due to the capacity, the new element introduced into the circuit, and for rates a certain amount below the normal, the opposition offered by the unbalanced condenser is greater than that previously afforded by the self-induction alone.

In applying this principle to preventing interference due to induction on telephone circuits, Messrs. William Stanley, Jr., of Pittsfield, Mass., and John F. Kelly, of this city, have recently devised the method illustrated in the accompanying engravings. In Fig. 1, A is a telephone line grounded at G, and P a receiver. In order to oppose disturbing currents, a self-induction coil L and a condenser, C are introduced into the circuit between the receiver and the line.

The relative values of these devices are readily adjusted by varying the length of the coil and the size of the condenser, so as to hinder to a very great extent the propagation of waves of a frequency below a predetermined limit, while favoring those producing speech.

In Fig. 2 this arrangement is modified by the addition of a shunt S from line to ground around the condenser and the receiver, which is so adjusted as to capacity and self-induction by means of a condenser C' of comparatively large capacity and a self-induction coil L of comparatively low self-induction so as to possess a high degree of receptivity for long waves. In Fig. 3 is shown a similar arrangement, except that the shunt S is arranged to have a high self-induction and low resistance, which would tend to shunt the long waves and oppose the short.

ELECTROMOTIVE FORCE, WITH SPECIAL REFERENCE TO THE EXTENSION OF OHM'S LAW.—I.

BY

Maurice Oudin, M.S.

A celebrated physicist has said that science alone has the claim to be called such, whose laws can be expressed by mathematical relations. Such are the sciences of mechanics, heat, light, sound, electricity and magnetism; in fact, all the physical sciences save chemistry, and even the last is approaching that state where it will be included in the list. Actual measurement, involving the application of numerics is the only means we possess of verifying mathematical laws. Newton was ready to abandon his grand hypothesis of the law of universal gravitation, because an error was made in measuring a degree upon which he had based his computations. The idea of potential long remained a mathematical abstraction. It was only when applied by Green to the calculation of electrical forces that its true use and significance were recognized. The truth of the mathematical statement that the inside of a hollow sphere is free from electrification was not verified until Michael Faraday built his experimental cage. Without the ability to express the proper relations of facts and to interpret those relations, our knowledge can at the most be meagre and uncertain.

The simplest and best-known law in electrical science is that enunciated by George Simon Ohm. The result of his mathematical speculations on the transmission of electricity through a conductor was first published in Poggendorf's Annalen in 1825. The essay afterwards appeared in book form in 1827, and was translated into English by Dr. Francis in the year 1841. It has been a matter of frequent comment that the great men of Germany have not always received due recognition and in many cases have gained their reputation late in life. It is difficult for us to understand the marked disapproval and even bitterness with which Ohms' work was received. His theory was utterly discredited and then ignored. Indeed Faraday was unfamiliar with the law of Ohm, and Henry likewise was ignorant of its existence although in dealing with electric currents he had intuitively recognized the principles involved. Two decades ago the vague terms intensity and quantity, were the usual means of indicating currents of high and low electromotive force.

This same uncertainty was attached to the phenomena of electrical science generally. There was no system of absolute measurement in general use until after the exhaustive work of the British Association on electrical standards, nearly 30 years ago. And this notwithstanding that the theory of electricity had almost reached its present state of development. Henry took the intensity of the shock experienced from a current of electricity as an indication of its strength, and earlier in the history of the science the distance to which a pith ball was repelled and the jumping distance in air of a spark were also means of indicating magnitude of electrical phenomena. Even after the general introduction of standard instruments into our lecture-rooms the greatest ignorance regarding their constants prevailed for a long time.

The application of Ohm's law helped to bring order out of this chaotic uncertainty. Only the necessities of practice, however, caused it to be dragged out of the waste heap. The successful application of its principles in telegraphy called the attention of scientific men to this law, the simplest in electrical science and of an importance the most truly immense.

Of the three fundamental quantities of a galvanic circuit, electromotive force is the most important. That quality called resistance is entirely dependent upon the specific nature of the substance of which the conductor is composed. A current is the result of an E. M. F. acting at the time or previously. Electricity in the sense of quantity of electrical separation has invariably associated with it an E. M. F., just as heat involves the idea of temperature or a suspended weight that of gravity. An E. M. F. can exist without the presence of the other two constants. The terminals of a voltaic cell and of an open coil moving near a magnet offer examples of the presence of an E. M. F. unaccompanied by a continuous current. It is not within the scope of this paper to view the practical side of the subject, nor to indicate the relation of the galvanic quantities to other electrical quantities. I shall confine myself to an exposition of the sources and manifestations of electricity in motion, dwelling more particularly upon the theory of E. M. F. as it is the chief factor in the modification of Ohm's law.

When a Leyden jar is discharged through a circuit, or a current from any source is maintained in a wire we say there is a transfer of electricity from a point at a certain potential to one at a lower potential. The property of producing this difference of potential in virtue of which electricity is set in motion, is ascribed to a cause called electromotive force. It is not a force at all as we understand the meaning of force as used in mechanics. The word is here used by analogy only; there is no identity whatever. Just as a force must be applied to lift a weight a certain height (a point of higher potential with respect to its original position), so by analogy, when there occurs an electrical separation, as at the electrodes of a battery, we call that producing it an E. M. F. In the mechanical illustration, if the support be removed the weight will fall to a gravitational plane of lower potential. Join the terminals of the battery and a current will flow from the positive or point of higher potential, to the negative or point of lower potential.

It is important that the distinction between E. M. F. and difference of potential should be clearly made, as there exists much confusion with regard to the proper use of these terms. In a circuit in which a source of E. M. F. is localized, there is between any two points a difference of potential. The line integral of the fall of potential measures the E. M. F. There can be no D. P. without a previous E. M. F., but we may have the latter without the former. As for instance when a cylindrical magnet is suddenly introduced into a coil of wire. An E. M. F. is set up in the wire, yet every point in the circuit is at the same potential. The same is true when an annular vessel filled with water is made to rotate in its plane. A motion of the liquid ensues although there is no difference of level. Analogies are useful, and to further illustrate my point, conceive a pump raising water to a height, say, of 20 feet. Here in a crude way the force actuating the pump corresponds to E. M. F., and the new elevation of the water with respect to its original level to D. P. Remove the E. M. F. and in consequence of the D. P. a current flows. In short, we may say, E. M. F. produces a D. P., and is measured by it.

The relation of E. M. F. and energy is a close one, indeed E. M. F. may be said to be absolutely inseparable from the idea of energy. Although, as we have seen, an E. M. F. may exist without an actual flow of electricity it requires for its excitation an expenditure of energy, and produces what we may call an electrical displacement. The work done in the deflection of an electrometer needle, under the influence of electrostatic forces against the torsion of a wire, proves this by Joule's famous principle of the conservation of energy. The amount of work involved is necessarily small. It would require instruments of great precision and refinement to determine the difference of work required to suddenly insert a magnet and a soft iron bar into an open circuited coil. The moment the circuit is closed, however, and the magnet thrust in, a current flows and then the force necessary for the operation is considerable. In electrostatics, difference of potential is measured by work done. Two pith balls of opposite and equal charges cannot be separated without a change in the energy of the system, the amount of which is represented by the equation—

$$\text{Energy} = m\left(\frac{1}{r} - \frac{1}{R}\right)$$

where m is the total electrification or quantity of electricity, and r and R are the original and final distances separating the pith balls. In its final state the energy of the above system is at a maximum and wholly potential. If left to itself it speedily falls to a minimum, the potential energy becoming kinetic in the process.

The change from one condition to the other always manifests the presence of a force. It is only when a change of energy of one form into another occurs or tends to occur that we are aware of the existence of an E. M. F. In the case of the pith balls it will be observed that there is a transfer of electricity against the attracting forces. The work done on the system is $M. V$, the product of the quantity of electricity into the difference of potential. Such a transfer of electricity is analogous to a current; it is identical in its effects, as Prof. Rowland and others have shown, when the transfer is made with the velocity of light, which is the rate of transmission of an electric impulse along a conductor. All generators of electricity are transformers of energy, the dynamo transforms energy of mechanical motion into electrical energy, the battery that of chemical affinity, and the thermopile that of heat into electrical energy. The resulting current is a manifestation of some kind of motion. It is evidence of a transfer of energy. The E. M. F. at the terminals of a generator is a measure of the urging or tendency of the generator to transform mechanical, chemical or heat energy into electrical energy. The product of these two quantities, current and E. M. F. gives the total energy or activity of the circuit.

There are two ways of viewing the manner in which an E. M. F. gives rise to a current. We may regard the E. M. F. as a force applied, either at the ends of the conductor, like the pressure of a pump drawing water through a pipe, or literally throughout the whole extent of the conductor like the vanes of a paddle-wheel. The outcome of recent experiments seem to show that the last view is the correct one. Oersted's discovery of the disturbing influence upon a compass needle by a current, as shown by Faraday, indicated the existence of a medium that transmitted electrical stresses. The mathematical treatment was undertaken by Maxwell. The results were found to be in strict accordance with Faraday's experiments. It remained for Hertz of Bonn to prove, as far as experiment can prove, the existence of a medium, and to confirm Maxwell's theory that the medium in which electrical stresses are propagated is identical with the light-transmitting medium—the ether. It is here we must abandon hydrostatic analogy, for there is no external disturbance to indicate a flow of water through a pipe. Conducting bodies are regarded as breaks in the ether, offering an easy passage to a flow of electricity. The battery, dynamo, or other generator is conceived as placing the surrounding medium under a strain. The stress thus produced is propagated along the line of least resistance, viz., the conductor, and in consequence there follows that action called electrical current. The medium plays the principal role, the function of the conductor being to determine the direction in the medium in which the transfer of electrical energy shall take place.

To Galvani is due the discovery of a new electrical manifestation; but the scientific mind of Volta developed the immense possibilities of an uncertain phenomenon. With the invention of the voltaic cell that branch of electrical science which deals with the phenomena of current flow had its beginning. For over half a century the voltaic cell was the only means of evoking large currents of electricity. Although for almost all practical purposes it has been replaced by the dynamo, its great historic interest, and especially the uncertainty attached to the theory of its action, claim for it a prominent place. In Volta's time the question as to the seat of the E. M. F. in the battery arose, and the dispute has been kept up with intermittent vigor ever since. The two great theories are the contact and the chemical. The advocates of the former claim that E. M. F. of the cell is due to the mere contact of dissimilar substances. The holders of the chemical theory formerly denied the existence of an E. M. F. not due in some way to chemical action.

Some authorities now advance a theory which is in the nature of a compromise. If a piece of copper and a piece of zinc be brought in contact, there is found to be an E. M. F. acting across the junction. If these be joined at their free ends by a substance having a chemical affinity for either metal a current is developed and maintained constant as the result of the chemical action, and at the expense of one of the metals. In other words, contact produces E. M. F. which on closed circuit gives rise to a current when some extraneous means are supplied to keep the E. M. F. constantly renewed.

Sir Humphrey Davy was the first to attempt to reconcile the two theories. Faraday noticed that the composition of the electrolyte was always altered by the passage of a current, and so attributed the flow to chemical action. Sir William Thomson brought out a paper in 1851 demonstrating the existence of an E. M. F. at a junction of two metals from the well-known phenomenon called after its first observer, the Peltier effect. By far the most elaborate experimental work in this subject was carried out by Professors Aryton and Perry in Japan. They established beyond a doubt the law that the total E. M. F. of a circuit may be reckoned by adding up the E. M. F. observed for every pair of substances in contact.

"LIKE UNTO LIKE."

The editor of one of the leading technical journals of this city, in forwarding a subscription for a friend, says: "This is a Christmas present of a mighty nice electrical journal to a mighty smart young electrician."

"MASSAGE" WITH CURRENTS OF HIGH FREQUENCY.

BY

Nikola Tesla

I TRUST that the present brief communication will not be interpreted by the readers of THE ELECTRICAL ENGINEER as an effort on my part to put myself on record as a "patent medicine" man, for a serious worker cannot despise anything more than the misuse and abuse of electricity which we have frequent occasion to witness. My remarks are elicited by the lively interest which prominent medical practitioners evince at every real advance in electrical investigation. The progress in recent years has been so great that every electrican and electrical engineer is confident that electricity will become the means of accomplishing many things that have been heretofore, with our existing knowledge, deemed impossible. No wonder then that progressive physicians also should expect to find in it a powerful tool and help in new curative processes. Since I had the honor to bring before the American Institute of Electrical Engineers some results in utilizing alternating currents of high tension, I have received many letters from noted physicians inquiring as to the physical effects of such currents of high frequency. It may be remembered that I then demonstrated that a body perfectly well insulated in air can be heated by simply connecting it with a source of rapidly alternating high potential. The heating in this case is due in all probability to the bombardment of the body by air, or possibly by some other medium, which is molecular or atomic in construction, and the presence of which has so far escaped our analysis—for according to my ideas, the true ether radiation with such frequencies as even a few millions per second must be very small. This body may be a good conductor or it may be a very poor conductor of electricity with little change in the result. The human body is, in such a case, a fine conductor, and if a person insulated in a room, or no matter where, is brought into contact with such a source of rapidly alternating high potential, the skin is heated by bombardment. It is a mere question of the dimensions and character of the apparatus to produce any degree of heating desired.

It has occurred to me whether, with such apparatus properly prepared, it would not be possible for a skilled physician, to find in it a means for the effective treatment of various types of disease. The heating will, of course, be superficial, that is, on the skin, and would result, whether the person operated on were in bed or walking around a room, whether dressed in thick clothes or whether reduced to nakedness. In fact, to put it broadly, it is conceivable that a person entirely nude at the North Pole might keep himself comfortably warm in this manner.

Without vouching for all the results, which must of course, be determined by experience and observation, I can at least warrant the fact that heating would occur by the use of this method of subjecting the human body to bombardment by alternating currents of high potential and frequency such as I have long worked with. It is only reasonable to expect that some of the novel effects will be wholly different from those obtainable with the old familiar therapeutic methods generally used. Whether they would all be beneficial or not remains to be proved.

"HOW TO MAKE INVENTIONS."

MR. E. P. THOMPSON is receiving many encomiums on his book just issued with the above title. The *Boston Transcript* says it is "almost literally worth its weight in gold." The *American Machinist* says that it is "invaluable to those who wish to make invention a business and provi le themselves with means of preparation."

"Make-and-break"—means "make" for the man who sells that invention and "break" for the man who buys it.—Dr. Elisha Gray.

POLYPHASAL CURRENTS.

NOTWITHSTANDING the widespread attention which alternate-current motor and generator work has attracted during the last few years, the subject appears to be one which is but faintly grasped by the majority of electricians, judging from the lack of knowledge of essential principles displayed. It is therefore a subject for congratulation that there is now available a discussion of the nature of polyphasal currents, which will enable those not already familiar with the subject to obtain an excellent insight into their true nature and effects. In the course of his paper, read before the American Institute of Electrical Engineers, Dr. Pupin takes occasion to dwell at some length on the claims made by Dobrowolsky in Germany as to the superiority of his apparatus over that of Tesla, Bradley and others, in that there is no fluctuation in the strength of the field in his motors. Dr. Pupin well shows the untenable position taken by Dobrowolsky by proving the very slight difference which exists between two and three-phase types of motors in this respect. But, for those who have given close attention to the work of Mr. Tesla, this question would appear to have been settled long ago. A perusal of Mr. Tesla's work will show that he dwelt on these very points in his original paper read before the American Institute of Electrical Engineers in May, 1888, and from which we quote as follows:

> The inductive effect exerted upon the secondary coils will be mainly due to the shifting or movement of the magnetic action; but there may also be currents set up in the circuits in consequence of the variations in the intensity of the poles. However, by properly designing the generator and determining the magnetizing effect of the primary coils, the latter element may be made to disappear. The intensity of the poles being maintained constant, the action of the apparatus will be perfect, and the same result will be secured as though the shifting were effected by means of a commutator with an infinite number of bars.

This shows that for the uniform shifting no more than two phases are required, and that it is only necessary to design the generator properly in order to obtain the desired result. Dr. Pupin refers to this also in his paper, where he points out toward the end that "nearly constant rotary magnetic fields can be produced in practice by a small number of phases, probably not more than three, by properly shaping the curve of the impressed E. M. F." It may not be out of place to remark here that Mr. Tesla in his original patents has also shown multiphase generators and motors, and dwelt on these points even more directly than he did in the paper read before the Institute in 1888, and we may also quote from that paper the following significant remark:

> In transformers and in a certain class of motors the fluctuation of the poles is not of great importance, but in another class of these motors it is desirable to obtain the theoretical result.

This statement applies to the two types of motors shown by him, namely, synchronizing and torque motors respectively. Dr. Pupin correctly points out the impossibility of telling from the number of phases the amount of the fluctuation. With two or with three phases only, practically the same result is obtained as though there were an infinite number of phases, but we think that, inasmuch as a motor should in most cases possess a certain tendency to synchronism, practice will show the inadvisability of employing too great a number of phases, as in such a case the falling off in speed would result in a diminished output per weight and would disqualify the motor for many purposes. As regards polyphasal generators, it seems to us, as Dr. Pupin puts it, that a high number of phases is impracticable and their employment hardly warranted in the light of the above statements, it being evident that two or three phases are quite equal to accomplishing the desired results.

The paper read by Dr. Pupin also serves to call attention to some curious analogies between polyphasal and continuous-current generators and as such they must necessarily impart to the former qualities which have heretofore not been deemed to be inherent in them. We can only express again our gratification at the work of Dr. Pupin and re-echo the sentiment of Prof. Elihu Thomson, who presided, that the paper contains the only clear exposition published thus far of the principles which underlie the polyphasal-current systems. It is understood that Dr. Pupin will give a brief series of papers—two or three—before the Institute on this subject. With the principles thus clearly pointed out and with the advantages to be derived from the use of condensers in connection with alternate current apparatus, especially motors, the time can not be far distant when the latter will have become as familiar an object as the continuous current motor is to-day.

"KNOCKING OUT" THE BERLINER PATENT.

The picturesque misinformation that cultivated Englishmen possess about this country is strikingly exemplified in an able editorial on "the Microphone in America," appearing in the December 4 issue of the London *Electrician.* Its view of the granting of the Berliner patent is thus expressed: "It is as if one had appropriated a wrong umbrella and after wearing it out taken it back again, getting a new one in its place. You cannot do that in polite society; *but you can in the New York Patent Office.*" Our contemporary adds that "there is talk of invoking *the aid of the Legislature* to put an end to collusive and injurious "interferences.' It is a pity that our contemporary, who is usually so well informed and so sound in judgment, should be under the impression that the "New York Patent Office" allows this sort of thing, or that the matter is subject to the tender mercies of our State Legislature. It is the Chicago Board of Trade that is responsible in such cases, and these collusive interferences can only be put an end to by the "referendum" in the District of Columbia, or by a constitutional ballot in the thirteen original States of the Union. No doubt this is a roundabout way of correcting an abuse, but it has been carefully modeled after the precedent which requires that the Parliament of the British Empire shall sit in judgment on the wish of Puddlecombe-by-the-Haystack to have a street railway.

TRANSFORMERS WITH OPEN MAGNETIC CIRCUIT.

The designs which have been adopted in transformer work may be said to have kept very close to those of the dynamo in so far as the nature of the magnetic circuit is concerned, and this is probably a direct outcome of the modern conception of the magnetic circuit and its treatment analogously to the electric circuit. The reduction in magnetic reluctance effected in transformers with closed iron cores, over the older forms embodying open magnetic circuits, was immediately followed by increased output at a given frequency and by better regulating qualities. But there are not wanting those who find good qualities in the older types, notably among them being Mr. Swinburne, whose "hedgehog" type of transformer is well known to our readers. The principle advantage claimed by Mr. Swinburne is increased efficiency at light loads as compared with the closed circuit type. With the evident object of retaining this benefit, while at the same time avoiding the loss of magnetic lines met with in the straight core, Mr. Poleschko has designed the type of transformer illustrated on another page. While there has been considerable discussion on the relative merits of these two types of transformers, we still lack the authoritative figures of an impartial comparative test, and we suggest this as a subject of research.

ANNUNCIATOR AND BELL WORK.

Though probably among the oldest of the applications embodying electrical signaling devices, the methods of construction and installation in annunciator and bell work have probably undergone very few changes from those practiced twenty years ago, and "electrical bell hanger" has indeed become a term of reproach in the profession. That this term, however, does not necessarily imply an utter lack of knowledge of electrical principles or of proper appreciation of the value of good work is well brought out in the interesting paper of Mr. Charles G. Armstrong on "Improvements in Annunciator and Bell Work," read before the Brotherhood of Electrical Mechanics in Chicago. Mr. Armstrong urges in the first place the discarding, as far as possible, of the large number of batteries frequently scattered about in large buildings feeding different bell circuits, and their replacement by a properly designed dynamo-generator. He also points out the necessity of employing a better quality of wire than that represented by the venerable annunciator wire, and he prefers weatherproof for this purpose. He also advocates the use of interior conduits, and, in general, the collection of all electrical signaling apparatus at one central point and its supervision by a competent attendant. Mr. Armstrong's paper is one of the best and most practical that we have seen for a long time.

"Catch-as-Catch-Can" Executions.

An official report has now been made by Drs. McDonald and Ward on the Loppy execution, from which it appears it took ten minutes to prove to that unfortunate villain that death by electricity is instantaneous. As the *New York Times,* in an admirable article on the subject remarks: "The man was killed by sections, at odd jobs, in an off-and-on sort of fashion, 15 seconds at a time. They began to kill him at 11:54:36; at 12:05, ten minutes and 24 seconds later, they discovered 'the fact that death had occurred.' They declare furthermore that death was apparently instantaneous and painless. * * * If death was really instantaneous, it must have occurred at the first contact, and the other three were superfluous and revolting." We are glad to see the *Times* and other decent papers coming to the conclusion that this electrical execution must stop.

A Shower Bath of Currents.

The attention of medical men is likely to be arrested by the suggestive little note in our issue this week from Mr. Nikola Tesla, on some peculiar phenomena associated with the effect of rapidly alternating currents of high potential on the human body. As Mr. Tesla points out, the surface of the body can thus be heated under almost any conditions; and it would obviously be easy to direct or concentrate this effect upon any part needing treatment, and this whether the patient be even lying in bed unable to stir hand or foot. The medical profession has so intelligent an interest in the therapeutic use of electricity that we believe it will soon find employment for this novel method of application. It is curious how many side issues a new line of investigation opens up.

Transformer Calculations.

In this issue Mr. Charles Steinmetz concludes his series of articles on the Elementary Theory of the Alternating Current Transformer. The graphical study of mathematical problems largely facilitates their conception in giving to the values their relative dimensions in a tangible form, such as figures alone do not convey. As such, the work of Mr. Steinmetz will prove an interesting treatise and the results of his tests on existing apparatus bear out well the accuracy of the assumptions made by him and upon which his calculations were based.

ELEMENTARY GEOMETRICAL THEORY OF THE ALTERNATE-CURRENT TRANSFORMER.—XX.

(*Concluded.*)

BY

Chas. Steinmetz.

THE secondary circuit is not free from self-induction either, and the secondary current C_1 must lag behind the secondary E. M. F., E_1 by an angle ω_1. The constants of the transformer were:

Cross-section of iron = 63.3 square centimetres.
Length " = 30.8 centimetres.

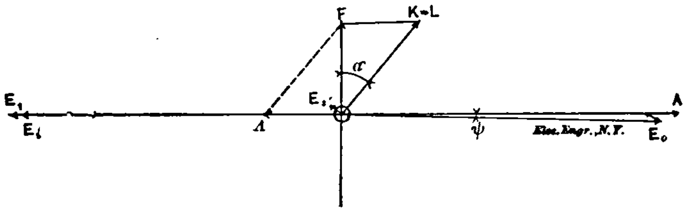

FIG. 34.

Internal resistance of secondary = .04 ohms.
" " " primary = 21.8 ohms.
Number of secondary turns n_1 = 35.
" primary " n = 675.

From these we derive the results:

	Drop of potential in secondary.	Secondary induced E. M. F.	Primary resulting E. M. F.	Primary induced E. M. F.	Secondary M. M. F.	Primary M. M. F.	Ideal M. M. F. of hysteresis.
	E_{11}	E_1	E	E_i	L_1	L	$A \quad \frac{H n_1}{E_1}$ [1]
1	.4	49.7	14	958	373	428	49.1
2	.2	50.8	8	980	204	259	57.2
3	..	51.4	4	991	44	128	63.9
4	..	53.5	3	1030	...	99	62.6

1. These values of hysteretic loss being derived as the difference of primary watts and secondary volt-amperes, must be too small for increasing secondary load, as the real secondary watts are *less* than the volt-amperes, because of the shifting of phase ω_1, caused by the self-induction of the secondary circuit.

From the value of ideal hysteretic M. M. F. for open circuit, $A = 62.6$ ampere turns, we get the angle of magnetic lag, $\sin \alpha = \frac{A}{L} = .6323$. The angle $\alpha = 39°$, and the resulting M. M. F., $F = \sqrt{L^2 - A^2} = 76.7$ ampere turns, while the direct determination of this angle, as the complementary angle to the difference of phase between primary current and secondary E. M. F., gives

WESTINGHOUSE 10 LIGHT TRANSFORMER.

Frequency, $N = 132$ complete periods per second. Secondary induced E. M. F., $E_1 = 50$ volts effective.

		Phase of primary current.	Phase of impressed primary E. M. F.	Difference of phase between primary current and impressed E. M. F.	Secondary current.	Primary current.	Secondary M. M. F.	Primary M. M. F.	E. M. F. consumed by secondary internal resistance.	Primary resulting, or heating E. M. F.	E. M. F. of self-induction in primary circuit.	E. M. F. of self-induction in secondary circuit.	Angle of secondary retardation.	Primary impressed E. M. F.
		ϕ	ψ	ω	C_1	C	L_1	L	E_{11}	E	E_s	E_{1s}	ω_1	E_0
1	Full load...	12.5°	—10.5°	23°	10.65	.647	378	437	.4	14	197	2.5	8°	1070
2	Half load...	17°	— 6.5°	23.5°	5.83	.403	204	272	.2	8	123	1.3	1.5°	1050
3	$\frac{1}{10}$ load.....	36°	— 2.5°	38.5°	1.26	.188	44	127	..	4	57	.3	.8°	1040
4	Open sec...	49°	— 1.5°	50.5°	.....	.141	...	95	..	3	43	...	....	1030

Angle of magnetic lag, $\alpha = 41°$.
Impressed M. M. F., $K = 95$ ampere turns.
Resulting M. M. F., $F = 75$ ampere turns.
Ideal M. M. F. of hysteresis, $A = 58$ ampere turns.
Secondary induced E. M. F., $E_1 = 50$ volts effective.
Primary induced E. M. F., $E_i = 964$ volts effective.
Loss of energy by hysteresis, $H = 88$ watts.

The electric quantities were found by the tests:

		Primary impressed E. M. F.	Primary current.	Secondary terminal pressure.	Secondary current.	Frequency.	Hysteretic loss.
		E_0	C	E_t	C_1	N	H[1]
1	Full load..........	1020	.634	49.3	10.65	132	69.7
2	Half load........ ...	1036	.383	50.6	5.83	132	83.1
3	$\frac{1}{10}$ load............	1021	.190	51.4	1.26	138	93.9
4	Open circuit.......	1030	.147	53.5	.....	138	95.7

$$\sin \alpha = \cos (C E_1) \frac{\text{mean } (c\, e_1)}{\sqrt{\text{mean}^2\, c \times \text{mean}^2\, e_1}} = .6514;$$

angle $\alpha = 40°$. The indirect way, by means of the diagram, gave $\alpha = 39°$, which is almost the same, though the wave of current is anything but sinusoidal.

The angle $\alpha = 40°$ gives as the ideal M. M. F. of hysteresis, $A = L \sin \alpha = 63.5$ ampere turns, against 62.6 ampere turns found directly, and the resulting M. M. F., $F = L \cos \alpha = 75.9$ ampere turns, against 76.7 ampere turns, as found before.

It is therefore evident that even in cases where the wave differs widely in shape from the sine form, the polar diagram of transformers represents the phenomenon very fairly.

If the resulting M. M. F., $F = 76$ ampere turns for open circuit, that is for the induction, $E_1 = 53.5$ volts, and the frequency, $N = 138$, for full load, that is, for $E_1 = 49.7$ volts, and $N = 132$, we derive,

$$F = 76 \times \frac{49.7}{53.5} \times \frac{138}{132} = 74 \text{ ampere turns}$$

and are now enabled to produce to polar diagram of this transformer, for open circuit and for full load in Figs. 34 and 35.

Fig. 34 gives us the self-induction of the secondary circuit, causing a shifting of phase of secondary current against secondary E. M. F. by an angle : $a_1 = 3°$, and the ideal hysteretic M. M. F. for full load, $A = 47$, against 49.1, as observed, causing an angle of magnetic lag, $\alpha = 33°$.

The E. M. F. of self-induction is derived from E_0, E_1, E, it being perpendicular to the current C. Hence,

1. $E_1 = 192$ volts for full load.
2. 116 " " half "
3. 55 " " $\frac{1}{10}$ "
4. 43 " " open circuit.

because it is proportional to the primary current and the frequency.

To compare the diagrams for different loads we reduce the electric quantities to the same magnetization and to the same frequency, by means of the law of the 1.7th power, so far as hysteresis is concerned, and otherwise by direct proportion.

Let the frequency be : $N = 132$, the secondary induced E. M. F.: $E_1 = 50$ volts. Then we derive the values given in the table, and represented in the complete diagram, Fig. 35.

It is especially interesting to notice here that, when reducing the four sets of transformer tests to the same conditions, the steady decrease of hysteretic loss for increasing load, observed by Prof. Ryan on this transformer, 95.7, 93.9, 83.1, and 69.7 watts, disappears, and the four values of hysteretic loss for different loads become 82, 85, 81 and 72 watts. The figure for full load, 72 watts, will be influenced greatly by a slight error of observation in one of the component factors, and this figure is the only one which differs much from the mean value.

Hence, *these tests cannot be used to prove a decrease of hysteretic loss*, but on the contrary, if the last figure be excluded, seem rather to indicate a *constancy and independence of the hysteretic loss from the load*, as is to be expected from theoretical reasons.

A comparison of this Westinghouse transformer with the Ganz & Co. transformer cannot well be made, because the one is a small 1 h. p. and the other a large 10 h. p. transformer, and therefore the larger transformer will give a very much more favorable diagram, as, indeed, Figs. 33 and 36 show.

These diagrams show one thing plainly; that a large transformer is much more efficient, and compounds better than a small one, and that therefore the practice of supplying each house separately by small transformers is inferior to that of supplying a whole district with a large transformer.

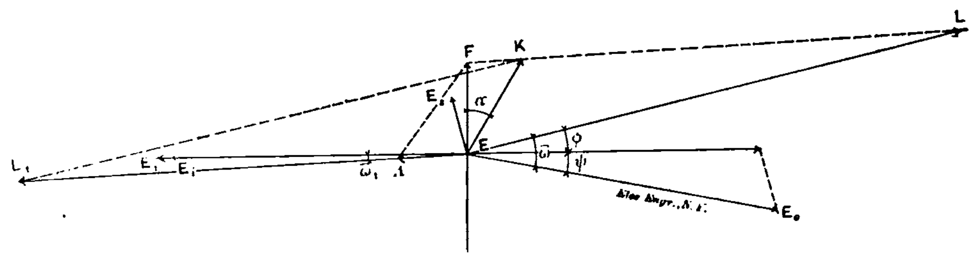

Fig. 35.

ELECTRIC CARS IN PARIS.

The Compagnie des Tramways Nord, says the *Bulletin International*, will shortly inaugurate a new service of cars between the Opera and Saint Denis. The cars will be run by electricity by means of Laurent Cély accumulators supplied by the Société pour le Travail Electrique des Métaux at a price of 4.25 cents per car mile. The route has several severe gradients; between the Rue Faubourg-Montmartre and the Rue Rochechouart the gradient is 5.5 per cent., or one in 18½. The line is nearly four miles in length. The result of this further introduction of storage cars will be watched with great interest.

A NEW THERMO-ELECTRIC BATTERY.

An ingenious little thermo-electric battery has recently been perfected which presents the following features: A small block made of a certain alloy has a small wire or a strip of nickel imbedded in it near each end; the alloy consists of antimony, three parts, and zinc, two parts. The wires project in a vertical direction from the horizontal top face of the block, and the end which is to be heated is protected from fusion by a casing made of iron. To form a battery, a number of these blocks are taken and joined in series, and they are so disposed that their cased ends can be heated to a high temperature without fusing the unprotected portions.

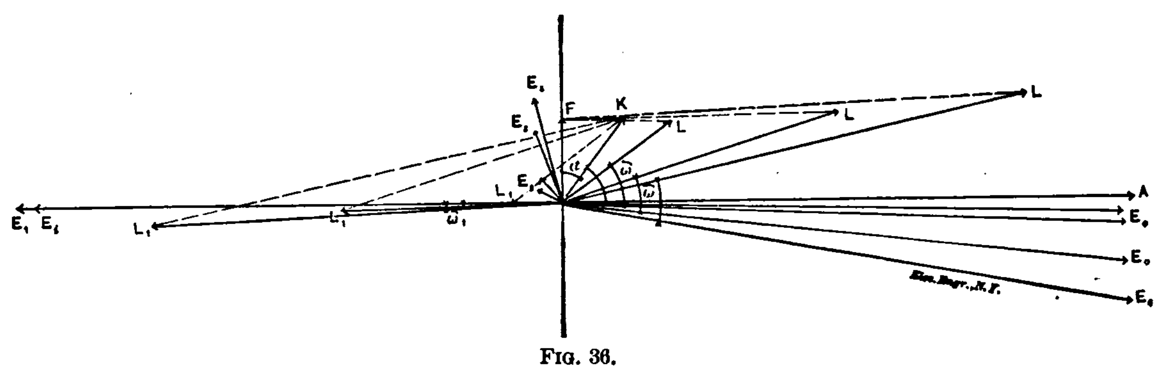

Fig. 36.

THE ATHENS, GA., ELECTRIC RAILWAY.

THE Athens Electric Railway was built by the Equitable Engineering and Construction Co., Drexel Building, Philadelphia, who took the contract for supplying the overhead electrical construction, station electrical apparatus, and electrical car equipments. This road has the McGuire trucks, and the Rae 30 h. p. electric motors. There are five cars in daily service, and five miles of track laid with 40 pound "T" rail. The power plant consists of one 80,000 watt Rae generator, driven by a Ball compound high-speed engine.

This road has been running since the middle of June and not a single cent has been spent for repairs on any part of the apparatus. The entire electrical work was done by Mr. George B. Abele, of the Equitable Co., and is one of the best pieces of electric railway work in the South. Our illustration gives a good idea of the construction and appearance of this typical Southern road. Mr. John T. Voss, manager of the road, wrote the Equitable Co. recently as follows: "The Rae motors and dynamo installed by you on our road have done all you claimed for them and have proved highly satisfactory to us. The cost of repairs is small compared with other systems which we have investigated;

THE ATHENS, GA., ELECTRIC RAILWAY.

the motors make less noise, and there is less necessity for keeping a skilled electrician in our employ than with any other system known to us, owing to the extreme simplicity of the electrical details of the machinery. If at any time you want to refer to us, we will be glad to favor you."

THE MEASUREMENT OF SMALL CURRENTS AND POTENTIAL DIFFERENCES.

THE third meeting of the Electrical Department of the Brooklyn Institute for the season was held on Friday evening, Nov. 20, 1891 in the large lecture-room of the Y. M. C. A., President Hamblet in the chair.

After the reading of the minutes of the previous meeting, the president introduced Mr. Edward H. Lyon, who gave a description of a method of measuring very feeble currents and small differences of potential of which we present the following abstract: Mr. Lyon first gave a diagram of the well-known method of La

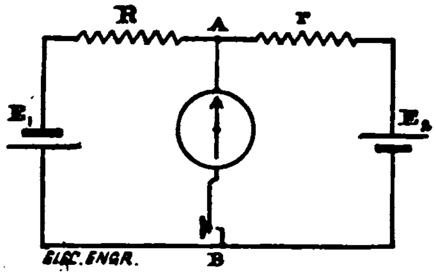

FIG. 1.—LA COINE METHOD.

Coine for comparing the electromotive force of two batteries, as shown in Fig. 1, where the battery to be measured E_2 opposes a standard battery E_1, through the galvanometer bridge A B; R being a fixed resistance of a thousand ohms or more, and r an adjustable resistance, such as a rheostat, which is varied until no deflection is obtained on the galvanometer, when $E_1 : E_2 :: R : r$. The battery resistance need not be considered unless very high.

The Poggendorff method was then shown in Fig. 2. In this method a standard battery and galvanometer are shunted around a known resistance forming part of the circuit in which is placed the battery to be measured, the position of the contact B being varied until a balance is obtained.

Mr. Lyon stated that in the manufacture of instruments for the measurement of the heavy currents and high potentials dealt with in central station practice considerable perfection had been attained, but there was no satisfactory instrument on the market for the measurement of small differences of E. M. F. and current, which was portable and at the same time sensitive and accurate.

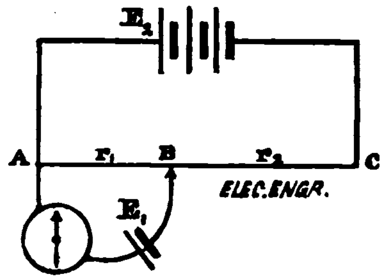

FIG. 2.—POGGENDORFF METHOD.

The instrument described by Mr. Lyon possessed both of these qualifications, and consisted of the combination of the La Coine and Poggendorff methods with a Wheatstone bridge, galvanometer and small cell of dry battery, the whole being placed in a compact carrying case.

If it were necessary to measure a battery having an E. M. F. of 1.002 volt or current of .041 ampere, this method insured the accuracy of the third place of decimals. It was not generally known that a dry battery which was worthless for many commercial purposes made an excellent standard cell if closed for short intervals only through a thousand ohms or more, and its E. M. F. would not change appreciably for a long time. He had found Dr. Gassner's very constant for this purpose, although others might be equally good. A small dry cell kept in a warm closet and used occasionally, had only lost .01 volt, since June 6th last.

An illustration of this method was then given. Fig. 3 shows an ordinary Wheatstone bridge with infinity plug removed and a

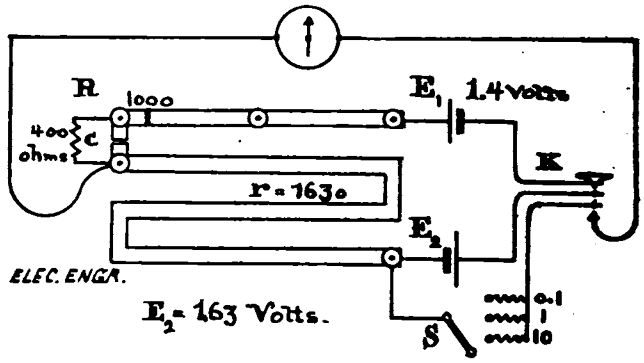

FIG. 3.—LYON METHOD.

compensating resistance coil inserted to insure direct readings. This coil may be adjusted to any change that occurs in the E. M. F. of the standard cell—1,000 ohms is unplugged in one of the arms of the bridge. This with the compensating coil, brought the fixed resistance R up to 1,400 ohms, as the standard cell was known to have an E. M. F. of 1.4 volt. It was found necessary to unplug 1,630 ohms to obtain a balance when the successive contact key K was closed; therefore $E_2 = 1.63$ volt.

For the measurement of current the shunt S is arranged so that the difference of potential may be measured on either side of a known resistance placed around the battery or inserted in the circuit whose current is to be measured. For instance, if one ohm is inserted in any circuit the difference of potential at its terminals has the same value as the current flowing. Therefore a direct-reading voltmeter or ammeter is obtained which still leaves the bridge serviceable for the ordinary measurements of resistance and insulation.

The internal resistance of a battery may be obtained by first measuring its E. M. F. with the shunt S open, which is E; then with, say, the 10-ohm coil thrown around the battery, which may be E'. Then the resistance of the battery $= \frac{E - E'}{E'} \times 10$. It is convenient to have shunt coils of 0.1, 1. and 10 ohms, respectively. To calibrate the dry battery insert a Latimer-Clark or Daniell cell with r, which, with the Daniell, might be 1.079 ohms; then adjust the compensating coil C until a balance is obtained.

After Mr. Lyon had concluded his remarks, Mr. J. Stanford Brown took exception to the statement with regard to commercial ammeters for measuring powerful currents, saying that there were no accurate ones, *i. e.*, accurate within even 5 per cent., on the market. He then described in outline the method of measuring potentials of alternating-current circuits through converters with known reduction factors, etc.,

Mr. Charles E. Emery made some remarks on a bridge method of measuring low resistances, by which, with a little care, the same instruments could be used within considerable limits.

In reply to an inquiry, Mr. Lyon stated that the temperature of the rheostat coils was never affected in ordinary battery measurements. In the case of large currents, as high as 1,000 amperes could be determined by getting the drop in potential through a known resistance, as he had shown.

Mr. Lyon was given a vote of thanks and the president then announced the following committee as appointed to represent the Electrical Department of the Institute at the World's Fair in 1893: J. Stanford Brown, W. D. Sargent, W. S. Barstow, E. F. Peck and F. V. Henshaw.

IMPROVEMENTS IN ANNUNCIATOR AND BELL WORK.[1]

BY CHARLES G. ARMSTRONG.

THE subject of which I will speak will be that of electric bell and annunciator service, especially in large and complicated installations. It is indeed strange, that while all other branches of electrical work have been pushed forward, this one important branch has been seriously neglected. It is almost considered a disgrace for an electrician to be a bell man, in fact it requires some considerable degree of courage for one to announce publicly that he professes to engage in that particular line of business; but I wish to assure you that there is no business where a good class of men are more needed than in bell, annunciator, burglar alarm and district telegraph work, as it requires a better knowledge of electricity and a clearer head than to know how to run the simple parallel lines for electric lighting purposes.

History tells us that James Marsh, an Englishman, in 1824 invented an electric bell which consisted of a pendulum, vibrating automatically between the poles of a permanent magnet. John Mirand, in 1850, invented the electric bell practically as it is to-day, using the vibrating hammer, a push-button, an annunciator, and all of the kindred appliances, for which he obtained a British patent in the year mentioned. Now, strange as it may seem, all inventors turned their attention to a better method of producing electricity before they thought of bettering the supply of current for the electric bell.

In the rush to perfect the electric light, the electric bell and the annunciator, with its modifications, the burgular alarm, were left almost as they were invented, with very few improvements. But of all the neglect of improvement in this particular line, that which received the least attention was the generator of current for bell or annunciator work. It is true that good batteries can be obtained, but it is also true that good batteries are very poor at best.

Let us take, for instance, the large modern hotel with, say, 500 rooms. That means 500 bells, 500 annunciator drops, one or two dozen extra bells, chamber maids' calls, fire-alarm gongs and porter bells. It means an extensive system of speaking tubes which are within themselves almost useless without the ever ready electric bell, and perhaps, on the whole, it will mean 1,200 electrical appliances, scattered over a building which may cover an acre of ground, or more, and distributed over from 6 to 10 stories or more in height.

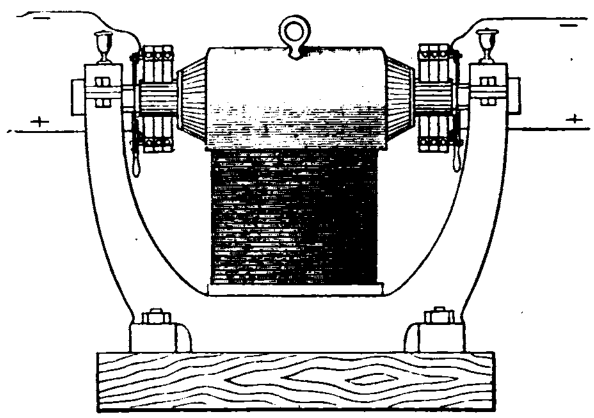
How are you going to handle all these bells? By batteries, of course; there is nothing else. But let us see if there may not be a better way. I present to you a drawing of a machine which was designed by me some years ago and which we will call the battery dynamo. I do not claim to be the inventor of this dynamo but do claim to be the first to use this peculiar form of generator for electric bell service. Since I have had this machine in operation, Professor Thomson and others have used what they call a constant-current transformer, which is very similar in form but entirely different in winding. The drawing which I exhibit is of this little machine which was built for me by Mr. Elmer Sperry and which consists of a bifurcated field having two windings, one end of which is a motor and the other end a dynamo or generator. The armature is double, the two windings being entirely insulated from each other. The motor end is a small shunt-wound motor, wound for 110 volts or any other voltage that one may wish to use and is connected to some convenient supply of electricity, such as may be had in any large city. In many cases you will have that supply within your own buildings, as modern hotels generally have an independent plant that runs night and day; or current can be obtained from some public vender of electricity. The winding of the generating armature is so proportioned that it will give from 1 to 2 amperes at 25 volts pressure, according to the requirements of the plant. I find, however, that this is about the proper current to use.

Now the windings and conditions under which the armature works are such that on a short circuit, the greatest current developed would not be dangerous in any degree to the machine; in other words while having a generator at once desirable and unvarying, you will also have a machine that will run 24 hours a day year in and year out, with scarcely any attention and will give current at all times as desired.

From this dynamo we will carry leads or battery wires with fair cross-section and good insulation. These leads will be run in a looped circuit for equal potential. The loops will have sufficient resistance, when taken together with the resistance of each bell, such that no bell will be overloaded and all will get just enough current to give the best results.

With this arrangement there is no corrosion, no liquid to evaporate, no zincs to waste, no dirty, expensive and unreliable chemical batteries to work with.

Let us now take the case of the batteries. We have the annunciator system, most likely divided into three or four stations, each station being run with from 10 to 20 cells of battery, until, when completed, we will have from 50 to 150 cells of battery scattered throughout the house at such points as we can find space for them, for nobody ever heard of an architect providing space for batteries. In addition to this unwieldy source of supply we must



A MOTOR GENERATOR FOR HOTEL BELL CIRCUITS.

keep sal ammoniac, zincs, etc., handy, and we must constantly visit the different batteries to see that they do not freeze or that the zinc is not corroded or some trivial thing out of order by which certain bells are silenced, thus condemning our whole system, which lacks nothing but a reliable source of constant supply.

In considering the disadvantages of batteries, not the least point is that you are compelled to deal with currents of low voltage or else have too many batteries in service. For instance, 1,000 feet of No. 18 wire offers a resistance of $6\frac{4}{10}$ ohms. It is no exaggeration to state that many circuits in our large buildings are 500 feet long, which would offer a resistance of over three (3) ohms, if it were one continuous wire. A loose binding-post or bad connection would easily raise this circuit to 8 or 10 ohms, which, in connection with a bell of from 4 to 6 ohms and an annunciator magnet of perhaps $1\frac{1}{2}$ to 2 ohms more, would give from 16 to 20 ohms resistance in the entire line. It would follow that with, say, a battery of 10 cells in average condition, giving about 10 volts with large internal resistance, the current would be so feeble as not to operate a sensitive bell, making it possible to have trouble with all apparatus apparently in good condition, while with the battery-dynamo system, with 20 or 30 volts pressure and practically no internal resistance and with the difference of 10 or 15 ohms in the resistance of the line, it would still give sufficient current to ring the bells, and nothing but an absolute break in the line would render the service inoperative.

In regard to call bells, my plan is to place in every room a bell connected with a push-button at the hall door with no connections whatever to the office, treating each room as if it were a private residence. I connect this circuit to the ever ready looped mains leading from the battery dynamo. This method has many points to commend it, not the least of which is the fact that it is of great importance, often, for the patrons of the hotel to depend on certain trains. Many cases of lawsuits for damages have been brought and won against hotels for not having called guests at the appointed hour. The fact that the clerk pushed the button in the lower office would not be evidence in law that he had rung the bell in that particular guest's room, but if the call boy goes to the room mentioned and pushes the button on the outside of the door, he can hear the bell ring and can also receive an answer from the guest that he has been awakened, which would be good

1. Abstract of a paper read before the Brotherhood of Electrical Mechanics, Chicago.

evidence in law and would protect the hotel against any claims for damages.

Further, I do not approve of placing annunciators on different floors of hotels or placing annunciators in the office of hotels, except they be very small ones. A room should be provided near the main office for electrical apparatus, in which the telephone, annunciator or annunciators, speaking tubes and all such apparatus should terminate. This room should be placed in charge of a competent, intelligent young man who has some knowledge of electricity. Sub-offices can then be placed on the various floors which will connect with this main office by speaking tubes, or better yet by pneumatic tubes. All calls will then be placed on record and transmitted to the nearest call boy station and executed with the least amount of delay.

In regard to wire, except your building be entirely of wood, do not use annunciator wire and do not use bare rubber-covered wire, for neither is as good as plain weather-proof. The cost of braided rubber-covered wire is so high as to be practically prohibitory. But weather-proof wire, where saturated with some petroleum compound, I find to be a splendid wire for such purpose, from the fact that it is moisture proof and that it is practically free from damage by mice or rats which are the worst enemies of wire that I know of. Mice dearly love rubber and a very small quantity of moisture will ground an annunciator wire, while weather-proof wire is offensive to mice and rats on account of its waxy covering, and is sufficiently impervious to moisture to make it very efficient for this class of work. It is true that it costs more than annunciator wire, but the first cost only is to be considered, and in no first-class installation, such as I am describing, will the architects or owners object to paying the small additional cost in order to have the better satisfaction, which invariably follows the use of good material. In selecting wire be sure to get one very heavily saturated with compound, the more, the better, as it not only protects from rats and mice but from moisture and abrasion. I admit that in wooden buildings where lath and pine studding is used, annunciator wire will do very well for use, but when you consider that bare wire, properly placed under the same conditions, would answer nearly as well, you will see that it is no recommendation for the annunciator wire.

As to the manner of laying wires in the modern fireproof structures with tile partitions, I prefer to use the paper tubing which is now manufactured under the name of interior conduits. One sample is covered with brass. This is designed to use where it is necessary to have the wires exposed. There are a few cases perhaps where it may be necessary, but it can be polished and made very ornamental if desired. The other tube is to be covered entirely by the plastering and offers a channel into which the wires can be drawn at any time. In the halls at suitable points I place wooden troughs, concealed by the decorations, so that every wire in the building can be inspected from end to end without taking up a carpet, removing any plastering or in any way disturbing the occupants of the building.

It has been my object for many months to improve in every way possible the present method of laying wires within large buildings, and I always keep in view the fact that accessibility to the wires is the greatest object to be attained in work of this kind. The architect who spends months designing the beautiful decorations for our modern buildings is certainly not to be blamed for losing his patience when, on account of faulty insulation, the wires have to be torn out and his decorations totally destroyed or marked by patching which is never satisfactory. By the proper design and arrangement in conduits, every inch of the wires, from the annunciator to the push-button, can be drawn out in a few moments and repaired in case of accident from any cause whatever.

In regard to district telegraph or fire-alarm work, this battery dynamo is equally as efficient as it is for bell work, as it at once does away with the uncertainty of batteries, concentrates your apparatus and greatly reduces the cost of maintenance. In the city of Chicago, which undoubtedly has the best fire-alarm system of any city in the world to-day, there are in service nearly 3,500 cells of battery. This does not include the batteries used in Hyde Park and Englewood. It would be perfectly feasible to replace every cell with from six to 10 of these little machines.

In closing my remarks I would like to say to each and every one of you, Make it your object to discourage and discountenance everything in electricity that is bad, and encourage that which is good.

In this connection I will call your attention to two things which I wish to emphasize in particular. First, the placing of electric gas lights on fixtures which carry electric lights. It is the practice in work of this kind to ground one side of the battery. Now as you are all well aware, the fixture man has gone to considerable expense and taken valuable time to place on every fixture an insulating joint, the object of which is to entirely separate that portion of the electric light which is most apt to ground, from the sockets and pipes, which of course afford excellent ground. You proceed to undo all this work by bridging over his insulating joint with the gas lighting wires which are little better than bare wire, so far as insulation goes, and practically annulling the effect of the insulating joint.

Another dangerous thing is the electric trap-door, and there is a building in this city where a sort of "dead fall" controlled by an electric trigger is placed at every point of exit. Hundreds of people, men, women and children are employed in that building every day. In case of fire, every stairway, the elevator shafts, and almost every means of exit will be automatically closed. Against such devices as this I should expect to find you all arrayed.

ON POLYPHASAL GENERATORS.[1]

BY M. I. PUPIN, PH. D., COLUMBIA COLLEGE.

FEW will deny the importance of the polyphasal current systems; none the fascination of their study. This belief induced me to present the following brief essay before the Institute.

The experimental researches in this new and promising field of electrotechnics are not yet numerous, but still the results already obtained are of so decisive a character as to leave no doubt whatever as to the extremely high practical importance which is attached to electrical generators, motors and transformers constructed according to requirement imposeds upon us by this new

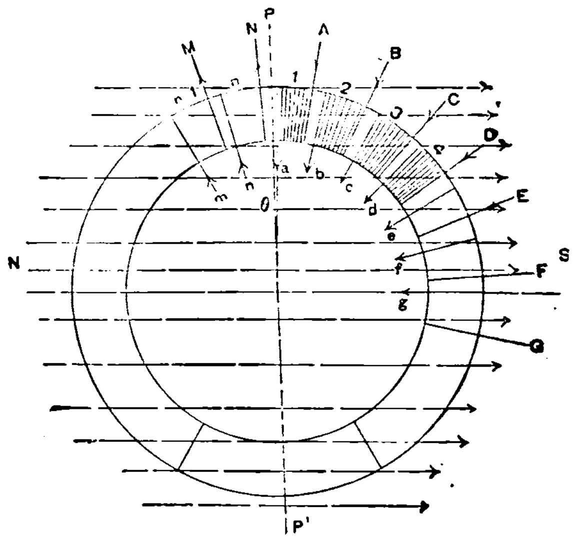


Fig. 1.

method of combining a set of variable electromotive forces. For who among us does not thoroughly appreciate the beautiful inventions of Nikola Tesla and the completeness of the success which Dobrowolsky and Brown obtained by the practical applications of these inventions?

The exact quantitative relations involved in the polyphasal system of currents are not, I venture to say, quite as well known as its practical results. To give an impulse to further inquiry in that direction is one of the principal aims of this modest investigation. For the present I propose to confine myself to the polyphasal generators in general, and particularly to polyphasal generators whose system of electromotive forces is capable of producing a rotary magnetic field of constant strength. The last point seems to me to be one of the vital points in this new method of electrical distribution. It is in this particular point that Mr. Dobrowolsky claims his system to be superior to that of Nikola Tesla.

Let us consider the theoretically simplest form of a polyphasal generator, as shown in Fig. 1. A non-magnetizable ring with n open equal coils at equal distances from each other rotates uniformly through a perfectly homogeneous magnetic field. Let PP' be the neutral plane of the field. At the instant when coil 1 is at the angular distance θ from the neutral plane PP' the E. M. F. generated in the various coils will be

$$e_1 = K \sin(\theta + \alpha)$$

$$e_2 = K \sin\left(\theta + \alpha + \frac{2\,\pi}{n}\right)$$

. . . .

. . . .

1. Read at the sixty-second meeting of the American Institute of Electrical Engineers, New York, December 16th, 1891.

$$e_n = K \sin \left\{ \theta + \alpha + (n-1)\frac{2\pi}{n} \right\}$$

Where K is a constant depending, as is well known, on the field intensity, the speed of rotation, the number of turns in the coil and the area of the plane of a turn; α is the angular width of one-half of the coil.

Since

$$\sin(\theta+\alpha)+\sin(\theta+\alpha+\frac{2\pi}{n}+\ldots\ldots+\sin\left\{\theta+\alpha+(n-1)\frac{2\pi}{n}\right\} = 0$$

it follows that

$$e_1 + e_2 + e_3 + \ldots\ldots + e_n = 0 \ldots\ldots (1).$$

That is to say, the sum of electromotive forces generated in the various coils which are on one side of the neutral plane is numerically equal and of opposite sign to that of the coils on the other side of this plane. This result is well known and self-evident. It is, however, far from self-evident that relation (1), which I shall call the *relation of continuity* for the electromotive forces, will be satisfied by every magnetic field.

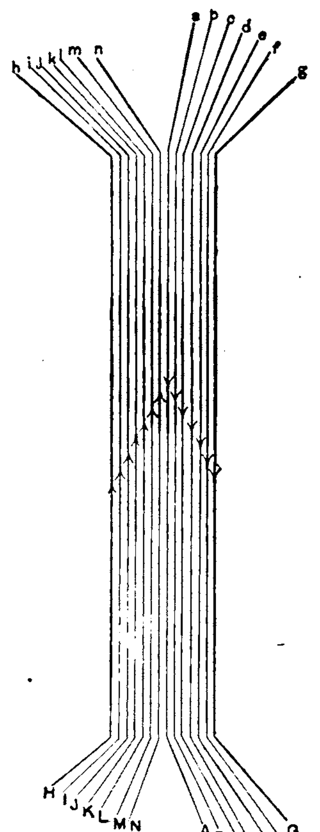

Fig. 2.

Close each coil separately by conductors of equal resistance and self-induction. Let $c_1, c_2 \ldots\ldots c_n$ denote the currents in the n separate circuits. It is evident that

$$c_1 = \frac{K}{I}\sin(\theta + \alpha - \varphi)$$

$$c_2 = \frac{K}{I}\sin(\theta + \alpha + \frac{2\pi}{n} - \varphi)$$

$$c_3 = \frac{K}{I}\sin(\theta + \alpha + 2\frac{2\pi}{n} - \varphi)$$

$$c_n = \frac{K}{I}\sin\left\{\theta + \alpha + (n-1)\frac{2\pi}{n} - \varphi\right\}$$

Where I is the impedance in each circuit and φ the angle of retardation. Hence, we have

$$c_1 + c_2 + c_3 + \ldots\ldots + c_n = 0 \ldots\ldots (2).$$

That is to say, the relation of continuity is satisfied for the currents also.

Let the wires $a\,A$, $b\,B, \ldots\ldots n\,N$ (Fig. 2) represent a part of each of the n conductors of this system. Then, according to relation (2), the sum of the currents in these n linear conductors being always zero, if we join them all into one conductor there would be no current in this wire, but the currents in the n circuits would circulate exactly the same as before. In fact, the common juncture is useless and can and should be cut out.

The diagram, Fig. 3, represents this method of connecting for a three-phase system. Consider, now, n equal coils distributed at angular distances of $\frac{2\pi}{n}$ over a laminated iron ring B, each coil being a part of the n conductors coming from the generator Diagram Fig. 4 illustrates this for a three-phase system. Let the n currents be denoted now by $c_1', c_2', \ldots\ldots c_n'$. We shall have now,

$$c_1' = \frac{K}{I'}\sin(\theta + \alpha - \varphi')$$

$$c_2' = \frac{K}{I'}\sin(\theta + \alpha + \frac{2\pi}{n} - \varphi')$$

$$c_n' = \frac{K}{I'}\sin\left\{\Theta + \alpha + (n-1)\frac{2\pi}{n}\varphi'\right\}$$

and therefore

$$c_1' + c_2' + \ldots\ldots + c_n' = 0 \qquad (3)$$

The introduction of the iron ring with the n coils into the n phasal system has changed the impedance I, and the angle of retardation φ; but this change is evidently the same for all coils. The correctness of this statement might, perhaps, be questioned, if we suppose that the system of the n variable currents was at any moment strong enough to saturate the iron ring; I therefore suppose that the intensity of magnetization in the ring is never over 10,000 C. G. S. lines of force. We shall presently see that in the case of a properly built generator the saturation of the iron ring will not vitiate the correctness of the above statement in the slightest.

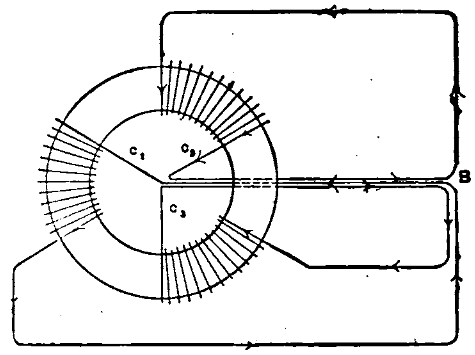

Fig. 3.

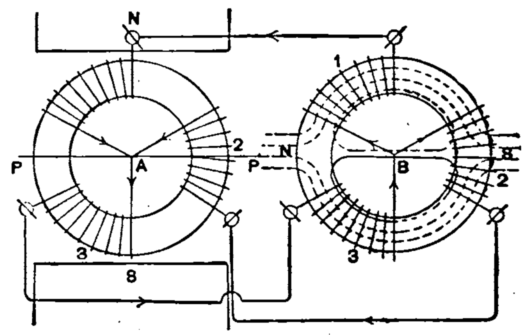

Fig. 4.

Let s be the number of turns in each of the n coils. Relation (3) gives

$$4\pi s c_1' + 4\pi s c_2' + \ldots\ldots + 4\pi s c_n' = 0 \qquad (4)$$

That is to say, the relation of continuity is satisfied by the magneto-motive forces.

Relation (4) translated into physical language means that the magnetization in the iron ring is due to two equal magneto-motive forces working in multiple arc. The magnetic field produced is perfectly symmetrical with respect to the ring as indicated by the dotted lines in Fig. 4.[1]

MR. C. O. HARRIS, formerly of Clower, Harris & Co., Dallas Tex., was in the city last week. Mr. Harris has secured some excellent agencies, and will open an office in Dallas.

---

1. This will be always strictly true if we employ an even number of coils, even if the number of phases is odd, because then the distribution of the ampère turns is perfectly symmetrical.

SOME PRACTICAL FORMULÆ FOR STREET CAR MOTORS.

BY

Thorburn Reid.

The following analysis was undertaken with the object of obtaining some simple, practical formulæ, which could be used by a practical man in his everyday work. Accuracy has been sacrificed to simplicity, since accuracy in this case would hardly be required by the engineer, and, if it were, it could seldom, if ever, be attained on account of the wide variations in the conditions affecting the problem.

First take the case of a gramme ring armature in a two-pole field, the field coils being in series with the armature coils. If e is the counter E. M. F, S_2 the number of turns on the armature, n the revolutions per minute, and N the number of volt lines (10^8 c. g. s. lines = one volt line),

$$e = S_2 N n. \tag{1}$$

But $N = \dfrac{S_1 C}{\rho}$ where $S_1 C$ is the number of ampere turns in field and ρ is the magnetic resistance of the magnetic circuit. Therefore, $e = \dfrac{S_1 S_2}{\rho} C n$ (2)

If R be the resistance of the field plus the armature, and E the line E. M. F., then

$$C = \frac{E - e}{R} = \frac{E - \dfrac{S_1 S_2}{\rho} C n}{R}$$

solving for C, we have

$$C = \frac{E}{R + \dfrac{S_1 S_2}{\rho} n} \tag{3}$$

If w be the work done by the motor,

$$w = C e = \frac{S_1 S_2}{\rho} C^2 n \tag{4}$$

S_1 and S_2 and ρ are constants of the motor. ρ, however, varies somewhat with the saturation of the field. We will not, however, introduce too large an error by considering it constant throughout the range. If, therefore, we substitute for $\dfrac{S_1 S_2}{\rho}$ the letter a, a constant, (3) and (4) become

$$C = \frac{E}{R + a n} \ (3) \qquad w = a C^2 n \ (4).$$

The value of this constant may be obtained easily if we have the dimensions of the magnetic circuit and a saturation curve of the iron in field and armature, but this, in the present stage of electrical manufacture, is not generally to be had. The following method is far simpler, and no doubt more accurate:

Let the motor whose constant is required be run under load and a reading be taken of E, C and n. Substituting these values in equation (3) we may obtain the value of a thus: $a = \dfrac{E - C R}{C n}$ (5)

This may be made more accurate and the variation in ρ taken into account by taking readings at varying loads and currents and obtaining the value of a for each case.

The value of a thus obtained will then be good for all motors of that type and size for all practical purposes. Of course, if the number of turns on field or armature be varied, the value of a will be changed.

If the motor be of the four-pole type, or if its armature be a Siemens instead of a Gramme ring, the same equations may be used, provided a is obtained by experiment, as above; for in the former case the only change to be made is to multiply n by 2, which, being a constant, would be included in a, and in the latter case the right-hand member of equations (1) and (2) would be multiplied by 2, which would again be included in a, since (2) could be written, $e = a C n$. Another convenient formula is the following:

If m be the speed of the car in miles per hour, d the diameter of the car wheel in inches, and r the ratio of reduction, or the ratio of the revolutions of the armature to those of the car wheel, we will have

$$n = \frac{5280 \times 12 \times m \times r}{60 \times \pi \times d} = \frac{304 \ m \ r}{d} \tag{6}$$

Having obtained the value of a, then the next step is to apply these equations to problems occurring in practice. A problem, which often occurs, is, what E. M. F. is required on the overhead line to drive a car up a particular grade at a certain rate of speed.

From (3) we have $E = C(R + a n)$ in which everything is known except C. But C can be obtained from equation (4), provided we know the value of w. w depends on five things—friction, grade, condition of track, curvature of track and speed. No general formula can be given for the resistance due to friction, condition of track or curvature. These can only be determined by experience and must be largely a matter of guess-work. The friction will vary largely at different times in the same car, depending on the care with which the gears and bearings are oiled and on whether the track is wet or dry, clean or dusty or muddy. A rough value may be arrived at by taking readings of the current and line E. M. F. at varying speeds with the car running on a level, straight track. This resistance may be taken to vary directly with the weight of the car plus its passengers. We obtain w by substituting these readings in equation (4). We find the work required to overcome the grade as follows:

$$w_g = \frac{P \times ft.\ per\ min. \times 746 \times g}{100 \times 33{,}000}$$

where P is the weight of car plus passengers and g is the grade in per cent. That is, the rise in feet per hundred feet. Or $w_g = .02 \ m \ g \ P$

where m is as before the miles per hour.

The work which would be done by the motors then in climbing the grade will be that obtained by equation (7) plus the work required on a straight, level track, since this latter factor is assumed to be constant whether the car is going up or down grade or on a level.

In making the experiments to obtain w on a level we must be careful to notice the load that the car carries, since this work at any speed varies directly as the weight of car plus its passengers. Probably the simplest procedure would be to divide the work thus obtained by the weight of cars plus passengers, thus obtaining the work for one pound, which can then be multiplied by the total weight (average weight of a full-grown passenger may be taken to be 125 pounds), calling this value w_1, the complete formula will be

$$w = P(w_1 + .02 \, m \, g). \tag{8}$$

Of course, w_1 must be determined for the same speed as that required at the point in question or else it must be estimated from the data at hand. Probably the best assumption we may make is that the work on a level varies as the speed, or

$$w_1 = b \, n \tag{9}$$

b being a constant depending on the condition of the road-bed, etc., and is most easily determined by running the car and taking readings of C, E, and n, substituting for w_1 and n in equation (9) and solving for b.

Having thus obtained the value of w, we may substitute it in (4) and obtain C and then substitue C in (3) and obtain (E). We are thus enabled to determine the size of wire required in the feeders to maintain a certain speed at any point on the line.

Society and Club Notes.

NATIONAL ELECTRIC LIGHT ASSOCIATION.

The fifteenth convention of the Association will be held at the Iroquois Hotel, Buffalo, N. Y., on February 23, 24, and 25. Secretary Porter announces that Mr. C. O. Baker, Jr., has been appointed general master of transportation with headquarters at the office of the Association, 136 Liberty street, where all communications relating to transportation should be addressed. Steps are already being taken to make the meeting a great success.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

At the meeting of the council on December 16, the following gentlemen were admitted to associate membership:

Ayres, Brown, professor of physics and electrical engineering, Tulane University, New Orleans, La.

Benjamin, Park, electrical expert and engineer, 32 Park Place, New York City.

Bishop, James Draper, electrical expert, John A. Roeblings' Sons Co., 345 West Thirty-fourth street, New York City.

Parcelle, Albert L., electrician and inventor, 157 Washington street, Boston, Mass.

Pike, Clayton W., instructor in electrical engineering, University of Pennsylvania, Philadelphia, Pa.

Robb, Wm. Lispenard, professor of physics, Trinity College, Hartford, Conn.

Applications for transfer from associate to full membership, as follows, were approved:

Smith, T. Carpenter, firm of M. R. Muckle, Jr., & Co., Philadelphia, Pa.

Taintor, Giles, assistant electrician, N. E. Tel. & Tel. Co., Boston, Mass.

Pattison, F. A., firm of Pattison Bros., consulting and constructing electrical engineers, 135 Broadway, New York.

THE FRANKLIN EXPERIMENTAL CLUB.

The Franklin Experimental Club, of Newark, N. J., has changed its regular meeting night from the second and fourth Tuesdays of the month, to the second and fourth Saturdays in the month. There has been a considerable increase in the membership of late and a committee has been appointed to look for larger and more suitable quarters, the club having outgrown its present facilities. Among the subjects that have been taken up at the recent meetings, are "Induction," "Construction of Transformers and Applications of Alternate Currents," "Vibratory Phenomena." A series of talks illustrated by experiments are now being given upon the latter subjects by the various members, illustrating in a most interesting way the phenomena of sound, light, heat, and electricity, and their correlation.

THE BOSTON ELECTRIC CLUB.

Mr. R. F. Ross, secretary of the Boston Electric Club, writes us:

It having been announced in some of the electrical journals that "the New England Electric Club is to be formed to take the place of the Boston Electric Club," will you kindly, in justice to the Boston Electric Club, state in your next issue that such is not a fact. The Boston Electric Club is not dead, nor have we surrendered our charter. We have simply given up our permanent headquarters and disposed of our furniture and effects. Henceforth the club will be perpetuated in the form of monthly dinners, lectures, etc. Our constitution and by-laws have been revised, annual dues reduced to an almost nominal figure, and such other changes made that we think will tell beneficially, and on the first Monday evening in January (the 4th), we propose having our Inaugural Dinner. I know nothing of the New England Electric Club except what has been published nor, have I seen any one who can tell me anything about it.

College Notes.

ELECTRICAL ENGINEERING AT THE A. & M. COLLEGE.

The trustees of this college (Birmingham, Ala.) are keeping in progress with the age, and have established a Special School of Electrical Engineering and equipped a laboratory with different styles of dynamos and electrical appliances for instruction in the applications of electricity. We are indebted to Prof. A. F. McKissick for an interesting little pamphlet on the subject. The equipment is still small, but it is the intention of the Alabama Polytechnic Institute to build it up year by year.

Reports of Companies.

THE CARD ELECTRIC MOTOR CO.

Changes in the management of the Card Electric Motor Co. during the last few days started the rumor that this company had failed; in fact such information was telegraphed to a number of cities. However, The Electrical Engineer, having a representative in the vicinity, immediately took steps to ascertain the true state of affairs. It seems that the entire concern has been purchased outright by Mr. J. W. Wilshire, with a view to its immediate re-incorporation under the laws of Ohio, it having been heretofore under the laws of Kentucky. Mr. Dixon, the efficient general manager of the old Card Company, will remain in that capacity with the new organization. The wealth of the individual stockholders of the Card Electric Motor Co. made it seem incredible that the house was going into the hands of a receiver. In the meantime we are informed that most of the creditors have only recently received checks in full settlement of their accounts —another very good indication of the condition of the company's finances. Mr. Wilshire expects to have things running along smoothly under the new regime in the course of a few weeks, and in the meantime the factory is working "full blast" as usual.

Appointments, Etc.

Mr. W. H. Girvan, general superintendent of the Central New York Telephone Co., with headquarters at Syracuse, has handed in his resignation, to take effect Dec. 31. The resignation has been accepted, and Walter W. Nicholson, of Utica, has been appointed to fill the position. Geo. W. Wood, who has been division superintendent in Herkimer county, with an office in Little Falls, will succeed Mr. Nicholson as division superintendent for Oneida, Madison and Lewis counties. Mr. Nicholson, the new general superintendent, is a son of General Manager Charles A. Nicholson, of Utica, formerly of Rome. He will have his office in room 46, Mann Building, Utica, on the same floor with the executive offices of the company.

Mr. George Albree has assumed the duties of superintendent of the Boston division of the New England Telephone Co., relieving Mr. Denver, who will continue to serve as assistant to Mr. Keller.

Mr. Homer E. Mason has succeeded Mr. H. A. Wyckoff as superintendent of the Delhi Electric Light Co., of Delhi, N. Y.

Personal.

Mr. George North, M. I. M. E. and A. I. E. E., who has been for some years general manager of Woodhouse & Rawson United, Limited, the well-known electrical and mechanical engineers of London, England, has resigned his appointment in order to commence business as a consulting engineer, valuer and arbitrator, at 90 Queen street, London, E. C. A special feature of Mr. North's business will be the purchase, sale and development of new patents and inventions; and he will also act as London agent for mechanical and electrical specialties.

Obituary.

W. H. BAUER.

Mr. W. H. Bauer, one of the oldest telegraph operators in the country, died on December 14, at his residence, Baltimore, Md., of pneumonia. Mr. Bauer was 73 years of age and had been an operator since 1846. He worked for the Southern Telegraph Company until its amalgamation with the Western Union, when he went into the employ of the Baltimore and Ohio, where he remained up to twelve years ago, when he returned to private life. Mr. Bauer took an active interest in Masonry. The son of the deceased, Mr. Alexander H. Bauer, the electrical engineer of the Pullman Car Company, came on from Chicago to attend the funeral. Mr. Bauer was buried with Masonic honors.

Letters to the Editor.

REACTIVE COILS AND THE RIES REGULATING SOCKET.

In your issue of Dec. 16th, Prof. Elihu Thomson, in commenting upon Mr. Otis K. Stuart's article on "Reactive Coils," published in your issue of the previous week, takes occasion to criticise the results obtained by the Ries Regulating Socket, kindly referred to by Mr. Stuart as being probably the most interesting application of the reactive coil principle, and at the same time endeavors to show that he anticipated the invention in his patent No. 428,647, and states that he had in operation some years ago several such "regulating arrangements" in his house in Lynn.

In view of Prof. Thomson's own admission that the principle involved in the construction of reactive coils was known many years before he was born, and in view of the fact that not only reactive coils, but reactive coil regulators were well known in the art and had long since been used by myself and others for regulating the flow of alternating current to incandescent lamps and other translating devices, it is scarcely necessary for me to say that a patent describing a specific improvement in reactive coils, as does the one referred to by Prof. Thomson, is not only something entirely different from a regulating socket, but scarcely amounts to an invention over the prior art in view of the earlier patents to Hopkinson (Eng. 3,362 of 1881) and others, showing substantially the same arrangement.

The use of reactive coils for regulating groups of lamps, of which Thomson's patent referred to is an example, has been customary in isolated cases almost since the introduction of the alternating-current system of lighting in this country, as exemplified by the well-known but somewhat bulky "stage regulator" in common use; and it is quite probable that the "regulating arrangements" used in Prof. Thomson's house were of this character. I venture to say (and I am supported in this assertion by Prof. Thomson's closing sentence) that, despite the professor's ingenuity and varied experience with alternating-current apparatus, he had not only never made, but had never even *thought it possible to construct*, prior to the time he experimented with the Ries regulating socket, a reactive coil small enough to go into a lamp socket and yet perform the work required of it as thoroughly and efficiently as this socket does it.

In regard to Prof. Thomson's statement that the economy effected by the Ries regulating socket is "problematical," all that need be said is that if the professor had taken the time to measure the amount of energy consumed by the lamp and socket at the lower stages of light, upon one of his own wattmeters (provided he had one sensitive enough to measure it), and compared the result with the number of watts consumed by the same lamp at full candle power, he would have found this method of regulation to effect a very considerable and most surprising economy that would at once have settled any lingering doubts he may have had on this question. Of course, it is well known that, as stated by him, a certain amount of energy is absorbed in heating the filament before it reaches the incandescent stage, but it is a fact not so generally known that the energy thus absorbed forms an exceedingly small fraction of the total number of watts required to raise the lamp to full candle power.

While the writer is not as yet at liberty to go into a detailed description of the socket, he may say that by its use he has been enabled to burn from eight to ten 25 c. p. incandescent lamps at a dull red glow, sufficient to enable one to locate the position of each lamp in the dark, at a consumption of less energy than was required to burn one of these lamps at full candle power. As the light is turned down, not only the current, but the electromotive force at the lamp terminals necessary to pass this current through the filament, is reduced. And since the efficiency of the socket itself, owing in part to its peculiar construction, is almost perfect under the conditions noted, the amount of energy consumed in producing this light is exceedingly small.

It is true that lamps are much more efficient when burning at high than at low candle powers, but this fact, if it has any bearing at all upon the socket, only makes it the more valuable, for the reason that the socket is not merely capable of burning the lamp at its normal brilliancy or candle power the same as any ordinary socket, and is ordinarily intended to be so used when the usual amount of light is desired, but because by its use the consumer is enabled to burn his lamps, if the latter are of the proper voltage, *above* as well as *below* their normal candle power. It will therefore be seen that by means of this socket the consumer is not only entirely independent of the variations of potential that are constantly occurring on the line from occasional overload and other causes, and which frequently prevent him from obtaining sufficient light, but he is enabled at all times to obtain a maximum amount of light, when much light is wanted, at a higher lamp efficiency and therefore at a proportionally less cost per candle power for current, as well as to turn down the light and thus save both current and lamps when less light is desired, or to keep ome of his lamps burning at a still lower degree of brilliancy during the entire night where, under the present conditions, they would be turned out altogether. In short, this socket gives the consumer complete control of his own lamps, and for the first time places the incandescent electric light upon an equal footing with gas, in that it permits him to burn much or little light, as he may desire, during the time his lamps are in service, and at a cost for current directly proportional to the energy consumed.

The history of invention shows that it is an exceedingly simple matter after a thing has been successfully done, to see how something else *might* have been made to do the same thing. But the fact remains that, despite the great demand that exists and has always existed since the invention of the incandescent electric lamp itself, for a simple and efficient holding device that would permit of turning the lamp up and down without waste of current, and despite the further fact that reactive coils of the ordinary type have been for several years in almost daily use by many of the most prominent electricians and experimenters of the world, and have occupied a foremost place in nearly every electrical laboratory and workshop, it has nevertheless remained for the writer to produce the desired article to successfully supply this demand by the invention of the Ries "Regulating Socket." It is perhaps needless to add that alternating current incandescent lighting is already beginning to feel the impetus that this socket has given to it, and that not only the public generally, but central stations supplying current on the meter system, are reaping a decided benefit therefrom.

ELIAS E. RIES.

BALTIMORE, MD., December 17th, 1891.

THE HUM OF MOTORS.

I was much interested in the article by Mr. Charles J. Hayes entitled "The Hum of Motors," which appeared in your issue of December 16, 1891. I have been much puzzled to find a satisfactory explanation of the phenomenon which he discusses, but I am forced to confess that I am unable to understand his explanation of the cause.

Sound-waves in the air are necessarily either set up by the movement of some body surrounded by, or in contact with the transmitting gas, or set up by some force or forces other than those derived from motion. If sound-waves are derived from motion, that motion must be one capable of moving the surrounding air.

Mr. Hayes explains at some length a possible raising or distortion of the armature under each pole-face which, he thinks, though ever so slight, would be capable of setting the air in vibration, as the rotation of the armature shifts the points of distortion along the surface of the armature. In his words: "Now, by revolving the armature it will be seen that every part of its circumference will be brought in succession in front of each of the poles, and, consequently, attracted and slightly raised as it passes, producing a progressive undulatory movement of the iron, like waves on a body of water."

Mr. Hayes' waves, like his hypothesis, may be progressive, but they are not *sound*, and, indeed, I may add they are not even progressive, since it is merely the particles of the armature that progress. The undulatory distortion is fixed in space. His simile of waves on water would better be those fixed waves that one sees on some swiftly flowing rapids where no movement exists save that of the moving particles that lie within the fixed contour of the whole body.

As there can be no movement of the air produced by such fixed undulations, I am unable to find in his supposition any cause of the phenomenon of the hum of armatures. It is this point that I would beg him to elucidate, as, till he does, his speculations are hardly entitled to rank with the less plausible but perhaps more admissible theories already somewhat numerous.

HAROLD BINNEY.

NEW YORK.

THE BURNET ROSETTE AND SWITCH.

In the early days of the electric light business we learned that the way to invent a dynamo was to take the other fellow's machine and paint it red. This is good doctrine and has been generally accepted and widely followed. Once in a while, however, it happens that the inventor neglects to apply the saving coat of red paint, and I wish to call attention to a very flagrant case of the kind. In the issue of THE ELECTRICAL ENGINEER for December 9th, appears an article with the above heading written by H. W. Burnet, describing a rosette and switch which has been advertised and sold by the Electrical Supply Co. for about a year. As the article referred to does a slight injustice to my company I wish to state the facts as a matter of justice.

The original of the rosette switch in question was designed by me, and the drawing is now before me, bearing date January 18, 1889. It is designated "Ceiling Cut-Out with Off and On Switch," to be operated by one pendant cord. Nothing was done with this until in the summer of 1890 I ordered from Mr. Burnet, for the Electrical Supply Co., two or three models, and later 500 of the cut-outs, which are identical with the half tone shown on page 622 of THE ELECTRICAL ENGINEER of December 9th, 1891. I learn from the *Patent Office Gazette* that Mr. Burnet has applied for and received a patent on this device. This he is entirely welcome to keep for what it is worth, as the particular mechanical action involved has been superseded by a simpler and more satisfactory one.

The whole thing is of the very slightest importance. Sensible inventors are not in the habit of taking out patents on this class of mechanism at all, very much less going out of their way to patent other people's inventions of such small value. I would not waste space and time in calling attention to the matter at all, but for the particularly brazen nature of Mr. Burnet's assumption. In my small experience as an inventor, it has not fallen to my lot before to meet with any one willing to accept orders for models, to build the same according to instructions, to fill an order for goods in quantity built according to such models, and afterwards claim the whole thing and apply for a patent.

CHARLES WIRT.

CHICAGO, Dec. 12, 1891.

Legal Notes.

INCANDESCENT LAMP LITIGATION—THE UNITED STATES ELECTRIC LIGHTING CO. vs. THE EDISON LAMP CO.

ARGUMENT OF FREDERIC H. BETTS FOR THE EDISON COMPANY.

MR. BETTS in opening the case for the defence, remarked that his brother Kerr in his opening as well as in his concluding remarks had made a statement with which he thought he ought to begin; namely, that the case was one of strong equity on the part of complainant. He could not but disagree entirely with that statement. Let us—said Mr. Betts—carry ourselves back and try to appreciate the true status of the several inventors at the time when this invention was made.

About the year 1877 the whole world of electrical thought had been intensely interested in the problem of the production of electric light by incandescence. Many inventors, both in this country and abroad, had been struggling with this problem for more than 30 years. The whole atmosphere of thought had now been quickened by a sense of some impending discovery, which should render practical the dreams of inventors and scientists. Fontaine had in many respects fairly stated the condition of the affairs existing at the time he wrote. He said :—

Lighting by incandescence has been studied for a long time ; but its application generally presents so great difficulties that at the present day it may be considered as within a purely scientific domain, although a certain number of apparatus exists working moderately well.

That had been the condition of affairs in 1877. The best result which had been attained, according to Fontaine, had been an average duration of the carbon of 21 minutes, but in no case had its length of life been greater than two hours. It would seem, therefore, that had anybody really invented anything tending to materially increase the life of the incandescent lamp he would not have been slow to have communicated that momentous discovery to those who were able to appreciate the importance of such an invention. Weston, the patentee in this case, was a well-known electrician, who is and has been for many years an expert. He had been equipped even at that time, with all the requisite facilities for construction and experimentation. He was an expert in words too, with a remarkable facility of stating in the most favorable way to himself any claims which he might put forward. Upon the face of this case there stood out one most important fact. There was no contemporaneous record of the experiments which Weston is alleged to have made. On the contrary, the evidence of the witnesses who have testified in support of his contention wholly fails to corroborate him in respect to the most vital points. He contended that Weston stood wholly alone in his endeavor to prove that he had perfected a process of treating carbon conductors, or that he had applied that process to the making of conductors of incandescent lamps, at the early date assigned by him, the summer of 1877; or that he had then in fact acquired any knowledge or made any discovery in advance of that which the world previously possessed.

Very different was the way in which other inventors had acted in regard to this same invention. Sawyer and Man had been proved without contradiction to have practised this process of making carbon as early as the 6th of March, 1878. They had filed an application for a patent accompanied by a model which contained a treated carbon. Their patent had been issued June 25, 1878. October 15, 1878, they had filed an application for the process of treating carbons, which had been granted January 7, 1879. Weston's application had not been filed until two years and four months afterwards. Sawyer and Man had exhibited their lamps in the most public manner. Large numbers had been invited to see them. The process of hydrocarbon treatment had been employed in their factory. It had been fully described and illustrated in publications more than two years before Weston had applied for his patent. Another inventor, Maxim, testified that he had also practiced this process, that he had made such a lamp as early as June, 1878, and that he had filed an application for a patent in October, 1878. It was idle for complainant to contend that Maxim had not appreciated what he was doing. Maxim had been the electrician of the United States Electric Lighting Company. They had prosecuted his application. They had asserted him to be the first inventor. An interference had been declared between Maxim and Sawyer and Man, in which Sawyer and Man had been successful and had been declared the prior inventors. Maxim had thereupon dropped the contested claim. In June, 1880, the United States Company commenced making lamps. All through 1880 they had made lamps at Bridgeport and late in that year they started up a plant of lamps, lamps made by Maxim and not by Weston. The United States Company were then exploiting Maxim's invention, as appears by an article in the record from the *Evening Post*. Not until the spring of 1881 was Weston first heard of in this connection. Mr. Curtis in his testimony has said that it was in February or March, 1881, that he first formed the acquaintance of Weston. Mr. Betts then read from the testimony the history of the unsuccessful negotiations with Sawyer and Man in relation to this invention. This was in the spring of 1881. Weston had done nothing to get his invention into public notice, while Sawyer and Man had done everything they could do, by patenting, publishing, and manufacturing lamps as well as they could manufacture them. The United States Company had tried to get a license from them and it was only after it had failed to do so that Weston had first been heard of. In a conference in 1881 between Curtis and Weston, Weston had made the claim that he was the inventor. In 1881, after the public had for two years been in possession of the full knowledge of this invention an application had been filed in behalf of Weston. Subsequently, it did not appear when, the Sawyer and Man patents had also come into the control of the Westinghouse Company, which also now controlled the United States Company. Now it had become very important to belittle everything that Sawyer and Man had done, for by means of a patent granted in 1885, this complainant company would obtain control of the invention for a much longer term. There was nothing to show that the application of Weston had ever been thought of by him or by anybody else, until the exigencies of this complainant had compelled it to have an application for a patent made in the name of Weston.

His brother Kerr has contended that the work of Maxim had eventuated in nothing practical, but he did not think that the facts would sustain him in his contention. The first commercial plant had not been made by Weston, nor did he have anything to do with it. He (Mr. Betts), asserted that the public derived a practical knowledge of this invention, not from Weston, but from somebody else. By way of emphasizing this state of facts he would refer to the stipulation in the record. Depositions taken in a suit on the Sawyer and Man patent had been stipulated into a suit on the Weston patent and the suit had been brought on that patent, because it had the longest time to run. It had been admitted by Mr. Pope, the complainant's own expert, that no less than four prior patents—two English and two United States patents—contained a full disclosure of the invention, or sufficiently full at least, to enable a person skilled in the art to practice the invention.

Such a state of facts—continued Mr. Betts—puts upon the complainant the burden of proving, with the utmost certainty and beyond all reasonable doubt, that Edward Weston had completed the invention before any of these others inventors.

Another feature which he should refer to showed that there was no great equity in this case. The Edison Lamp Company did not use this invention in commercial practice. There was proof of a course of experimentation, of a few weeks, or a few months; the making of a few thousand carbons at the lamp factory in 1884 and 1885. There was not one particle of proof that they had ever put one of these carbons into a lamp. The process had been abandoned; it had never been used in a single commercial lamp from the beginning down to the present time. The Edison lamp was made of bamboo, carbonized in a furnace and then electrically heated in a vacuum to drive out occluded gases. It was sealed up by electrically heating, not in a carbonaceous atmosphere, but in a vacuum. The witnesses had testified as to the number of carbons treated; some 20,000 others 9,000, and so on, figures which might sound large, but which were wholly insignificant in view of the fact that at the present time 25,000 lamps per day were being manufactured with untreated carbons, so that the whole amount testified about actually did not amount to one day's commercial production. The defendant had been prosecuted for a mere experimental use of a process which had never been used in its commercial manufacture.

There were three propositions of law to which he should ask his Honor's assent as applied to the facts of the present case.

First.—He is the first inventor, in the eye of the law, who reduces the invention to a fixed, positive and practical form; for until he has done this he is not in a position to give to the public what it has a right to demand. In a race of diligence between two inventors, he is not the inventor who first conceives the possibility of producing a certain result, but he who so perfects the invention that its utility, practicability and success, for the purpose for which it is intended, is actually demonstrated, or is capable of being demonstrated to those who see it. *Second*, if the party first to conceive and subsequently to reduce the invention to practice, does not use reasonable diligence in asserting his rights, and in the meantime the public derives a knowledge of the invention from other sources, or if by other inventors the public have been put in possession of the invention by public use or sale, he loses his rights. *Third*, when the burden of proof is upon a defendant to establish the date of his invention and patent, his proof must be of such a character as to be beyond all reasonable doubt. The rule is the same as against the plaintiff, when once the defendant, as in this case, has succeeded in shifting the burden of proof, by establishing beyond a reasonable doubt that some party other than the plaintiff's patentee, had, prior to the date of the patent, made the same invention. The burden of proof being thereby shifted, it becomes incumbent upon Weston and those claiming under him to adduce the most positive proof in support of his contention. Mr. Betts read from the opinion in *Thayer* vs. *Hart* (22 Blatchf., 229) which, he contended, applied precisely to the present case. He contended also that the evidence in behalf of Weston had proved nothing more, at most, than the performance of some abortive, inconclusive, and uninstructive experiment.

Mr. Betts next proceeded to analyze the patent in suit. He said that the preamble was almost exactly plagiarized from Sawyer and Man's English patent. Weston had nevertheless recognized the state of the art as shown in Despretz's experiments. He then read an account of Despretz's experiments, as published in the *Chemist* in 1849-1850, in which carbon rods had been electrically heated in a hydrocarbon atmosphere, and said that the statements of the experimenter showed precisely what the effect would be in all cases.

A careful perusal of the specification showed that it drew a distinction in the result or stated two different results; first, the filling up of the pores, rendering the carbon more dense and reducing its resistance, and second, building up the surface, or if irregular in diameter or resistance every part of the carbon is made of equal resistance or diameter. His Honor would find that the claim of the patent had been carefully limited to the process of "building up", and had moreover been so limited by the Patent Office. It was not for a general, but for a particular use of the process for building up the carbon. Next he would refer to the file-wrapper and contents and see what Weston's original claim was:—

The method of preparing carbon and conductor for incandescent lamps, by electrically heating them while surrounded by or saturated with a carbonaceous substance, as described.

His Honor would note that this was much broader than the claim which had afterwards been substituted, and had been made so in view of the publication of Despretz, which had been cited against it as an anticipation. He contended that this change materially narrowed the scope of the claim. Apparently the attorney had become satisfied that it was so broad he would not like to risk it, and so he had limited it to a process of building up imperfect carbons. The significance of that point was, that there was not one particle of proof that the defendant had ever utilized the process for building up imperfect carbons. All the witnesses had said it had been used "for drawing down resistance." The carbons were perfect—so perfect that the Edison Company to-day made all their carbons in this way without any treatment whatever.

The claim was for the treatment of carbon conductors *for incandescent lamps*. What force ought to be given to those last three words? The Despretz patents had been cited against Sawyer and Man. The English court had said:—"Yes, perhaps Despretz had described the same process; but it having been proved that Sawyer and Man had made a lamp, and had placed the carbon in it, had they not done something more?" Those three words must either be erased as superfluous, or they must be left in and a limiting effect given to them. If the patentee had never succeeded in making an incandescent lamp, how could he be said to have made a discovery or invention in incandescent lamps? He must show that he had successfully applied it in that way, yet the evidence had shown that he had not invented a practical lamp until 1881, and meanwhile Sawyer and Man had made lamps, and Maxim had made lamps, which were perfectly successful. It was not Weston who had done it. Those three words therefore "for incandescent lamps" had placed Weston in this dilemma:—If he claimed to have made the invention when he electrically heated the carbon in oil, he had made no advance on Despretz; or if he claimed to have been first in the use of the process as applied to incandescent lamps, then he was not the inventor, because in that respect Sawyer and Man and Maxim had both preceded him. The Sawyer and Man lamp had been fully described and illustrated at the time in the *Scientific American*. The difficulty with this lamp had been twofold. First it had not a filamentary carbon, which was necessary in order to achieve commercial success, and second, it was not an all-glass lamp. It had a metal base, which was subject to leakage. Nevertheless a test made by Stowell of the Sawyer-Man lamp had shown a life of 36 hours. This had been a reduction to practice, although the lamp had broken down from too much current. Mr. Betts then read from the *Scienticfi American* of March 8th, 1879, an article which, he contended, was a full disclosure of the process, two or two and half years before Weston had made his application. On the 14th of October 1878, Sawyer and Man had sold to the Electro-Dynamic Company a considerable number of patents together with the process in controversy, and the patent for the process had been assigned to the same company on February 3, 1879. What better evidence could there have been of the "sale" of the process more than two years prior to Weston's application? Mr. Betts read from the statute as to the effect of a prior sale, and asked what better evidence there could be of the "sale" of the thing patented than the fact that it had been sold. It was not material that they had not sold lamps. To manufacture and sell lamps required a large amount of capital. Newspaper articles had been published virtually offering the invention for sale. In connection with an invention of this class he knew of no better evidence that it had been "on sale".

The invention of Sawyer and Man had been embodied in a lamp so early that a patent had been granted in June, 1878. The defendants had met the obligation placed upon them by the rule of law and had shifted the burden of proof upon the complainants. Weston must now prove that he had made the invention in a fixed, positive and practical form, at an earlier date than Sawyer and Man. He would call attention to the fact that the complainant's evidence upon this point was exceedingly weak. Quimby was a patent solicitor and an expert, but there was not one word in his evidence about the making of an incandescent lamp. He had only said that the invention was useful for an incandescent lamp. Weston had never suggested to Quimby, so far as the record showed, that the invention was useful for incandescent lamps, nor had Mr. Quimby ever seen an incandescent lamp. Despretz thirty years before had done everything that Quimby saw. What was there that had advanced the sum of human knowledge one iota, in what Weston had shown Quimby? Then there was the evidence of Broadbent. Weston had not said to him that it had to do with incandescent lamps. Another significant fact:—Page, now one of the attorneys for the complainant had acted as Weston's attorney. In 1881 Page had only known him as connected with dynamo machines, arc lamps and plating apparatus. He would submit that Weston's contention was not consistent with the probabilities of the case. If Weston had ever done anything that he had regarded as of importance why should he not have communicated it to Quimby or to Page? Now they could appreciate the importance of the testimony of the witnesses which defendant had called in rebuttal. Huber, a man of great intelligence employed in the same establishment, had testified that he had seen nothing of the alleged invention nor had he seen any incandescent lamps. It was possible and even probable that he might not have seen a temporary or casual experiment, but his testimony had shown conclusively that there could have been no continuous experimentation nor diligent effort to reduce the invention to practice. The evidence had shown that Weston could not have made any invention which he himself had regarded as of any importance, for if he had done so his people all around him must have seen something of it. If he had done what he now says he had done, it was a matter too important to have been hidden under a bushel.

Again the dates were of great importance. There was no dispute as to what Sawyer and Man had done in March, 1878. It wouldn't do for Weston to say in a vague way: "I did the same thing in 1877." He must satisfy the court that there were good reasons for his saying that he had done this in 1877. A critical examination showed that he came very far from sustaining such an allegation, either by his own or by corroborative evidence.

As to the question of infringement it had not been proved that the invention had ever been used or had ever been sold by the defendant company. Mr. Betts read from Robinson on Patents, patent and other authorities, in support of the position that experimentation, merely in order to ascertain whether the process would really reduce the resistance of carbons, was not an infringement. No case of infringement had been made out.

Mr. Betts then reviewed the proof adduced in behalf of Sawyer and Man, and contended that it clearly showed that the public had been put in full possession of the invention and of full information in respect to the invention. Referring to the contention of the complainants that the exhibitions made by Sawyer and Man for purposes of display or for exploiting their electrical enterprises did not constitute the public use, Mr. Betts said that such a criticism came with peculiarly bad grace from those who sought to uphold Weston's invention. Surely Sawyer and Man had proceeded much farther than ever Weston had, for Weston had admitted that he had never made a lamp that lasted two hours. Sawyer and Man's lamp was very far from being as perfect as modern lamps, but it nevertheless was a great improvement upon its predecessors. The criticism that Sawyer and

Man's lamp never went into practical use, also came with bad grace from complainants. There had not been a particle of proof that Weston ever made a practical lamp until after it had been done by others. Maxim had commercial lamps in use in 1880. Sawyer and Man had long before that put the public in possession of the invention. The more the beauty and utility of the process became apparent, the greater became the improbability that Weston had made the invention. During the period referred to he had taken out 16 patents relating to other electrical inventions, and there was in them not one hint of a discovery of this kind. The testimony of three witnesses, his intimate associates, had been such as to preclude the possibility of any continued experimentation. It was impossible that these people should not have seen some evidence of such a discovery as complainants now claim.

Mr. Weston does not fix any date by himself or witnesses with sufficient accuracy to satisfy the courts of his priority. He has entirely failed to meet the requirements of the statute in that respect. Mr. Quimby's testimony that he saw the experiment in the basement of the "church" building, renders it important to know when Weston had his laboratory in that building. Weston fixes the date some time between the organization of the Dynamo Electric Company and his removal, and his memory, induced perhaps by his wishes, made him fix the date of his removal in 1878. The rent receipt, in the absence of any statement to the contrary, may be fairly assumed to have been for rent paid in advance, so that the date for removal cannot positively be put prior to October 1, 1878. The testimony of Quimby was very vague. He was favorable to Weston and he tried to fix the date in 1877, but was it reasonable to suppose that Quimby had any accurate recollection of the date when he saw the experiment? Would such evidence as his satisfy the obligation on the part of the complainant? He would submit that complainant had wholly failed to meet the burden of proof which had been laid upon them in this respect.

Mr. Weston had not regarded the invention as solely applicable to incandescent lamps. If he had been experimenting as a matter of scientific curiosity he had not gone beyond Despretz, for if there was any invention it must have lain in the application of the discovery to a practical purpose. Mr. Weston in 1877, had been a large manufacturer of arc light carbons. How was it that an invention useful in the very line of his business had never been so used, if he had actually made it? There was no explanation other than the explanation that Weston had never done anything at that time which he had regarded as important. Complainant must stand wholly on Weston's uncorroborated statement.

This process of treating carbons in oil or in gas evolved from oil, had never been practiced in a commercial way. The thing that was done in many incandescent lamp factories was the treating of the carbons in attenuated hydrocarbon gas, and this was found in Maxim's patent. The testimony of Vandegrift, or Shallenberger, and of Smith, all prove that carbons were always commercially treated by gas, so that it appeared that if the invention had been left where Weston has it nobody would have ever used it. It lacked the details which would render it of commercial utility. But Weston had described no apparatus for treating carbons in gas, much less in attenuated gas; on the contrary he had described a process which never had been used and was of no commercial value. Mr. Betts then commented further upon the evidence of Mr. Weston, and contended that he had wholly failed to make out a case entitling him to the favorable consideration of the court. Edison had patented a carbon filament lamp in January, 1880, and the court had declared him to be the inventor of the practical incandescent lamp. If Weston had made an incandescent lamp in 1877, why had he not been called as a witness in these important cases?

As to the question of what constituted "public use and sale," Mr. Betts said that he did not think what Maxim had done amounted to a public use and sale within two years. But as to Sawyer and Man, it was another matter. The cases which had been referred to by the other side were those in which the courts had dealt leniently with an inventor who had made his best efforts to put his invention in the market. But in the present case Sawyer and Man had certainly given to the public the fullest information in respect to their process There had been no secrecy about it. When the invention was a process, it was certain that nothing could more fully put the public in possession of it than the publication of a full description of it in the scientific journals.

Mr. Betts contended that the evidence showed conclusively that in his opinion awarding priority to Weston over Sawyer and Man, Commissioner Butterworth had overlooked the question of public use No such question had arisen as between Weston and Maxim, but he thought there was ground for holding that there had been abandonment on the part of Weston. All the time in which he had been doing nothing, other inventors had been at work, and had repeatedly described the invention in patents and in publications, and this he thought was sufficient to show that intervening rights had accrued. Despretz had certainly published what the result would be upon a carbon thread or rod heated to incandescence in a hydrocarbon atmosphere. He submitted that it made no difference what relation this had to the subsequent invention of others. The results of Despretz were in all substantial respects the results described by Weston. He certainly did not think that Weston was legally entitled to any patent for this invention.

RIGHT OF NEW STREET RAILWAYS TO USE EXISTING TRACKS.

THE Supreme Court of California, has disposed of the well-known case of the Pacific Railway Company et al. against Judge Wade of Los Angeles in an elaborate opinion. The public interest was incited by an argument for a writ of prohibition against Judge Wade to prevent him from assessing the amount of damages for and granting the right of way over the street cable road of the petitioners to the Los Angeles Consolidated Electric Railway Company. The gist of the decision is embodied in the following: "There can be no private property in a street, except the fee of the owner, which is held subject to the easement as long as the public continue to use the street as a highway. The maintenance of horse railroads and running of cars upon public streets of the city of Los Angeles for the carriage of passengers is a mere special mode of using the highway, nothing more. The right to maintain such a railroad does not exclude the public from using the street. The opinion therefore sustained the action of Judge Wade and held that the property of the petitioners is in custodia legis, and therefore the court can grant a right of way to any person or corporation and assess damages and compensation to be paid therefor, without citing or consulting the corporation, but simply upon the application of the receiver in possession of its property. The writ of prohibition against Judge Wade therefore was dismissed."

Literature.

Modern Practice of the Electric Telegraph: A Technical Handbook for Electricians, Managers and Operators. By Franklin Leonard Pope. Fourteenth edition. *New York. D. Van Nostrand Company,* 1891. *8vo. pp. xii,* 234. Price, $1.50.

THE first edition of Mr. Pope's useful and popular manual is dated 1869; a somewhat remote antiquity in electrical history. Telegraphy was then almost the sole electrical art of public significance, and some of its finer achievements were yet to come. The duplex was not yet commercially available, and the quadruplex had not arrived. In successive editions the author has kept "Modern Practice" fairly abreast with telegraphic progress, and in the case of this last edition the book is virtually rewritten and much expanded. The first edition had 128 pages; the thirteenth 160; while the book now has 234. In its original form it is familiar to most telegraphers of twenty years' standing; as recast and enlarged it well repays perusal by old acquaintances as well as by the younger men of the telegraph service. The well-ordered arrangement of numbered paragraphs and of chapters, characteristic of the first edition, has been preserved so far as the necessary introduction of new matter would permit. As before, the author has limited the scope of the handbook to the Morse signaling system, excluding type-printing, synchronous-multiplex, automatic, submarine and other methods. The duplex and quadruplex systems, now so widely employed, are amply and very lucidly described and explained; their principles of action are set forth with great clearness. A number of pages in chapter viii (Equipment of American Telegraph Lines) are given to the application of dynamos to telegraphy, a method of supplying current that has transformed the old-time battery-room of such a station as that of the Western Union Company in New York—with its endless rows and shelves of blue-stone batteries—into the semblance of a compact machine shop.

In no instance is the amplification of Mr. Pope's book more noticeable than in chapters iv, v and vi of the new edition, which treat upon the theory of electrical measurements, the laws and conditions of electrical action and of electro-magnetism. These topics, which scarcely entered the thoughts of American telegraphers a generation ago, and which were allowed but a meagre space in the early editions of "Modern Practice" (the first of which appeared but a year or two after the introduction in America in a small and tentative way of systematic line testing), are here treated with a fulness quite adequate to the requirements of those engaged in our now greatly improved telegraph service. The theoretical and technical points are perspicuously set forth in relatively simple but accurate language, the nomenclature being adapted to the best existing usage. There is also included due reference to the more recent views and speculations as to the nature of electricity. The author's cleverness in illustrating his descriptions and expositions is manifest in the many drawings and diagrams employed throughout the book. They are not only truly illustrative of the text, but in appearance are quite worthy of the fine typography and handsome make-up of the book.

A special word should be said in praise of the consideration for readers shown by an author who takes pains to provide so ample and useful an index as that given by Mr. Pope in his last edition

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED DECEMBER 15, 1891.

Alarms and Signals:—

Electric Signaling Apparatus, G. E. Miller, 464,979. Filed Apr. 3, 1891.
An electric signaling apparatus for railway trains.

Conductors, Conduits and Insulators:—

Electric Conductor, W. E. Oehrle, 464,986. Filed Sept. 14, 1891.
An insulated conductor for electric light wires.

Coupling for Electric Conductors, W. C. Preston, 465,202. Filed Apr. 27, 1891.
Consists of a short tube adapted to hold the ends of the conductors snugly, the conductor being held in place by wedges driven into an opening in said tube.

Electric Connector, W. F. Z. Desant, 465,430. Filed May 20, 1890.

Dynamos and Motors:—

Dynamo-Electric Machine, W. P. Wiemann, 465,104. Filed Dec. 30, 1890.
A dynamo comprising metallic end plates carrying rigid field-magnet cores, a magnetizable iron mass carried by the shaft extending through said field cores, the exciting coils wound on the field-magnet cores and the armature having its cores provided with pole pieces which form multiples of the polar projections on the iron mass.

Commutator Connection for Dynamo-Electric Machines, C. O. C. Billberg, 465,233. Filed Oct. 7, 1890.
Provides means for readily detaching the armature wires from their commutator strips for purposes of repair, etc.

Brush Holder for Dynamo-Electric Machines or Motors, C. O. C. Billberg, 465,234. Filed April 25, 1891.
Has for its object to maintain a proper bearing of the brush at all times upon the commutator.

Switch-Actuating Mechanism for Electric Motors, C. G. Armstrong, 465,401. Filed May 11, 1891.
Relates to construction of devices for stopping and starting electric motors.

Electric Motor Switch, E. W. Rice, Jr., 465,292. Filed Mar. 28, 1889.
Has for its object to prevent damage to the electrical apparatus from a sudden heavy flow of current.

Electric Motor, H. Groswith, Reissue 11,210. Filed Oct. 26, 1891.
An electric motor having a duplicate set of elements, a common external connection to one brush of each commutator and a pair of contacts connected respectively to the two other brushes for external connection.

Galvanic and Thermo-Electric Batteries:—

Packet or Pad for Electric Batteries, L. H. Rogers, 465,206. Filed Feb. 20, 1891.
Consists in enclosing an electrolytic chemical within an envelope of porous material.

Lamps and Appurtenances:—

Portable Electric-Lamp Holder, J. Baker and H. S. Graham, 465,039. Filed Mar. 5, 1891.
Provides means for lengthening or shortening the conducting wires of an incandescent lamp.

Measurement:—

Electrical Indicating-Instrument, E. Weston, 465,442. Filed Mar. 11, 1891.
An ampere meter in which the fixed coil is eliminated and the movable coil is closed in the annular field produced between the poles as a permanent magnet.

Metallurgical:—

Process of Extracting Copper Pyrites, T. A. Edison, 465,250. Filed Feb. 17, 1890.
Claim 1 follows:
The method of concentrating chalco-pyrites ores by eliminating magnetically any magnetic material therein, while the copper and iron pyrites are non-magnetic, and then heating the remainder to such a temperature as to render the chalco-pyrites magnetic and separating the reduced chalco-pyrites magnetically.

Magnetic Ore Separator, C. M. Ball, 465,349. Filed Dec. 11, 1890.

Medical and Surgical:—

Electric Belt, A. Erikson, 465,093. Filed June 25, 1891.

Miscellaneous:—

Means for Propelling Boats by Electricity, O. Büsser, 464,955. Filed Feb. 10, 1891.
Relates to a method of towing canal boats by means of an electric motor on the deck of the boat, acting on a stationary cable sunk in the canal, and a trolley wire strung along the bank of the canal.

Automatic Circuit-Breaker, W. R. McLain, 465,046. Filed Sept. 18, 1890.
Has for its object a method of automatically increasing the break in the circuit at the instant of the melting of the fuse wire.

Riveting by Electricity, E. E. Ries, 465,089. Filed Sept. 15, 1888.
See Patent Notes.

Feed-Water Regulator, G. W. Schilling, 465,212. Filed Jan. 27, 1891.

Method of Controlling Alternating-Current Induction, E. Thomson, 465,-078. Filed Apr. 17, 1889.
Consists in varying the angle of the magnetic axis of two coils in inductive relation to a closed magnetic circuit.

Adjustable Rheostat, F. J. Sprague and C. R. Pratt, 465,218. Filed Aug. 25, 1891.
A rheostat having a large number of contact plates in the switch by means of which the resistance is varied, said plates being so mounted as to occupy a small space and provide a rapidly-moving co-operating contact.

Electrical Sewer-Gas Indicator, J. J. Lawler, 465,278. Filed Mar. 4, 1891.
An electric signal for sewerage systems.

Electric Fan, P. Diehl and E. H. Bennett, Jr., 465,360. Filed Apr. 4, 1891.

Electric Fan, P. Diehl and E. H. Bennett, Jr., 465,361. Filed Apr. 8, 1891.
A novel arrangement of suspended ceiling fan.

Bracket for Supporting Electric Conductors, J. A. Duggan, 465,365. Filed July 15, 1891.

Production of Insulating Coatings or Linings in Electrolytic Apparatus, L. Grabau, 465,309. Filed Aug. 9, 1887.
A melting pot having a cell surrounding an electrode, the cell being open at the bottom and having double walls forming a chamber provided with a feed and exhaust port and a discharge passage connected with the neck of the cell for the discharge of the matter.

Electric Heater, W. H. Boles, 465,423. Filed Mar. 21, 1891.

Electric Switch and Case for the Same, C. P. Chappell, 465,425. Filed Nov. 4, 1891.
Method of protecting the contact plates of switches from exposure to the weather.

Mining Machine, J. C. Werner, 465,150. Filed May 11, 1891.
Claim 1 follows:
The combination of two rotary cutter bars and an intermediate rotary clearing-worm, the cutter bars operating independently of each other and of the worm.

Railways and Appliances:—

Electric Car-Brake, E. Verstraete, 465,034. Filed Feb. 5, 1891.

Converter System for Electric Railways, M. W. Dewey, 465,359. Filed May 11, 1891.
Provides cores for the primary or road-bed coils that will form and maintain closed magnetic circuits.

Train-Signaling Apparatus, P. Synnestvedt, 465,396. Filed April 27, 1891.
An electrically operated compressed air or steam train signal.

Electric Railway, G. F. Green, 465,407. Filed Sept. 15, 1879.

Electrical Railway, G. F. Greene, 465,432. Filed May 15, 1886.
See Patent Notes this issue.

Telephones and Apparatus:—

Telephone, C. Cuttriss, 464,959. Filed July 22, 1891.
A telephone receiver without electrodes. See THE ELECTRICAL ENGINEER Dec. 16th.

Patent Notes.

E. E. RIES' PATENT ON RIVETING BY ELECTRICITY.

ON Dec. 15 a patent was issued to Mr. E. E. Ries, of Baltimore, entitled "Electric Riveting," No. 465,089. This patent describes the process in which the rivets are inserted in the holes in a cold state, which are then heated to incandescence by the passage of an electric current through the same and are maintained at incandescence during the operation of heading, by which the operation of riveting is greatly facilitated. The patent contains seven claims, of which we give the three following:

1. The method or process of riveting which consists in heating the rivet when inserted in the rivet hole or holes by the passage of an electric current through the same and then heading the rivet, substantially as described.

3. The method or process of riveting which consists in heating the rivet when inserted in the rivet hole or holes to the required degree of incandescence by the passage through the same of an electric current of suitable quantity and tension, then heading the rivet and maintaining the same in the desired state of incandescence by suitably regulating the current during the heading operation, substantially as described.

5. The method or process of riveting metal structures together, which consists in first inserting a rivet into the rivet-hole, then making electrical contact between the ends of the rivet and an anvil and the heading-die, respectively, which constitute the terminals of an electric circuit, then charging said circuit with an electric current or currents until the rivet is heated to the desired degree of incandescence, and then forcing the heading-die upon the rivet until the heading operation is completed, substantially as described.

GREEN'S ELECTRIC RAILWAY PATENTS.

CONSIDERABLE interest has been manifested in the issuance of two patents to George F. Green, of Kalamazoo, Mich., as they date back to the early days of electric railroading and were the subject of prolonged interference proceedings. The patents are entitled "Electric Railway," Nos. 465,407 and 465,432, December 15, 1891, and were filed respectively September 15, 1879, and May 15, 1886.

Claim 4 of the first patent is follows:

The combination of a railway track, one or more stationary means of electric supply, electrical conductors extending from said means of electric supply along the lines of said track, and consisting wholly or in part of the rails thereof, vehicles moving along said track, rotating electro-dynamic motors fixed upon said vehicles for imparting motion thereto, and wheels supporting said vehicles upon the track, and also serving to maintain continuous electrical connection between said means of electric supply and said rotating motors, substantially as described.

Claim 3 of the second patent is as follows:

The combination of one or more sources of electric supply, a railway track, a wheeled vehicle moving upon or along said track, a conducting circuit composed wholly or in part of insulated conductors extending along the line of travel of said vehicle, one or more rotating electric motors mounted upon said vehicle for propelling the same and included in said circuit of conductors, and a circuit controller placed on said vehicle, and also included in said circuit of conductors, substantially as described.

It is claimed that Mr. Green conceived his invention long prior to the filing of his patent, and that he built and operated a small model as far back as 1874, for the purpose of exhibiting his invention to capitalists and demonstrating its practicability.

ELECTRIC SMELTING—COWLES CO. vs. PITTSBURGH REDUCTION CO.

THE Cowles Electric Smelting Company has filed a bill in equity in the United States Court, Cleveland, O., against the Pittsburgh Reduction Company. The bill asks for an injunction preventing the defendant company from using certain patents for smelting ores by electric currents, claiming priority for the invention and patent. It is similar to a suit filed by the Pittsburgh Reduction Company against the Cowles Company in the Cleveland courts, and is only another chapter of the bitter fight which the two companies are waging against each other.

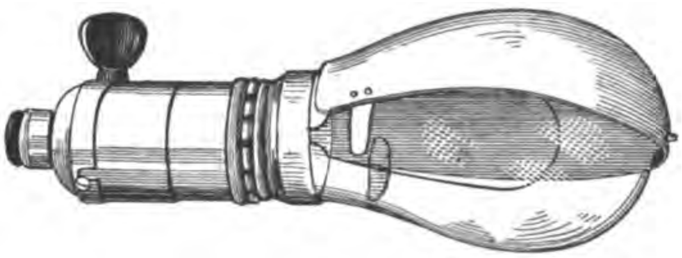
TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

Interest the public in your business by advertising its facts.

THE NOVELTY ELECTRIC CO.'S HALF REFLECTOR.

A NUMBER of interesting novelties and new designs in electric light fixtures and supplies have recently been brought out by the Novelty Electric Co., 50, 52, 54 North Fourth Street, Philadelphia. One of these, illustrated herewith, is their "No. 1 Half Reflector." It is a simple and efficient device, and very reasonable in price. The half-round reflector springs at once into position on the glass



NOVELTY ELECTRIC CO.'S HALF REFLECTOR.

bulb of any incandescent lamp, and a small hole at the lower end of the reflector engages with the little projection or "nipple" at the tip of the lamp. These reflectors are made in a variety of forms and admit the use of the ordinary shade at the same time.

BURTON ELECTRIC HEATERS.

THE Electric Merchandise Co., Chicago, has received this week an order for four sets of Burton electric heaters from the Aspen Mining Company, Aspen, Col., to be used in the company's motor stations. The Benson & Halcyon Heights Railroad Company, Omaha, Neb.; Edison General Electric Company, Portland, Ore.; Maschinenfabrik Oerlikon, Oerlikon bei Zurich, Switzerland; Newburyport & Amesbury Horse Railroad Company, Newburyport, Mass.; Warrensburg Electric Light Company, Warrensburg, Mo., are among the number of companies placing recent orders for heaters. The following letter has been received:

ALLENTOWN AND BETHLEHEM RAPID TRANSIT CO.
Allentown, Pa., Dec. 10, 1891.

BURTON ELECTRIC CO.,
Richmond, Va.

DEAR SIRS: Please ship eight more electric heaters with switches, being the equipment for two cars same as we had before. They are giving excellent satisfaction and are liked by the patrons of the road much better than the stoves.

Yours truly,
(Signed) A. H. HAYWARD, Sup't.

WALDO & STOUT.

THIS firm has just been organized at Bridgeport, Conn., for the purpose of embarking in the business of founders in aluminum, silicon and manganese bronze. The firm consists of Dr. Leonard E. Waldo, who is well known to the electrical profession from his work in the perfection of aluminum and silicon bronzes. Mr. Newton E. Stout will have the care of the business management.

The new foundries of the firm will be located on Railroad avenue extension, near the Wilmot & Hobbs factories, and a new road will at once be opened to that thoroughfare. The foundries will be devoted to making new alloys of copper with aluminum, silicon and manganese in the shape of bronze and brass castings. The design of the furnaces is the Swedish patent furnace for casting wrought iron, and oil will be used as fuel. It has also been decided to erect very complete facilities for the proper testing, both chemical and physical, of the metal for engineering or other purposes. Among other things a contract has been made for the construction of a testing machine to break bars up to a tensile strength of 200,000 pounds.

The new company hope to get their first building completed by early summer. Their structures will be spread over an acre of land, and additions will be erected over the rest of the site as the work extends. The buildings will be constructed of brick, and on account of the use of oil as fuel the roof in the centre will be about fifty feet from the ground. Two acres more are held in reserve for future buildings. Mr. Erwin S. Sperry will act as superintendant of the factory.

ALEXANDER, BARNEY & CHAPIN.

THIS enterprising firm have been compelled for the third time since the establishment of their business, to enlarge their store to keep pace with their ever-increasing trade. They had to abandon the "Exchange" and tear down the offices formerly used by the purchasing agent and general sales agent, and add all that part to their store. New shelves and counters have been put up, and they have thereby not only gained a great deal of room, but the appearance of the store seems to be improved.

Among the many novelties shown at their establishment for the holiday season is a Christmas tree lighted by miniature incandescent lamps, which is attracting a great deal of attention in their window. It is seldom that a handsomer show is made during the holidays than that displayed by the A. B. C. Co. at the present time.

GAS ENGINES AND DYNAMOS FOR ISOLATED PLANTS.

ONE of the exhibits that attracted a great deal of attention at the American Institute Fair was a complete isolated plant composed of a 2 h. p. Hartig improved gas engine and a 16-light Riker low speed dynamo. The gas engine having two cylinders gets an impulse at each revolution, thus obviating any flicker in the electric light. The dynamo is compound wound and has a 10-inch pulley driven from the 44-inch fly-wheel on the gas engine. It runs at the low speed of 810 revolutions per minute, the gas engine making 185 revolutions per minute. The extremely low speed of the dynamo has also a great deal to do with the steadiness of the lights.

Below will be seen a table showing the actual amount of gas consumed per hour and cost for a specified number of lamps. This plant took the award of excellence at the fair.

Mr. Hartig does not claim the highest efficiency for his engine, but guarantees it to run at a more uniform speed than any other machine in the market.

Num. of 16c. p. 110 volt lamps.	Volts.	Speed.	Gas consumed in cubic feet.	Cost per hour gas @ 1.25 per M.
16	110	810	80	10 cts.
12	110	820	60	7.5 cts.
8	110	830	52	6.5 "
4	110	840	44	5.5 "

Running free the engine consumed 20 cubic feet of gas.

THE UNITED STATES PORTELECTRIC CO.

ARTICLES of incorporation of the United States Portelectric Company, with a capital of $5,000,000, were forwarded from New York to West Virginia last week, the company having been organized under the laws of that State. The following are the incorporators: Thomas L. James, ex-Postmaster General; ex-Judge A. J. Dittenhoefer, John Straiton, Charles F. James, Percival Knauth, William James, John T. Williams, Colonel Henry Huss, Frank Lawton, and Whipple V. Phillips. The company controls a device for the transportation of mail and express packages at a high rate of speed, which, it has been reported, will probably be utilized by the Post Office Department. There has been an experimental plant in operation in Dorchester, Mass., for the past year. The *modus operandi* was illustrated and described in THE ELECTRICAL ENGINEER, May 27, 1891.

A CHRISTMAS TREE TWIG.

THE American Electrical Works have long had the reputation for taste and ingenuity in the little souvenirs they send their friends from time to time. The latest of their productions in this line is a pretty Christmas card, bearing a twig from their Christmas tree, associated with the usual good wishes of the season and the sentiment: "Heaven give you many, many merry days."

TO MANUFACTURE THE FIBROUS BATTERIES.

We have received information that the Fibrous dry battery and the disque Leclanché porous cup are hereafter to be manufactured exclusively by Messrs. Thompson & Robertson, 258 Broadway. This battery and cup, it will be remembered, have been manufactured for some time past by Messrs. Taylor & Walsh, of this city, whose interest the firm of Thompson & Robertson have purchased. The first-named member of this firm is the Hon. Roscoe H. Thompson, formerly of Boston, and the late treasurer of the Fibrone Manufacturing Company, of this city. Mr. J. Hart Robertson, under whose supervision the batteries will be manufactured, is a member of the New York Electric Club, and a well-known electrician, the most prominent of his inventions probably being the writing telegraph. Mr. Robertson, however, considers the fibrous battery the most promising of his inventions, and will give all his time to its manufacture at the company's factory in Bloomfield, N. J. Mr. Louis Walsh will be the manager of the sales department. Mr. Walsh is probably best known to the electrical trade through his connection with the Crosby Electric Company, of this city. The Fibrous dry battery is adapted for all open-circuit work, is small, being only 4¾ x 8 inches, and cylindrical in shape, and is said to be the only dry battery in the market that is not sealed. The company have already received many flattering testimonials in regard to this battery.

E. T. BIRDSALL, M. E.

Mr. E. T. Birdsall, of 115 Broadway, has been retained as the consulting engineer for the new Hotel Grenoble, a fine building to be put up by the well-known builder Noble. Mr. Birdsall will have charge of all the mechanical and engineering details, and will put in a fine electric light plant of about 1,200 lights. He has also been retained for the big new Municipal Building on Centre street, which will be at least two years before it is completed. Mr. Birdsall has of late had many calls of this nature upon his time.

PHILADELPHIA NOTES.

Mr. Chas. K. Westbrook, manager of the Isolated Light and Power Department of the Thomson-Houston Electric Light Co., announces the following recent sales and installations, viz.: Philadelphia and Reading Coal and Iron Co., Pottsville, Pa., 35 arc; Pencoyd Iron Co., Pencoyd, Pa., 50 arc; H. C. Hamilton & Son, Manayunk, 500 incandescent; So. Baltimore Car Works, Baltimore, Md., 35 arc; B. and O. Railroad Co., Brunswick, Md., 25 arc; Delaware Hosiery Co., Dover, Del., 250 incandescent; Penn. Supply Co., Wilkesbarre, Pa., 90 incandescent; Stinson Bros., Philadelphia, 45 arc; Cayuta Wheel Foundry Co., Sayer, Pa., 125 incandescent: Boyd, White & Co., Philadelphia, 18 arc; Shoneman & Bros., Eighth street, 6 arc; and a 75 incandescent plant for use on the boat of the Board of Police Commissioners at Baltimore, Md.

The Car Shops of the Bristol (Tenn.) Belt Line Railway Co., of which Mr. W. A. Stadelman of this city is general manager, were completely destroyed by fire last week, together with cars, motors, tools, etc., and are supposed to have been set on fire by tramps after having killed the watchman, Mr. John Overstreets, whose body was found in the ruins burned to a crisp and surrounded by four iron barrel hoops. The company has placed an order with the J. G. Brill Co. for new cars, and the road will soon be put in operation again. The road was of the Short system and had only been in operation about two months.

Vallee Bros. & Co. have this week completed the contract for wiring the Williamson Free School, which has been progressing for over a year. This firm have for several months confined themselves strictly to the electrical supply business, but the above contract was taken before the construction work was abandoned. They are agents for the Buckeye incandescent lamp, of which they have sold over ten thousand this fall. The agency for the Russell mast-arms has recently been awarded this firm.

La Roche Electric Co.—At a meeting of the board of directors of the La Roche Electric Works, last week, it was decided to build a factory for the manufacture of their electrical apparatus. A committee was appointed to select a desirable site which will be suitable for shipping facilities. This move was made in order to meet the large increase of business, which has outgrown the capacity of their present quarters.

The Century Electric Club has just been organized in this city for the advancement of its members in the electrical field, in which they are all engaged. The work will consist in reading papers, etc., discussions, and a regular review of periodicals.

"Star Electrix." The irresistible Mr. D. C. Spruance, of the Star Electrix Co., is home for the holidays from the West and reports the largest crop of orders ever known by the oldest inhabitants.

Curtis Bay, Md.—I was in error last week in stating that Mr. W. A. Stadelman had closed a contract with the Curtis Bay Railway Co. of Baltimore. It should have read Mr. W. A. Stearns, of the Edison Co.

Mr. M. S. Shapleigh, agent for the Electrical Supply Co., reports a large increase in business over last year. They have just put upon the market several new specialties which have merit.

Mr. S. Ashton Hand, vice-president of the Equitable Engineering and Construction Co., has gone to Chicago and other points West on a business trip.

Mr. C. A. Benton, of the Detroit Electric Works, was in the city last week on business, and took wing northward for New York.

WESTERN NOTES.

The Electric Appliance Company, as general Western agents of the Consolidated Electric Manufacturing Company, of Boston, are putting in a very large stock of their celebrated goods. Their sockets, wall sockets and receptacles are samples of the manufacturer's art. Their Davis arc light cut-out has been demonstrated as being a wonderfully practical article, and is used exclusively throughout Boston by the Boston Electric Light Company. Their arc light hanger boards, switches, etc., are very desirable articles at attractive prices. Their telescope switchboard plug and socket, with auxiliary transfer plug, fills a long-felt want. The Electric Appliance Company is certainly to be congratulated upon securing control of so valuable a line of specialties.

The Laclede Gas Light Co., St. Louis, will double the capacity of its incandescent electric lighting plant, and has ordered of the Pond Engineering Company, two 250 h. p. compound condensing Armington & Sims engines, with Blake pumps, and independent condensing apparatus. This work was awarded, after strong competition from all the leading high-speed engines, to the Pond Engineering Co., who will put in the foundations, and superintend the installation and starting of the plant. It is expected that one of these engines will be in operation by Jan. 1st, 1892, and the other shortly thereafter. The first engine will be belted direct to a 2,500 light alternator. The foundations will be carried to solid rock.

The Electrical Supply Co., Chicago, have converted the front end of their large store into an elegantly finished sample-room. This is separated from the sales department by a combination of handsome upright display cases and a beautifully patterned grille reaching to the high ceiling. All the woodwork is oak, finished in hard oil. The floor is of the same material, laid in mosaic figures, oiled and polished. Displayed in the cases and arranged about the room are samples of every conceivable article for electrical use. To such an extent has this been carried that the display amounts to a small exposition in itself. No visitor to Chicago should fail to see it.

The Patton Motor & Mfg. Co. are receiving inquiries from street railway men from all over the country in regard to their street railway system, recently described in The Electrical Engineer, some of which are highly interesting. They are building two complete outfits with the utmost dispatch, and which will be shipped to their respective destinations in a short time. Their car at Pullman is still running day in and day out with the same persistent regularity and refusal to break down under all the severe tests to which it has been subjected.

Mr. J. K. Pumpelly is busily employed in developing his new mechanical form of storage battery, in which he has not only made important changes from any heretofore made, but which, it is stated, does not infringe on any of the storage battery patents. His plant is located at No. 205 Springer Building, and he will shortly place these new cells on the market.

Mr. C. O. Harris, of Dallas, was in town last week looking after a number of standard articles which he will handle in Texas and the neighboring States. As a member of the late firm of Clower, Harris & Co. he built up quite a trade for supplies, and will no doubt find a ready market for the class of goods which he will offer.

The Chas. Munson Belting Co., through Mr. H. B. Morgan, have secured the order for the belting for the L. Z. Leiter Building, comprising two 48 inch, seven 10 inch, two 12 inch and one 6 inch belts. This is the largest private electric plant in the city of Chicago.

☞ ***Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Miscellaneous, etc., will be found in the advertising pages.***

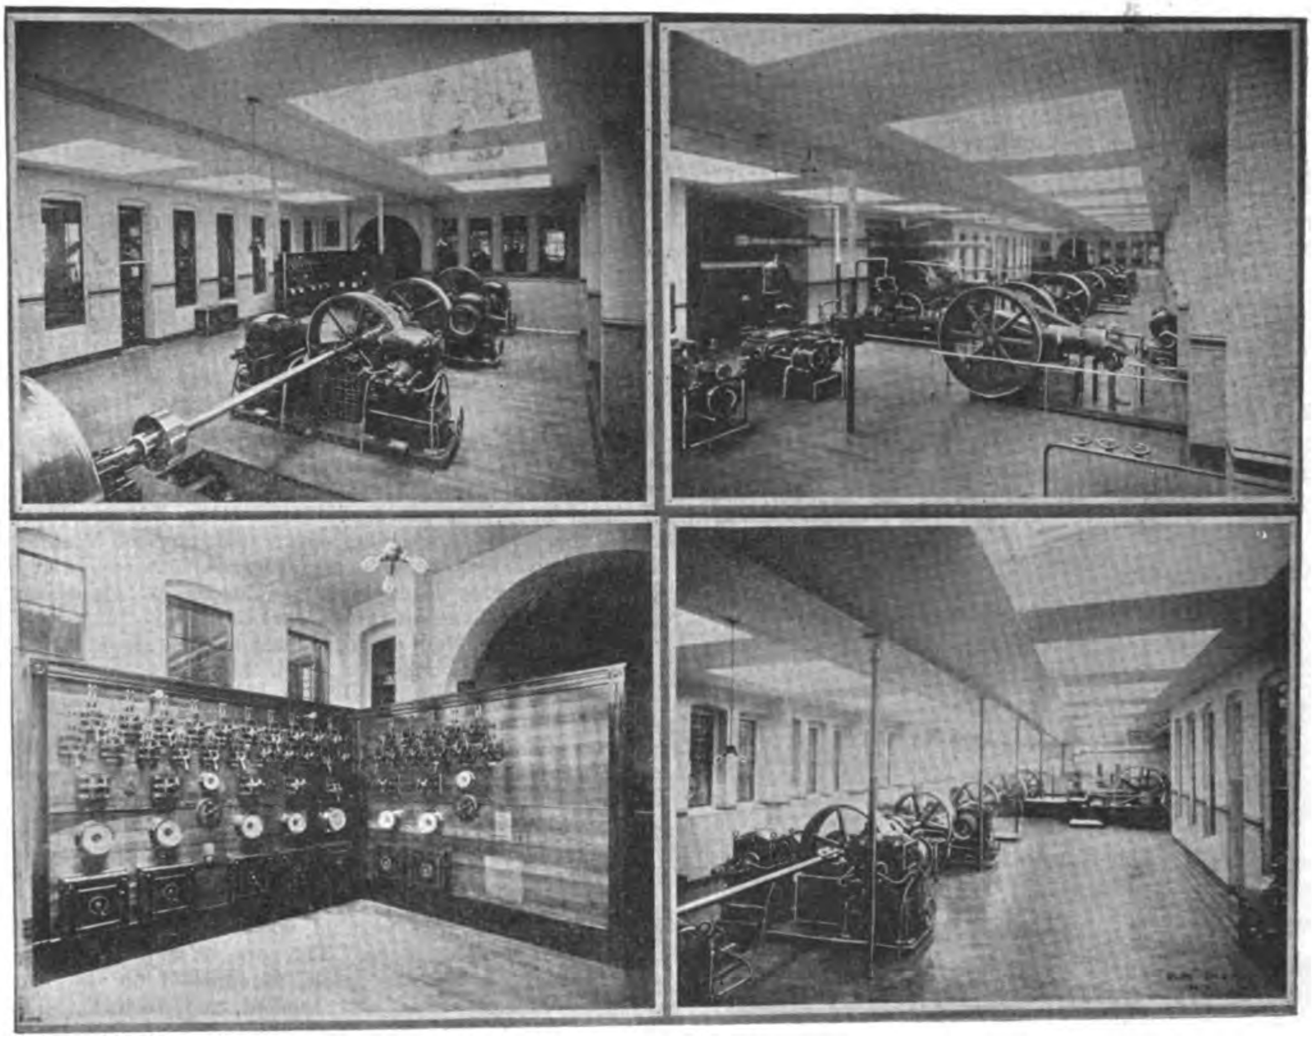
THE
Electrical Engineer.

VOL. XII. DECEMBER 30, 1891. No. 191.

LIGHTING THE WALTHAM WATCH FACTORY.

SOME three years ago the Waltham watch factory, at Waltham, Mass., after having experimented with several systems of electric lighting, concluded to put in a large isolated plant, and upon careful investigation placed the order with the Mather Electric Company, through Claflin & Kimball, their New England agents, for a plant of 2,000 lights. This plant, Figs. 1, 2, 3 and 4, was installed originally in the summer and fall of 1888, and has since been increased by the further addition of 1,250 lights dynamo capacity. They have already connected nearly 5,000 lights through the various departments of their extensive works.

The dynamos supplied by the Mather Company are of the Anthony type, whose special feature lies in the construction of the field magnets, which are constructed of laminated wrought iron of very thin plates, the magnet being stamped out of wrought iron, and thus composing a field without any joints in the entire magnetic circuit. In this way the high efficiency of the Mather dynamo is retained, together with a gain in decreased weight of the machines and slow speed of the dynamos. The dynamos have a capacity of from five to six hundred lights each, running at a speed of about eight hundred revolutions per minute.



FIGS. 1, 2, 3 AND 4.—MATHER ELECTRIC LIGHT PLANT, DRIVEN BY EVANS FRICTION SYSTEM, WALTHAM WATCH CO., WALTHAM, MASS.

The switchboard arrangements of the plant, Fig. 3, are very complete, and include a full set of instruments for each dynamo, the whole being so arranged that the dynamos are run in multiple, the dynamos being switched into circuit as the current is called for throughout the building. Each department of the building, thirty-two in number, is supplied by an entirely separate circuit from the dynamo-room, thus placing the lights of any of the departments of the building under the control of the electrician in the dynamo-room.

It was the original intention when the plant was installed to use storage batteries as an auxiliary to the dynamos, and a storage battery plant of a capacity of 500 lights was originally installed, but its use has been gradually superseded by the use of dynamos, as the batteries do not appear to be entirely suitable for the purpose for which they were used.

As will be seen from the cuts, the dynamos are driven by the Evans friction system, driving direct from the main shaft. This system gives easy control of the individual dynamos, allowing them to be started and stopped at will without the use of friction clutches. The dynamos are so arranged that they may be driven either from the main shaft from the main engine of the Corliss type, or they may be driven direct by means of a Ball compound engine of 300 h. p., which is shown in Fig. 3.

As an auxiliary to the regular dynamo plant, a small dynamo of 250 lights capacity has been installed for the purpose of furnishing light during the night for watchmen purposes and for sweeping the factory, every foot of the immense establishment being swept every night.

This plant has been very satisfactory to the Waltham Watch Company, and has reflected great credit on the work of the Mather Electric Company and its agents, Claflin & Kimball. When it is remembered what a particularly perfect service is required in the delicate work of watchmaking, it can be easily understood that a system that is satisfactory for such work must be entirely satisfactory for any of the ordinary classes of manufacturing. This we believe to be one of the best, if not the best, and largest isolated plants for manufacturing purposes run as a plant from one point. It has operated now some three years without a single breakdown or interruption of service of any kind.

THE WADDELL-ENTZ ELECTRIC MOTORS AND DYNAMOS.

THERE was a time, not many years ago, when the designing of dynamos and motors was in the hands of that

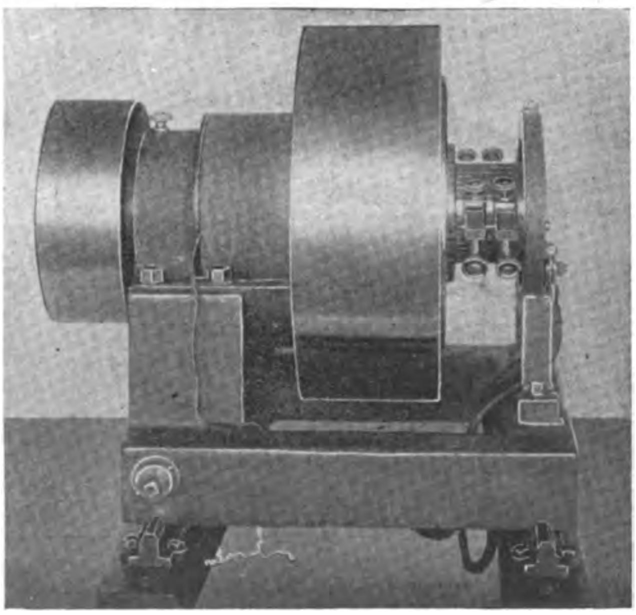


FIG. 1.—THE WADDELL-ENTZ DYNAMO.

class known by the generic term of "inventor," whose chief aim seemed to lie in the direction of constructing machines not with the view, particularly, of obtaining the highest results, but of working out a design which should differ as far as possible from that of all other existing machines. This practice has fortunately gone very largely out of fashion, and in its place we find the efforts of designers bent in the direction of constructing machines

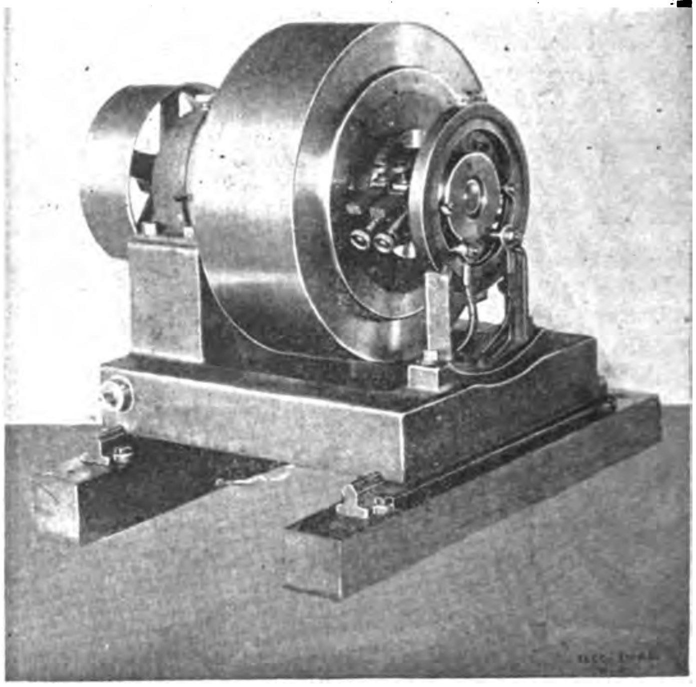

FIG. 2.—THE WADDELL-ENTZ DYNAMO.

which shall be not only of very high electrical efficiency, but in which the design is such that the machine can be produced with the least possible cost. A good example of this modern tendency is to be found in the design adopted in the machines now being constructed by the Waddell-Entz Electric Co., of this city, and our readers will be interested in the description of the means which have been employed to effect the desired purpose.

The machine which we illustrate in the accompanying engravings has a capacity of 2 kilowatts, and in its design Messrs. Waddell and Entz have had in mind constantly, first, the securing of high electrical efficiency with a mechanical construction such that the parts should be subject to the least manipulation and machine work. It was for these reasons that the type of field and armature shown was adopted. As will be noted, the field magnets are energized by a single coil wound upon a core which has a projecting horn which forms the upper pole piece. This core is let into a hub, which has a low projecting flange running parallel with the core, and which forms the lower pole-piece. The core, as well as the outside surface of the pole itself, is finished on the same mandrel, and is bored and bushed, and turned at the end. The energizing coil is slipped on to the core, which is held in place securely by two screws which prevent it from turning and at the same time from slipping in and out. The core is of malleable iron, and, as already stated, is bushed, and forms the bearing for the armature shaft. In order to provide for ample oiling the magnet is cored, thus providing an oil chamber; at each end of this core a ring passes over the shaft and dips down into the oil below, so that as the shaft revolves a continual supply of oil is fed to the bearing. As a result, the machine requires no attention in this regard for weeks at a time. In the larger machines having four or more poles a second bearing is provided, but in the two-pole machines, as stated above, the armature is entirely supported by a single long bearing passing through the centre of the magnet core.

The construction of the armature adopted in this machine has been very carefully worked out, and a somewhat striking feature of the machine is the fact that no wire whatever is visible, the armature being inclosed in a brass cover. The armature is built up of soft iron rings stamped in a press, and one of its principal characteristics lies in the fact that it is built up and held in position without the employment of bolt holes passing through the armature. By this design the full section of the iron is utilized, which is particularly desirable in multipolar machines. The rings, insulated by paper, are perfectly smooth, and require no turning in the lathe after they come from the stamping press. For the purpose of building up into an armature they are put into a press between two outside rings of brass, and are then screwed up under pressure. spider is bolted to the armature ring by means of the same bolts which serve to bind the armature plates together, and the brass cover is then slipped over the armature and held in place by screws. By the employment of the bolts on the outside of the armature not only is the reduction of the magnetic circuit obviated, but, in addition, the insulation of the plates from one another is not destroyed, as has frequently been proved to be the case of the bolts passing through, and which therefore require to be insulated and thus serve to still further increase the size of the hole and thus reduce the iron section.

As the pole-pieces are situated entirely on the inside of the ring, all trouble due to shifting of the wires by centrifugal force is avoided, as the revolution of the armature merely tends to keep the inside of the wire more firmly in place; besides, the action of the magnetic lines is such as to make the wire hug the armature more closely.

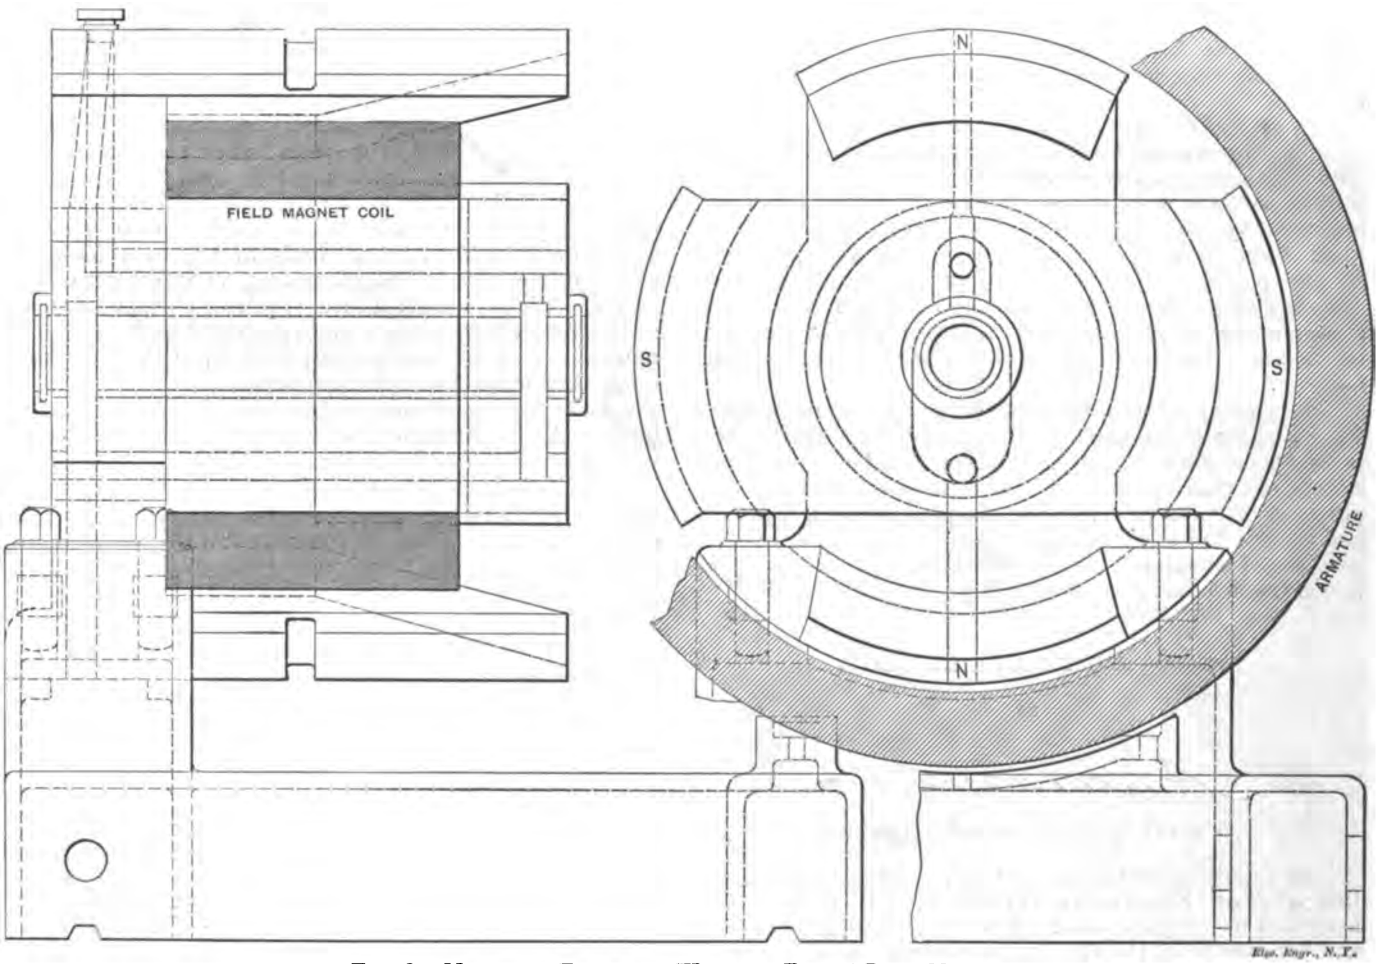

Fig. 3.—Magnetic Frame of Waddell-Entz 4-Pole Machine.

The outer brass rings are then clamped together by a series of bolts spaced evenly around the armature and screwed up by nuts while the plates are under pressure, so that when the pressure is released the armature comes out as a solid ring.

The bolts encircling the armature are placed on the outside circumference, leaving the inner entirely smooth, and are of small diameter, being so spaced that they form grooves for the winding. They thus afford a positive driving and take the place of teeth without, however, introducing disturbing reactions. They also avoid the slotting of the armature and thus can be stamped out with a smooth, round die. The armature is therefore practically ready to wind as soon as it comes out of the press, so that the least possible time is lost. While this operation is going on, the commutator is being built up upon the spider through the center of which passes the shaft. When complete, the

In the two-kilowatt machine illustrated, the brushes are held by a stand encircling the end of the commutator. Each pair of brushes is mounted on a separate ring, these rings being insulated from each and held in position in the frame. The machine is so designed that the brushes, once set, require no shifting, the machine being sparkless at all loads.

The machine, it will be noted, is mounted on a pair of rails, and for the purpose of tightening the belt a screw passes through a threaded eye cast into one of the rails. By this means, while being shifted to and fro, it is at the same time positively held in position and its stability thus increased. The machine work required in the building up of these dynamos, it will thus be noticed, consists almost exclusively of boring and turning, the only planing necessary being that required for the rail grooves. On account of the design adopted, it will be seen that each part of the machine can be separately constructed, the armature being independent of the commutator and spider, and each of the magnetic parts also is capable of separate finishing. The result is that the machine can be constructed in the least possible time as no one part need be delayed while another is being finished, a most desirable feature in the rapid filling of orders.

The design of the frame of the four-pole machine is illustrated in Fig. 3. Here, it will be seen, a single energizing coil is also employed, but an outer bearing is added to give stability to the armature.

These machines are built in sizes varying from 2 to 100 kilowatts. In the two-kilowatt machine the armature resistance, warm, is .0295 ohm, and it is wound with two No. 15 B. & S. wires. The field resistance, including the regulating box, is 100 ohms. This gives a drop of 5.04 volts in the armature, and an efficiency of 90 per cent. at 1,100 revolutions of the armature. The floor space occupied by this machine is remarkably small, the dimensions of the machine being as follows: Length, 18¼ inches, outside of pulley; width, 19 inches, outside of rails; height, 18 inches.

The 25 K. W. machine has six poles, an armature resistance of .015 ohm, and a field magnet resistance of 30 ohms. The diameter of the armature is 39¼ inches and it runs at a speed of 390 revolutions per minute. The floor space occupied by this machine is 46½ × 46½, and 48 inches high. The 50 K. W. machine has 8 poles and the 100 K. W. 10 poles; the latter running at 200 revolutions per minute and occupying a floor space of 78x82 inches, and standing 82½ inches high, with a diameter of armature of 68 inches. Each of these machines has but a single magnet coil.

The factory of the Waddell-Entz Co. at Bridgeport, Conn., where these machines are now being constructed, is equipped with the most modern machinery, and it is safe to say that by their use, in connection with the simplicity of the design employed, the production of dynamos and motors has been brought down to a degree of simplicity and cheapness which would hardly have been believed possible but a short while ago.

ELECTRICITY AT THE PLOW.

BY

A. A. Denton

Of the U. S. Department of Agriculture.

The following statements are not, perhaps, in the regular line of The Electrical Engineer, but if they turn attention to practical problems which immediately concern the prosperity of the Great Plains of the West, they will be well worth space in its columns.

In the States which occupy the Great Plains there is an immense area, nearly level, free from stones, trees, or other impediments to cultivation of the soil by power machines. The sole power now available for the cultivation of this almost boundless farm, is animal power. Western farmers wisely, perhaps, certainly necessarily, discard hand implements, so far as possible, and depend almost wholly upon animal power machines in the production of immense crops of grain. The use of animal power always has been, and always will be subject to limitations. Manufactures made comparatively little improvement until the adoption of efficient prime motors. Disconnect engines and motors and turn the shafting of a manufactory by flexion of muscle, and see how essential to modern manufactures are modern motors. So long as commerce was dependent upon galley slaves or upon slow-moving caravans, so long it was necessarily limited. Agriculture is now where Manufactures and Commerce were before the adoption of efficient motors, and like them it will make wonderful progress when it substitutes tireless motors for animal power.

As a consequence of this limitation of power in agriculture, a very large part of the Great West lies fallow and unproductive. The annual prairie fires harvest the natural crop of grass. The useless smoke of these prairie fires should take the form of food supply for the hungry millions of the earth. They should be replaced by wheat fields of vast extent. The rapid extension of agriculture in the Great West is simply a matter of the application of efficient motors equal to the demand of agricultural work in that section.

There has been very great improvement in agricultural work in the last half century, and all of that improvement is due to the substitution of animal power, or of steam power, for manual labor. The application of animal power to the reaper performs the labor of 30 men. The application of power to the threshing machine saves two-thirds of the manual labor formerly required. The application of steam power in the locomotive renders the carriage of farm products easy. It is in consequence of these comparatively recent applications of power that the Western States have developed production to a degree which would have been impossible in previous centuries. And it is in this line, the adoption of efficient motors, that agriculture will make still more wonderful progress. Only a beginning has yet been made in the application of power to agricultural work. Agriculture is inferior to manufacture, as its prime motor, animal power, is inferior to steam power. Western agriculture requires to take a step in advance, by substituting a more powerful motor for animal power. In agriculture proper, that is, in the growing of crops, invention has accomplished but little, and that is simply in the line of substituting animal power for manual labor. At the dawn of civilization, the barbarian farmer, with his rude plow drawn by bullocks, was not so greatly inferior in accomplishment to the Western farmer with his steel plow drawn by his overworked team. In the saving of crops, after they are produced, invention has done much. We harvest 20 acres of grain per day, we thresh 20 acres per day, we carry the grain 500 miles per day to market, but by the inefficiency of its motive power the plow is limited to two acres per day. Our reapers can reap more grain, our threshers can thresh more grain, our locomotives can pull longer trains, loaded with grain, but Western agriculture is held back by the inability of animal motors to plow faster and deeper and more cheaply. It is thwarted, in a measure, by plowing done out of season, done badly, and expensively. It is limited by the amount of work which can be got out of its tired motors.

There is cruelty to animals in our Western system of agriculture. With immense work and with feeble motors the result is the destruction of the motor. With limitless power in the earth, in the air, and in the sea, we drive helpless animal motors to death. Invention has placed the burden of agriculture upon them, and they are broken down when they should be in their prime.

It appears useless to exploit steam as a motor in agriculture. The steam engine has apparently been improved nearly to its limit. The difficulties in the way of applying it to agricultural work appear to be inherent and unavoidable. On foundation or on rails it is indeed a giant; when it touches earth it is powerless.

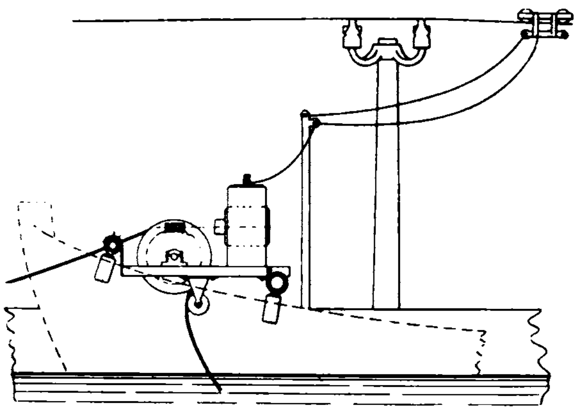
It appears otherwise with the electric motor. It is simple, its few wearing parts can be protected from dust, it has ample power, it has not excessive weight, it carries neither fuel nor water.

In its simplest expression, the problem is the dragging a plow, a harrow, a seeding machine, a reaper or a wagon loaded with grain, half a mile, in a straight line, reversing, and dragging it back again, simply passing to and fro, until the entire field is worked.

In the many applications of electrical work, this, the most important and the extensive application of all appears to have been entirely overlooked. This shall lighten human labor, shall relieve suffering animals, shall increase production, decrease cost and cheapen food. We will wonder, a few years hence, how men produced food for all mankind by use of the whip. And we will point to the old-fashioned plowman, urging his tired and slow-moving team, as we point to the old-fashioned man who swings the old-fashioned cradle in grain. There is urgent demand in agriculture for electrical engineering.

TOWING CANAL BOATS BY ELECTRICITY.

The fact that a vast amount of freight is still transported by means of canal boats, and that these boats are



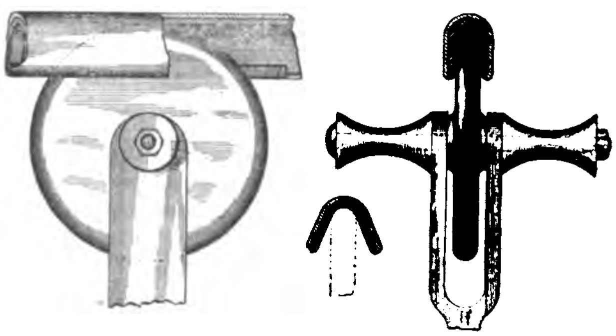
Towing Canal Boats by Electricity.

still drawn by horses or mules, as in the days of Rameses or Tiglathpileser, lends especial interest to a recent invention of a German engineer, Mr. Otto Büsser which is well illustrated in the accompanying drawing. As will be seen, a stationary cable is laid at the bottom of the canal and is grasped by a set of sheaves on the deck of the boat, actuated by an electric motor. The current is supplied to the latter by means of trolley wires strung along the bank, the trolley making contact on the upper side of the wires and being towed along by the flexible conductors.

A peculiar feature of this arrangement is that the whole installation is portable, and is readily fixed to the gunwales of the boat as it enters the canal, and removed at the further end. This is accomplished by fastening the motor upon a bed-plate resting upon adjustable cross-rods at whose ends are pivoted vertically clamps which fit over the gunwales and are firmly held by set-screws.

THE SARGENT INSULATED TROLLEY WIRE.

In order to obviate the necessity of guard wires in overhead electric railway construction, and to remove, at the



Figs. 1 and 2.—Sargent's Insulated Trolley Wire.

the same time, a serious source of trouble in the management of such roads, Mr. Charles E. Sargent, of Chicago, has devised the novel form of trolley wire shown in the accompanying illustrations.

As will be seen, the conductor is ∩-shaped in section, and has its upper and outer side covered with insulation, the trolley wheel being without flanges, and traveling in the uninsulated groove formed by the inside of the ∩.

The two spools of insulating material seen on opposite sides of the wheel, Fig. 2, are for the purpose of striking against the lower surface of the wire and limiting the upward movement of the free end of the trolley-arm when the trolley-wheel misses the wire.

This form of wire, has of course, considerably more rigidity than the ordinary cylindrical wire in use now, but this, it is claimed, is not sufficient to prevent its being coiled readily on rollers for transportion.

THE MOORE TROLLEY AND AUTOMATIC DEVICE FOR CONDUIT RAILWAY WORK.

BY

D. McFarlan Moore

The partial success of a number of conduit electric railways in Europe has led many to believe that the solution of the electric railway problem lies in some form of

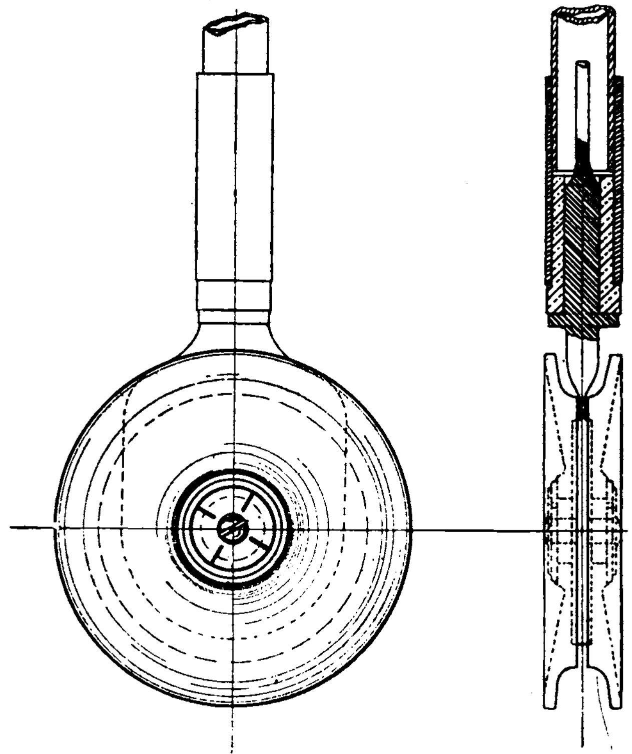


Fig. 1.—Moore's Conduit Trolley.

the conduit system, and particularly as the use of the overhead wire is absolutely prohibited in many large cities, such as New York and Chicago. It seems also to be well recognized that in the ideal conduit system of electric railways the trolley or contact device should be permanently attached to the motor truck, and not be detachable from it.

This result can be successfully accomplished by the use of the trolley illustrated in the engraving, Fig. 1. It is designed to be lifted from the conduit at any point on the line, and as such is the narrowest trolley that can possibly be constructed, being a trolley wheel without a yoke. As each half of the trolley has its own bearing, it may be termed a split trolley wheel. Each half of the wheel runs independently of the other half; this is advantageous in rounding curves, as it makes the contact more perfect. The principle involved in this trolley is by no means confined to railway work, as it can be applied in many instances for moving contacts in general, and especially when large working conductors are used. Its construction is simple and cheap, and its various parts can easily be replaced. Its design is such that the slot in the conduit need be only three-quarters of an inch, or less, in width.

The application of electric power for operating tram-cars, transfer tables, etc., in machine shops, foundries, mills and manufacturing establishments of all kinds is rapidly becoming an important part of electrical engineering railway work. In every case it is desirable, and in many cases absolutely necessary, that the trolley wire or working conductor should be beneath the ground or floor of the shop. This is necessitated in many instances by the use of traveling cranes, which preclude the possibility of employing an overhead trolley wire. In many large manufacturing establishments it is desirable also to have the tramway run not only inside of the various buildings, but also from building to building, and if the buildings are widely separated it may be required to connect them with the overhead system.

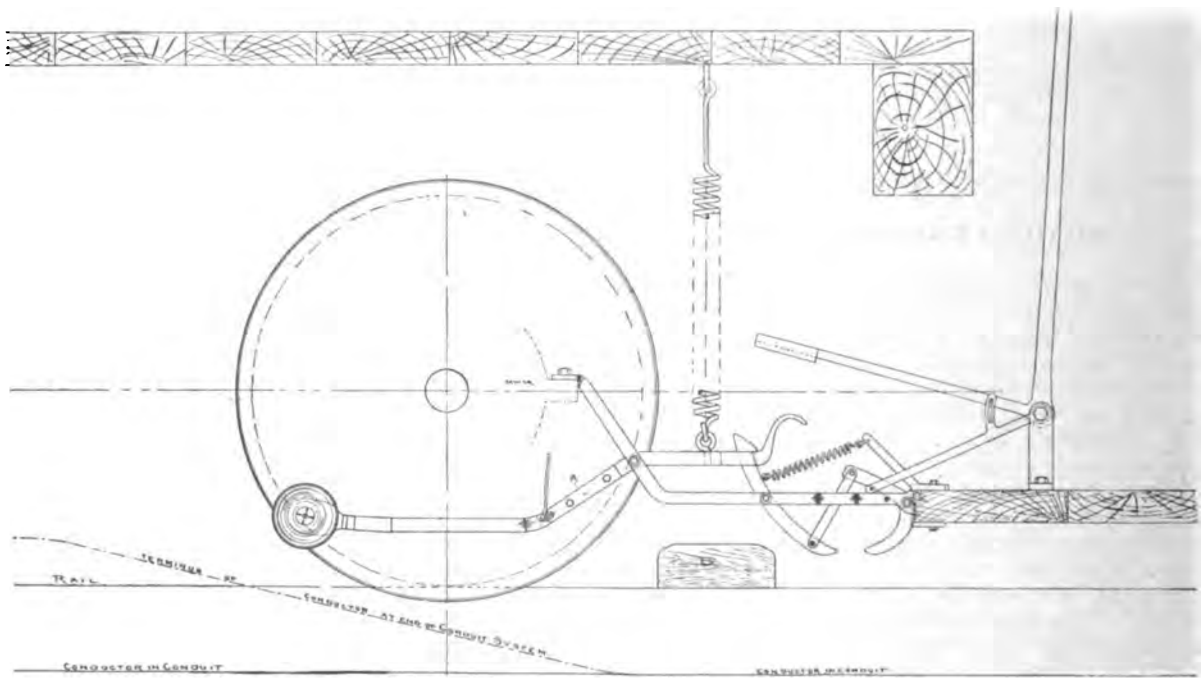

FIG. 2.—THE MOORE AUTOMATIC DEVICE FOR RAILWAY CONDUITS.

Fig. 2 shows an automatic arrangement for raising and lowering the trolley when necessary to change from the underground to the overhead system, and vice versa. As will be readily seen the levers are operated automatically by means of the block, B, placed in the centre of the track. The trolley is raised from the conduit by simply placing the conduit conductor on an incline, the inclined portion of course being "dead." The cheapest and best forms of conductors for conduit work when using this trolley are iron or copper bars or angle iron. The lever, C, is provided only as a positive arrangement in case the automatic device should not act, owing to the removal of a block or for some other like reason. In case a return conductor is required the main trolley lever can be forked at the point marked A, so that two trolleys can run in two conduit slots separated by about six inches.

L'Industrie Electrique, a new Parsian electrical journal, will be published from the beginning the year under the able editorship of M. E. Hospitalier.

HOW TO INVENT THE SUCCESSFUL COMPETING TELEPHONE.

BY

Edward P. Thompson

A POINT of valuable knowledge, among other matters, with which the would-be inventor of the successful competing telephone should be equipped, is the gist of each class of telephone, which has been invented thus far. It is almost safe to say that the successful competing transmitter will consist of some slight improvement over some existing improvement or original invention. The most powerful example, which presents itself, is the very transmitter which suggests the present problem. Although the result is far inferior, the Reis transmitter of musical sounds is exactly like the Berliner transmitter, except to those who know the gist of both. In each case two terminals of an electric circuit are normally in contact. However, when the device is in operation, the contacts separate in the one, and remain together in the other with variable pressure. It is found that all the telephones at present known are divisible into a comparatively few classes, and that a short sentence will give the pith of each. They are treated, not in any chronological order, but in the order in which they naturally appear in the mind. Even if read, not for the purpose of assisting in inventing, the classified knowledge may be useful in other ways.

The State of the Art.—In one or more transmitters at present known, electrical undulations, corresponding to air vibrations, are produced by causing the mechanical energy of the condensations and rarefactions of the air.

To vibrate a diaphragm of iron before the poles of a magnet.

To vibrate the diaphragm of iron before the poles of a magnet in which the core is partly or wholly of steel.

To vibrate a steel diaphragm before the poles of a magnet with or without a core.

To vibrate a magnet before the poles of a second magnet.

To vibrate an iron sheet *between* the poles of a magnet.

To vary the temperature of a heated conductor of very small diameter, such as a platinum wire, the condensations and rarefactions of the air causing the alternate heating and cooling of the conductor (comparatively) whereby its resistance is similarly varied.

To vary the temperature upon the face of a thermopile, the condensations and rarefactions of the air causing an alternate heating and cooling of the thermopile, whereby electrical undulations are produced (theoretical).

To vary the length of a continual spark between the two electrodes, the electromotive force of the current being sufficient to maintain the spark (theoretical).

To vary the linear resistance of a ligature, such as a carbon filament, the air vibrations causing a conducting liquid to rise and fall alternately along a part of the length of the wire.

Same as above, the air vibrations causing a second conductor to intermittently touch or short circuit variable portions of the first conductor.

To vary the amount of light falling upon a conductor, such as selenium, which is sensitive to light in such a manner, that for variable light, its resistance varies.

Same, except that a substance sensitive to heat rays is employed.

To vibrate a card board, supporting iron filings, before the poles of a magnet.

To circularly vibrate the armature of a minute dynamo, before the poles of the field magnet.

To vary the pressure existing between the two carbon or metallic or conducting liquid electrodes normally and abnormally in contact with each other.

Same, the number of the electrodes of one or both polarities, being increased.

Same, one of the electrodes, when metallic or carbon, being pulverized.

Same, in which one of the electrodes is a valve, loosely located upon the end of a tube which is the other electrode.

To vary the pressure upon the plates of a voltaic pile, an alternate increase and decrease of distance between the plates causing variable amounts of current generated.

To vary the shape of a globule of mercury balanced in a conducting liquid, the vibrations of the better conductor, mercury, varying the resistance of the circuit.

To vary the static charge of condenser plates, whereby the electric current of the line becomes varied as to its electromotive force.

Conditions of the Problem.—It is needless to mention that these are very severe. The transmitter must possess novelty over all those at present known, and further, it must be equal and if possible, superior, to the carbon transmitter. It should be applicable to long lines, and in such a manner that the receiver will give forth the words clearly and loud enough to be heard intelligently. It should serve the test of transmitting the ticks of a watch and whispering, when two or three feet away from itself not simply over a small distance, but for a mile or so. For a short distances it should transmit the sound of heavy breathing. It is assumed that a good Bell receiver is used, such as that on which the patent expires in March, 1893. One of the difficulties, in order to be as profitable, commercially as the carbon transmitter, is the cost of construction. The latter consists substantially of two pieces of compressed carbon powder, a diaphragm of tin-type metal, and the frame, the carbons being supported in a relatively yielding position, and means of adjustment being provided. It is one of the cheapest electrical devices manufacturable.

ELECTRIC LOCOMOTIVES IN FRANCE.

The French Northern Company will shortly make some trials with an electric locomotive between Paris and St. Denis, and afterwards, if these prove satisfactory, between Paris and Calais. On falling gradients the *vis viva* of the train will be utilized for recharging the accumulators.

IS IT NECESSARY TO BOND ELECTRIC RAILWAY TRACKS?

In an article on the Gibbon duplex rail that was published in The Electrical Engineer of Oct. 29, 1890, the suggestion was made editorially that with such a continuous rail it should no longer be necessary to "bond" electric railway tracks. Rail bonds are at present a necessary evil, and while many improvements have been made in them, very few electric railway managers would care to go on using them if they could be dispensed with. Not only do they often introduce seriously wasteful resistance, but very frequently they disappear altogether, leaving merely a stain in the earth to signify that they once were there, very much as Dickens represented one of his characters to have vanished, leaving only a grease spot behind. It therefore occurred to us that the Gibbon rail, altogether aside from its qualities as a rail, might offer an effective remedy for the "bonding" trouble. Learning recently that a section of this track had been furnished to the Brooklyn street railway companies, we obtained permission for a test of it by Mr. Townsend Wolcott, who has now submitted the following report to us under date of December 24:

I have examined, according to your request, the section of track furnished to the Atlantic Avenue Railway Co., Atlantic and Third Avenues, Brooklyn, by the Duplex Street Railway Track Company.

The track is so keyed together for the purpose of securing mechanical continuity and strength, that electrical continuity is at the same time secured, thus rendering the track a good electrical return for trolley or conduit roads, without any other bonding than that which is a part of the system and which does not involve extra expense as do the ordinary methods of bonding.

I made a bridge test of the above-mentioned section and found the resistance too small to give an indication on the bridge, although the latter showed .001 ohm very plainly. The test current had to pass through two keys and around one complete joint.

I think this track when properly laid, will be found practically equal to a continuous rail both mechanically and electrically.

Townsend Wolcott.

This seems to confirm our opinion very thoroughly, and we print his report as one of interest to our readers in the railway field. We have now suggested to Mr. Wolcott the desirability of a direct comparison, electrically, between this track and that of some electric road with "bonded" tracks lately finished. Such a comparison has now been undertaken, and we hope soon to give the results. In the meantime, we shall be glad to hear from any of our readers on this important subject.

INFLUENCE OF STEAM ON PERMANENT MAGNETS.

The influence of steam on magnets is the subject of an interesting note in the *Schweizerische Bauzeitung* in which reference is made to the researches of Strouhal and Barus. These have shown that with long-continued heating in steam, magnets lose from 28 to 67 per cent. of their power. If, after this, the magnets are remagnetized and again exposed to the action of steam, only a very slight loss of magnetic power is found to take place. The experiments which have been made would seem to warrant the conclusion also that after such treatment a magnet is less liable to deterioration from mechanical vibration as well as heat. In one of the experiments, a short magnet was boiled in water for four hours. It was then magnetized and held in an atmosphere of steam for two hours more, after which its magnetic moment was measured. It was then subjected to 50 blows from a piece of wood, both transversely and longitudinally. Again measuring its magnetic moment, showed a loss of $\frac{1}{600}$, and on repeating the hammering with the wooden bar the loss was $\frac{1}{400}$ of the original moment. In view of all this, repeated steaming and magnetizing is recommended as a good means of securing permanent magnetism in pieces of hard steel.

ELECTRIC ICE-HARVESTING MACHINERY.

BY

F. E. Kinsman.

In 1805 Mr. Frederick Tudor, of Boston, began the exportation of ice. In 1832 the entire quantity exported was less than 5,000 tons, all of which was taken from a pond in Cambridge, Mass. In 1846 there were 65,000 tons exported; in 1856 it reached 146,000 tons, while in 1875 the shipment of ice to southern cities and ports exceeded 1,000,000 tons. To-day we are shipping large quantities to European ports in addition to an extensive Southern trade; even in view of the fact that Norway is supplying large quantities, we are able to sell ice in Great Britain, in competition with nearby countries, and this notwithstanding the fact that our method of cutting and harvesting has not been materially altered since Mr. Tudor's first effort in 1805. Many efforts had been made to improve the process of cutting and handling ice, but with the exception of the improved form of the old-fashioned ice-plow, drawn by horses. which requires two men each, one to lead the horse, and the other to guide the plow—and the method of hoisting the ice into the storage building by steam power, practically nothing had been accomplished, until the year 1890, when the writer brought out his self propelling electrical ice-cutting machine, which can be made to do the work of any number of horses, and the necessary detail of laborers to manage them.

No branch of industry of any importance, has suffered such neglect, and at the same time assumed such enormous commercial importance as the ice business of the United States. Its importance to our every-day life, was clearly brought out by the great outcry that was raised by the press during the winter of 1889-1890, when it was found that there was likely to be an ice famine, and its domestic and sanitary value was even more clearly demonstrated by the comparatively high prices which the public were compelled to pay for that which was consumed, most of which was brought from the extreme northern sections of the United States. The difficulties of securing the crop from such points, and the high price consequent thereon, greatly stimulated the introduction of artificial ice-making apparatus. This was done to such an extent that, naturally, ice men began to realize the important character of their new competitor and to look about them for means of reducing the cost of harvesting and handling their product. They found that the principal points to be considered were, first, the matter of reducing first cost; second, the securing of locations where an unfailing supply could be had near the market. The first item, that of first cost is largely made up of the price paid for labor and teams. Owing to the knowledge on the part of the workmen of the fact that frequently but few days were vouchsafed the companies in which to secure their crop, they could practically place their own figures upon their services and for the use of their teams, where such were required.

Another item of grave importance, in the aggregate, was the loss of horses by drowning (one company is reported to have lost 27 in the winter of 1891 from this cause); another source of loss is from influenza contracted by exposure on the ice fields. The drawing of an ice plow being an absolutely dead weight, requires a constant drag, and those acquainted with the business well know how quickly a horse begins to perspire, even in the coldest weather. It only requires a stop of a few minutes for rest, or any other cause, to give them a severe chill and cold, which is likely to develop into lung fever or pulmonary diseases, which is said to be one of the largest indirect items of cost in the harvesting of natural ice.

Another important item, is the trimming of irregularly shaped cakes of ice, when they reach the foot of the hoisting apparatus. This irregularity is due to the fact that the plow now in use cuts but from three to four inches the first trip, and from two to three inches the second trip, and approximately two inches the third trip, a total of from six to nine inches, leaving, with 18 inch ice, from one-half to two-thirds to be split, and any irregularity in splitting has to be corrected before it is passed into the storage house. It has also been found that the old method of packing ice with layers of straw or sawdust between each tier, was troublesome and expensive. They therefore adopted the method of corrugating the cakes of ice, as they passed into the ice-house by a special attachment connected with the hoisting apparatus. This permitted the putting of the corrugated faces together, which answered the same purpose as straw or sawdust, namely, prevented the cakes from freezing together in a solid mass. This corrugating and trimming of the cakes of ice left around large houses a troublesome accumulation of refuse ice, the removal of which was not an insignificant item of cost. These matters are however to a certain extent governed by circumstances within the control of the companies themselves.

The second point, however, that of an unfailing supply, is one over which the companies have had no control in the past, and one in which the writer proposes to come to their assistance, by the use of apparatus with which they will in a measure be able to overcome the unfavorable condition of the season, and to harvest ice that is thinner than it is possible to harvest with horses.

It is well known that the temperature of the water under the ice is higher by from six to eight degrees than the ice. As it is impractical to remove the snows which fall upon the ice before it is thick enough to bear a horse, the thickness of the ice is somewhat reduced by having a comparatively warm body of water beneath it and a protecting blanket of snow upon it, which would not be the case if the snow could be economically removed as fast as it falls, thus exposing it to the lowest possible temperature.

This can be accomplished by the electrical self-propelling snow-removing apparatus, devised by the writer, with but comparatively little trouble and expense. The planing and cleaning machine is equipped with a scooping chamber, which can be dumped when once filled or upon approaching the shore limit of the ice field, while the planers can be raised or lowered sufficiently to remove the unevenness of the upper surface caused by rough and windy weather, when the ice first begins to make. These planers are detatchable at will; they are furnished either rotary on a plane with the ice, or revolving before the saws. The cutter or groover is so constructed as to admit of the easy adjustment of the knives for cutting between the thickness of ice, where, if it is desired, the shafts upon which the knives are mounted in gangs are also supplied with corrugators which corrugate the upper surface of the ice as it is cut. This corrugating upon the field is a decided improvement over doing the work at the ice-house, as all the refuse ice made or produced by cutting and corrugating is floated off on the water when the cakes are split from the main body, and become submerged in the water. Here it is well to mention the fact that, on account of the greater depth to which the main grooves are cut which divide the cakes, a much more even side is obtained, as the shorter the splitting space, the less divergence from a true line.

The electric ice-cutting machine designed by the writer is shown in side and end elevation respectively, in the accompanying engravings, Figs. 1 and 2. The illustrations are so clear as hardly to require a detailed explanaiion. The cutters are driven direct by the armature which has an elongated shaft upon which the cutters are mounted, thus obviating the necessity of using belting or gearing. The depth of the groove to be cut can be regulated by a hand-wheel under the control of the attendant, the cutters being raised by a worm-and-tooth segment. The same shaft that carries the cutters is provide with two worms which, acting through shafts and bevel gears, propel the wheels upon which the machine is mounted. By this means an exact ratio is obtained between the travel of the machine and the speed of the cutters. The direction of the machine is controlled by the hand-wheel and sprocket chain passing around the pivot of the rear wheel; but the machine may also be guided by a special "guide" running in the groove last cut.

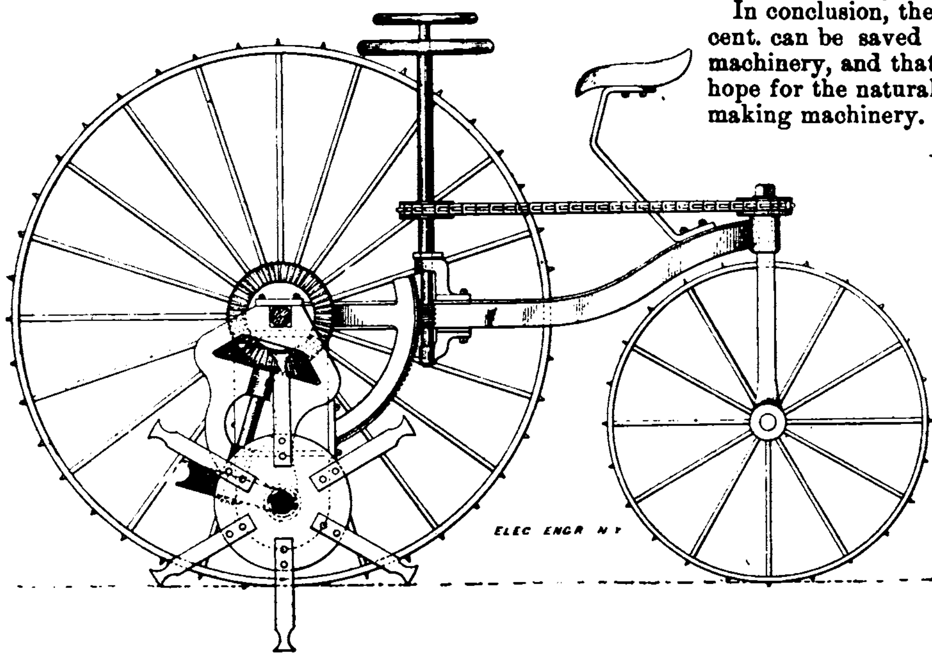

FIG. 1.—KINSMAN ELECTRIC ICE HARVESTER.

With this cutter it is possible to groove ordinary ice almost through to the water, as the machine produces no shock or jar upon the ice, and its width and length is sufficient to give it the advantage of a broad bearing surface, while the weight of a No. 2 machine does not exceed that of a fair-sized horse; a No. 4 machine, carrying a gang of four cutters is somewhat heavier but not enough as to prevent cutting very thin ice with it.

The great change secured by the use of electricity in ice cutting is that the apparatus weighs comparatively little, and that the current can be generated at a merely nominal cost by the same power that lifts the ice into the house; while the same engineer who now attends to the lifting apparatus also cares for the generator. It will therefore be seen that the entire cost of grooving ice on the field is reduced to the wages of a man who rides the machine and a few extra pounds of coal used in the furnace, and that the entire force can be concentrated upon the housing of the ice, thus admitting of a full crop, which would otherwise be prevented by a sudden change of weather. As stated, the total weight of a No. 2 machine, with a capacity equal to from fifteen to twenty horses does not exceed that of a fair-sized horse, but, unlike the horse, requires absolutely no attention when not in use. It does not take cold when standing still, nor is it a total loss if it accidentally goes overboard.

As to the method of transmitting the current to the motor on the machine, two methods are available. Use can be made either of a trolley wire supported on sliding stands, or the cutter can be supplied with a reel. In either case no difficulty would be experienced.

In conclusion, the writer believes that from 30 to 50 per cent. can be saved by the use of electric ice-harvesting machinery, and that this method stands to-day as the only hope for the natural ice men against improved modern ice-making machinery.

LENGTH OF ELECTRIC WAVES.

M. POINCARÉ has announced to the French Académie des Sciences that M. Blondlot has measured by a new method the length of waves of electric oscillations, and that he has found that this length is proportional to the square root of the capacity, and to that of the self-induction, as required by Sir Wm. Thomson's formula. The mean of his experiments has given for the speed of propagation of electric waves in a metallic wire a figure not greatly different from the speed of light—a difference less than can be accounted for by errors of observation. The result is confirmatory of Maxwell's theory that light is due to alternate currents of very short periodicity.

AN ELECTRIC ROAD AT NIAGARA FALLS.

A CORPS of engineers on the Canadian side are now mapping out the line of an electric road between Chippewa and Queenston. The route through Victoria Park will be located just under the bank, along the western boundary of the reservation. It is likely that the power for this road may be obtained from the Niagara River, and a much bigger scheme is on foot for a power canal cutting across from the river and emptying down the Queenston Heights below the whirlpool.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XII. NEW YORK, DECEMBER 30, 1891. No. 191

As we do not pound on a piano with all our strength to get a sound, but select different keys, so by using those components of light which we require, we may avoid wasting the other parts of the spectrum.—Prof. J. B. de Motte.

AGRICULTURAL ELECTRICAL ENGINEERING.

WE have from time to time printed notes on experiments which had been made looking to the influence of electricity on the growth of plants. These experiments may be divided into two classes; first, those involving the influence of the electric light directly upon vegetation; and, secondly, those in which the current was made to act directly upon the seed of the plant until its maturity. The experiments of Siemens some years ago and the more recent ones carried on in the Agricultural Department of Cornell University ought to show in some degree what can be expected by the first method, while the recent investigations by Specnew, in Russia, and others, give a fair indication of the value of the second method But electricity is capable of still further applications in agriculture in a direction which promises immediate results, and which cannot fail to secure for it the attention of agriculturists. The field still open to the electrical engineer is pointed out very forcibly by Mr. A. A. Denton, assistant in charge of the U. S. Department of Agriculture at Sterling, Kan., and consists in nothing less than the application of electric power to plowing. Mr. Denton points out that while we apply steam to the harvesting, threshing and transportation of grain, we are practically still pursuing the methods of thousands of years ago in the manipulation of the earth preparatory to the reception of the seed. As he puts it, while we can harvest and thresh 20 acres of grain per day, we can, by the method at present in vogue, in which animal power alone is employed, only plow up two acres a day. The problem to be solved, then, consists merely in providing a motor which shall be able to drag whatever appliance is necessary either for the tillage of the soil and the harvesting of the crop, in a straight line half a mile, reversing and dragging it back again until the entire field is worked. Mr. Denton considers the steam engine as unsuitable for this purpose and sees in the electric motor the ideal machine for this purpose. While the suggestion of the application of electric motors to the tilling of the soil was actually put in practice some 10 years ago in France, at Sermaize, it seems to have gone no further than the experimental stage. Mr. Denton's suggestion is, therefore, an eminently timely one and appears to involve no serious difficulties in its application. Nearly all the Western States have coal measures from which fuel can be drawn, so that the substitution of electric for animal power can be carried out with a large saving in time and cost. Many readers of THE ELECTRICAL ENGINEER will remember, too, that Mr. W. Forman Collins, of the staff of this paper, had an excellent article some months ago on the relation of electricity to the irrigation of the Western plains.

THE ARGUMENTS ON THE "HYDROCARBON" PATENTS.

THE argument of Mr. Christy, in behalf of the complainant in the recent trial of the suit of the United States Electric Lighting Co. against the Edison Lamp Co., involving the question of the validity of Weston's patent for the hydrocarbon treatment of incandescent lamp filaments, of which we give a full synopsis in another column, brings to a close the proceedings in this interesting and important case. In pursuance of a policy which has been consistently adhered to by the conductors of THE ELECTRICAL ENGINEER, that of placing upon record in its columns every matter of permanent interest affecting the leading electrical industries, no trouble or expense has been spared to present a full and adequate report of the arguments of counsel in each of the three great legal controversies, the final results of which must practically determine the ownership or control for some years to come, of the incandescent lamp manufacture of the United States. The first of these legal contests was the McKeesport case, so called, involving the Sawyer-Man patent for a fibrous carbon, and decided by Justice Bradley adversely to the patent; the second was the New York case, involving the Edison patent for the carbon filament, in which the patent was sustained by Justice Wallace; and the third is the New Jersey case recently tried in Philadelphia and now awaiting the decision of Justice Acheson, on Weston's hydrocarbon patent. Not only has no other journal attempted to give a report of the proceedings in these cases, but it may not be out of place to add that THE ELECTRICAL ENGINEER has received the highest commendation from eminent counsel engaged on both sides for the completeness, accuracy and impartiality of its reports of these trials. It is to the summary of the testimony of witnesses as given in the arguments of counsel, and to the opinions of the learned jurists with whom the ultimate decision of these controversies rests, that the future historian of the art of electric lighting must look for the greater part of his material, and this consideration must be our apology, if any be needed, for having devoted so large a space to matters which may seem to some of our readers of scarcely sufficient immediate interest to justify it.

ELECTRIC TRACTION FOR BROOKLYN.

A LONG fight at last is drawing to its close, and the great city of Brooklyn falls in line with the others that have already adopted electric traction. The common council has given permission to the Brooklyn City, Coney Island and Brooklyn, Brooklyn City and Newtown, and the Atlantic Avenue lines to change their motive power from horses to the overhead trolley system, and it is understood that Mayor Chapin will promptly approve the ordinance; while there is not the slightest reason to expect that the State Railroad Commissioners will change from their favorable attitude toward electric traction. This action by the Brooklyn city council means that about $12,000,000 will be spent there in the next two years in making the change, the Brooklyn City road spending alone at least half that amount.

The opposition to the change has been wild and absurd as usual, with the familiar stories of plague, nuisance and sudden death, and without a single fact in support of the allegations. The *Brooklyn Eagle* in an admirable editorial on the subject congratulates the citizens on the coming addition to the means of rapid transit, and points out that in like manner, though more vigorously, other boons were fought against in the City of Churches, such as the introduction of the water supply, the horse railroads, paid firemen, elevated roads, and uniformed police. All these things though bitterly opposed have come, and now everybody rejoices in their existence. So it will be with the trolley system. We are heartily glad to see that the street railway companies have made so successful a fight for themselves and for the public they serve.

ICE HARVESTING BY ELECTRICITY.

ON the preceding page we have referred to the adoption of the electric motor in agricultural operations, and the benefits which, it is shown, could be derived thereby. The arguments followed in that case are quite applicable to another case which, also, has thus far not received the attention that its importance would seem to merit. The methods pursued in ice harvesting have undergone no change in years, the horse being still the motive power employed. The manner in which the electric motor can be applied for the purpose and the saving in the cost of harvesting ice which can be effected by its use, furnish the subject of an interesting essay by Mr. F. E. Kinsman in this issue. As he points out, it permits not only of greater economy in the harvesting of thick ice, but it even permits of harvesting ice of such a thickness that it could not be attempted with horses; and thus admits of the profitable utilization of thin ice, which is now allowed to go to waste, although in mild winters it forms the only source of natural ice supply. It is not difficult to conceive, also, that a profitable business might be developed in the operation of portable ice-harvesting plants, so that the itinerant grain-threshing machine will find its counterpart in the traveling ice-harvesting machine.

THE SUCCESSFUL COMPETING TELEPHONE.

FOR several years subsequent to the invention of the Bell telephone and its successful application, a large percentage of the applications for patents filed in the Patent Office, in the Electrical Department, consisted of telephonic devices of one form or another, not a few of these relating to new forms of transmitters. Now that the transmitter in present use appears to be endowed with prolonged life by the recent issuance of the Berliner patent, we shall probably note a large increase in the number of telephonic inventions submitted to the Patent Office. Every intelligent inventor ought to know the state of the art in which he is seeking to effect improvement, and for those who have not followed the telephonic art with a view to its improvement, a résumé of the various methods of obtaining telephonic effects in an electric circuit will at this time prove of value. The admirable résumé of Mr. E. P. Thompson, on another page, shows that not a little ingenuity has been already expended in this direction. The experience of the past would seem to indicate that the demand for any invention has always been met when sufficient inducement has been offered to inventors, and in this case certainly the inducement is as great as that ever offered to an inventor. Mr. Thompson suggests a great many ways in which the goal may be reached.

"AMERICA'S GREATEST RAILROAD."

THE series of disastrous collisions which has accompanied the efforts of the management of "America's Greatest Railroad" to operate "the fastest and most perfect through train service in the world," provokes the very natural inquiry why it is, that on what is alleged to be "the only four-track railroad in the world," the passenger tracks should be incessantly blockaded by broken-down freight trains, and why in such case resort must necessarily be had to the archaic and futile expedient of sending a man back with a flag or lantern, who may go or may not, as may happen, and who may be seen or may not, as may happen, by the engineer of the approaching "flyer." The truth is, that two of the tracks of the "only" being one side of the North river and the other two the other side, it is somewhat difficult to separate effectually passenger and freight traffic; while the management seem to be as yet in a state of the most deplorable ignorance in respect to the utility, for signaling purposes, of an agent popularly known as electricity. We would by all means advise these ambitious people to take a course of elementary lessons in the modern art of conducting transportation, which might be done in the kindergarten department of the railway university at Altoona, or some other institution of the kind which is not hopelessly wedded to the outgrown traditions of the days of small things.

ISOLATED ELECTRIC LIGHTING BY LOW-TENSION ALTERNATING CURRENTS.

BY

It may seem curious to old-time electricians to hear any one seriously propose to revert to old and discarded methods of electric lighting and under a new name to flaunt them again before the public as something quite new and improved, yet this is precisely what is suggested in this paper. The development of the converter has totally changed the original "alternate current dynamo-electric machine" into the high-tension "alternator" of to-day which seems capable of anything—lighting, heating, welding, metal working, tempering, soldering or of twirling armatures hundreds of miles away. So, too, the development of the choking coil may lead us to revert to the original machine in all its simplicity, and to evolve, thereby, a more perfect method of isolated lighting than has ever existed before.

When the electric incandescent lamp was first invented it was said that the life it had was much increased by the use of the alternating current. I think this was conclusively proved at the time with such lamps as we had in 1880, though it does not apply so forcibly now, with the greatly improved vacuum and the hard and durable filaments such as are now made. Still the lamps *do* wear out slowly even now, the direct current attacking the ends of the horseshoe and the alternating wearing away the filament more evenly, but still surely, until it finally succumbs at the bend.

Electricians will remember, too, the alternating dynamo of 1880 of low tension and large quantity, and the installation of lamps in parallel or two or three in series. Before the days of compound winding for direct-current machines this system had its advantages in the steadiness of the electromotive force curve for all loads. All this is history now; we had no E. M. F. curves in those days. But this style of dynamo is gone. It was considered more expensive to construct than the newly discovered compound-wound, direct-current dynamo; it required too, a separate exciter and there was no advantage to compensate for the extra cost that such a machine entails. So it fell into disuse for several years until the converter was developed; then it assumed a new garb and new sphere of usefulness.

I propose to use again this style of machine connected, as of old, directly to the mains of the building to be lighted. The difficulties attending the installation of an alternating machine have been now overcome, and the dynamo of this pattern is now infinitely simple and little liable to derangement. Moreover, the commutator of the direct-current machine is generally in a neglected condition in isolated plants, and it soon wears out because the average attendant does not acquire the knack of keeping it in condition. In this new system the lamps are placed in parallel across the mains, and the Ries regulating socket is used. With this arrangement each lamp can be turned high or low just like gas, and the whole system then presents the appearance of being unique. The system is especially useful for the lighting of our large hotels which can now be fitted up from cellar to garret bedrooms, and all with absolute safety.

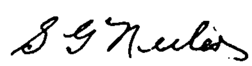
At present there is no electric light system that lends itself completely to this work. In the cities, gas is used in the bedrooms, and in the country, candles to help out the electric light plant downstairs. I have heard it stated by people ignorant of electricity that the electric light will not ascend above the first story. I am inclined to think the statement is correct of the several systems with which I am acquainted.

Extended experience with the Ries regulating socket has brought out very clearly the fact that there is great economy in systematically turning down the incandescent lamp when all its light is not required, although I am perfectly aware that theory conclusively proves the opposite to be true. There is economy in the life of the lamps themselves, and economy of power also; the lamp will last thousands of hours turned down this way, and still work out its 500 hours of good efficiency when turned on full. And then the current; the energy required to light up one corridor in a hotel would light up three or four well enough if the lamps were controllable and were adjusted to the requirements of the guests. If the light be wanted it is there; it indicates its own location and invites one to turn it on.

It is therefore contended that the low-tension alternator with the Ries regulating socket and lamps as described, introduce a combination which is an advance upon the usual practice of installing isolated plants, and that it will be found both on the score of economy and adaptability, greatly superior to any direct-current non-controllable system. It is, moreover, the only plan yet suggested for isolated lighting which is completely adapted to all the varied requirements of artificial illumination.

REACTIVE COILS IN PRACTICAL WORK.

BY



In The Electrical Engineer of Dec. 9, under the title of "Reactive Coils," Mr. Otis K. Stuart explains the principle underlying the action of the coils, by giving a very clear explanation of what takes place in a transformer, but does not take up the reactive coil as it is used commercially. In reading over Mr. Stuart's article it struck me that it would not be amiss to go a step further and explain just how the current flowing in a circuit is controlled by the reactive coil and it is with that idea in view that I have written the following, hoping the same might be of some benefit to those not already familiar with the subject.

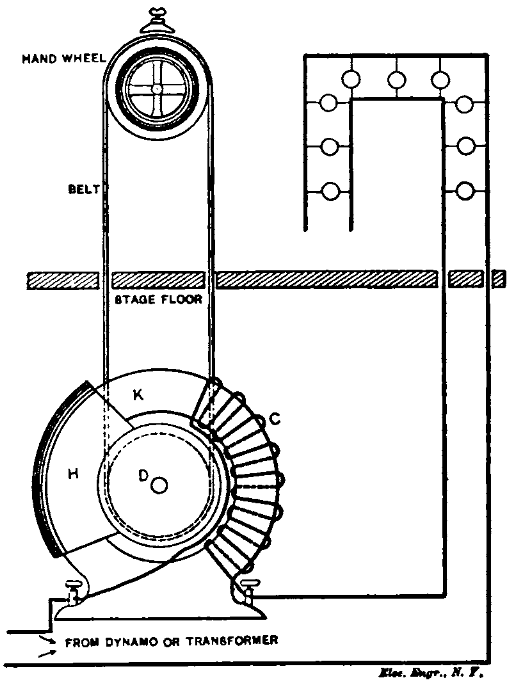
Mr. Stuart says: "A reactive coil placed directly in the circuit of an alternating system, therefore, can be made to control the amount of current going over the system. * * * Probably the most interesting application has recently been made use of by Mr. Elias E. Ries." He then gives a description of the socket, and says, "A very small reactive coil is so connected to a series of contacts that, by means of a movable arm * * * a relatively small or large amount of current may be admitted to the filament."

I think that one not familiar with the action of a reactive coil would be led to the conclusion that the only method of varying the strength of current would be by making a number of connections or "loops" into the coil and cutting out, or in, more turns which, of course, would accomplish the object, as exemplified in the Ries socket. But I think by far the most beautiful manner is that designed by Prof. Elihu Thomson and used by the Thomson-Houston Electric Company in their apparatus.

To explain clearly it will be necessary to understand that by placing a closed coil around an alternating magnetic field a current is induced in the coil forming the closed circuit, exactly similar to a transformer whose secondary is short-circuited. Now we may consider the action taking place in a Thomson-Houston reactive coil as illustrated in the accompanying diagram. This consists, primarily of a laminated iron core in the form of a closed ring K, about one part of which is wound a comparatively few turns of fine insulated wire C, covering about one-third of the circumference. Inside of this ring is a laminated iron drum D, fastened to which, and passing around the outer ring, is a copper hood H of large area, forming a closed coil about the ring and which fits closely, leaving a very small air space between it and the ring. This hood is fastened rigidly to the inner core and is provided with a handle or a pulley and belt so that it can be moved to occupy any position relatively to the winding on the ring.

When this hood is furthest away from the winding, the action is such as to increase the magnetizing effect of the coils by closing the magnetic circuit through the drum and hence to increase the number of lines flowing in the iron ring, so that the self-induction of the coil is very great and enough to nearly overcome the impressed electromotive force, thereby reducing the current flowing through the lamps.

By moving the hood so that it covers the winding, the current flowing in the hood would tend to counteract the magnetizing effect of the coils and by so doing lessen the self-induction of the same. When so placed, the relation



THE THOMSON REACTIVE COIL.

between the hood and the coils is the same as would exist in a transformer whose secondary was short-circuited and hence the coil offers but little resistance to the passage of the current. In any intermediate position of the hood the effect would be to increase, or decrease, the self-induction of the coil as the hood was moved further from, or nearer to, the winding.

The current used in the lamps is nearly in direct proportion to the brilliancy of the light; such being the case it is seen that in these reactive coils there is comparatively little loss of energy. The arrangement is such that when the hood completely envelops the winding, the coil is short-circuited, the hood completing the circuit across the terminals, and by so doing avoiding the loss due to the resistance of the coil and allowing the lamps to take their full amount of current. In the Ries socket the object is accomplished by cutting out sections of the winding and thereby reducing the self-induction in the wire and allowing a correspondingly greater current to flow.

The above, together with Mr. Stuart's article, will, I think, help to make the action of the reactive coil clear to those not already acquainted with the same. The illustration shows the arrangement employed for regulating the lights in theatres, the reactive coil being operated by a pulley and belt on the stage floor.

NOTE ON GALVANIZED IRON TELEGRAPH WIRE.

BY

Frederic A. C. Perrine

IN the London *Electrician* for December 28, 1888, there was printed an article giving the results of tests, and the requirements of galvanized iron telegraph wire as used by the Postal Telegraph Department of Great Britain. In this article it is stated that two qualities of wire are used, one known as "high-resistance" wire and the other as "low-resistance" wire, the first giving a resistance at 60 degrees F. of 12.7 ohms per mile for a wire of the standard gauge, 171 mils, while the low resistance wire is either of "special blend" iron, 11.3 ohms per mile, or "charcoal" iron, having a resistance under the same conditions of 11.2 ohms per mile. This low-resistance wire is used for circuits exceeding 200 miles and the high-resistance for shorter lines. A tabulation of the qualities of these three grades of wire is also given, together with a mile-ohm comparison with pure iron.

According to this, the breaking strength of the "blend" iron is 3.2 times the weight per mile, of the "charcoal" 2.87 times the weight per mile, and the "high-resistance" 3.5 times the weight per mile; the two "low-resistance" wires give from 16 to 17 per cent. elongation in breaking, and the "high-resistance" 17 to 18 per cent. For a wire from 209 mils in diameter to one of 121 mils in diameter the number of twists in six inches varies in the "blend" iron from 17 to 30, and in the "high-resistance" from 22 to 38. The weight per mile-ohm of pure iron is given as 4,368.94 lbs., of the "blend" iron as 4,520, of the "charcoal as 4,480, and of the "high-resistance" as 5,080.

These are very interesting results, and in some respects remarkable, but the writer has not stated whether they are maximum or minimum figures, or whether they are averages of actual tests; neither does he seem to take into account the alteration in the mile-ohm of pure iron due to galvanizing it, since he says: "The relative resistances of pure copper and Swedish charcoal iron, similar to that used for the best line wire, are as 1 : 6.034; or the resistance of commercial iron is 6.034 times that of pure copper, not 6.558 times, as is usually given in text books. From this it appears that iron wire may now be obtained having a conductivity of 98.44 per cent. of pure iron."

Still, when he gives the mile-ohm weight of the best galvanized "blend" wire it has only the conductivity of 97.51 per cent. of that of pure iron, whereas the effect of galvanizing should be to reduce rather than to increase the weight of the mile-ohm.

In this country there is but one quality of wire at present in use for telegraph service in commercial lines, where a consistent series of tests is maintained. For short local lines and railroad private wires a great deal of steel and puddled iron is employed, but in these cases the only requirement is that it should stay on the poles and conduct. But our great telegraph companies employ for their commercial lines only the quality of iron which is known to the trade as "*Ex. B. B.*," a rather generic term, which is so interpreted by the specifications of the telegraph companies as to exclude all except the best grades of Swedish and Norway irons, which are imported in rolled rods and drawn, annealed and galvanized in this country.

Of this *Ex. B. B.* galvanized iron wire, about two years ago I had averages cast up from a long series of tests made on wire manufactured for the Western Union Telegraph Company, and found that the results varied with the size of the wire to a considerable extent; but that for any one size, the various tests were fairly concordant, and show that one wire is about 4 per cent. poorer in conductivity than the figures given on the English "blend" low-resistance wire, while the figures given on the "high-resistance" wire would not fill the specifications of our telegraph companies.

The exact averages on our wire are:

Date of test.	Size, B. W. G.	Quantity tested.	Resistance per mile.	Weight per mile.	Weight per mile-ohm.	Breaking weight.	Twists in 6 inches.	Elongation, per cent.
Feb., '88, to Jan., '89..	4	85 miles	6.51	716.7	4,664	2,016	18.5	13.83
Jan., '88, to Dec., '88..	6	650 "	8.55	544.96	4,663.5	1,454	18.9	13.82
Sept., '88. to Jan., '89..	8	3,500 "	12.18	379.8	4,629.5	980.5	21.4	15.16
Sept., '87, to Nov., '89..	9	8,300 "	14.008	331.9	4,620.5	877	24.3	14.21

The gradual decrease in the weight of the mile-ohm here to be observed is partially due to the greater proportionate amount of zinc on the smaller wires, though from the decreased elongation as well as the increased tensile strength of the heavier wires there seems to be an indication of more perfect annealing in the case of the smaller wire.

These tests upon a given number of miles are obtained by inspection of the wire in lots of from 50 to 100 miles, out of which are selected at random a certain number of coils,—about 10 per cent.,—from which test pieces are cut and carefully measured. These may, therefore, be taken as fair averages of the wire as it is produced for stringing on the poles in service. In experimenting with various grades of iron before finally selecting that which has been taken as the standard, remarkable results were obtained, and irons were found of much better quality, but, unfortunately, of which the price, when brought to this country, was prohibitory.

I have before me the result of a test of three samples made September 26, 1881, of which the weight per mile-ohm was 4,259.5. One of No. 12 galvanized wire manufactured by the Palmer Wire Company, tested March 31, 1884, giving a mile-ohm weight of 4,226.25, as well as quite a large number of samples giving better results than 4,350 pounds per mile-ohm. A number of tests have also been taken at various times on the same wire, both before and after galvanizing, and in every case there is a reduction in the weight of the mile-ohm by at least 5 per cent., due to the greater conductivity of the zinc.

While the results given above would indicate that in this country our telegraph companies do not use as high a grade of iron as the British Postal Department, yet I should judge from the method in which the English figures are given that our averages are fully as high as theirs, while in neither case is the highest obtainable grade of iron used.

HEYL ACCUMULATOR.

In the accumulator recently introduced by M. G. E. Heyl, the electrodes are composed of combinations of plumbic, chromic or tungstic acids with calcium, barium or strontium. To increase the coefficient of output and capacity, the inventor uses more particularly compounds of calcium and lead for the reason that these are easily oxidizable. The combination $CaPbO_4$ corresponding to 68 per cent. of peroxide of lead, contains 4.56 per cent. of active oxygen. The other alkaline earths, or of baryta, or strontium, furnish analogous compounds applicable to the purpose. Besides the advantage resulting from the chemical nature, the compound $CaPbO_4$ would offer a further valuable property in its porosity; it might replace the diaphragm employed to separate the elements of cells. The analogous compounds of chromium and tungsten can be employed in the same manner.

ELECTROMOTIVE FORCE, WITH SPECIAL REFERENCE TO THE EXTENSION OF OHM'S LAW.—II.

BY

Maurice Oudin, M. S.

The measurements of E. M. F. have in all cases been made in air. The result cannot with certainty be considered the true contact force. What is measured is not the Volta effect of zinc and copper, but zinc, air and copper, which may be something quite different. With the object of finding out what influence atmosphere had upon E. M. F., Von Zahn placed a pair of metallic plates in a vacuum. The E. M. F. of the two elements was considerably lower than that in air. The impossibility of obtaining a perfect vacuum prevents any conclusion from this test. For the E. M. F. depends not at all on the quantity of the active material present. Though only a few molecules of oxygen remained in the vessel, the effect would not be materially changed. Clerk Maxwell suggested measuring the E. M. F. of two substances by the Peltier effect. Speaking of the Volta force in the first volume of his classical work, he says: "The greater part must be sought for not at the junction of the two metals, but at one or both surfaces which separate the metals from the air or other medium which forms the third element in the circuit." Oliver Lodge, who is at the head of what we may call the modern school of electricians, agrees with Maxwell's views as far as they go. The contact-force not being sufficient, we have seen, to account for the whole E. M. F., the question naturally arises, where is the true source? Prof. Lodge locates it at the junction of the zinc and electrolyte. He regards the air as a dielectric bath of oxygen. Metals immersed in it are attacked by the oxygen molecules If they do not succeed in combining with the metal, the effort to do so, the chemical strain, as it were, produces certain physical effects. Oxygen being an electro-negative element, attacks the metals with different degrees of intensity. Hence the difference of potential. The medium, air, may be replaced by a fluid. In the case of a gas the dielectric is in a state of strain. If an electrolyte be the medium a current flows on connecting the metals.

It is well known that the entire heat developed in any battery is exactly equal to the heat that would be obtained by burning or consuming the elements of which the battery is composed, in some chemical capable of acting upon these elements. Accordingly the energy of such a battery bears a direct relation to the chemical changes taking place. It would naturally follow that such dependency should exist between the transfer of energy in the battery and the E. M. F. developed. This relation calculated from the heat of combustion of the elements composing various batteries has been found to exist in some cases. But up to the present, whether from errors in our data or the omission of some necessary constant, this dependency has not been found to be universally true.

There seems now to be no doubt about the presence of a true contact force at the junction of two metals. It is scarcely appreciable, being, under the best conditions, less than the E. M. F. of a single voltaic cell. It is dependent, apparently, upon the unequal vibration of the molecules of the dissimilar substances. There is an impingement and a constraint of molecules having different velocities. The molecules of one metal fail to accommodate themselves to the time of vibration of the opposing molecules, and a flow is set up in the direction of greatest impact.

The so-called thermo E. M. F. discovered by Seebeck is a variety of contact force, produced when the junctions of a circuit formed of different metals are brought to different temperatures.

It has been found that for the production of a contact-force, it is not essential that the circuit should consist of different metals. A lack of homogeneity in two conductors of the same metal also gives rise to an E. M. F. when one juncture is heated.

Frictional electricity, or electricity in equilibrium, is the manifestation of contact-force. The specific resistance of substances that are good generators of static electricity is well nigh infinitely great compared with that of metals. In metallic bodies the excitation is at once propagated throughout the entire mass. In non-conductors it remains at the surface of contact, which is increased by the rubbing, and there accumulates. Consequently, while in metals the true contact-force is almost inappreciable, in non-conductors the same force may become very great.

One of the earliest known electrical phenomena was the property that certain crystalline bodies possess of acquiring opposite states of electrification at opposite ends, when subject to a variation of temperature. Tourmaline displays this property in a marked degree. It retains its charge for a considerable time, and if suspended in the presence of electrified bodies, it behaves much as a needle in a magnetic field. Certain crystals also become charged with electricity when subject to a mechanical strain or deformation. Quartz crystals, from their size and purity, show strong electrification under such conditions.

Another source of E. M. F. is the action of light on selenium, that rare element generally found associated with sulphur. The cell is usually made of two metals coated with selenium. Mr. Fritts used brass and gold plates. W. Siemens found the E. M. F. set up in diffused day-light proportional to the intensity of light, while Von Uljamn, using platinum plates thin to transparency, found it proportional to the square root of the intensity of the light. As the generation of a current requires energy, the question arises, Whence does it come? It is generally conceded not to be due to thermal action. It is either a chemical change resulting from the action of light, or a direct conversion of light waves into electrical energy. There is good ground for giving the preference to the latter explanation.

An E. M. F. is set up when a thin cross-shaped metallic strip conveying a current is placed in an intense magnetic field. If the terminals of a sensitive galvanometer and of a battery be connected to opposite arms, and the strip be placed so that its plane is at right angles to the direction of the magnetic field, the presence of a current will be indicated by a slight deflection of the galvanometer needle. This is the Hall effect.

A year ago there appeared in the technical press, an article on the generation of a magneto-optical E. M. F. It is well known that a ray of polarized light traversing a magnetic field in a direction parallel to the lines of force, will have its plane of polarization twisted an amount depending on the strength of field. Conversely, if by any means a polarized beam of light can be made to oscillate it ought to generate an alternating E. M. F. Prof. Sheldon claims to have reached such a result. It was shown however, by Prof. Brackett, of Princeton, that the E. M. F. detected could not have been due to the ascribed cause. We might expect from the reversibility of most physical phenomena that some effect would be produced. However, as a scientific authority suggests, since polarized light passing through a solution of sugar has its plane rotated it would follow that if polarized light fell on one side of a glass beaker containing water and its plane be rotated, sugar might be expected to fall out at the other.

The various sources of E. M. F. that have been described above are capable of evoking a continuous current. In such circuits the galvanic constants are related according to Ohm's law. Now there is another order of phenomena, where Ohm's law fails to apply. It was found early in the history of telegraphy, that when the key of the transmitting instrument was opened and shut many times in a minute, the effect upon the receiving magnet at the other end of the line was much diminished. The current for some reason did not attain its maximum value during the make and break of the circuit. With a given number of cells and a line of known resistance, the current in practice was less than it ought to have been by Ohm's law. Evidently the element of time, which did not enter into Ohm's law, had to be considered. It was not long before it was proved that the retardation of the full value of the current and its diminution when the circuit was rapidly made and broken was due to the electromagnetic induction of the circuit on itself, or, as it is briefly called, self-induction. To understand the modification of Ohm's law through self-induction, we must study the nature of induction and how this quality of a circuit gives rise to a counter E M. F.

The phenomena of induction were discovered by Faraday in 1831. Oersted had 11 years previous observed how a current affected an adjacent compass, causing it to deflect from its position in the magnetic meridian. This proved as a fundamental fact the existence of a magnetic field surrounding a wire conveying a current. Faraday took up the line of experimental investigation at this point, and by a series of brilliant and remarkable experiments brought out all the facts of electromagnetic induction. He found that when a wire was moved in the vicinity of a magnet, or when a wire conveying a current was moved relatively to another wire, a temporary E. M. F. was set up. He found this to vary in strength with the velocity with which the wire was moved. The same result was obtained when the conductors remained stationary and the current in one was increased or diminished. Although the phenomena of induction are many and complex, they arrange themselves under the heads of electromagnetic, self and mutual induction. The E. M. F. due to electromagnetic induction constitutes Faraday's principal discovery. Its general conditions have been stated. The name is restricted to that E. M. F. induced by the movement of a conductor near a magnet, or a wire conveying a current.

Both Henry and Faraday were early and indefatigable workers in the field of induction, and it is not so very strange that they independently discovered magnetic and self-induction. Priority of discovery of self-induction is given to Henry. He observed that when the current in a long wire was interrupted, a spark of some brightness appeared at the break, showing an increase in the strength of the original current. This is the so-called extra current. Henry explained the phenomenon, and gave it its present name. It is well worth while to notice here the insight Henry had at that early day into phenomena that only recently have assumed importance. In 1832 he discovered the oscillatory character of the lightning flash and also the discharge of Leyden jars. Years later Sir Wm. Thomson proved the same mathematically.

To properly understand induction, and more particularly self-induction, we must remember that a current traversing a wire produces a commotion in the medium surrounding it. We know that if such a wire be made to pass through a surface on which are sprinkled iron filings, the filings will arrange themselves in concentric rings around the wire. The circles thus formed show the direction in which the force of the current acts. When a current is started, the lines of force spread out on all sides like the ring waves in a pool of water from a central point of disturbance. When the current is broken, the lines of force collapse and fall back upon the wire. By the general theory of induction the springing up or dying away of magnetic lines produces an instantaneous E. M. F., always in such a direction as to oppose the change in the current. Hence self-induction prevents the current from immediately arriving at its maximum value on making the circuit, and causes it to persist a while after the break. It would appear as if a current of electricity possessed a quantity of the nature of inertia. A fly-wheel absorbs energy in passing from a condition of rest to a definite velocity, and then gives it all up again as work in some form on slowing down. To maintain its velocity uniform, if we neglect friction, no work need be done upon it. The analogy can be applied to the case of a wire carrying a current. Starting a current implies work done in the medium which is derived from the electrical energy of the current. Stopping the current restores the energy to the system. No expenditure of work is required to maintain its magnetic field when the current has assumed a steady regime. Faraday called that condition of the medium produced by a current the electro-tonic state. He lacked sufficient mathematical training to deduce the ultimate consequences of his experiments; but he recognized that induction depends on a change in the medium, and that in this operation work is involved.

Mutual induction is the third division of the general phenomena of induction. As self-induction is the flux of magnetic force produced around a circuit by any change in itself, so mutual induction is the magnetic flow set up in a circuit by any change in the current of an adjacent circuit. It is then the number of lines of force linked in two circuits when one circuit contains a varying current.

The current resulting from inductive E. M. F., or influenced by it, such as at the make or break of a circuit, or during any variable period, cannot, as we have seen, be calculated from Ohm's law. It is invariably less than it would be if it obeyed that law. The element of time has to be considered, that is, the delay in the current behind the E. M. F., and further, that any variation of the current implies work which, according to the sense of the change, is taken from, or added to, the energy of the current. The law of Ohm has to be modified to meet these cases by the introduction into the expression of a factor whose value depends on the conditions of the circuit and on the time. We apply this factor to Ohm's formula. It is then no longer a simple expression, but Ohm's law extended, or as Dr. J. A. Fleming calls it, when the factor becomes complex and troublesome "Ohm's law glorified." In circuits in which there exists a varying E. M. F., we have in place of Ohm's law, Helmholtz's well-known equation:

$$i = \frac{E}{R}\left((l - e - \frac{t}{T} \right)$$

In words this equation means that the current at any instant is equal to the current which would flow if there was no self-induction, less a quantity depending on the induction and resistance of the circuit, and also on the time from the instant when the circuit was made. A final solution of this equation when the E. M. F. varies periodically is:

$$i = \frac{E}{\sqrt{R^2 + p^2 l^2}} (\sin p\, t - \theta)$$

where p is 2π times the frequency of the current, and θ an angle, whose tangent is the ratio of $p\,L$ to R. To account for the diminution of the current in the variable state, the factor introduced into Ohm's law may be regarded as diminishing the impressed E. M. F. as in Helmholtz's expression, or as increasing the resistance in some way, as in the second equation. In practice the last form is more convenient, and we have in the denomination of the mathematical expression of Ohm's law thus modified a quantity to which the name impedance has been given, composed of the ordinary Ohmic resistance and a term inductive in character called the inductive resistance. As Helmholtz's equation shows an induction E. M. F. acts in opposition to the impressed E. M. F. As work is involved we might expect this result from conservation of energy. Such an opposing reaction is a counter E. M. F. Hence any work done in a circuit, such as electrolytic action, heating or cooling a junction, or moving a magnet, is a counter E. M. F., since it gives rise to an E. M. F. that opposes the original.

It follows that Ohm's law must be modified not only when there exists an induction E. M. F., but also when there is interposed in the circuit a counter E. M. F. due to any cause.

Whatever be the nature of the current, we find that the expression for its value, no matter how complex, retains the general features of Ohm's law. In all cases it may be resolved into two factors, one representing the value the current would have were the instantaneous conditions to continue—Ohm's law pure and simple—the other dependent upon the conditions under which the changes are taking place, and properly considered as modifying the first.

ON POLYPHASAL GENERATORS.—II.[1]

BY M. I. PUPIN, PH. D., COLUMBIA COLLEGE.

Consider now n iron ring cores of exactly the same dimensions and made of the same material. Let ρ be the reluctance of each ring. Let each of the n coils be interlinked with one of the iron rings; we shall have n homogeneous magnetic circuits, and as long as the magnetization of these rings is considerably below the saturation point we shall have

$$\frac{4\pi s c_1^1}{\rho} + \frac{4\pi s c_2^1}{\rho} + \dots\dots\dots\dots + \frac{4\pi s c^1_n}{\rho} = 0$$

That is to say, the magnetic induction in the n magnetic circuits obeys the same law as the n electric currents; we can therefore employ the method of polyphasal connection for the magnetic circuits also and we obtain what the Germans call a Verkettung der Magnetischen Ströme, which may be translated into English by a more accurate expression: Polyphasal *coupling* of magnetic circuits. A transformer constructed on this principle may be called a *coupled transformer.*

A simple consideration will show that the field rotates around the axis of the ring B synchronously with the rotation in the generator which produces the impressed E. M. forces. Consider the armature of the generator. Since the ampere turns on one side of the neutral plane are always equal and opposite in sign to the ampere turns on the other side of this plane it is evident that the magnetic field due to the ampere turns in the armature is fixed in space and perfectly symmetrical with respect to the plane of symmetry PP^1. We can therefore say that this field, though *fixed in space, rotates with respect to the armature* with the *same angular* velocity with which the armature rotates in space. The distribution of the ampere turns over the stationary ring B being at any moment the same as that over the armature ring, it follows that the magnetic field of B also rotates with respect to B synchronously with the rotation in the armature. An inspection of the diagram in Fig. 4 will show that when the rotation in the generator is reversed the rotation of the field B will also be reversed.

The strength of the rotating magnetic field will vary in strength because the strength of the two equal magneto-motive forces which are working in multiple arc will vary. The following simple consideration will show us the law of this variation. Two cases must be considered separately. First, when n is an odd number; secondly, when n is an even number.

CASE 1.

A simple definition will save me the tedious repetitions of long sentences. I define the sum of all the electromotive forces generated in all the turns which are at any moment on the same side of the neutral plane of the generator as the resultant impressed E. M. F. at that moment. The magnetomotive force of the rotating field will evidently vary according to the same law as the resultant impressed E. M. F. To find the law of variation of the resultant impressed E. M. F., consider the armature of the generator when the angle θ of coil 1 is zero. To make the reasoning shorter, I make now the angular width of each coil equal to $\frac{2\pi}{n}$, so that the n coils completely cover the ring, which makes $\alpha = \frac{\pi}{n}$. If this angular width is smaller, then a simple consideration will show that the law of variation which I am about to deduce will be exactly the same. In the position just mentioned, the coils 1, 2, 3, ... $\frac{n-1}{2}$ will all be on the same side of the neutral plane, whereas coil $\frac{n+1}{2}$ will be just half on one side and half on the other side of this plane. There is no electromotive force generated in this coil. As the above-mentioned angle θ begins to increase from zero, coil $\frac{n+1}{2}$ begins to contribute to

1. Read at the sixty-second meeting of the American Institute of Electrical Engineers, New York, December 16th, 1891.

the resultant impressed E. M. F., but this contribution is just counterbalanced by the loss due to the entrance of coil n into the opposite region of the neutral plane. The variation in the resultant impressed E. M. F. is therefore due solely to the change of position of the turns in the coils 1, 2, 3, ... $\frac{n+1}{2}$, or on one side and the corresponding turns on the other side of the neutral plane. This will be the case until coil $\frac{n-1}{2}$ has completely passed to one side of the neutral plane and coil n is just bisected by it. During this interval Θ has increased from zero to $\frac{1}{2}\,\frac{2\pi}{n}=\frac{\pi}{n}$. The value of the resultant impressed E. M. F. at any moment during this interval is easily found. Denote it by E, then

$$E = e_1 + e_2 + \dots\dots e_{\frac{n-1}{2}}$$

$$= K\left\{\sin\left(\theta+\frac{\pi}{n}\right)+\sin\left(\theta+\frac{\pi}{n}+\frac{2\pi}{n}\right)+\dots\dots\right.$$

$$\left.+\sin\left\{\theta+\frac{\pi}{n}+\left(\frac{(n-1)}{2}-1\right)\frac{2\pi}{n}\right\}\right\}$$

$$= K\left\{\sin\left(\theta+\frac{\pi}{n}\right)+\sin\left(\theta+\frac{\pi}{n}+\frac{2\pi}{n}\right)+\dots\dots\right.$$

$$\left.+\sin\left\{\theta+\frac{\pi}{n}+\left(\frac{n-3}{2}\right)\frac{2\pi}{n}\right\}\right\}$$

$$= \left\{\frac{K_1\sin\left(\theta+\frac{\pi}{n}+\frac{n-3}{4}\,\frac{2\pi}{n}\right)}{\sin\frac{\pi}{n}}\right\} = K_2\sin\left(\frac{\pi}{2}+\theta-\frac{\pi}{2n}\right)$$

$$= K_2\cos\left(\theta-\frac{\pi}{2n}\right)$$

It is evident that the resultant impressed E. M. F. E varies during the interval from $\theta=0$ to $\theta=\frac{\pi}{n}$ just like $\cos\left(\theta-\frac{\pi}{2n}\right)$; that is to say it varies just like a simple harmonic. When $\theta=\frac{\pi}{2n}$, E reaches a maximum which is equal to K_2, it has a minimum both when $\theta=0$ and when $\theta=\frac{\pi}{n}$; each of these minima equals $K_2\cos\frac{\pi}{2n}$. The ratio of the minimum to the maximum value equals $\cos\frac{\pi}{2n}$. For a three-phase system this ratio is .866, and it diminishes very rapidly as n increases. It is evident that after θ has reached the value $\frac{\pi}{n}$ the armature is, as far as concerns the resultant impressed E. M. F. in exactly the same position as at the start when $\theta=0$. We conclude therefore that E has $2\,n$ equal

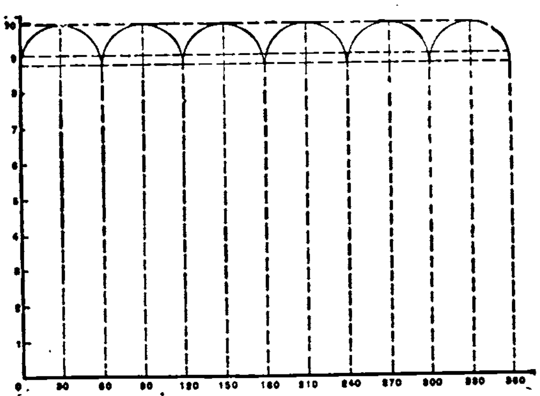


FIG. 5.

maxima and $2\,n$ equal minima during each revolution of the armature. In diagram Fig. 5 these fluctuations of E for a three-phase system are represented graphically.

CASE 2.

The same relations hold good when n is even. The maxima take place when $\theta=0,\ \frac{2\pi}{n},\ \frac{4\pi}{n},\ \dots\dots$ The minima when $\theta=\frac{\pi}{n},\ \frac{3\pi}{n},\ \frac{5\pi}{n},\ \dots\dots$ and the ratio of any minimum to any maximum is $\cos\frac{\pi}{n}$. Since the magneto-motive force varies according to the same law as the resultant impressed E. M. F., it follows that the strength of the rotary magnetic field fluctuates periodically, having $2\,n$ equal maxima and $2\,n$ equal minima during each revolution and the ratio of any minimum to any maximum equals $\cos\frac{\pi}{2n}$. That is, when n is odd, but when n is even then there are n maxima and n minima and the ratio of any minimum equals $\cos\frac{\pi}{n}$.

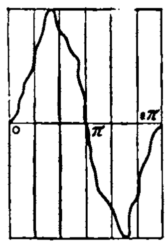

Fig. 6.

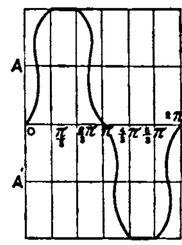

Fig. 7.

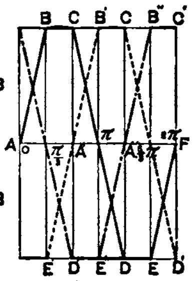

Fig. 8.

A polyphasal generator of this kind would produce a rotary magnetic field of constant strength only when $n=\infty$. For a three phase system the maximum variation would be nearly 14 per cent. of the maximum value. This agrees perfectly with Mr. Dobrowolsky's calculations, but I fail to see how these calculations could justify any one to assume that they hold good for all types of polyphasal generators[1]. The generator which we have considered could be actually constructed but its output would be so small in proportion to its size that we may dismiss it at once as an impracticable machine. We can make it practicable by substituting for the non-magnetizable ring which carries the armature coils a laminated iron ring and for the uniform magnetic field the magnetic field of a well made field magnet with its pole-pieces placed with respect to the armature coils in any one of the various ways sanctioned by practical experience. But in a generator of this kind the resultant impressed E. M. F. will no longer vary according to the law which I have pointed out a little while ago. To be sure, we shall still have the same number of maxima and minima, as may be inferred readily from our knowledge of the shape of the E. M. F. curve of a continuous current dynamo. We all know that this curve is not in general a straight line, but a wave line having as many maxima and as many minima as there are sections in the commutator. But the ratio of the maxima to the minima is no longer an a priori calculable quantity. If we knew the mathematical relation between the intensity of the field at any point of the armature surface and the co-ordinates of this point with respect to the neutral plane then we could calculate that ratio, but the amount of experimental and practical work involved in this problem would be very great. A much easier and practically much more important problem is to determine the conditions which must be fulfilled in the construction of a polyphasal generator, in order that it may be capable of producing a rotary magnetic field of constant intensity in the simplest possible way, that is, without the application of brushes and commutators. Mr. v. Dolivo-Dobrowolsky seems to think that the three-phasal generator is incapable of doing that, for he distinctly says that such a generator necessarily produces a rotary magnetic field whose strength varies 14 per cent. He also states that (evidently to obviate these fluctuations) the Allgemeine Elektricitaets Gesellschaft employ a method of transmitting currents of smaller differences of phase than one-third of the period through three wires. In this point they claim to be ahead of Tesla, Bradley, Haselwander and Wenstrom. In fact if one is not exceedingly careful in the perusal of Dobrowolsky's discussions of this subject he will be lead to believe that the rotary field in some of Tesla's motors varied as much as 40 per cent. and certainly not less than 14 per cent. I do not think that Mr. Dobrowolsky wishes to be understood as holding that opinion; for neither he nor anybody else excepting Tesla himself can know what these variations were. The number of phases employed tell us nothing definite about the range of these variations.

A polyphasal dynamo which is capable of producing a rotary magnetic field of constant intensity must be constructed in such a way that its resultant magneto-motive force must remain constant as long as speed and the magnetic field of the field magnets remain constant. As long as the variable electromotive force developed in each coil follows the law of a simple harmonic that result can never be accomplished by a finite number of phases,

1. M. v. Dolivo-Dobrowolsky: Der Drehstrom und seine Entwickelung; Officielle Ausstellungs Zeitung, Electricitaet, Heft 12.

but it may, perhaps, be accomplished by producing in each coil of the generator a variable electromotive force which varies according to some definite complex harmonic law. In a well-made commercial machine the electromotive forces developed in the various turns of the armature always vary according to some such a law. *The form of this complex harmonic law depends on the form of the magnetic field of the field magnets and also on the distribution of the coils over the armature.* The problem that remains to be investigated consists therefore of three parts: 1st. What must be the particular form of the complex harmonic E. M. F. developed in each coil of a polyphasal generator, in order that both the condition of continuity be fulfilled and also that the resultant impressed E. M. F. be continually constant. 2d. What form of the magnetic field of the field magnets will be capable of producing such an E. M. F. 3d. Can a continually constant resultant E. M. F. produce a rotary field of constant strength.

1st. The first part of this problem is purely mathematical. In a paper read before the New York Mathematical Society I indicated a method of discussing this part in a general way, and worked out completely two particular cases, namely, the cases of a three and four phasal system. The paper is given in the appendix.

2d. For a three-phasal system the form of the complex harmonic E. M. F. given in Fig. 7, will satisfy all the conditions. The form A, B, C, D, E, F, given in Fig. 8, is only a particular case and ought to be aimed at in the construction of the machine.

When there are only three turns within a space through which the armature moves with respect to the field during the time that corresponds to a complete period as in the case of the Lauffen generator (see Figs. 11 and 12), then the field of the field-magnets must be constant in intensity during an angle which corresponds to one-sixth of the period. I have indicated that in the diagram Fig. 9. In the case of bipolar three-phasal generators as indicated in the diagram Fig. 10, where we have six coils, the diametrically opposite pairs being connected in series, the pole faces must have an angular width of 120 degrees and the field must be constant in intensity within the region bounded at any moment by the armature and the pole faces. This is a practical problem offering no serious difficulties judging from the experimental results obtained by S. Thompson, Isenbeck, Mordey and others, and also from the experimental results obtained lately by a graduate of our school, Mr. Freedman, John Tyndall Fellow of Columbia College.

The curve of impressed E. M. F., which must be produced in the case of a four-phasal generator is given in Fig. 13, and needs no further commentary. Larger number of phases offer no special advantages whereas the disadvantages arising from employing a large number of phases are self-evident.

3d. When a coil in which a simple harmonic E. M. F. is developed is closed by a resistance, whether self-inductive or non-self-inductive, the current which is set up in the closed circuit will be a simple harmonic, having therefore all the characteristics of the impressed E. M. F. This, however, is not necessarily the case when the impressed E. M. F. is a complex harmonic. A complex harmonic E. M. F. is composed of a large number of simple harmonic E. M. forces of different frequencies, all the higher frequencies being multiples of the fundamental frequency. When, therefore, a coil in which a complex E. M. F. is generated, is closed by a conductor, and the current is started, the current will be also

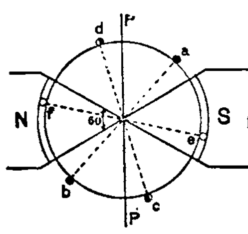

Fig. 9

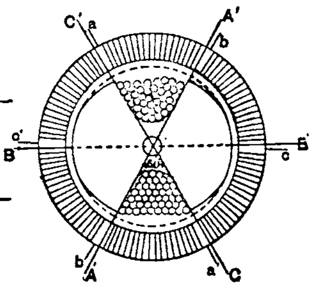

Fig. 10.

a complex harmonic, each simple harmonic component of the complex harmonic E. M. F. producing its own simple harmonic current which is a component of the resultant complex harmonic current. But since the component simple harmonic E. M. forces have each a different frequency, it follows that they will have a different impedance and the shifting of phase will be also different for each component current, currents of higher frequency having a larger shifting in phase and also the ratio of the amplitude of any one of the component currents to the amplitude of any other component of lower frequency, being smaller than the ratio of the amplitudes of the corresponding component E. M. forces. In this respect the propagation of the complex harmonic current-wave resembles very much the propagation of a complex harmonic sound-wave or a complex harmonic light-wave through an absorptive medium like air. The component simple harmonic waves of light and sound will in general suffer the less through the transmission, the longer their wave-length. Just as the sound and light-waves, after such a transmission, lose a great many characteristics of the original vibration which produced them, so an electric wave in its transmission through a conductor possessing ohmic resistance and electromagnetic, not to speak of the

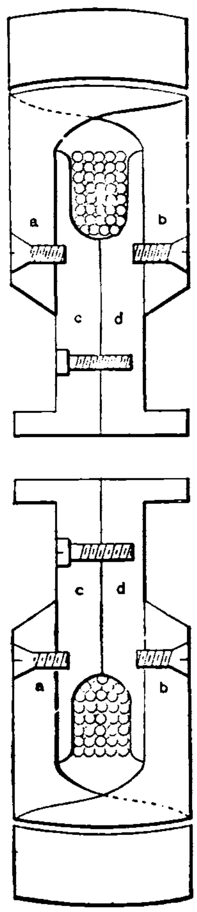

Fig. 11.

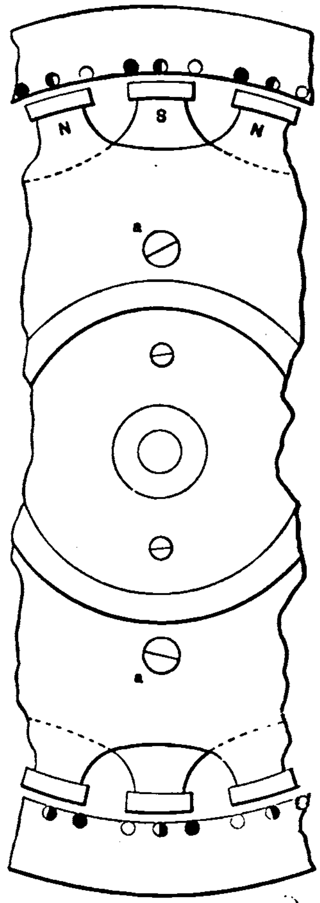

Fig. 12.

electrostatic, inductance will lose a great many characteristics of the impressed E. M. F.

To put this into simple symbolic language of mathematics,

Let L be the coefficient of self-induction of the circuit,

" R be the total resistance,

" $K \sum_{1}^{\infty}{}_{m} a_m \sin m\,p\,t$ be the complex harmonic impressed E. M. F. where $p = 2\,\pi \times$ fundamental frequency,

" x be the value of the current at any moment t.

We shall have, then,

$$L \frac{d\,x}{d\,t} + R\,x = K \sum_{1}^{\infty}{}_{m}\, a_m \sin m\,p\,t.$$

The solution of this differential equation gives

$$x = K \sum_{1}^{\infty}{}_{m} \frac{a_m}{\sqrt{R^2 + m^2\,p^2\,L^2}} \sin (m\,p\,t - \varphi_m)$$

$$\text{where } \tan \varphi_m = \frac{m\,p\,L}{R}$$

The current x is a complex harmonic, its component simple harmonic currents being

$$x = x_1 + x_2 + \ldots\ldots + x_m + \ldots\ldots \textit{ ad infin.}$$

$$\text{The current } x_a = \frac{K\,a_a}{\sqrt{R^2 + a^2\,p^2\,L^2}} \sin (a\,p\,t - \varphi_a)$$

$$\tan \varphi_a = \frac{a\,p\,L}{R}$$

Let E be the impressed E. M. F., then

$$E = e_1 + e_2 + e_3 + \ldots\ldots + e_m + \ldots\ldots \textit{ ad infin.}$$

The component simple harmonic E. M. F. e_a is given by

$$e_a = a_a \sin a\,p\,t$$

These relations give an exact quantitative expression to the preceding physical description.

These considerations made me hesitate at first in taking as granted that a polyphasal generator producing complex E. M. forces, such as I deduced mathematically in the course of my paper, would be capable of producing a rotary magnetic field of constant intensity. But I was glad to find out that my hesitation was groundless, at any rate in certain particular cases.

Consider the three-phasal generator whose diagram is given in Fig. 10. Take, now, another *well-laminated* armature wound in a similar way as the armature of the generator. Connect the three pairs of coils of the generator to the three sets of coils in armature 2. We shall have three separate circuits, the ohmic resistance and the self and mutual inductance in each circuit being the same. Denote by E_1 E_2 E_3 the three complex harmonic E. M. forces in the three circuits. Let x, y, z be the currents at any moment. Then we shall have

$$L\frac{dx}{dt} + M\frac{dy}{dt} + M\frac{dz}{dt} + Rx = E_1,$$

$$L\frac{dy}{dt} + M\frac{dx}{dt} + M\frac{dz}{dt} + Ry = E_2;$$

$$L\frac{dz}{dt} + M\frac{dx}{dt} + M\frac{dy}{dt} + Rz = E_3.$$

But since $E_1 + E_2 + E_3 = 0$ for all values of t it follows that

$$L\frac{d}{dt}(x+y+z) + 2M\frac{d}{dt}(x+y+z) + R(x+y+z)$$

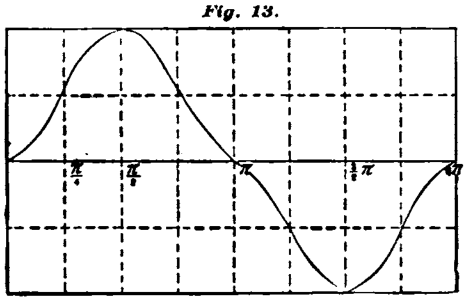
$= 0$ for all values of t. This can be true only if

$$x + y + z = 0$$

for all values of t. That is to say, the currents fulfill the condition of continuity. We can therefore employ the method of polyphasal connection. Substitute now in the first of the three differential equations

$$z = -(x+y)$$

Fig. 13.



and we obtain

$$(L-M)\frac{dx}{dt} + Rx = E_1 = K\sum_1^\infty{}_m\, a_m \sin mpt$$

The solution of this equation gives

$$x = K\sum_1^\infty{}_m \frac{a_m}{\sqrt{R^2 + m^2p^2(L-M)^2}}\sin(mpt - \varphi_m)$$

Similarly,

$$y = K\sum_1^\infty{}_m \frac{a_m}{\sqrt{R^2 + m^2p^2(L-M)^2}}\sin\left\{m\left(pt + \frac{2\pi}{3}\right) - \varphi_m\right\}$$

$$z = K\sum_1^\infty{}_m \frac{a_m}{\sqrt{R^2 + m^2p^2(L-M)^2}}\sin\left\{m\left(pt + \frac{4\pi}{3}\right) - \varphi_m\right\}$$

In the case under consideration both L and M are pretty small when the metallic parts of the magnetic circuits are near the saturation point, so that $L - M$ is exceedingly small, and $m^2p^2(L-M)^2$ will be very small in comparison to R^2 even for large values of m, unless the frequency is very high. Also, since

$$\tan\varphi_m = \frac{mp(L-M)}{R}$$

φ_m is exceedingly small unless p is very large, we shall have for moderate frequency generators

$$x = \frac{K}{R}\sum_1^\infty{}_m\, a_m \sin mpt$$

and similarly for y and z. The same method of reasoning may be easily applied to any number of phases. The mathematical operations will be considerably larger, but still the same results will be deduced without much difficulty.

That is to say, the curves for the currents are the same complex harmonics as those of the impressed E. M. F. The currents therefore produced a rotary magnetic field of nearly constant intensity; this is evidently true even if these currents produce a saturation in the iron part of the magnetic circuits.

The resemblance between a polyphasal generator and a continuous current dynamo, which these relations bring into view, is exceedingly striking and instructive.

The advantages gained from a polyphasal generator capable of producing a rotary magnetic field of constant intensity would be very much diminished indeed if it should turn out that it is impossible to devise a simple and efficient method of transformation[1] by means of which the polyphasal system of currents producing a rotary field of constant intensity (a constant rotary field system) can be transformed any number of times without losing its distinguishing characteristic. I intended to discuss this problem also this evening, but having been disappointed by the mechanician who is constructing several pieces of apparatus illustrating this problem, I decided to postpone this discussion to some other time.

To sum up:

1st. The consideration of simple harmonic impressed E. M. forces does tell the whole story of the polyphasal generators.

2nd. The law of variation of the strength of the rotary magnetic field which a polyhasal generator can produce is not as simple as Mr. v. D. Dobrowolsky thinks.

3rd. Polyphasal coupled transformers must be worked at *low magnetizations* and *low frequencies*, otherwise they will not satisfy the condition of continuity. It follows, therefore, that they will *probably be very large for the output which they can give.*

4th. It is very probable that nearly constant rotary magnetic fields can be produced in practice by a small number of phases (not more than three) by properly shaping the curve of the impressed E. M. F.

Letters to the Editor.

THE "JEWEL" INCANDESCENT LAMP TRADE-MARK.

In looking over the list of new incorporations, in a recent issue of the *Chicago Evening Post*, I noticed that certain parties, wholly unauthorized by me, have made application to the Secretary of State for the incorporation of a company for the manufacture of incandescent lamps, this company to be known as the "Jewel Incandescent Lamp Company."

The purpose of these parties, whoever they may be, is evidently to appropriate the name "Jewel" as applied to incandescent electric lamps; and for the purpose of defrauding me of my trade-mark, which I have extensively advertised and introduced, and which name has become very valuable.

The name or trade-mark "Jewel" as applied to incandescent lamps, originated with me, and is my personal property. Any attempts by other parties to pirate this name, is not only an injustice to me, but to users of the "Jewel" incandescent lamp.

By kindly giving this publication in your valuable paper, you will greatly oblige.

A TELEPHONE TRANSMITTER WITH METAL SPRINGS.

In The Electrical Engineer of Dec. 19th, a telephone transmitter without electrodes is illustrated and described.

In June, 1889, I constructed and operated transmitters based on this principle.

The springs used by me were metal; sometimes a round wire was employed; at other times a ribbon was coiled into a spiral and used.

Transmission was perfect, but not as loud as I hoped for. Carbon was suggested to me, but I had at that time no facilities for working it and abandoned it after repeatedly failing to construct a helix of it.

Elmira, N. Y., Dec. 21, 1891.

MR. MACKAY AS SANTA CLAUS AGAIN.

A few days before Christmas Mr. J. W. Mackay, president of the Commercial Cable Company, instructed Vice-president Ward to pay to each and every employé of the company half a month's salary as a Christmas bonus to mark his appreciation of their cheerful and co-operative efforts during the year. He also sent the following cable to the boys: "I want the staff to aid me in keeping the 'Commercial' to the front. Let it always retain its reputation as the 'leading cable company—leading in accuracy, leading in speed, leading in staff.'

"I wish you and your families a Merry Christmas and a Happy New Year."

1. Not only transformation of the power supplied by the generator into electrical power of higher or lower potential, but also transformation of this power into mechanical power. This, of course, leads into the discussion of rotary fields produced under practical conditions.

Legal Notes.

INCANDESCENT LAMP LITIGATION—THE UNITED STATES ELECTRIC LIGHTING CO. vs. THE EDISON LAMP CO.—III.

ARGUMENT OF GEORGE H. CHRISTY FOR THE UNITED STATES COMPANY.

THE closing argument for the complainant was made by George H. Christy, Esq., of Pittsburgh. Mr. Christy said he would commence with a word in reference to the general equities of the case. He understood his brother Betts to allege that the invention in question had been given to the public; first by Sawyer and Man and second by Maxim, and that this had been done at a date such that Weston was barred from procuring a valid patent, and therefore stood in no position of equity in this court. Moreover, he thought his brother Betts clearly implied that his clients were entitled to the benefit of any equity asserted on behalf of Sawyer and Man or of Maxim, but in that opinion he apprehended that his brother had made a serious mistake as regarded the doctrine of equity. Assuming for the present that he was correct in what he had said of Sawyer and Man, it merely proved that they had made something known to the public in the assertion of an adverse right belonging to themselves. Could the public take anything by such a disclosure? or could this defendant take anything as a matter of equity? So also in the case of Maxim; the defendant was in no position to assert any equity as regards this invention. It did not claim under either of those parties. It could only assert an equity as part of the general public; but the general public could be entitled to no equity in view of anything that had been done by Sawyer and Man, or by Maxim, for what they had done had been under a claim of title and exclusive right of their own. Moreover, the party who was claiming this equitable right was the party charged with being the infringer, but an infringer (if it could be shown that defendants did infringe), was in no position to assert equities by virtue of anybody else's title.

The claim of complainant's patent was for "building up said core with carbon obtained and deposited upon the same by and during the operation of electrically heating said core." Mr. Christy showed by extracts from the specification that the term "building up" included any result whereby the carbon which was separated from the surrounding liquid, vapor or atmosphere, was put on, or into, or anywhere with reference to the conductor so as to impart to it the qualities desired for a burner for an incandescent lamp. His brother Betts had said that the words "for incandescent lamps" in the claim must be rejected as surplusage, or used as a term of limitation; if surplusage, then it was anticipated by Despretz; if, on the other hand, it was a limiting phrase, then the invention had not been complete until Weston had found out, by actually trying a treated carbon in a lamp, that it was suitable for that purpose. He (Mr. Christy), believed the latter meaning to be correct; but his brother Betts had been in error in his conclusion that the invention could not be completed until Weston had found out that it might be used as a commercial success in an incandescent lamp. That was not the standard of invention at all. The standard by which it was to be judged was this: Was the carbon pencil, thread, filament, stick, whatever it was, in better condition for that use after treatment than it was before? If so, the conditions of invention had been practically fulfilled, and it had been so because Weston had progressed far enough to ascertain that fact. Mr. Christy then read from Fontaine's book of 1877, a statement that the examination of incandescent carbons through a strongly colored glass had rendered their defects visible. That test was a part of the state of the art as it then existed. Would Mr. Weston then have had any difficulty, looking at his carbon, before and after treatment, through a smoked glass, to ascertain whether the carbon had been improved? And if he had found—as his testimony had said that he did—that such was the case, the invention had then, if he (Mr. Christy) correctly understood the law, been complete and perfect at that time. The testimony of Mr. Vandergrift was that the test of visual inspection was the one used to-day, and the only reliable one known in the art.

His brother Betts had contended that there had been no sufficient proof of infringement, and that the Weston process, so far as it had related to the use of oil, had never been commercially used. "Why,"—said Mr. Christy,—"his own client had used it." That use had been the very infringement complained of. He then read from the testimony of defendant's employees in confirmation of his statement, and said that it did not lie in the mouth of defendant to say anything about defects of a patent based upon the use of oil, or based on the use of red heat, for it had used both. Defendant had said there was no proof of sale or use. It was not necessary. Defendant was engaged in the business of manufacturing lamps; presumptively, when it had been proven to have made use of a process in its factory, by its workmen, and apparently in the ordinary course of business, it was fair to infer that it had been done for a purpose. Under the law the construction of a thing in a commercial way was a commercial use, but the proofs were that defendant's workmen had put the carbons into lamps. It seemed to him that that testimony made out a clear case of infringement. Defendant contends that it made but a few, but for present purposes the number made was immaterial. When complainant had made out a *prima facie* case, all that was necessary was to prove one act of infringement, and then in case the bill was sustained, to ascertain the extent of infringement.

But the testimony of defendant's employees had shown that the infringing had continued off an on at intervals for months; that carbons not in conformity with the standard had been treated, while those of the proper or desired resistance had not been treated. He would say here parenthetically, that he understood Mr. Edison claimed to have discovered a new material for a filament made from bamboo and to have invented a process for carbonizing his bamboo carbons so perfectly that they did not need this treatment. He then read from an affidavit of Mr. Edison in certain proceedings in Canada, introduced by stipulation into this case, setting forth at length the great difficulties attending the commercial process of carbonizing filaments. It was fair to infer, continued Mr. Christy, from what had been said by Mr. Edison and by his witnesses, that some carbons were made not good enough for use, and that to the extent of those carbons defendant had employed this process. Defendant had said that it had quit using the process, but it had not promised that it would not use it any more. His Honor was aware that a defendant could not take anything by such a pretension as that, unless it appeared that it had gone permanently out of the business and intended to stay out.

Again defendant had said that all that had been done had been experimental, but the testimony had shown that Mr. Holtzer, the superintendent of the works, had directed the electrician to continue the process as to all carbons not up to the standard. Yet defendant contended that the whole thing was an experiment; that they had only done a few, and that there was no proof that any of them ever went into a lamp that was sold.

Turning to another point, Mr. Clarke defendant's alleged expert—he said "alleged," because Mr. Clarke, had admitted that he had had no experience in the treatment of carbon—had been asked whether or not from the testimony of Broadbent and Quimby, a man skilled in the art as it existed in 1877 and 1878, could have manufactured a successful commercial lamp. That was not a correct standard by which to judge of that testimony. It had been taken simply as to certain facts within the knowledge of the witesses, and was not required by any rule of law or practice to be in the nature of a specification; hence the inquiry made of Mr. Clarke was immaterial and irrelevant. Again Clarke had said that Quimby did not say that Weston had told him he was going to put those carbons into electric lamps. It was not necessary to tell a painter that a picture represented a sunset nor to so label it. It was not necessary for Quimby to be told that the thing which he saw done in a glass globe had been intended for an incandescent lamp; he would have known that by seeing the experiment.

Defendants had said that Mr. Edison was entitled to the credit of the successful commercial lamp; that he had made it by getting rid of gases, and by the use of a vacuum, etc., but there were one or two very singular things in this case. His Honor would understand as complainant's view, that Weston was not bound to proceed with his application for a patent until a reasonable probability appeared that he could get some reward by the sale or use of a commercial lamp. So long as no commercial lamp was known in the art, in which his invention could have been used, he had done perfectly right in delaying his application and he had done it for good reasons. Defendants on that statement of facts, had been challenged to prove, if they could, that their inventor, Edison, or anybody else, had had a commercially successful lamp in such a way as to get some equity to itthemselves as distinguished from Weston. If Mr. Edison had been the inventor that they claim, or if he had solved this problem in the fall of 1879, did it not seem probable that the fact would have been proven in this case? To whom had they gone for that credit? Not to Edison, but to Maxim; to the use made by him and the present complainant in November, 1880, and they had tried to bring themselves in as entitled to any benefit which might possibly have arisen in behalf of Mr. Maxim.

(To be continued.)

Appointments, Etc.

MR. B. L. FREEDY, who has been manager of the telephone exchange in St. Paul, has gone to Fargo, Dak., to assume management of the exchange there, while Mr. W. F. Burns, of Fargo, removes to St. Paul.

MR. ALEX. CHURCHWARD, the assistant electrician of the Riker Electric Motor Co. during the past year, has now been appointed general superintendent and electrician of that company.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED DECEMBER 22, 1891.

Alarms and Signals :—

Low-Water Alarm, F. St. Clair, 465,767. Filed April 11, 1891.
A steam low-water alarm, electrically actuated.

Train-Signaling Apparatus, P. Synnestvedt, 465,501. Filed Oct. 13, 1890.
An electric signal, by means of which the conductor of a railway train may readily communicate with the engineer.

Combined Signal and Telephone System, T. W. O'Brien, 465,648. Filed July 20, 1891.
Comprises an organization of electric circuits and appliances enabling a speaking instrument to be employed as a useful auxiliary to the ordinary system of arbitrary bell signals.

Electric Circuit Closer for Burglar Alarms, W. C. Thompson, 465,602. Filed Oct. 19, 1889.
A window sash burglar alarm.

Annunciator for the Supposed Dead, W. H. White, 465,548. Filed Nov. 24, 1890.

Clocks :—

Independent Electric Clock, W. J. Dudley, 465,655. Filed July 11, 1891.

Conductors, Conduits and Insulators :—

Conduit for Electric Wires, H. W. Jones, 465,564. Filed April 1, 1891.
Claim 1 follows:
A conduit for electric wires composed of strips of compacted asbestos fibre, wound in opposite directions, and waterproofing material, and cementing material.

Distribution :—

System of Electrical Distribution, F. A. La Roche, 465,594. Filed Oct. 9, 1890.
Has for its object the equalization of the difference of potential between the leads of an electric light or power circuit.

Means for Turning On and Off Electric Currents, T. C. Smith and B. D. Acker, 465,805. Filed Oct. 1, 1890.
A method of locally controlling an electric light circuit.

Dynamos and Motors :—

Dynamo-Electric Machine, R. Thury, 465,808. Filed Aug. 4, 1891.
A multipolar dynamo having two concentric rows of field magnets with the unlike poles of each series in juxtaposition, a rotatable armature composed of a divided hollow thin iron cylinder covered on the inner face with internal conductors and on the outer face with external conductors, and connections at the respective faces of the armature.

Lamps and Appurtenances :—

Globe-Holder for Electric-Arc Lamps, H. A. Foster, 465,470. Filed Nov. 3, 1890.
A clamping device for attaching globes to arc lamps.

Hanging Device for Arc Lamps, W. K. Howard, Jr., 465,665. Filed Oct. 30, 1890.
An automatic catch for arc lamps.

Electric Arc Lamp, H. C. Waldecker, 465,685. Filed Apr. 8, 1891.
Method of regulating the feed of arc lamp carbons by means of a piston loosely fitted into a tube containing liquid, which checks any sudden movement of the carbon.

Incandescent Electric Lamp Fixture, G. E. Villaret and V. E. Rondel, 465,684. Filed May 23, 1891.

Electric Arc Lamp, H. P. Ball, 465,514. Filed June 13, 1891.
A cut-out for arc lamps, provided with a mechanical lock for holding the circuit closed.

Cut-Out for Incandescent Lamps, H. C. Wirt, 465,508. Filed Mar. 28, 1890.
An automatic short-circuting device for series incandescent lamps.

Measurement :—

Electrical Testing Instrument, R. Varley, Jr., 465,809. Filed Jan. 15, 1891.
A testing instrument for the purpose of locating very minute insulation faults in electric wires.

Metallurgical :—

Electrolytic Apparatus for Treating Metals, E. S. Hayden, 465,525. Filed Nov. 5, 1887.
Claim 1 follows:
In an electrolytic bath having a number of plates unconnected electrolytically excepting through a solution in the bath, and having narrow partitions extending from opposite sides of the bath adapted to hold the plates in a vertical position and out of contact with each other, and stops wholly between the partitions supporting the plates above the bottom of the bath.

Miscellaneous :—

Electric Switch, G. E. Painter, 465,618. Filed Apr. 16, 1891.
A small, compact, and inconspicuous switch for residences, etc.

Rheostat, W. S. Andrews and A. K. Warren, 465,512. Filed Aug. 25, 1891.
A rheostat for electric fan motors.

Electric Snap-Switch, W. S. Andrews, 465,511. Filed May 7, 1891.
A simple and inexpensive construction for the snap-switches.

Electric Switch, H. Barton, 465,444. Filed Dec. 15, 1890.
An electric switch in which, when the connections are made, the contact-piece is locked in position, and can only be released by pressure properly applied at the handle.

Railways and Appliances :—

Electric Railway Trolley, F. J. Sprague and P. O'Shaughnessy, 465,806. Filed Jan. 22, 1889.
A trolley employing a single horizontally-placed spiral spring, for the purpose of keeping an even pressure against the trolley wire.

Electric Railway, W. H. Applegate, 465,613. Filed Nov. 10, 1890.
A conduit railway in which a traveling conductor maintains electrical contact with the main lead without exposing the entire length thereof.

Gearing for Electric-Motor Cars, O. F. Evans, 465,592. Filed Jan. 24, 1891.
A worm-gear for use in connection with high-speed motors on electric cars.

Electric-Railway Trolley, C. S. Foster, 465,469. Filed May 31, 1890.
A mechanism for securing the trolley on the trolley-wire so that it cannot become accidentally detached.

Guard for Trolley-Wire Insulators, F. O. Blackwell, 465,447. Filed May 29, 1891.
The guard for preventing the trolley from striking the insulator, when thrown from the wire.

Telephones and Apparatus :—

Adjustable Support for Telephones, C. H. Gatchell, 465,778. Filed Aug. 26 1891.
An adjustable bracket for telephone receivers.

Society and Club Notes.

THE THOMPSON SCIENTIFIC CLUB, LYNN, MASS.

At the regular meeting of the club the annual election of officers was held. The following were elected: President, J. B. Cahoon; 1st vice-president, H. G. Reist; 2d vice-president, F. C. Bates; secretary, F. Sheible; treasurer, J. B. Barr; librarian, E. D. Priest. Reviewers: Engineering, H. G. Reist; physics, H. S. Rodgers; natural science, J. E. Randall. Executive Committee: Messrs. Randall, Cahoon, Reist, Bates, Barr, Towner, Priest.

The rapid growth of the club is apparent when we consider that it was organized in May, 1889, and moved into its present extensive quarters last February. The reports of officers for the past year showed the club entirely out of debt, with quite a balance in the treasury. At present there are about 100 books and pamphlets in the library, together with 24 subscriptions to current scientific and popular periodicals, the latest addition being the *Century Dictionary*.

The club now numbers 134 members. At the last meeting Prof. Chas. R. Cross was elected an honorary member of the club.

The course of public scientific lectures now being held is in every way a success. The proceeds of this course will go towards fitting up the library of the club.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

The subjoined resolution, passed by the international congress committee and the council of the American Institute of Electrical Engineers, is the outcome of the recent visit to New York city of Dr. Elisha Gray of Chicago, chairman of the Committee on the World's Electrical Congress.

Dr. Gray, after several informal interviews with officers and members of the institute, was invited to attend a meeting of the congress committee on December 16, where a mutual exchange of views upon the subject was had, and the result is entirely satisfactory to all parties interested.

Resolved, That the American Institute of Electrical Engineers, having already taken action during the past three years, by correspondence and otherwise, towards the holding of an International Electrical Congress in connection with the Columbian World's Fair, hereby expresses its desire and intention to co-operate, by all means in its power with the World's Congress Auxiliary of the World's Columbian Exposition, through its Electrical Congress Committee, in furthering the gathering of such a congress at Chicago in 1893, and in making it a successful and worthy representation of the best electrical science and practice in all parts of the world.

THE ELECTRIC CLUB.

On New Year's Eve (Thusday) Mr. Joseph Howard, the celebrated journalist and member of the club, will deliver a lecture at the club house entitled "A Plain Talk about Journalism." It may be counted upon as one of his most brilliant efforts, and will be heard by a large audience. The lecture will be followed by a high class musical programme.

THE NEW YORK ELECTRICAL SOCIETY.

At Columbia College, on Wednesday, Dec. 30, before the New York Electrical Society, Mr. A. A. Knudson will read a paper on 'Electrical Fakes." Such a subject is full of interest and amusement, and it will lose nothing at Mr. Knudson's hands.

THE MAGNETIC CLUB.

The annual meeting of the Magnetic Club of New York will be held January 14, at 195 Broadway, for the election of officers and four members of the governing committee.

DID NOT RECEIVE THE ITEM.

An electrical concern recently sent out some lamps with the note that the lamps shipped were "3.6 watts No. 3 base." The shipping list came back with the statement that the lamps had arrived but that the above item had not come to hand.

smaller than the total combined power of the hoists, so that great economy of room as well as of power is had; or the station may be away from the docks entirely. Mr. Williams also proposes to utilize the power plant for lights to facilitate work at night, and has devised some special apparatus for safely lighting the interior of the vessels while being unloaded, as well as the docks. The motor employed by the company is the single-magnet type of 30 h. p. and together with the controlling devices was designed for this special work by Mr. Frank B. Rae, of Detroit.

One great advantage of the Nicholson system is the presence on the tram-car of the operator, who is at all times over the scene of work, and has perfect control of the movements of the car. This obviates the necessity of the signal men used in the steam cable systems. The mechanical parts subject to wear and tear are reduced to a minimum in the electric hoist, and the absence of the boiler and engine plant of the steam systems occupying room valuable for storage of ore, is an important feature. The first cost of construction, the cost of maintenance and the expenditure for labor are all much less with the electric system than where steam cables are used.

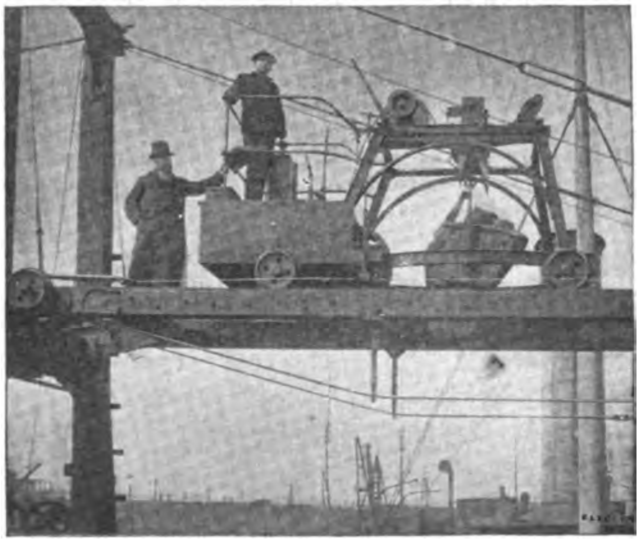

FIG. 2.—THE NICHOLSON ELECTRIC HOISTING AND CONVEYING MACHINE FOR HANDLING FREIGHT ON DOCKS, etc.

A few figures concerning the iron and coal interests of the great lakes may show to what a magnitude the work of loading and unloading vessels has reached on those inland waters.

During six months of navigation in 1890, nine million tons of iron ore was transported by vessels from the mines on Lake Michigan and Lake Superior to ports on Lake Erie, where it was unloaded. At Cleveland alone last year, two million tons of ore were unloaded at the docks, and one million tons of coal were shipped to the upper lake ports. In order to accomplish this amount of work, many of the docks have been equipped with steam systems of hoisting and conveying, at a great expense. The average cost of the ore tramways or "bridges" equipped is $10,000, and oftentimes six of these bridges are placed opposite one vessel for unloading.

These steam hoists only work in the day-time, while the Nicholson system is designed to work at night as well as during the day, thereby reducing the length of time necessary for vessels to remain at the discharging port. In these days of radical changes, time is the most important element to the vessels of lake marine, and with the advent of the "Whaleback" barges and steamers of greater speed and carrying capacity, the terminal companies must equip their docks with hoisting plant giving the greatest dispatch.

The Nicholson system appears to supply this want and not only will many of the docks at the lake ports recognize this and equip with electric hoisting and conveying machines, but other ports where it is desirable to unload merchandise from steamers, such as boxes, casks, bales, etc., and remove the goods to some point for storage more cheaply than by using 'longshoremen, will adopt this economical system.

The Nicholson Electric Hoist Company has been organized by Mr. Williams in Cleveland, and the directors are men largely identified with the shipping and iron mining interests of that region. Mr. C. W. Foote, formerly agent of the Sprague and Thomson-Houston Companies at Cleveland, is the general manager of the company. The mechanical work and bridges will be constructed by the Cleveland Ship Building Company, while the electrical equipment will for some time to come be purchased in the open market.

COMPENSATING RESISTANCES FOR GALVANOMETER SHUNTS.

BY

Charles P. Frey

THE ordinary operation of connecting a resistance commonly called a shunt in multiple with the coils of a galvanometer, and thereby decreasing the current flowing through the instrument, and consequently confining the swing of the needle to an observable range, is too well known to require description. In order to reduce the deflections to known proportions, it is necessary to use coils in both galvanometer and shunt, the resistances of which have an ascertained value. Briefly, the formula for shunts is as follows: If the total current (C) divides between two resistances, the lesser resistance will carry the greater current and vice versa. The proportion of current traveling through the galvanometer will be $C\frac{S}{G+S}$, and the current flowing through the shunt will be $C\frac{G}{G+S}$.

For convenience in calculation, the resistances of shunt coils are usually proportionately adjusted so as to reduce the galvanometric sensitiveness to its $\frac{1}{10}$, $\frac{1}{100}$ and $\frac{1}{1000}$ part.

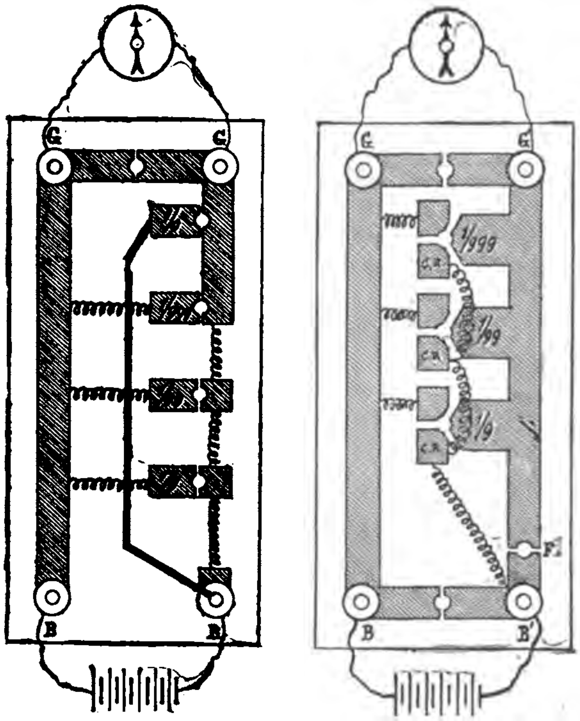
Shunt coils form an important adjunct to a galvanometer, especially when the latter is of the reflecting type, and is to be employed in connection with other apparatus for determining the value of high resistances. When the conditions of lines or the insulating qualities of materials used for covering wires are to be tested, shunts are almost indispensable. In high-resistance measurements, the usual method of employing shunts is to determine the "constant" of a galvanometer by means of the $\frac{1}{1000}$ shunt, and noting the deflection.

The "constant" once determined, the insulation of the line, etc., is generally measured by cutting out the shunt and any resistance that may have been introduced in the circuit, and taking readings with the galvanometer at maximum sensitiveness. An error in the degree of deflection obtained when the shunt is used will hence introduce an error in the basis for calculation. It is therefore evident that it is of intrinsic importance to secure shunts upon the correct adjustment of which dependence can be placed. When purchased from reliable manufacturers, there is usually no cause for apprehension on this score, but nevertheless there is a source of error involved in the use of ordinary shunt coils which, as one writer has it, "introduces an element of vagueness in the result." The fact is, a shunt having a resistance of, for instance, exactly $\frac{1}{9}$ the resistance of the galvanometer, will *not* reduce the deflection to precisely $\frac{1}{10}$, although the formula previously referred to seems to proclaim that such will be the case.

Disproportionate deflections are sometimes correctly attributed to lack of proper adjustment in the position of the scale. Obviously it is essential to adjust the scale so that it will be perpendicular to the reflected beam when the latter is not moving, but even this precaution will not eliminate the discrepancy.

Several prominent writers on the subject of electrical "testing," among others, Sprague, Ayrton, Gordon and Kempe, have mentioned the peculiar characteristic of shunts referred to, but only one author (Kempe, as far as the writer of this article can discover) has treated the subject exhaustively. In his excellent handbook on Testing, Kempe explains as follows :

. . . . "When a shunt is introduced between the terminals of a galvanometer which reduces its sensitiveness to one-half, or a shunt equal to the resistance of the galvanometer, it will not exactly halve the current passing through the instrument. If we used a tangent galvanometer, we would find, if the deflection without the shunt was 40 divisions on the tangent scale, the introduction of the shunt would not bring the deflection down to 20, but some deflection greater than 20. The reason of this is that the introduction of the shunt reduces the total resistance in the battery circuit, and consequently increases the strength of the current passing out of the battery. It is this increased current, then, which splits between the galvanometer and shunt, and not the original current. To make up for this decreased resistance caused by the introduction of the shunt, it is necessary to add in the battery-circuit a *compensating resistance* equal in value to the amount by which the original resistance was reduced."



KEMPE'S ARRANGEMENT. FREY'S ARRANGEMENT.

FIGS. 1 AND 2.—COMPENSATING SHUNTS.

In addition to the above extract, Kempe devotes several pages of his work to mathematical considerations of the subject, and also describes and illustrates a compensating shunt-box of his own invention, a highly ingenious contrivance, which will be explained in this article.

The value of a compensating resistance (if introduced in the battery-circuit) must, in order to maintain a uniform current, be equivalent to the difference between the resistance of galvanometer and shunt in multiple, and that of the galvanometer only. When the resistance of the galvanometer is, for instance, 5494.5 ohms, and its sensitiveness is to be reduced to its $\frac{1}{10}$ part, the value of the shunt will be $5494.5 \times \frac{1}{10 - 1} = 610.5$.

The resistance of the divided circuit (galv. and shunt) will be $\frac{G\,S}{G + S} = 549.45$. The compensating resistance will be

$$5494.5 \times \frac{10 - 1}{10} = 4945.05$$

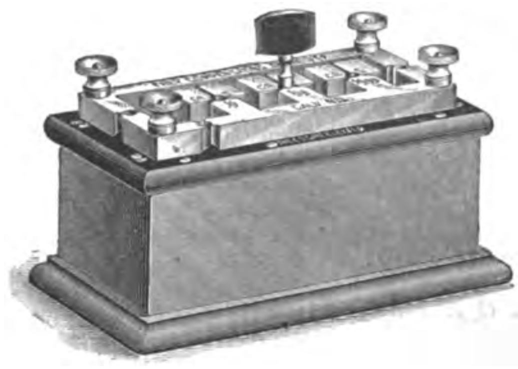


FIG. 3.—FREY COMPENSATING SHUNT.

Or, the compensating resistance (C) may be determined as follows: $C = G - \frac{G\,S}{G + S}$. In simple arithmetic the compensator equals, in this case, $5494.5 - 549.45 = 4945.05$.

Kempe's device for combining shunts and compensating resistance so that both may be thrown in circuit by means of one plug, is illustrated by Fig. 1. By following the path of the connections it will be seen that by placing a plug in the hole marked $\frac{1}{0}$ the shunt is cut out. Now removing the plug to the $\frac{1}{999}$ position will throw in circuit a shunt equal to $\frac{1}{999}$ of G and also introduce in the battery circuit a compensator consisting of three branches connected together in series, which jointly equal $\frac{999}{1000}$ of G.

Placing the plug in the $\frac{1}{99}$ position will, however, necessitate a change in the ratio of the corresponding shunt coil, since that part of the compensating coil which is between the $\frac{1}{99}$ and $\frac{1}{999}$ contact blocks, is now added to the *galvanometer circuit*. Hence this resistance becomes an inconvenient factor which must be taken into consideration in determining the value of the $\frac{1}{99}$ shunt. When the $\frac{1}{9}$ shunt is to be used, matters are still further complicated, as will be seen by referring to the diagram. The formula for determining the value of shunts and compensators of this type may be found in Kempe's treatise. The instrument itself has not however come into general use, owing probably to the intricate adjustment required, and the difficulty involved in testing the various requisite resistances. Figs. 2 and 3 illustrate a shunt box with compensating resistances which (the writer believes) embodies all of the essential features of Kempe's arrangement without the attendant complications already referred to. Its construction is exceedingly simple, and can be at once understood by tracing the path of connections on Fig. 2. It consists primarily of three shunt coils of usual proportionate resistances. These can be successively thrown in circuit together with suitable compensating coils, by means of a single plug, which, when inserted, connects in each case two independent blocks with a common conductor. The battery wires are connected at B and B' as shown and the galvanometer at G and G'. Now if one of the shunt coils is in use and an extra plug (not required for actual tests) be inserted at F, the compensating coils will be short-circuited, and since the principle of adjusting the shunt coils to $\frac{1}{9}$, $\frac{1}{99}$, and $\frac{1}{999}$ (or any other preferred fraction) of the galvanometric resistance is maintained throughout, the box will not, under the given conditions, differ from one of conventional pattern as far as the shunt coils are concerned. When, however, the extra plug at *F* is removed, the path of the current from the battery will be from the insulated block at *B′ through the compensating resistance* to the nearest block marked *C R*. If the plug is inserted at $\frac{1}{9}$, the current will then split between the $\frac{1}{9}$ shunt and galvanometer coil. Between the first block *C R* and the second is another compensator connected in series with the first one, and between the second and last block is a third coil connected in series with the two others.

Since each block will be insulated when unplugged, the wire used for the $\frac{1}{9}$ compensator may form part of the compensator for the $\frac{1}{99}$, etc.

The resistance of the three parts of the compensating coils is determined as follows: Let *G* (the galvanometric resistance) be 5494.5 ohms. The $\frac{1}{9}$ shunt compensator will then be 4945.05 ohms (see preceding formula). The total resistance of the $\frac{1}{99}$ compensator will be 5439.555; but since part of this resistance is furnished by the $\frac{1}{9}$ compensator, the resistance of the coil between the first and second blocks marked *C R* will be 5439.555 — 4945.05 = 494.505, while the resistance between the second and third block marked *C R* will be: 5489.0055 — 5439.555 = 49.4505. Hence it is obvious that the resistance of the entire circuit will remain uniform, whether shunt coils are used or not. When it is desired to use the galvanometer at maximum sensitiveness, the plug is removed from the shunt coils and inserted at *F*. This simultaneously cuts out both shunt and compensating resistance and permits the current to travel directly to the galvanometer, through the brass bars.

Removing the plug entirely leaves the circuit open. To short circuit the battery and leave the galvanometer open, the plug is placed between *B* and *B′* and finally when experiments are concluded, the galvanometer can be short circuited and the battery circuit left open by placing the plug between *G* and *G′*.

In addition to general ease of manipulation, this form of compensating shunt has the advantage of being easily and quickly tested for accuracy with the aid of a rheostat and bridge. The resistances of the shunts only can of course be tested by connecting *G* and *G′* and shifting the plug. By connecting at *B′* and *G′* the compensating coils can be measured in the same manner.

GREELEY LABORATORY, GREENBUSH, N. Y.

THE POLESCHKO TRANSFORMER.

ALL existing transformers may be classed in two groups; in the one, such as the Ruhmkorff coil, the Gaulard & Gibbs and the Swinburne "hedgehog" transformer, the iron core is in the form of a cylinder; in the other the iron core is in the form of a closed geometrical figure, annular as in the Zipernowski, Deri and Blathy, or otherwise, as in the Westinghouse, Ferranti, &c. In transformers of the first group, the lines of force generated in the iron core by the action of the primary helix are given off as a bundle from the north pole and proceed to the south pole across the outer space, where they form closed curves of all possible radii. The secondary coil in this case is in the intermediate space between the iron core and the exterior system of the lines of force. In transformers of the second group, all the lines of force generated in the iron core by the action of the primary coil remain entirely in the core itself without appearing at the exterior. These lines of force remaining in the iron core can only pass in the interior of the spirals of the secondary coil or they may encircle the outer secondary coil. In both cases the lines of force never touch the secondary helix itself.

In transformers of the first group, as well as the other, the secondary coil is not traversed by all the lines of force which circulate in the iron. It is only a small portion of the lines of force which detach themselves, so to speak, from the general magnetic flow which reaches the secondary coil in closing along short elementary curves.

Recently however, Mr. Arcadius Poleschko, of St. Petersburg, Russia, has devised an arrangement, shown in the accompanying illustrations, by which the magnetic

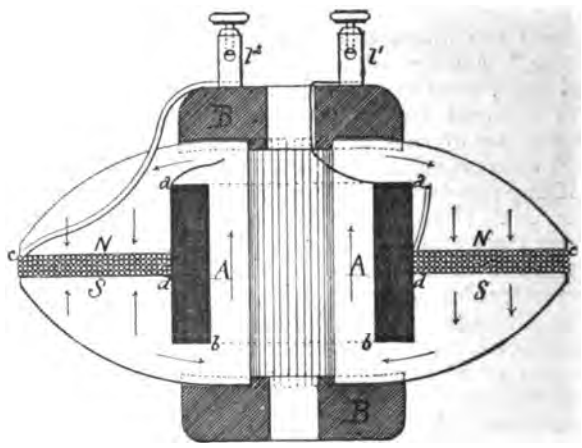

FIG. 1.—THE POLESCHKO TRANSFORMER.

flux in the iron is all made to pass entirely across the secondary coil. In this apparatus the secondary helix $\pm l_2$ $\mp l_2$ is influenced in the first place by the current in the primary helix $\pm l_1$ $\mp l_1$, and in addition by the whole of the magnetic flux which is developed in the iron core A A by the action of the primary coil upon this core.

The core consists of blades or thin plates of sheet iron. The plates A A, the shape of which is shown in Fig. 1, are arranged in the form of a ring and inserted at the top and bottom into two insulating hubs B B. The primary coil $\pm l_1$ $\mp l_1$ is arranged in the vertical cavity *ab* within the interior of the core, Fig. 1, and the secondary coil $\pm l_2$ $\mp l_2$ is arranged outside the first in the form of a flat ring of small height, but of great breadth, in the direction of the diameter of the ring. The secondary coil of this shape is placed in a narrow channel *cd* in the core, extending substantially at right angles to the slot *ab*. The ends of the two coils are led to corresponding terminals on the insulating hub.

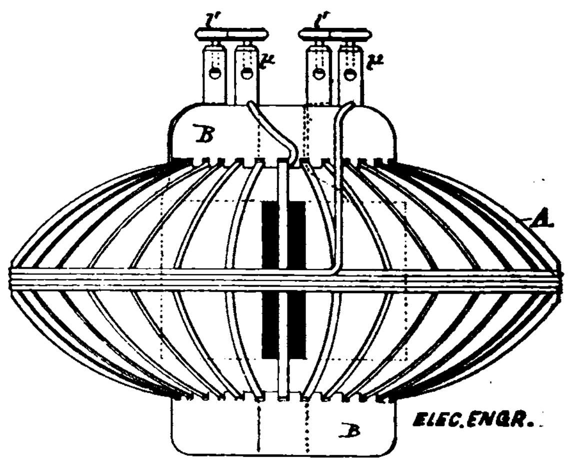

FIG. 2.—THE POLESCHKO TRANSFORMER.

The channel which cuts the mass of the core across the direction of the lines of magnetic force increases very considerably the rapidity of demagnetization and diminishes the hysteresis. The thin iron plates of the core are insulated one from another by air. This arrangement of core has the double advantage of avoiding Foucault currents and of increasing the cooling surface.

THE ELECTRICAL USES OF EUREKA TEMPERED COPPER.

Among the numerous improvements in detail which have aided in raising the electrical arts to their present high standard, those relating to the manipulation of cop-

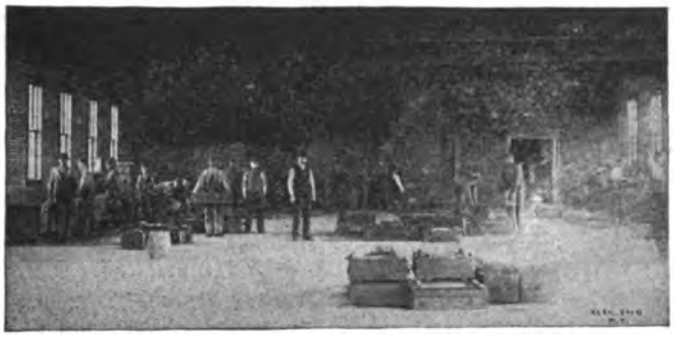

Fig. 1.—Moulding Room, Eureka Tempered Copper Co.'s Factory, North East, Pa.

per itself may well claim a prominent position. As copper in its various forms constitutes a vital material of all electrical apparatus, and especially that of dynamo-electric machinery, a process by which its life could be prolonged was, therefore, a problem, the solution of which might well occupy the time of investigators. It was already known that copper had been tempered by the ancients, as borne witness to by specimens of copper edge-tools in many museums; but the tempering of copper was a lost art, until within a few years, when Mr. Almer Thomas discovered the process as the result of a prolonged attempt to overcome a seemingly insurmountable difficulty. The history of the discovery is well worth recording here. It would seem that trouble with a wrist-pin box in the oil regions of Pennsylvania, while drilling an oil well, led

Fig. 2.—"Gate" Room.

him to experiment with all the remedies and mixtures of metal, and, finding none that would keep cool where he had to use the box, he tried copper, but with no better results. He then, with true Yankee grit, determined to try a scheme of making the box do the work and, after days of patient labor, he succeeded.

From this successful start many annoying wrist-pins in all the surrounding country were repaired and engineers felt that their days of trouble were fast disappearing. Mr. Thomas had in effect discovered, first, a method of casting pure copper without alloys of any kind and free from blow-holes; and, second, a method by which the copper so cast could be hardened sufficiently for all mechanical uses and imparted a strength equal to that of ordinary steel, or, if desired, made as malleable as wrought-iron and capable of being welded or forged into any desired shape by any blacksmith.

The marvelous success met with at once enlisted the attention of capitalists, and the Hon. W. L. Scott and Messrs. Alfred Short and Luzern Merket were associated with Mr. Thomas in the advancement of the new art. This resulted in the formation of the Eureka Tempered Copper Co.

Mr. Alfred Short, who has been a conspicuous figure in all enterprises of a mechanical nature in North East, Pa., was made president and general manager of the company, and in less than two years the company was enabled to construct a building devoted entirely to its own uses. This building is constructed of brick with slate roof, a model in design, furnishing free ventilation, and the moulding-room, shown in the engraving, Fig. 1, is 150 feet by 50 feet and 16 feet in the clear, being probably without ex-

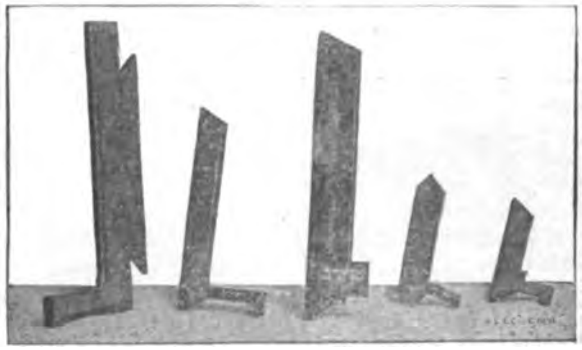

Fig. 3.—Various Forms of Commutator Segments.

ception the largest copper foundry in the world. It is designed to accommodate 12 massive copper furnaces.

The gate-room, Fig. 2, adjoins the moulding-room, where are located many workmen cutting off gates and grinding the surplus from castings. The gate-room was formerly the old moulding-room and is 50 feet by 50 feet.

With a material of this character at their command, and knowing the difficulties encountered with commutators and brushes, it is not to be wondered at that the company devoted the first eighteen months of their existence entirely to the manufacture of commutator segments and brushes.

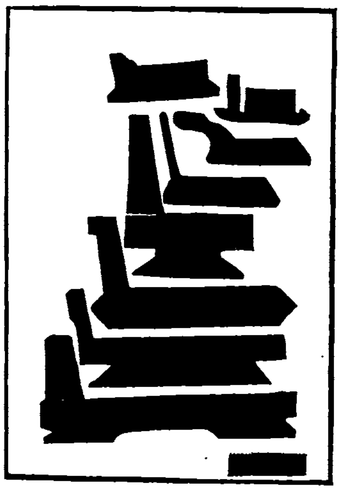

Fig. 4.—Various Forms of Commutator Segments.

For, in spite of the many attempts which have been made to supersede the employment of copper subjected to wear in electrical apparatus, the fact remains that at the present time, no substitute is available which can be said to compare with copper for such purposes. This quest for a substitute was early inaugurated in the present electrical era, and as a result we may note the employment at various times of commutator bars of brass and various alloys, and, in one instance even, of iron, but they all lack the essential qualities of conductivity and toughness which copper alone possesses, and which is brought out in a marked degree in the tempered copper manufactured by the Eureka Tempered Copper Company. This metal combines those peculiar qualities which enable the commutator bar to withstand the peculiar action to which all surfaces transmitting heavy electric currents are subjected. This quality, once pointed out, was quickly appreciated by the manufacturers of electrical apparatus with the result that at present scarcely a single part of electrical machinery subject to rubbing contact and wear is now employed in which the Eureka tempered copper is not in use. Thus, in the accompanying engraving Fig. 3, are illustrated a variety of commutator segments employed in various types of machines which in themselves form an interesting study of methods of construction of this particular and important part of all direct current dynamos. Still other forms of commutator

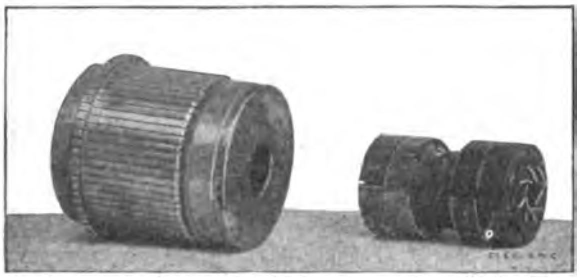

FIG. 5.—LOW AND HIGH POTENTIAL COMMUTATOR.

segments are shown in Fig. 4, each having its peculiar individuality. Fig. 5 shows two well-known types of commutators, that to the left being the usual type employed with the Gramme and Siemens type of armature; and that to the right, a Brush commutator.

But there are still other important surfaces subject to wear on the dynamo, namely, the brushes, and in this direction, also, the Eureka Company has applied its metal with eminent success. Fig. 6 shows the various types of brushes, from those with fine slits up to the type embodying almost a solid construction, adapted to various types of machines. These brushes partake of the same nature as the commutator segments in their wearing qualities, in toughness, as well as in their conductivity, and, as a con-

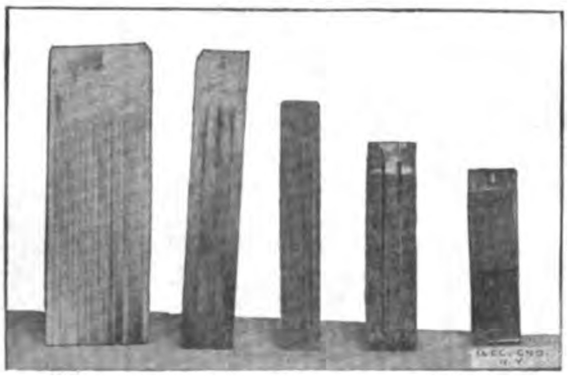

FIG. 6.—TYPES OF TEMPERED COPPER BRUSHES.

sequence, where both are used the sparking at the commutator is reduced to a minimum.

The large wear met with in some of the practical details of electric railway work has also developed several important applications for tempered copper there. Among these we may mention its employment in the gears employed to transmit the power from the motor to the car axle, and also for trolley wheels to take the current from the overhead wire, examples of which are shown in Fig. 7. In the case of the gear wheel, its peculiar toughness gives it not only a long life, but the anomalous structure of tempered copper largely reduces the noise, which is so noticeable and disagreeable a feature in steel pinions. In the case of

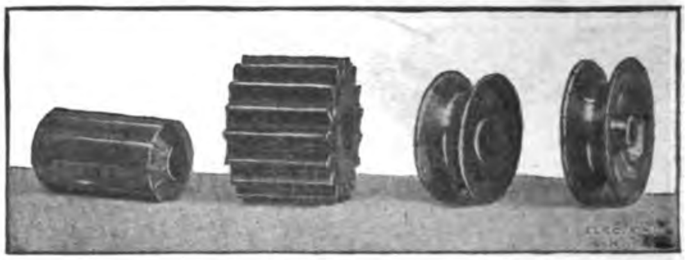

FIG. 7.—RAILWAY GEARS AND TROLLEY WHEELS, TEMPERED COPPER.

the Eureka tempered copper trolley wheels, its wearing qualities have also largely reduced the difficulties encountered by this necessary adjunct to electric railway work. That important *vade mecum* of the electrical worker, the soldering iron, has also brought out the admirable qualities of tempered copper, and our illustration, Fig. 8, shows two forms of such soldering irons, which are very little liable to "burn." This illustration also shows a segment of a Thomson-Houston commutator, for which this copper has been largely employed.

Numerous tests have shown tempered copper to consist

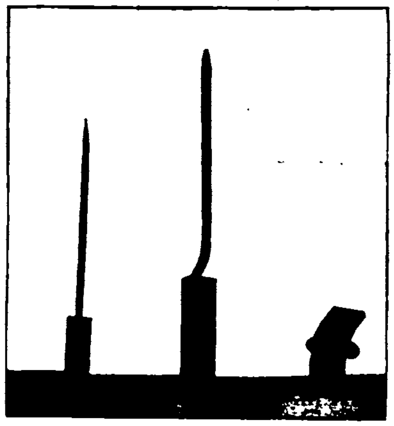

FIG. 8.—TEMPERED COPPER SOLDERING TOOLS.

of copper 99.981 per cent. pure, with a tensile strength of 64,000 lbs. per square inch and a compression strength of 189,000 lbs. to the square inch. A test made a short while ago by the Austrian Government Industrial Department at Vienna, showed a higher tensile strength than many of the steels which had been tested there.

Wire made from tempered copper is being largely used for all purposes where great strength is desired, and its purity renders its conductivity far greater than copper alloys. Besides this, its fibrous nature makes it an excellent metal for bearings, to which purpose it is now being largely applied.

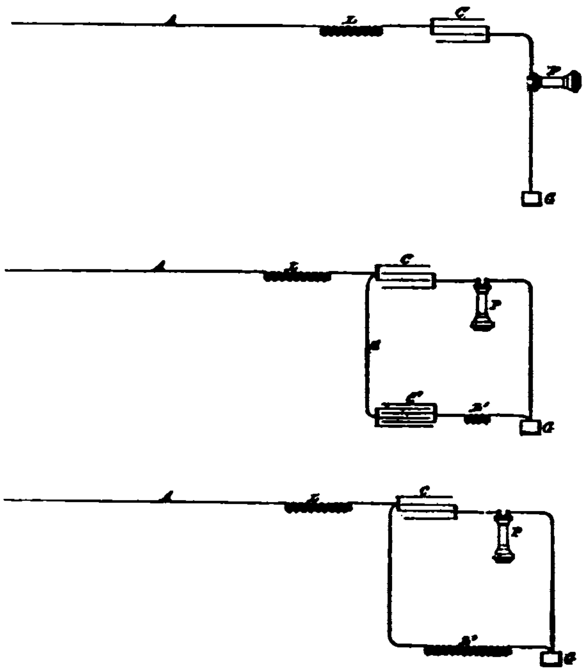
We may note here also that in recognition of the remarkable and valuable properties of Eureka tempered copper, the company has been awarded the John Scott Medal of the Franklin Institute.

Besides the shops illustrated, the works of the company embrace a large store and packing room. The products here assembled include everything made of copper, from the smallest contact buttons or spiral springs, to bearings weighing half a ton each. The machine shop and pattern-room are also extensive and all buildings are equipped with machinery of most modern construction and latest improvement.

The situation on the line of the Lake Shore Railroad, and the New York, Chicago and St. Louis Railroad, with branch tracks running into the works, gives them unexcelled shipping facilities. Each department of the immense works is under the direct charge of a foreman of thorough training and experience, and only skilled workmen find employment in the works. With these advantages the company are enabled to produce the best quality of work, which is attested by the fact that there is scarcely an electrical manufacturing concern in the country that does not use tempered copper in one form or another. The growth and success of this important enterprise is a most striking instance of the manner in which electricity stimulates work in other fields; and the subject has seemed to us specially worthy of extended treatment in our columns.

STANLEY AND KELLY'S INDUCTION PREVENTER FOR TELEPHONE LINES.

It is a well-known fact that the self-induction and capacity of an electric circuit over which a current of a given periodicity is flowing may be adjusted relatively to



Figs. 1, 2 and 3.—Stanley & Kelly's Telephone Induction Killer.

each other and to the current so that only the dead resistance of the circuit will be opposed to the passage of such current. In general, if n be used to denote the number of complete waves of the current per second, L, the coefficient of self-induction of the circuit, and M, its capacity in microfarads, then any line that possesses the necessary values of L and M in the equation

$$n = \frac{10^3}{2\pi\sqrt{LM}}$$

will offer no other opposition to a current of n waves than that of ohmic resistance. It is obvious, however, that for all other frequencies an opposition other than that of ohmic resistance will appear, for higher frequencies, due to an unbalanced self-induction, for lower, to an unbalanced capacity. It is clear, moreover, that as the capacity introduced continues to neutralize the self-induction to some extent for all frequencies, that all rates above the normal will get through more readily than if no capacity were present, although the farther they are from the normal the less will they be helped. It is otherwise with lower frequencies. Here the opposition is due to the capacity, the new element introduced into the circuit, and for rates a certain amount below the normal, the opposition offered by the unbalanced condenser is greater than that previously afforded by the self-induction alone.

In applying this principle to preventing interference due to induction on telephone circuits, Messrs. William Stanley, Jr., of Pittsfield, Mass., and John F. Kelly, of this city, have recently devised the method illustrated in the accompanying engravings. In Fig. 1, A is a telephone line grounded at G, and P a receiver. In order to oppose disturbing currents, a self-induction coil L and a condenser, C are introduced into the circuit between the receiver and the line.

The relative values of these devices are readily adjusted by varying the length of the coil and the size of the condenser, so as to hinder to a very great extent the propagation of waves of a frequency below a predetermined limit, while favoring those producing speech.

In Fig. 2 this arrangement is modified by the addition of a shunt S from line to ground around the condenser and the receiver, which is so adjusted as to capacity and self-induction by means of a condenser C′ of comparatively large capacity and a self-induction coil L of comparatively low self-induction so as to possess a high degree of receptivity for long waves. In Fig. 3 is shown a similar arrangement, except that the shunt S is arranged to have a high self-induction and low resistance, which would tend to shunt the long waves and oppose the short.

ELECTROMOTIVE FORCE, WITH SPECIAL REFERENCE TO THE EXTENSION OF OHM'S LAW.—I.

BY

Maurice Oudin, M.S.

A celebrated physicist has said that science alone has the claim to be called such, whose laws can be expressed by mathematical relations. Such are the sciences of mechanics, heat, light, sound, electricity and magnetism; in fact, all the physical sciences save chemistry, and even the last is approaching that state where it will be included in the list. Actual measurement, involving the application of numerics is the only means we possess of verifying mathematical laws. Newton was ready to abandon his grand hypothesis of the law of universal gravitation, because an error was made in measuring a degree upon which he had based his computations. The idea of potential long remained a mathematical abstraction. It was only when applied by Green to the calculation of electrical forces that its true use and significance were recognized. The truth of the mathematical statement that the inside of a hollow sphere is free from electrification was not verified until Michael Faraday built his experimental cage. Without the ability to express the proper relations of facts and to interpret those relations, our knowledge can at the most be meagre and uncertain.

The simplest and best-known law in electrical science is that enunciated by George Simon Ohm. The result of his mathematical speculations on the transmission of electricity through a conductor was first published in Poggendorf's Annalen in 1825. The essay afterwards appeared in book form in 1827, and was translated into English by Dr. Francis in the year 1841. It has been a matter of frequent comment that the great men of Germany have not always received due recognition and in many cases have gained their reputation late in life. It is difficult for us to understand the marked disapproval and even bitterness with which Ohms' work was received. His theory was utterly discredited and then ignored. Indeed Faraday was unfamiliar with the law of Ohm, and Henry likewise was ignorant of its existence although in dealing with electric currents he had intuitively recognized the principles involved. Two decades ago the vague terms intensity and quantity, were the usual means of indicating currents of high and low electromotive force.

This same uncertainty was attached to the phenomena of electrical science generally. There was no system of absolute measurement in general use until after the exhaustive work of the British Association on electrical standards, nearly 30 years ago. And this notwithstanding that the theory of electricity had almost reached its present state of development. Henry took the intensity of the shock experienced from a current of electricity as an indication of its strength, and earlier in the history of the science the distance to which a pith ball was repelled and the jumping distance in air of a spark were also means of indicating magnitude of electrical phenomena. Even after the general introduction of standard instruments into our lecture-rooms the greatest ignorance regarding their constants prevailed for a long time.

The application of Ohm's law helped to bring order out of this chaotic uncertainty. Only the necessities of practice, however, caused it to be dragged out of the waste heap. The successful application of its principles in telegraphy called the attention of scientific men to this law, the simplest in electrical science and of an importance the most truly immense.

Of the three fundamental quantities of a galvanic circuit, electromotive force is the most important. That quality called resistance is entirely dependent upon the specific nature of the substance of which the conductor is composed. A current is the result of an E. M. F. acting at the time or previously. Electricity in the sense of quantity of electrical separation has invariably associated with it an E. M. F., just as heat involves the idea of temperature or a suspended weight that of gravity. An E. M. F. can exist without the presence of the other two constants. The terminals of a voltaic cell and of an open coil moving near a magnet offer examples of the presence of an E. M. F. unaccompanied by a continuous current. It is not within the scope of this paper to view the practical side of the subject, nor to indicate the relation of the galvanic quantities to other electrical quantities. I shall confine myself to an exposition of the sources and manifestations of electricity in motion, dwelling more particularly upon the theory of E. M. F. as it is the chief factor in the modification of Ohm's law.

When a Leyden jar is discharged through a circuit, or a current from any source is maintained in a wire we say there is a transfer of electricity from a point at a certain potential to one at a lower potential. The property of producing this difference of potential in virtue of which electricity is set in motion, is ascribed to a cause called electromotive force. It is not a force at all as we understand the meaning of force as used in mechanics. The word is here used by analogy only; there is no identity whatever. Just as a force must be applied to lift a weight a certain height (a point of higher potential with respect to its original position), so by analogy, when there occurs an electrical separation, as at the electrodes of a battery, we call that producing it an E. M. F. In the mechanical illustration, if the support be removed the weight will fall to a gravitational plane of lower potential. Join the terminals of the battery and a current will flow from the positive or point of higher potential, to the negative or point of lower potential.

It is important that the distinction between E. M. F. and difference of potential should be clearly made, as there exists much confusion with regard to the proper use of these terms. In a circuit in which a source of E. M. F. is localized, there is between any two points a difference of potential. The line integral of the fall of potential measures the E. M. F. There can be no D. P. without a previous E. M. F., but we may have the latter without the former. As for instance when a cylindrical magnet is suddenly introduced into a coil of wire. An E. M. F. is set up in the wire, yet every point in the circuit is at the same potential. The same is true when an annular vessel filled with water is made to rotate in its plane. A motion of the liquid ensues although there is no difference of level. Analogies are useful, and to further illustrate my point, conceive a pump raising water to a height, say, of 20 feet. Here in a crude way the force actuating the pump corresponds to E. M. F., and the new elevation of the water with respect to its original level to D. P. Remove the E. M. F. and in consequence of the D. P. a current flows. In short, we may say, E. M. F. produces a D. P., and is measured by it.

The relation of E. M. F. and energy is a close one, indeed E. M. F. may be said to be absolutely inseparable from the idea of energy. Although, as we have seen, an E. M. F. may exist without an actual flow of electricity it requires for its excitation an expenditure of energy, and produces what we may call an electrical displacement. The work done in the deflection of an electrometer needle, under the influence of electrostatic forces against the torsion of a wire, proves this by Joule's famous principle of the conservation of energy. The amount of work involved is necessarily small. It would require instruments of great precision and refinement to determine the difference of work required to suddenly insert a magnet and a soft iron bar into an open circuited coil. The moment the circuit is closed, however, and the magnet thrust in, a current flows and then the force necessary for the operation is considerable. In electrostatics, difference of potential is measured by work done. Two pith balls of opposite and equal charges cannot be separated without a change in the energy of the system, the amount of which is represented by the equation—

$$\text{Energy} = m\left(\frac{1}{r} - \frac{1}{R}\right)$$

where m is the total electrification or quantity of electricity, and r and R are the original and final distances separating the pith balls. In its final state the energy of the above system is at a maximum and wholly potential. If left to itself it speedily falls to a minimum, the potential energy becoming kinetic in the process.

The change from one condition to the other always manifests the presence of a force. It is only when a change of energy of one form into another occurs or tends to occur that we are aware of the existence of an E. M. F. In the case of the pith balls it will be observed that there is a transfer of electricity against the attracting forces. The work done on the system is $M. V$, the product of the quantity of electricity into the difference of potential. Such a transfer of electricity is analogous to a current; it is identical in its effects, as Prof. Rowland and others have shown, when the transfer is made with the velocity of light, which is the rate of transmission of an electric impulse along a conductor. All generators of electricity are transformers of energy, the dynamo transforms energy of mechanical motion into electrical energy, the battery that of chemical affinity, and the thermopile that of heat into electrical energy. The resulting current is a manifestation of some kind of motion. It is evidence of a transfer of energy. The E. M. F. at the terminals of a generator is a measure of the urging or tendency of the generator to transform mechanical, chemical or heat energy into electrical energy. The product of these two quantities, current and E. M. F. gives the total energy or activity of the circuit.

There are two ways of viewing the manner in which an E. M. F. gives rise to a current. We may regard the E. M. F. as a force applied, either at the ends of the conductor, like the pressure of a pump drawing water through a pipe, or literally throughout the whole extent of the conductor like the vanes of a paddle-wheel. The outcome of recent experiments seem to show that the last view is the correct one. Oersted's discovery of the disturbing influence upon a compass needle by a current, as shown by Faraday, indicated the existence of a medium that transmitted electrical stresses. The mathematical treatment was undertaken by Maxwell. The results were found to be in strict accordance with Faraday's experiments. It remained for Hertz of Bonn to prove, as far as experiment can prove, the existence of a medium, and to confirm Maxwell's theory that the medium in which electrical stresses are propagated is identical with the light-transmitting medium—the ether. It is here we must abandon hydrostatic analogy, for there is no external disturbance to indicate a flow of water through a pipe. Conducting bodies are regarded as breaks in the ether, offering an easy passage to a flow of electricity. The battery, dynamo, or other generator is conceived as placing the surrounding medium under a strain. The stress thus produced is propagated along the line of least resistance, viz., the conductor, and in consequence there follows that action called electrical current. The medium plays the principal role, the function of the conductor being to determine the direction in the medium in which the transfer of electrical energy shall take place.

To Galvani is due the discovery of a new electrical manifestation; but the scientific mind of Volta developed the immense possibilities of an uncertain phenomenon. With the invention of the voltaic cell that branch of electrical science which deals with the phenomena of current flow had its beginning. For over half a century the voltaic cell was the only means of evoking large currents of electricity. Although for almost all practical purposes it has been replaced by the dynamo, its great historic interest, and especially the uncertainty attached to the theory of its action, claim for it a prominent place. In Volta's time the question as to the seat of the E. M. F. in the battery arose, and the dispute has been kept up with intermittent vigor ever since. The two great theories are the contact and the chemical. The advocates of the former claim that E. M. F. of the cell is due to the mere contact of dissimilar substances. The holders of the chemical theory formerly denied the existence of an E. M. F. not due in some way to chemical action.

Some authorities now advance a theory which is in the nature of a compromise. If a piece of copper and a piece of zinc be brought in contact, there is found to be an E. M. F. acting across the junction. If these be joined at their free ends by a substance having a chemical affinity for either metal a current is developed and maintained constant as the result of the chemical action, and at the expense of one of the metals. In other words, contact produces E. M. F. which on closed circuit gives rise to a current when some extraneous means are supplied to keep the E. M F. constantly renewed.

Sir Humphrey Davy was the first to attempt to reconcile the two theories. Faraday noticed that the composition of the electrolyte was always altered by the passage of a current, and so attributed the flow to chemical action. Sir William Thomson brought out a paper in 1851 demonstrating the existence of an E. M. F. at a junction of two metals from the well-known phenomenon called after its first observer, the Peltier effect. By far the most elaborate experimental work in this subject was carried out by Professors Aryton and Perry in Japan. They established beyond a doubt the law that the total E. M. F. of a circuit may be reckoned by adding up the E. M. F. observed for every pair of substances in contact.

"LIKE UNTO LIKE."

The editor of one of the leading technical journals of this city, in forwarding a subscription for a friend, says: "This is a Christmas present of a mighty nice electrical journal to a mighty smart young electrician."

"MASSAGE" WITH CURRENTS OF HIGH FREQUENCY.

BY

Nikola Tesla

I TRUST that the present brief communication will not be interpreted by the readers of THE ELECTRICAL ENGINEER as an effort on my part to put myself on record as a "patent medicine" man, for a serious worker cannot despise anything more than the misuse and abuse of electricity which we have frequent occasion to witness. My remarks are elicited by the lively interest which prominent medical practitioners evince at every real advance in electrical investigation. The progress in recent years has been so great that every electrican and electrical engineer is confident that electricity will become the means of accomplishing many things that have been heretofore, with our existing knowledge, deemed impossible. No wonder then that progressive physicians also should expect to find in it a powerful tool and help in new curative processes. Since I had the honor to bring before the American Institute of Electrical Engineers some results in utilizing alternating currents of high tension, I have received many letters from noted physicians inquiring as to the physical effects of such currents of high frequency. It may be remembered that I then demonstrated that a body perfectly well insulated in air can be heated by simply connecting it with a source of rapidly alternating high potential. The heating in this case is due in all probability to the bombardment of the body by air, or possibly by some other medium, which is molecular or atomic in construction, and the presence of which has so far escaped our analysis—for according to my ideas, the true ether radiation with such frequencies as even a few millions per second must be very small. This body may be a good conductor or it may be a very poor conductor of electricity with little change in the result. The human body is, in such a case, a fine conductor, and if a person insulated in a room, or no matter where, is brought into contact with such a source of rapidly alternating high potential, the skin is heated by bombardment. It is a mere question of the dimensions and character of the apparatus to produce any degree of heating desired.

It has occurred to me whether, with such apparatus properly prepared, it would not be possible for a skilled physician, to find in it a means for the effective treatment of various types of disease. The heating will, of course, be superficial, that is, on the skin, and would result, whether the person operated on were in bed or walking around a room, whether dressed in thick clothes or whether reduced to nakedness. In fact, to put it broadly, it is conceivable that a person entirely nude at the North Pole might keep himself comfortably warm in this manner.

Without vouching for all the results, which must of course, be determined by experience and observation, I can at least warrant the fact that heating would occur by the use of this method of subjecting the human body to bombardment by alternating currents of high potential and frequency such as I have long worked with. It is only reasonable to expect that some of the novel effects will be wholly different from those obtainable with the old familiar therapeutic methods generally used. Whether they would all be beneficial or not remains to be proved.

"HOW TO MAKE INVENTIONS."

MR. E. P. THOMPSON is receiving many encomiums on his book just issued with the above title. The *Boston Transcript* says it is "almost literally worth its weight in gold." The *American Machinist* says that it is "invaluable to those who wish to make invention a business and provi le themselves with means of preparation."

"Make-and-break"—means "make" for the man who sells that invention and "break" for the man who buys it.—Dr. Elisha Gray.

POLYPHASAL CURRENTS.

NOTWITHSTANDING the widespread attention which alternate-current motor and generator work has attracted during the last few years, the subject appears to be one which is but faintly grasped by the majority of electricians, judging from the lack of knowledge of essential principles displayed. It is therefore a subject for congratulation that there is now available a discussion of the nature of polyphasal currents, which will enable those not already familiar with the subject to obtain an excellent insight into their true nature and effects. In the course of his paper, read before the American Institute of Electrical Engineers, Dr. Pupin takes occasion to dwell at some length on the claims made by Dobrowolsky in Germany as to the superiority of his apparatus over that of Tesla, Bradley and others, in that there is no fluctuation in the strength of the field in his motors. Dr. Pupin well shows the untenable position taken by Dobrowolsky by proving the very slight difference which exists between two and three-phase types of motors in this respect. But, for those who have given close attention to the work of Mr. Tesla, this question would appear to have been settled long ago. A perusal of Mr. Tesla's work will show that he dwelt on these very points in his original paper read before the American Institute of Electrical Engineers in May, 1888, and from which we quote as follows:

> The inductive effect exerted upon the secondary coils will be mainly due to the shifting or movement of the magnetic action; but there may also be currents set up in the circuits in consequence of the variations in the intensity of the poles. However, by properly designing the generator and determining the magnetizing effect of the primary coils, the latter element may be made to disappear. The intensity of the poles being maintained constant, the action of the apparatus will be perfect, and the same result will be secured as though the shifting were effected by means of a commutator with an infinite number of bars.

This shows that for the uniform shifting no more than two phases are required, and that it is only necessary to design the generator properly in order to obtain the desired result. Dr. Pupin refers to this also in his paper, where he points out toward the end that "nearly constant rotary magnetic fields can be produced in practice by a small number of phases, probably not more than three, by properly shaping the curve of the impressed E. M. F." It may not be out of place to remark here that Mr. Tesla in his original patents has also shown multiphase generators and motors, and dwelt on these points even more directly than he did in the paper read before the Institute in 1888, and we may also quote from that paper the following significant remark:

> In transformers and in a certain class of motors the fluctuation of the poles is not of great importance, but in another class of these motors it is desirable to obtain the theoretical result.

This statement applies to the two types of motors shown by him, namely, synchronizing and torque motors respectively. Dr. Pupin correctly points out the impossibility of telling from the number of phases the amount of the fluctuation. With two or with three phases only, practically the same result is obtained as though there were an infinite number of phases, but we think that, inasmuch as a motor should in most cases possess a certain tendency to synchronism, practice will show the inadvisability of employing too great a number of phases, as in such a case the falling off in speed would result in a diminished output per weight and would disqualify the motor for many purposes. As regards polyphasal generators, it seems to us, as Dr. Pupin puts it, that a high number of phases is impracticable and their employment hardly warranted in the light of the above statements, it being evident that two or three phases are quite equal to accomplishing the desired results.

The paper read by Dr. Pupin also serves to call attention to some curious analogies between polyphasal and continuous-current generators and as such they must necessarily impart to the former qualities which have heretofore not been deemed to be inherent in them. We can only express again our gratification at the work of Dr. Pupin and re-echo the sentiment of Prof. Elihu Thomson, who presided, that the paper contains the only clear exposition published thus far of the principles which underlie the polyphasal-current systems. It is understood that Dr. Pupin will give a brief series of papers—two or three—before the Institute on this subject. With the principles thus clearly pointed out and with the advantages to be derived from the use of condensers in connection with alternate current apparatus, especially motors, the time can not be far distant when the latter will have become as familiar an object as the continuous current motor is to-day.

"KNOCKING OUT" THE BERLINER PATENT.

THE picturesque misinformation that cultivated Englishmen possess about this country is strikingly exemplified in an able editorial on "the Microphone in America," appearing in the December 4 issue of the London *Electrician*. Its view of the granting of the Berliner patent is thus expressed: "It is as if one had appropriated a wrong umbrella and after wearing it out taken it back again, getting a new one in its place. You cannot do that in polite society; *but you can in the New York Patent Office*." Our contemporary adds that "there is talk of invoking *the aid of the Legislature* to put an end to collusive and injurious "interferences.' It is a pity that our contemporary, who is usually so well informed and so sound in judgment, should be under the impression that the "New York Patent Office" allows this sort of thing, or that the matter is subject to the tender mercies of our State Legislature. It is the Chicago Board of Trade that is responsible in such cases, and these collusive interferences can only be put an end to by the "referendum" in the District of Columbia, or by a constitutional ballot in the thirteen original States of the Union. No doubt this is a roundabout way of correcting an abuse, but it has been carefully modeled after the precedent which requires that the Parliament of the British Empire shall sit in judgment on the wish of Puddlecombe-by-the-Haystack to have a street railway.

TRANSFORMERS WITH OPEN MAGNETIC CIRCUIT.

The designs which have been adopted in transformer work may be said to have kept very close to those of the dynamo in so far as the nature of the magnetic circuit is concerned, and this is probably a direct outcome of the modern conception of the magnetic circuit and its treatment analogously to the electric circuit. The reduction in magnetic reluctance effected in transformers with closed iron cores, over the older forms embodying open magnetic circuits, was immediately followed by increased output at a given frequency and by better regulating qualities. But there are not wanting those who find good qualities in the older types, notably among them being Mr. Swinburne, whose "hedgehog" type of transformer is well known to our readers. The principle advantage claimed by Mr. Swinburne is increased efficiency at light loads as compared with the closed circuit type. With the evident object of retaining this benefit, while at the same time avoiding the loss of magnetic lines met with in the straight core, Mr. Poleschko has designed the type of transformer illustrated on another page. While there has been considerable discussion on the relative merits of these two types of transformers, we still lack the authoritative figures of an impartial comparative test, and we suggest this as a subject of research.

ANNUNCIATOR AND BELL WORK.

THOUGH probably among the oldest of the applications embodying electrical signaling devices, the methods of construction and installation in annunciator and bell work have probably undergone very few changes from those practiced twenty years ago, and "electrical bell hanger" has indeed become a term of reproach in the profession. That this term, however, does not necessarily imply an utter lack of knowledge of electrical principles or of proper appreciation of the value of good work is well brought out in the interesting paper of Mr. Charles G. Armstrong on "Improvements in Annunciator and Bell Work," read before the Brotherhood of Electrical Mechanics in Chicago. Mr. Armstrong urges in the first place the discarding, as far as possible, of the large number of batteries frequently scattered about in large buildings feeding different bell circuits, and their replacement by a properly designed dynamo-generator. He also points out the necessity of employing a better quality of wire than that represented by the venerable annunciator wire, and he prefers weather-proof for this purpose. He also advocates the use of interior conduits, and, in general, the collection of all electrical signaling apparatus at one central point and its supervision by a competent attendant. Mr. Armstrong's paper is one of the best and most practical that we have seen for a long time.

"Catch-as-Catch-Can" Executions.

AN official report has now been made by Drs. McDonald and Ward on the Loppy execution, from which it appears it took ten minutes to prove to that unfortunate villain that death by electricity is instantaneous. As the *New York Times*, in an admirable article on the subject remarks: "The man was killed by sections, at odd jobs, in an off-and-on sort of fashion, 15 seconds at a time. They began to kill him at 11:54:36; at 12:05, ten minutes and 24 seconds later, they discovered 'the fact that death had occurred.' They declare furthermore that death was apparently instantaneous and painless. * * * If death was really instantaneous, it must have occurred at the first contact, and the other three were superfluous and revolting." We are glad to see the *Times* and other decent papers coming to the conclusion that this electrical execution must stop.

A Shower Bath of Currents.

The attention of medical men is likely to be arrested by the suggestive little note in our issue this week from Mr. Nikola Tesla, on some peculiar phenomena associated with the effect of rapidly alternating currents of high potential on the human body. As Mr. Tesla points out, the surface of the body can thus be heated under almost any conditions; and it would obviously be easy to direct or concentrate this effect upon any part needing treatment, and this whether the patient be even lying in bed unable to stir hand or foot. The medical profession has so intelligent an interest in the therapeutic use of electricity that we believe it will soon find employment for this novel method of application. It is curious how many side issues a new line of investigation opens up.

Transformer Calculations.

IN this issue Mr. Charles Steinmetz concludes his series of articles on the Elementary Theory of the Alternating Current Transformer. The graphical study of mathematical problems largely facilitates their conception in giving to the values their relative dimensions in a tangible form, such as figures alone do not convey. As such, the work of Mr. Steinmetz will prove an interesting treatise and the results of his tests on existing apparatus bear out well the accuracy of the assumptions made by him and upon which his calculations were based.

ELEMENTARY GEOMETRICAL THEORY OF THE ALTERNATE-CURRENT TRANSFORMER.—XX.

(*Concluded.*)

BY

Chas. Steinmetz.

The secondary circuit is not free from self-induction either, and the secondary current C_1 must lag behind the secondary E. M. F., E_1 by an angle ω_1. The constants of the transformer were:

Cross-section of iron = 63.3 square centimetres.
Length " = 30.8 centimetres.

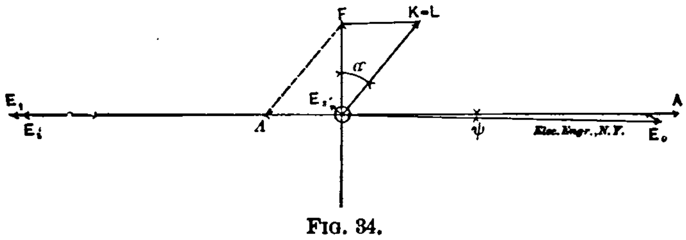

FIG. 34.

Internal resistance of secondary = .04 ohms.
" " " primary = 21.8 ohms.
Number of secondary turns n_1 = 35.
" primary " n = 675.

The electric quantities were found by the tests:

		Primary impressed E. M. F.	Primary current.	Secondary terminal pressure.	Secondary current.	Frequency.	Hysteretic loss.
		E_0	C	E_t	C_1	N	H[1]
1	Full load..........	1020	.634	49.3	10.65	132	69.7
2	Half load....... ...	1036	.383	50.6	5.83	132	83.1
3	$\frac{1}{10}$ load............	1021	.190	51.4	1.26	138	93.9
4	Open circuit.......	1030	.147	53.5	.....	138	95.7

From these we derive the results:

	Drop of potential in secondary.	Secondary induced E. M. F.	Primary resulting E. M. F.	Primary induced E. M. F.	Secondary M. M. F.	Primary M. M. F.	Ideal M. M. F. of hysteresis.
	E_{11}	E_1	E	E_i	L_1	L	$A = \frac{H n_1^{1}}{E_1}$
1	.4	49.7	14	958	373	428	49.1
2	.2	50.8	8	980	204	259	57.2
3	..	51.4	4	991	44	128	63.9
4	..	53.5	3	1030	...	99	62.6

1. These values of hysteretic loss being derived as the difference of primary watts and secondary volt-amperes, must be too small for increasing secondary load, as the real secondary watts are *less* than the volt-amperes, because of the shifting of phase ω_1, caused by the self-induction of the secondary circuit.

From the value of ideal hysteretic M. M. F. for open circuit, $A = 62.6$ ampere turns, we get the angle of magnetic lag, $\sin \alpha = \frac{A}{L} = .6323$. The angle $\alpha = 39°$, and the resulting M. M. F., $F = \sqrt{L^2 - A^2} = 76.7$ ampere turns, while the direct determination of this angle, as the complementary angle to the difference of phase between primary current and secondary E. M. F., gives

$$\sin \alpha = \cos (C\, E_1) \frac{\text{mean } (c\, e_1)}{\sqrt{\text{mean}^2\, c \times \text{mean}^2\, e_1}} = .6514;$$

angle $\alpha = 40°$. The indirect way, by means of the diagram, gave $\alpha = 39°$, which is almost the same, though the wave of current is anything but sinusoidal.

The angle $\alpha = 40°$ gives as the ideal M. M. F. of hysteresis, $A = L \sin \alpha = 63.5$ ampere turns, against 62.6 ampere turns found directly, and the resulting M. M. F., $F = L \cos \alpha = 75.9$ ampere turns, against 76.7 ampere turns, as found before.

It is therefore evident that even in cases where the wave differs widely in shape from the sine form, the polar diagram of transformers represents the phenomenon very fairly.

If the resulting M. M. F., $F = 76$ ampere turns for open circuit, that is for the induction, $E_1 = 53.5$ volts, and the

WESTINGHOUSE 10 LIGHT TRANSFORMER.

Frequency, $N = 132$ complete periods per second. Secondary induced E. M. F., $E_1 = 50$ volts effective.

		Phase of primary current.	Phase of impressed primary E. M. F.	Difference of phase between primary current and impressed E. M. F.	Secondary current.	Primary current.	Secondary M. M. F.	Primary M. M. F.	E. M. F. consumed by secondary internal resistance.	Primary resulting, or heating E. M. F.	E. M. F. of self-induction in primary circuit.	E. M. F. of self-induction in secondary circuit.	Angle of secondary retardation.	Primary impressed E. M. F.
		ϕ	ψ	ω	C_1	C	L_1	L	E_{11}	E	E_s	E_{1s}	ω_1	E_0
1	Full load...	12.5°	—10.5°	23°	10.65	.647	373	437	.4	14	197	2.5	3°	1070
2	Half load...	17°	— 6.5°	23.5°	5.83	.403	204	272	.2	8	123	1.3	1.5°	1050
3	$\frac{1}{10}$ load.....	36°	— 2.5°	38.5°	1.26	.188	44	127	..	4	57	.3	.3°	1040
4	Open sec...	49°	— 1.5°	50.5°	.....	.141	...	95	..	3	43	...	....	1030

Angle of magnetic lag, $\alpha = 41°$.
Impressed M. M. F., $K = 95$ ampere turns.
Resulting M. M. F., $F = 75$ ampere turns.
Ideal M. M. F. of hysteresis, $A = 58$ ampere turns.
Secondary induced E. M. F., $E_1 = 50$ volts effective.
Primary induced E. M. F., $E_i = 964$ volts effective.
Loss of energy by hysteresis, $H = 83$ watts.

frequency, $N = 138$, for full load, that is, for $E_1 = 49.7$ volts, and $N = 132$, we derive,

$$F = 76 \times \frac{49.7}{53.5} \times \frac{138}{132} = 74 \text{ ampere turns}$$

and are now enabled to produce to polar diagram of this transformer, for open circuit and for full load in Figs. 34 and 35.

Fig. 34 gives us the self-induction of the secondary circuit, causing a shifting of phase of secondary current against secondary E. M. F. by an angle : $a_1 = 3°$, and the

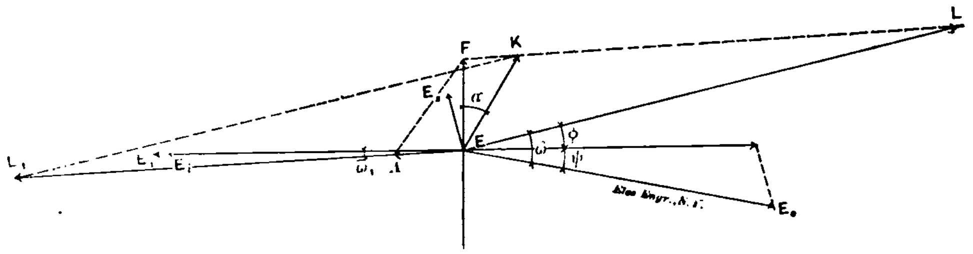

Fig. 35.

ideal hysteretic M. M. F. for full load, $A = 47$, against 49.1, as observed, causing an angle of magnetic lag, $\alpha = 33°$.

The E. M. F. of self-induction is derived from E_0, E, E, it being perpendicular to the current C. Hence,

1. $E_1 = 192$ volts for full load.
2. 116 " " half "
3. 55 " " $\frac{1}{10}$ "
4. 43 " " open circuit.

because it is proportional to the primary current and the frequency.

To compare the diagrams for different loads we reduce the electric quantities to the same magnetization and to the same frequency, by means of the law of the 1.7th power, so far as hysteresis is concerned, and otherwise by direct proportion.

Let the frequency be : $N = 132$, the secondary induced E. M. F.: $E_1 = 50$ volts. Then we derive the values given in the table, and represented in the complete diagram, Fig. 35.

It is especially interesting to notice here that, when reducing the four sets of transformer tests to the same conditions, the steady decrease of hysteretic loss for increasing load, observed by Prof. Ryan on this transformer, 95.7, 93.9, 83.1, and 69.7 watts, disappears, and the four values of hysteretic loss for different loads become 82, 85, 81 and 72 watts. The figure for full load, 72 watts, will be influenced greatly by a slight error of observation in one of the component factors, and this figure is the only one which differs much from the mean value.

Hence, *these tests cannot be used to prove a decrease of hysteretic loss,* but on the contrary, if the last figure be excluded, seem rather to indicate a *constancy and independence of the hysteretic loss from the load,* as is to be expected from theoretical reasons.

A comparison of this Westinghouse transformer with the Ganz & Co. transformer cannot well be made, because the one is a small 1 h. p. and the other a large 10 h. p. transformer, and therefore the larger transformer will give a very much more favorable diagram, as, indeed, Figs. 33 and 36 show.

These diagrams show one thing plainly; that a large transformer is much more efficient, and compounds better than a small one, and that therefore the practice of supplying each house separately by small transformers is inferior to that of supplying a whole district with a large transformer.

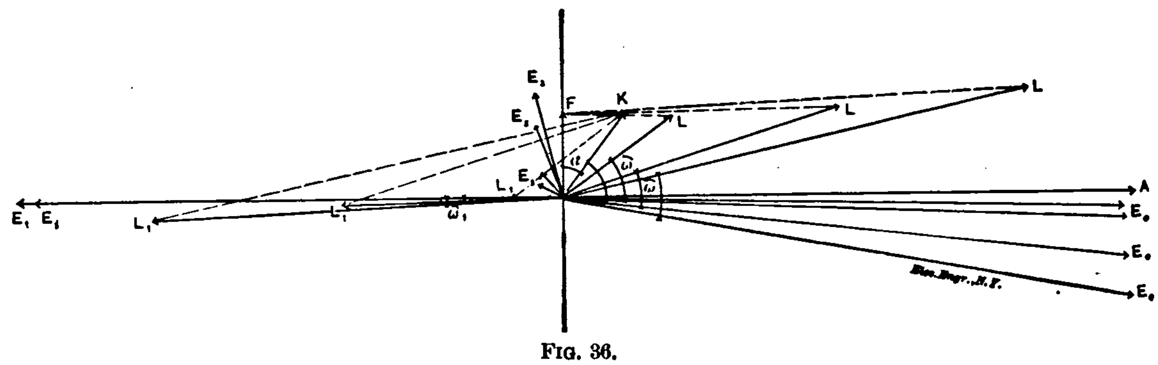

Fig. 36.

ELECTRIC CARS IN PARIS.

The Compagnie des Tramways Nord, says the *Bulletin International,* will shortly inaugurate a new service of cars between the Opera and Saint Denis. The cars will be run by electricity by means of Laurent Cély accumulators supplied by the Société pour le Travail Electrique des Métaux at a price of 4.25 cents per car mile. The route has several severe gradients; between the Rue Faubourg-Montmartre and the Rue Rochechouart the gradient is 5.5 per cent., or one in 18½. The line is nearly four miles in length. The result of this further introduction of storage cars will be watched with great interest.

A NEW THERMO-ELECTRIC BATTERY.

An ingenious little thermo-electric battery has recently been perfected which presents the following features: A small block made of a certain alloy has a small wire or a strip of nickel imbedded in it near each end; the alloy consists of antimony, three parts, and zinc, two parts. The wires project in a vertical direction from the horizontal top face of the block, and the end which is to be heated is protected from fusion by a casing made of iron. To form a battery, a number of these blocks are taken and joined in series, and they are so disposed that their cased ends can be heated to a high temperature without fusing the unprotected portions.

THE ATHENS, GA., ELECTRIC RAILWAY.

The Athens Electric Railway was built by the Equitable Engineering and Construction Co., Drexel Building, Philadelphia, who took the contract for supplying the overhead electrical construction, station electrical apparatus, and electrical car equipments. This road has the McGuire trucks, and the Rae 30 h. p. electric motors. There are five cars in daily service, and five miles of track laid with 40 pound "T" rail. The power plant consists of one 80,000 watt Rae generator, driven by a Ball compound high-speed engine.

This road has been running since the middle of June and not a single cent has been spent for repairs on any part of the apparatus. The entire electrical work was done by Mr. George B. Abele, of the Equitable Co., and is one of the best pieces of electric railway work in the South. Our illustration gives a good idea of the construction and appearance of this typical Southern road. Mr. John T. Voss, manager of the road, wrote the Equitable Co. recently as follows: "The Rae motors and dynamo installed by you on our road have done all you claimed for them and have proved highly satisfactory to us. The cost of repairs is small compared with other systems which we have investigated;

The Athens, Ga., Electric Railway.

the motors make less noise, and there is less necessity for keeping a skilled electrician in our employ than with any other system known to us, owing to the extreme simplicity of the electrical details of the machinery. If at any time you want to refer to us, we will be glad to favor you."

THE MEASUREMENT OF SMALL CURRENTS AND POTENTIAL DIFFERENCES.

The third meeting of the Electrical Department of the Brooklyn Institute for the season was held on Friday evening, Nov. 20, 1891 in the large lecture-room of the Y. M. C. A., President Hamblet in the chair.

After the reading of the minutes of the previous meeting, the president introduced Mr. Edward H. Lyon, who gave a description of a method of measuring very feeble currents and small differences of potential of which we present the following abstract: Mr. Lyon first gave a diagram of the well-known method of La

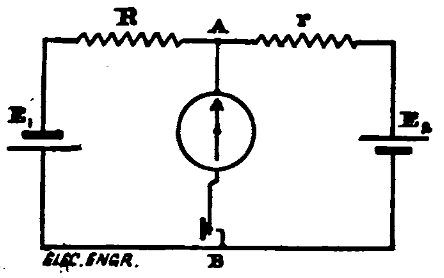

Fig. 1.—La Coine Method.

Coine for comparing the electromotive force of two batteries, as shown in Fig. 1, where the battery to be measured E_2 opposes a standard battery E_1, through the galvanometer bridge A B; R being a fixed resistance of a thousand ohms or more, and r an adjustable resistance, such as a rheostat, which is varied until no deflection is obtained on the galvanometer, when $E_1 : E_2 :: R : r$. The battery resistance need not be considered unless very high.

The Poggendorff method was then shown in Fig. 2. In this method a standard battery and galvanometer are shunted around a known resistance forming part of the circuit in which is placed the battery to be measured, the position of the contact B being varied until a balance is obtained.

Mr. Lyon stated that in the manufacture of instruments for the measurement of the heavy currents and high potentials dealt with in central station practice considerable perfection had been attained, but there was no satisfactory instrument on the market for the measurement of small differences of E. M. F. and current, which was portable and at the same time sensitive and accurate.

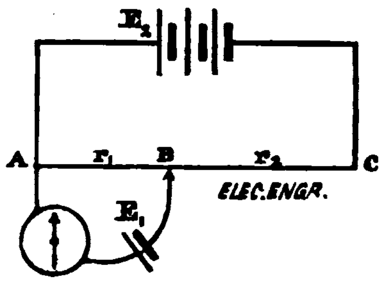

Fig. 2.—Poggendorff Method.

The instrument described by Mr. Lyon possessed both of these qualifications, and consisted of the combination of the La Coine and Poggendorff methods with a Wheatstone bridge, galvanometer and small cell of dry battery, the whole being placed in a compact carrying case.

If it were necessary to measure a battery having an E. M. F. of 1.002 volt or current of .041 ampere, this method insured the accuracy of the third place of decimals. It was not generally known that a dry battery which was worthless for many commercial purposes made an excellent standard cell if closed for short intervals only through a thousand ohms or more, and its E. M. F. would not change appreciably for a long time. He had found Dr. Gassner's very constant for this purpose, although others might be equally good. A small dry cell kept in a warm closet and used occasionally, had only lost .01 volt, since June 6th last.

An illustration of this method was then given. Fig. 3 shows an ordinary Wheatstone bridge with infinity plug removed and a

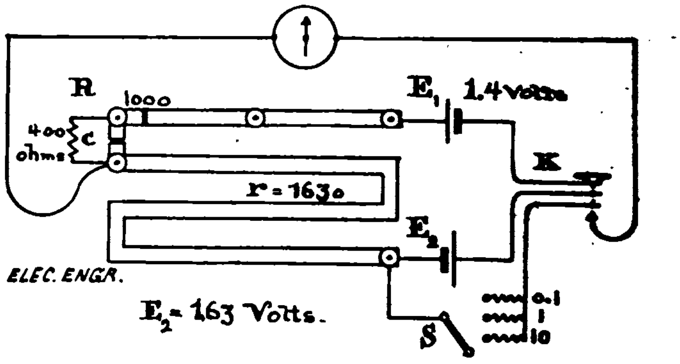

Fig. 3.—Lyon Method.

compensating resistance coil inserted to insure direct readings. This coil may be adjusted to any change that occurs in the E. M. F. of the standard cell—1,000 ohms is unplugged in one of the arms of the bridge. This with the compensating coil, brought the fixed resistance R up to 1,400 ohms, as the standard cell was known to have an E. M. F. of 1.4 volt. It was found necessary to unplug 1,630 ohms to obtain a balance when the successive contact key K was closed; therefore $E_2 = 1.63$ volt.

For the measurement of current the shunt S is arranged so that the difference of potential may be measured on either side of a known resistance placed around the battery or inserted in the circuit whose current is to be measured. For instance, if one ohm is inserted in any circuit the difference of potential at its terminals has the same value as the current flowing. Therefore a direct-reading voltmeter or ammeter is obtained which still leaves the bridge serviceable for the ordinary measurements of resistance and insulation.

The internal resistance of a battery may be obtained by first measuring its E. M. F. with the shunt S open, which is E; then with, say, the 10-ohm coil thrown around the battery, which may be E'. Then the resistance of the battery $= \frac{E - E'}{E'} \times 10$. It is convenient to have shunt coils of 0.1, 1. and 10 ohms, respectively. To calibrate the dry battery insert a Latimer-Clark or Daniell cell with r, which, with the Daniell, might be 1.079 ohms; then adjust the compensating coil C until a balance is obtained.

After Mr. Lyon had concluded his remarks, Mr. J. Stanford Brown took exception to the statement with regard to commercial ammeters for measuring powerful currents, saying that there were no accurate ones, *i. e.*, accurate within even 5 per cent., on the market. He then described in outline the method of measuring potentials of alternating-current circuits through converters with known reduction factors, etc.,

Mr. Charles E. Emery made some remarks on a bridge method of measuring low resistances, by which, with a little care, the same instruments could be used within considerable limits.

In reply to an inquiry, Mr. Lyon stated that the temperature of the rheostat coils was never affected in ordinary battery measurements. In the case of large currents, as high as 1,000 amperes could be determined by getting the drop in potential through a known resistance, as he had shown.

Mr. Lyon was given a vote of thanks and the president then announced the following committee as appointed to represent the Electrical Department of the Institute at the World's Fair in 1893: J. Stanford Brown, W. D. Sargent, W. S. Barstow, E. F. Peck and F. V. Henshaw.

IMPROVEMENTS IN ANNUNCIATOR AND BELL WORK.[1]

BY CHARLES G. ARMSTRONG.

The subject of which I will speak will be that of electric bell and annunciator service, especially in large and complicated installations. It is indeed strange, that while all other branches of electrical work have been pushed forward, this one important branch has been seriously neglected. It is almost considered a disgrace for an electrician to be a bell man, in fact it requires some considerable degree of courage for one to announce publicly that he professes to engage in that particular line of business; but I wish to assure you that there is no business where a good class of men are more needed than in bell, annunciator, burglar alarm and district telegraph work, as it requires a better knowledge of electricity and a clearer head than to know how to run the simple parallel lines for electric lighting purposes.

History tells us that James Marsh, an Englishman, in 1824 invented an electric bell which consisted of a pendulum, vibrating automatically between the poles of a permanent magnet. John Mirand, in 1850, invented the electric bell practically as it is to-day, using the vibrating hammer, a push-button, an annunciator, and all of the kindred appliances, for which he obtained a British patent in the year mentioned. Now, strange as it may seem, all inventors turned their attention to a better method of producing electricity before they thought of bettering the supply of current for the electric bell.

In the rush to perfect the electric light, the electric bell and the annunciator, with its modifications, the burgular alarm, were left almost as they were invented, with very few improvements. But of all the neglect of improvement in this particular line, that which received the least attention was the generator of current for bell or annunciator work. It is true that good batteries can be obtained, but it is also true that good batteries are very poor at best.

Let us take, for instance, the large modern hotel with, say, 500 rooms. That means 500 bells, 500 annunciator drops, one or two dozen extra bells, chamber maids' calls, fire-alarm gongs and porter bells. It means an extensive system of speaking tubes which are within themselves almost useless without the ever ready electric bell, and perhaps, on the whole, it will mean 1,200 electrical appliances, scattered over a building which may cover an acre of ground, or more, and distributed over from 6 to 10 stories or more in height.

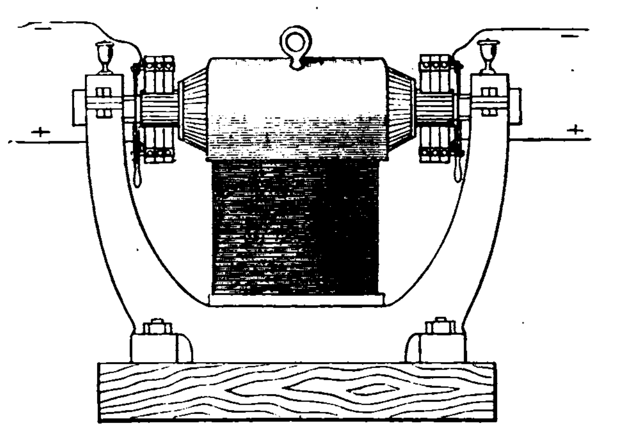
How are you going to handle all these bells? By batteries, of course; there is nothing else. But let us see if there may not be a better way. I present to you a drawing of a machine which was designed by me some years ago and which we will call the battery dynamo. I do not claim to be the inventor of this dynamo but do claim to be the first to use this peculiar form of generator for electric bell service. Since I have had this machine in operation, Professor Thomson and others have used what they call a constant-current transformer, which is very similar in form but entirely different in winding. The drawing which I exhibit is of this little machine which was built for me by Mr. Elmer Sperry and which consists of a bifurcated field having two windings, one end of which is a motor and the other end a dynamo or generator. The armature is double, the two windings being entirely insulated from each other. The motor end is a small shunt-wound motor, wound for 110 volts or any other voltage that one may wish to use and is connected to some convenient supply of electricity, such as may be had in any large city. In many cases you will have that supply within your own buildings, as modern hotels generally have an independent plant that runs night and day; or current can be obtained from some public vender of electricity. The winding of the generating armature is so proportioned that it will give from 1 to 2 amperes at 25 volts pressure, according to the requirements of the plant. I find, however, that this is about the proper current to use.

Now the windings and conditions under which the armature works are such that on a short circuit, the greatest current developed would not be dangerous in any degree to the machine; in other words while having a generator at once desirable and unvarying, you will also have a machine that will run 24 hours a day year in and year out, with scarcely any attention and will give current at all times as desired.

From this dynamo we will carry leads or battery wires with fair cross-section and good insulation. These leads will be run in a looped circuit for equal potential. The loops will have sufficient resistance, when taken together with the resistance of each bell, such that no bell will be overloaded and all will get just enough current to give the best results.

With this arrangement there is no corrosion, no liquid to evaporate, no zincs to waste, no dirty, expensive and unreliable chemical batteries to work with.

Let us now take the case of the batteries. We have the annunciator system, most likely divided into three or four stations, each station being run with from 10 to 20 cells of battery, until, when completed, we will have from 50 to 150 cells of battery scattered throughout the house at such points as we can find space for them, for nobody ever heard of an architect providing space for batteries. In addition to this unwieldy source of supply we must



A Motor Generator for Hotel Bell Circuits.

keep sal ammoniac, zincs, etc., handy, and we must constantly visit the different batteries to see that they do not freeze or that the zinc is not corroded or some trivial thing out of order by which certain bells are silenced, thus condemning our whole system, which lacks nothing but a reliable source of constant supply.

In considering the disadvantages of batteries, not the least point is that you are compelled to deal with currents of low voltage or else have too many batteries in service. For instance, 1,000 feet of No. 18 wire offers a resistance of 6$\frac{4}{10}$ ohms. It is no exaggeration to state that many circuits in our large buildings are 500 feet long, which would offer a resistance of over three (3) ohms, if it were one continuous wire. A loose binding-post or bad connection would easily raise this circuit to 8 or 10 ohms, which, in connection with a bell of from 4 to 6 ohms and an annunciator magnet of perhaps 1½ to 2 ohms more, would give from 16 to 20 ohms resistance in the entire line. It would follow that with, say, a battery of 10 cells in average condition, giving about 10 volts with large internal resistance, the current would be so feeble as not to operate a sensitive bell, making it possible to have trouble with all apparatus apparently in good condition, while with the battery-dynamo system, with 20 or 30 volts pressure and practically no internal resistance and with the difference of 10 or 15 ohms in the resistance of the line, it would still give sufficient current to ring the bells, and nothing but an absolute break in the line would render the service inoperative.

In regard to call bells, my plan is to place in every room a bell connected with a push-button at the hall door with no connections whatever to the office, treating each room as if it were a private residence. I connect this circuit to the ever ready looped mains leading from the battery dynamo. This method has many points to commend it, not the least of which is the fact that it is of great importance, often, for the patrons of the hotel to depend on certain trains. Many cases of lawsuits for damages have been brought and won against hotels for not having called guests at the appointed hour. The fact that the clerk pushed the button in the lower office would not be evidence in law that he had rung the bell in that particular guest's room, but if the call boy goes to the room mentioned and pushes the button on the outside of the door, he can hear the bell ring and can also receive an answer from the guest that he has been awakened, which would be good

1. Abstract of a paper read before the Brotherhood of Electrical Mechanics, Chicago.

evidence in law and would protect the hotel against any claims for damages.

Further, I do not approve of placing annunciators on different floors of hotels or placing annunciators in the office of hotels, except they be very small ones. A room should be provided near the main office for electrical apparatus, in which the telephone, annunciator or annunciators, speaking tubes and all such apparatus should terminate. This room should be placed in charge of a competent, intelligent young man who has some knowledge of electricity. Sub-offices can then be placed on the various floors which will connect with this main office by speaking tubes, or better yet by pneumatic tubes. All calls will then be placed on record and transmitted to the nearest call boy station and executed with the least amount of delay.

In regard to wire, except your building be entirely of wood, do not use annunciator wire and do not use bare rubber-covered wire, for neither is as good as plain weather-proof. The cost of braided rubber-covered wire is so high as to be practically prohibitory. But weather-proof wire, where saturated with some petroleum compound, I find to be a splendid wire for such purpose, from the fact that it is moisture proof and that it is practically free from damage by mice or rats which are the worst enemies of wire that I know of. Mice dearly love rubber and a very small quantity of moisture will ground an annunciator wire, while weather-proof wire is offensive to mice and rats on account of its waxy covering, and is sufficiently impervious to moisture to make it very efficient for this class of work. It is true that it costs more than annunciator wire, but the first cost only is to be considered, and in no first-class installation, such as I am describing, will the architects or owners object to paying the small additional cost in order to have the better satisfaction, which invariably follows the use of good material. In selecting wire be sure to get one very heavily saturated with compound, the more, the better, as it not only protects from rats and mice but from moisture and abrasion. I admit that in wooden buildings where lath and pine studding is used, annunciator wire will do very well for use, but when you consider that bare wire, properly placed under the same conditions, would answer nearly as well, you will see that it is no recommendation for the annunciator wire.

As to the manner of laying wires in the modern fireproof structures with tile partitions, I prefer to use the paper tubing which is now manufactured under the name of interior conduits. One sample is covered with brass. This is designed to use where it is necessary to have the wires exposed. There are a few cases perhaps where it may be necessary, but it can be polished and made very ornamental if desired. The other tube is to be covered entirely by the plastering and offers a channel into which the wires can be drawn at any time. In the halls at suitable points I place wooden troughs, concealed by the decorations, so that every wire in the building can be inspected from end to end without taking up a carpet, removing any plastering or in any way disturbing the occupants of the building.

It has been my object for many months to improve in every way possible the present method of laying wires within large buildings, and I always keep in view the fact that accessibility to the wires is the greatest object to be attained in work of this kind. The architect who spends months designing the beautiful decorations for our modern buildings is certainly not to be blamed for losing his patience when, on account of faulty insulation, the wires have to be torn out and his decorations totally destroyed or marked by patching which is never satisfactory. By the proper design and arrangement in conduits, every inch of the wires, from the annunciator to the push-button, can be drawn out in a few moments and repaired in case of accident from any cause whatever.

In regard to district telegraph or fire-alarm work, this battery dynamo is equally as efficient as it is for bell work, as it at once does away with the uncertainty of batteries, concentrates your apparatus and greatly reduces the cost of maintenance. In the city of Chicago, which undoubtedly has the best fire-alarm system of any city in the world to-day, there are in service nearly 8,500 cells of battery. This does not include the batteries used in Hyde Park and Englewood. It would be perfectly feasible to replace every cell with from six to 10 of these little machines.

In closing my remarks I would like to say to each and every one of you, Make it your object to discourage and discountenance everything in electricity that is bad, and encourage that which is good.

In this connection I will call your attention to two things which I wish to emphasize in particular. First, the placing of electric gas lights on fixtures which carry electric lights. It is the practice in work of this kind to ground one side of the battery. Now as you are all well aware, the fixture man has gone to considerable expense and taken valuable time to place on every fixture an insulating joint, the object of which is to entirely separate that portion of the electric light which is most apt to ground, from the sockets and pipes, which of course afford excellent ground. You proceed to undo all this work by bridging over his insulating joint with the gas lighting wires which are little better than bare wire, so far as insulation goes, and practically annulling the effect of the insulating joint.

Another dangerous thing is the electric trap-door, and there is a building in this city where a sort of "dead fall" controlled by an electric trigger is placed at every point of exit. Hundreds of people, men, women and children are employed in that building every day. In case of fire, every stairway, the elevator shafts, and almost every means of exit will be automatically closed. Against such devices as this I should expect to find you all arrayed.

ON POLYPHASAL GENERATORS.[1]

BY M. I. PUPIN, PH. D., COLUMBIA COLLEGE.

FEW will deny the importance of the polyphasal current systems; none the fascination of their study. This belief induced me to present the following brief essay before the Institute.

The experimental researches in this new and promising field of electrotechnics are not yet numerous, but still the results already obtained are of so decisive a character as to leave no doubt whatever as to the extremely high practical importance which is attached to electrical generators, motors and transformers constructed according to requirement imposeds upon us by this new

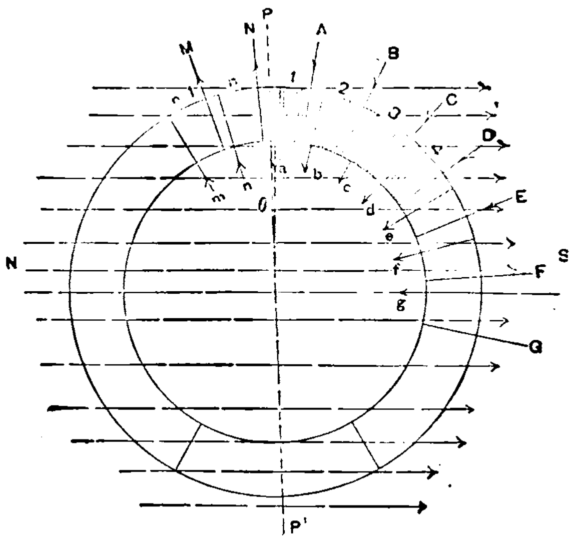


Fig. 1.

method of combining a set of variable electromotive forces. For who among us does not thoroughly appreciate the beautiful inventions of Nikola Tesla and the completeness of the success which Dobrowolsky and Brown obtained by the practical applications of these inventions?

The exact quantitative relations involved in the polyphasal system of currents are not, I venture to say, quite as well known as its practical results. To give an impulse to further inquiry in that direction is one of the principal aims of this modest investigation. For the present I propose to confine myself to the polyphasal generators in general, and particularly to polyphasal generators whose system of electromotive forces is capable of producing a rotary magnetic field of constant strength. The last point seems to me to be one of the vital points in this new method of electrical distribution. It is in this particular point that Mr. Dobrowolsky claims his system to be superior to that of Nikola Tesla.

Let us consider the theoretically simplest form of a polyphasal generator, as shown in Fig. 1. A non-magnetizable ring with n open equal coils at equal distances from each other rotates uniformly through a perfectly homogeneous magnetic field. Let PP′ be the neutral plane of the field. At the instant when coil 1 is at the angular distance θ from the neutral plane PP′ the E. M. F. generated in the various coils will be

$$e_1 = K \sin(\theta + \alpha)$$

$$e_2 = K \sin\left(\theta + \alpha + \frac{2\pi}{n}\right)$$

....

....

1. Read at the sixty-second meeting of the American Institute of Electrical Engineers, New York, December 16th, 1891.

$$e_n = K \sin \left\{ \theta + \alpha + (n-1) \frac{2\pi}{n} \right\}$$

Where K is a constant depending, as is well known, on the field intensity, the speed of rotation, the number of turns in the coil and the area of the plane of a turn; α is the angular width of one-half of the coil.

Since

$$\sin(\theta+\alpha) + \sin\left(\theta+\alpha+\frac{2\pi}{n}\right) + \ldots\ldots + \sin\left\{\theta+\alpha+(n-1)\frac{2\pi}{n}\right\} = 0$$

it follows that

$$e_1 + e_2 + e_3 + \ldots\ldots + e_n = 0 \ldots\ldots (1).$$

That is to say, the sum of electromotive forces generated in the various coils which are on one side of the neutral plane is numerically equal and of opposite sign to that of the coils on the other side of this plane. This result is well known and self-evident. It is, however, far from self-evident that relation (1), which I shall call the *relation of continuity* for the electromotive forces, will be satisfied by every magnetic field.

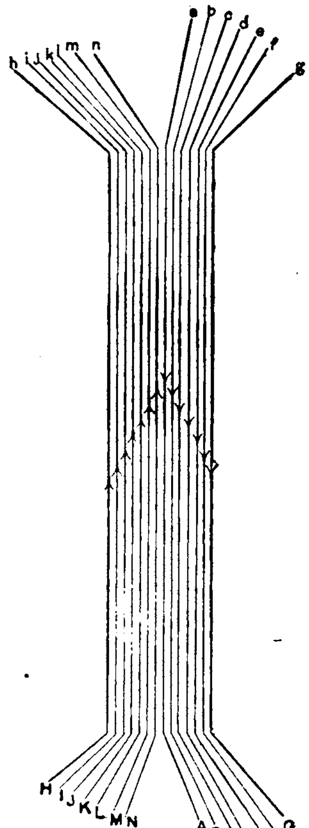

Fig. 2.

Close each coil separately by conductors of equal resistance and self-induction. Let $c_1, c_2 \ldots\ldots c_n$ denote the currents in the n separate circuits. It is evident that

$$c_1 = \frac{K}{I} \sin(\theta + \alpha - \varphi)$$

$$c_2 = \frac{K}{I} \sin\left(\theta + \alpha + \frac{2\pi}{n} - \varphi\right)$$

$$c_3 = \frac{K}{I} \sin\left(\theta + \alpha + 2\frac{2\pi}{n} - \varphi\right)$$

$$c_n = \frac{K}{I} \sin\left\{\theta + \alpha + (n-1)\frac{2\pi}{n} - \varphi\right\}$$

Where I is the impedance in each circuit and φ the angle of retardation. Hence, we have

$$c_1 + c_2 + c_3 + \ldots\ldots + c_n = 0 \ldots\ldots (2).$$

That is to say, the relation of continuity is satisfied for the currents also.

Let the wires $a\,A$, $b\,B, \ldots\ldots n\,N$ (Fig. 2) represent a part of each of the n conductors of this system. Then, according to relation (2), the sum of the currents in these n linear conductors being always zero, if we join them all into one conductor there would be no current in this wire, but the currents in the n circuits would circulate exactly the same as before. In fact, the common juncture is useless and can and should be cut out.

The diagram, Fig. 3, represents this method of connecting for a three-phase system. Consider, now, n equal coils distributed at angular distances of $\frac{2\pi}{n}$ over a laminated iron ring B, each coil being a part of the n conductors coming from the generator Diagram Fig. 4 illustrates this for a three-phase system. Let the n currents be denoted now by $c_1', c_2', \ldots\ldots c_n'$. We shall have now,

$$c_1' = \frac{K}{I'} \sin(\theta + \alpha - \varphi')$$

$$c_2' = \frac{K}{I'} \sin\left(\theta + \alpha + \frac{2\pi}{n} - \varphi'\right)$$

$$c_n' = \frac{K}{I'} \sin\left\{\Theta + \alpha + (n-1)\frac{2\pi}{n}\varphi'\right\}$$

and therefore

$$c_1' + c_2' + \ldots\ldots + c_n' = 0 \qquad (3)$$

The introduction of the iron ring with the n coils into the n phasal system has changed the impedance I, and the angle of retardation φ; but this change is evidently the same for all coils. The correctness of this statement might, perhaps, be questioned, if we suppose that the system of the n variable currents was at any moment strong enough to saturate the iron ring; I therefore suppose that the intensity of magnetization in the ring is never over 10,000 C. G. S. lines of force. We shall presently see that in the case of a properly built generator the saturation of the iron ring will not vitiate the correctness of the above statement in the slightest.

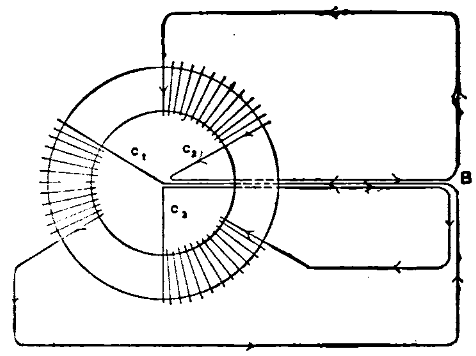

Fig. 3.

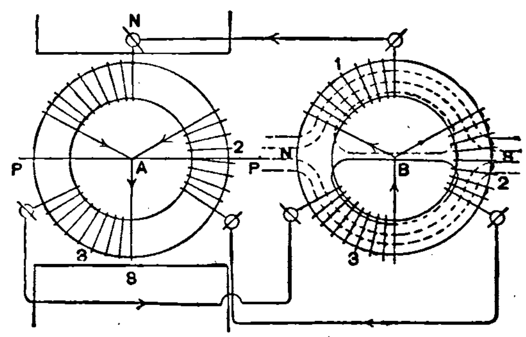

Fig. 4.

Let s be the number of turns in each of the n coils. Relation (3) gives

$$4\pi s c_1' + 4\pi s c_2' + \ldots\ldots + 4\pi s c_n' = 0 \qquad (4)$$

That is to say, the relation of continuity is satisfied by the magneto-motive forces.

Relation (4) translated into physical language means that the magnetization in the iron ring is due to two equal magneto-motive forces working in multiple arc. The magnetic field produced is perfectly symmetrical with respect to the ring as indicated by the dotted lines in Fig. 4.[1]

MR. C. O. HARRIS, formerly of Clower, Harris & Co., Dallas Tex., was in the city last week. Mr. Harris has secured some excellent agencies, and will open an office in Dallas.

---

1. This will be always strictly true if we employ an even number of coils, even if the number of phases is odd, because then the distribution of the ampère turns is perfectly symmetrical.

SOME PRACTICAL FORMULÆ FOR STREET CAR MOTORS.

BY

Thorburn Reid.

THE following analysis was undertaken with the object of obtaining some simple, practical formulæ, which could be used by a practical man in his everyday work. Accuracy has been sacrificed to simplicity, since accuracy in this case would hardly be required by the engineer, and, if it were, it could seldom, if ever, be attained on account of the wide variations in the conditions affecting the problem.

First take the case of a gramme ring armature in a two-pole field, the field coils being in series with the armature coils. If e is the counter E. M. F, S_2 the number of turns on the armature, n the revolutions per minute, and N the number of volt lines (10^8 c. g. s. lines = one volt line),

$$e = S_2 N n. \qquad (1)$$

But $N = \frac{S_1 C}{\rho}$ where $S_1 C$ is the number of ampere turns in field and ρ is the magnetic resistance of the magnetic circuit. Therefore, $e = \frac{S_1 S_2}{\rho} C n$ (2)

If R be the resistance of the field plus the armature, and E the line E. M. F., then

$$C = \frac{E - e}{R} = \frac{E - \frac{S_1 S_2}{\rho} C n}{R}$$

solving for C, we have

$$C = \frac{E}{R + \frac{S_1 S_2}{\rho} n} \qquad (3)$$

If w be the work done by the motor,

$$w = C e = \frac{S_1 S_2}{\rho} C^2 n \qquad (4)$$

S_1 and S_2 and ρ are constants of the motor. ρ, however, varies somewhat with the saturation of the field. We will not, however, introduce too large an error by considering it constant throughout the range. If, therefore, we substitute for $\frac{S_1 S_2}{\rho}$ the letter a, a constant, (3) and (4) become

$$C = \frac{E}{R + a n} \;\; (3) \qquad w = a\, C^2\, n \;\; (4).$$

The value of this constant may be obtained easily if we have the dimensions of the magnetic circuit and a saturation curve of the iron in field and armature, but this, in the present stage of electrical manufacture, is not generally to be had. The following method is far simpler, and no doubt more accurate:

Let the motor whose constant is required be run under load and a reading be taken of E, C and n. Substituting these values in equation (3) we may obtain the value of a thus: $a = \frac{E - C R}{C n}$ (5)

This may be made more accurate and the variation in ρ taken into account by taking readings at varying loads and currents and obtaining the value of a for each case.

The value of a thus obtained will then be good for all motors of that type and size for all practical purposes. Of course, if the number of turns on field or armature be varied, the value of a will be changed.

If the motor be of the four-pole type, or if its armature be a Siemens instead of a Gramme ring, the same equations may be used, provided a is obtained by experiment, as above; for in the former case the only change to be made is to multiply n by 2, which, being a constant, would be included in a, and in the latter case the right-hand member of equations (1) and (2) would be multiplied by 2, which would again be included in a, since (2) could be written, $e = a\, C\, n$. Another convenient formula is the following:

If m be the speed of the car in miles per hour, d the diameter of the car wheel in inches, and r the ratio of reduction, or the ratio of the revolutions of the armature to those of the car wheel, we will have

$$n = \frac{5280 \times 12 \times m \times r}{60 \times \pi \times d} = \frac{304\ m\ r}{d} \qquad (6)$$

Having obtained the value of a, then the next step is to apply these equations to problems occurring in practice. A problem, which often occurs, is, what E. M. F. is required on the overhead line to drive a car up a particular grade at a certain rate of speed.

From (3) we have $E = C (R + a\, n)$ in which everything is known except C. But C can be obtained from equation (4), provided we know the value of w. w depends on five things—friction, grade, condition of track, curvature of track and speed. No general formula can be given for the resistance due to friction, condition of track or curvature. These can only be determined by experience and must be largely a matter of guess-work. The friction will vary largely at different times in the same car, depending on the care with which the gears and bearings are oiled and on whether the track is wet or dry, clean or dusty or muddy. A rough value may be arrived at by taking readings of the current and line E. M. F. at varying speeds with the car running on a level, straight track. This resistance may be taken to vary directly with the weight of the car plus its passengers. We obtain w by substituting these readings in equation (4). We find the work required to overcome the grade as follows:

$$w_g = \frac{P \times \mathit{ft.\ per\ min.} \times 746 \times g}{100 \times 33{,}000}$$

where P is the weight of car plus passengers and g is the grade in per cent. That is, the rise in feet per hundred feet. Or $\qquad w_g = .02\ m\ g\ P$

where m is as before the miles per hour.

The work which would be done by the motors then in climbing the grade will be that obtained by equation (7) plus the work required on a straight, level track, since this latter factor is assumed to be constant whether the car is going up or down grade or on a level.

In making the experiments to obtain w on a level we must be careful to notice the load that the car carries, since this work at any speed varies directly as the weight of car plus its passengers. Probably the simplest procedure would be to divide the work thus obtained by the weight of cars plus passengers, thus obtaining the work for one pound, which can then be multiplied by the total weight (average weight of a full-grown passenger may be taken to be 125 pounds), calling this value w_1, the complete formula will be

$$w = P (w_1 + .02\, m\, g). \qquad (8)$$

Of course, w_1 must be determined for the same speed as that required at the point in question or else it must be estimated from the data at hand. Probably the best assumption we may make is that the work on a level varies as the speed, or

$$w_1 = b\, n \qquad (9)$$

b being a constant depending on the condition of the road-bed, etc., and is most easily determined by running the car and taking readings of C, E, and n, substituting for w_1 and n in equation (9) and solving for b.

Having thus obtained the value of w, we may substitute it in (4) and obtain C and then substitue C in (3) and obtain (E). We are thus enabled to determine the size of wire required in the feeders to maintain a certain speed at any point on the line.

Society and Club Notes.

NATIONAL ELECTRIC LIGHT ASSOCIATION.

THE fifteenth convention of the Association will be held at the Iroquois Hotel, Buffalo, N. Y., on February 23, 24, and 25. Secretary Porter announces that Mr. C. O. Baker, Jr., has been appointed general master of transportation with headquarters at the office of the Association, 136 Liberty street, where all communications relating to transportation should be addressed. Steps are already being taken to make the meeting a great success.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

AT the meeting of the council on December 16, the following gentlemen were admitted to associate membership:

Ayres, Brown, professor of physics and electrical engineering, Tulane University, New Orleans, La.

Benjamin. Park. electrical expert and engineer, 32 Park Place, New York City.

Bishop, James Draper, electrical expert, John A. Roeblings' Sons Co., 845 West Thirty-fourth street, New York City.

Parcelle, Albert L., electrician and inventor, 157 Washington street, Boston, Mass.

Pike, Clayton W., instructor in electrical engineering, University of Pennsylvania, Philadelphia, Pa.

Robb, Wm. Lispenard, professor of physics, Trinity College, Hartford, Conn.

Applications for transfer from associate to full membership, as follows, were approved:

Smith, T. Carpenter, firm of M. R. Muckle, Jr., & Co., Philadelphia, Pa.

Taintor, Giles, assistant electrician, N. E. Tel. & Tel. Co., Boston, Mass.

Pattison, F. A., firm of Pattison Bros., consulting and constructing electrical engineers, 135 Broadway, New York.

THE FRANKLIN EXPERIMENTAL CLUB.

THE Franklin Experimental Club, of Newark, N. J., has changed its regular meeting night from the second and fourth Tuesdays of the month, to the second and fourth Saturdays in the month. There has been a considerable increase in the membership of late and a committee has been appointed to look for larger and more suitable quarters, the club having outgrown its present facilities. Among the subjects that have been taken up at the recent meetings, are "Induction," "Construction of Transformers and Applications of Alternate Currents," "Vibratory Phenomena." A series of talks illustrated by experiments are now being given upon the latter subjects by the various members, illustrating in a most interesting way the phenomena of sound, light, heat, and electricity, and their correlation.

THE BOSTON ELECTRIC CLUB.

MR. R. F. ROSS, secretary of the Boston Electric Club, writes us:

It having been announced in some of the electrical journals that "the New England Electric Club is to be formed to take the place of the Boston Electric Club," will you kindly, in justice to the Boston Electric Club, state in your next issue that such is not a fact. The Boston Electric Club is not dead, nor have we surrendered our charter. We have simply given up our permanent headquarters and disposed of our furniture and effects. Henceforth the club will be perpetuated in the form of monthly dinners, lectures, etc. Our constitution and by-laws have been revised, annual dues reduced to an almost nominal figure, and such other changes made that we think will tell beneficially, and on the first Monday evening in January (the 4th), we propose having our Inaugural Dinner. I know nothing of the New England Electric Club except what has been published nor, have I seen any one who can tell me anything about it.

College Notes.

ELECTRICAL ENGINEERING AT THE A. & M. COLLEGE.

THE trustees of this college (Birmingham, Ala.) are keeping in progress with the age, and have established a Special School of Electrical Engineering and equipped a laboratory with different styles of dynamos and electrical appliances for instruction in the applications of electricity. We are indebted to Prof. A. F. McKissick for an interesting little pamphlet on the subject. The equipment is still small, but it is the intention of the Alabama Polytechnic Institute to build it up year by year.

Reports of Companies.

THE CARD ELECTRIC MOTOR CO.

CHANGES in the management of the Card Electric Motor Co. during the last few days started the rumor that this company had failed; in fact such information was telegraphed to a number of cities. However, THE ELECTRICAL ENGINEER, having a representative in the vicinity, immediately took steps to ascertain the true state of affairs. It seems that the entire concern has been purchased outright by Mr. J. W. Wilshire, with a view to its immediate re-incorporation under the laws of Ohio, it having been heretofore under the laws of Kentucky. Mr. Dixon, the efficient general manager of the old Card Company, will remain in that capacity with the new organization. The wealth of the individual stockholders of the Card Electric Motor Co. made it seem incredible that the house was going into the hands of a receiver. In the meantime we are informed that most of the creditors have only recently received checks in full settlement of their accounts—another very good indication of the condition of the company's finances. Mr. Wilshire expects to have things running along smoothly under the new regime in the course of a few weeks, and in the meantime the factory is working "full blast" as usual.

Appointments, Etc.

MR. W. H. GIRVAN, general superintendent of the Central New York Telephone Co., with headquarters at Syracuse, has handed in his resignation, to take effect Dec. 31. The resignation has been accepted, and Walter W. Nicholson, of Utica, has been appointed to fill the position. Geo. W. Wood, who has been division superintendent in Herkimer county, with an office in Little Falls, will succeed Mr. Nicholson as division superintendent for Oneida, Madison and Lewis counties. Mr. Nicholson, the new general superintendent, is a son of General Manager Charles A. Nicholson, of Utica, formerly of Rome. He will have his office in room 46, Mann Building, Utica, on the same floor with the executive offices of the company.

MR. GEORGE ALBREE has assumed the duties of superintendent of the Boston division of the New England Telephone Co., relieving Mr. Denver, who will continue to serve as assistant to Mr. Keller.

MR. HOMER E. MASON has succeeded Mr. H. A. Wyckoff as superintendent of the Delhi Electric Light Co., of Delhi, N. Y.

Personal.

MR. GEORGE NORTH, M. I. M. E. and A. I. E. E., who has been for some years general manager of Woodhouse & Rawson United, Limited, the well-known electrical and mechanical engineers of London, England, has resigned his appointment in order to commence business as a consulting engineer, valuer and arbitrator, at 90 Queen street, London, E. C. A special feature of Mr. North's business will be the purchase, sale and development of new patents and inventions; and he will also act as London agent for mechanical and electrical specialties.

Obituary.

W. H. BAUER.

MR. W. H. BAUER, one of the oldest telegraph operators in the country, died on December 14, at his residence, Baltimore, Md., of pneumonia. Mr. Bauer was 73 years of age and had been an operator since 1846. He worked for the Southern Telegraph Company until its amalgamation with the Western Union, when he went into the employ of the Baltimore and Ohio, where he remained up to twelve years ago, when he returned to private life. Mr. Bauer took an active interest in Masonry. The son of the deceased, Mr. Alexander H. Bauer, the electrical engineer of the Pullman Car Company, came on from Chicago to attend the funeral. Mr. Bauer was buried with Masonic honors.

Letters to the Editor.

REACTIVE COILS AND THE RIES REGULATING SOCKET.

IN your issue of Dec. 16th, Prof. Elihu Thomson, in commenting upon Mr. Otis K. Stuart's article on "Reactive Coils," published in your issue of the previous week, takes occasion to criticise the results obtained by the Ries Regulating Socket, kindly referred to by Mr. Stuart as being probably the most interesting application of the reactive coil principle, and at the same time endeavors to show that he anticipated the invention in his patent No. 428,647, and states that he had in operation some years ago several such "regulating arrangements" in his house in Lynn.

In view of Prof. Thomson's own admission that the principle involved in the construction of reactive coils was known many years before he was born, and in view of the fact that not only reactive coils, but reactive coil regulators were well known in the art and had long since been used by myself and others for regulating the flow of alternating current to incandescent lamps and other translating devices, it is scarcely necessary for me to say that a patent describing a specific improvement in reactive coils, as does the one referred to by Prof. Thomson, is not only something entirely different from a regulating socket, but scarcely amounts to an invention over the prior art in view of the earlier patents to Hopkinson (Eng. 3,362 of 1881) and others, showing substantially the same arrangement.

The use of reactive coils for regulating groups of lamps, of which Thomson's patent referred to is an example, has been customary in isolated cases almost since the introduction of the alternating-current system of lighting in this country, as exemplified by the well-known but somewhat bulky "stage regulator" in common use; and it is quite probable that the "regulating arrangements" used in Prof. Thomson's house were of this character. I venture to say (and I am supported in this assertion by Prof. Thomson's closing sentence) that, despite the professor's ingenuity and varied experience with alternating-current apparatus, he had not only never made, but had never even *thought it possible to construct*, prior to the time he experimented with the Ries regulating socket, a reactive coil small enough to go into a lamp socket and yet perform the work required of it as thoroughly and efficiently as this socket does it.

In regard to Prof. Thomson's statement that the economy effected by the Ries regulating socket is "problematical," all that need be said is that if the professor had taken the time to measure the amount of energy consumed by the lamp and socket at the lower stages of light, upon one of his own wattmeters (provided he had one sensitive enough to measure it), and compared the result with the number of watts consumed by the same lamp at full candle power, he would have found this method of regulation to effect a very considerable and most surprising economy that would at once have settled any lingering doubts he may have had on this question. Of course, it is well known that, as stated by him, a certain amount of energy is absorbed in heating the filament before it reaches the incandescent stage, but it is a fact not so generally known that the energy thus absorbed forms an exceedingly small fraction of the total number of watts required to raise the lamp to full candle power.

While the writer is not as yet at liberty to go into a detailed description of the socket, he may say that by its use he has been enabled to burn from eight to ten 25 c. p. incandescent lamps at a dull red glow, sufficient to enable one to locate the position of each lamp in the dark, at a consumption of less energy than was required to burn one of these lamps at full candle power. As the light is turned down, not only the current, but the electromotive force at the lamp terminals necessary to pass this current through the filament, is reduced. And since the efficiency of the socket itself, owing in part to its peculiar construction, is almost perfect under the conditions noted, the amount of energy consumed in producing this light is exceedingly small.

It is true that lamps are much more efficient when burning at high than at low candle powers, but this fact, if it has any bearing at all upon the socket, only makes it the more valuable, for the reason that the socket is not merely capable of burning the lamp at its normal brilliancy or candle power the same as any ordinary socket, and is ordinarily intended to be so used when the usual amount of light is desired, but because by its use the consumer is enabled to burn his lamps, if the latter are of the proper voltage, *above* as well as *below* their normal candle power. It will therefore be seen that by means of this socket the consumer is not only entirely independent of the variations of potential that are constantly occurring on the line from occasional overload and other causes, and which frequently prevent him from obtaining sufficient light, but he is enabled at all times to obtain a maximum amount of light, when much light is wanted, at a higher lamp efficiency and therefore at a proportionally less cost per candle power for current, as well as to turn down the light and thus save both current and lamps when less light is desired, or to keep ome of his lamps burning at a still lower degree of brilliancy during the entire night where, under the present conditions, they would be turned out altogether. In short, this socket gives the consumer complete control of his own lamps, and for the first time places the incandescent electric light upon an equal footing with gas, in that it permits him to burn much or little light, as he may desire, during the time his lamps are in service, and at a cost for current directly proportional to the energy consumed.

The history of invention shows that it is an exceedingly simple matter after a thing has been successfully done, to see how something else *might* have been made to do the same thing. But the fact remains that, despite the great demand that exists and has always existed since the invention of the incandescent electric lamp itself, for a simple and efficient holding device that would permit of turning the lamp up and down without waste of current, and despite the further fact that reactive coils of the ordinary type have been for several years in almost daily use by many of the most prominent electricians and experimenters of the world, and have occupied a foremost place in nearly every electrical laboratory and workshop, it has nevertheless remained for the writer to produce the desired article to successfully supply this demand by the invention of the Ries "Regulating Socket." It is perhaps needless to add that alternating current incandescent lighting is already beginning to feel the impetus that this socket has given to it, and that not only the public generally, but central stations supplying current on the meter system, are reaping a decided benefit therefrom.

ELIAS E. RIES.

BALTIMORE, MD., December 17th, 1891.

THE HUM OF MOTORS.

I WAS much interested in the article by Mr. Charles J. Hayes entitled "The Hum of Motors," which appeared in your issue of December 16, 1891. I have been much puzzled to find a satisfactory explanation of the phenomenon which he discusses, but I am forced to confess that I am unable to understand his explanation of the cause.

Sound-waves in the air are necessarily either set up by the movement of some body surrounded by, or in contact with the transmitting gas, or set up by some force or forces other than those derived from motion. If sound-waves are derived from motion, that motion must be one capable of moving the surrounding air.

Mr. Hayes explains at some length a possible raising or distortion of the armature under each pole-face which, he thinks, though ever so slight, would be capable of setting the air in vibration, as the rotation of the armature shifts the points of distortion along the surface of the armature. In his words: "Now, by revolving the armature it will be seen that every part of its circumference will be brought in succession in front of each of the poles, and, consequently, attracted and slightly raised as it passes, producing a progressive undulatory movement of the iron, like waves on a body of water."

Mr. Hayes' waves, like his hypothesis, may be progressive, but they are not *sound*, and, indeed, I may add they are not even progressive, since it is merely the particles of the armature that progress. The undulatory distortion is fixed in space. His simile of waves on water would better be those fixed waves that one sees on some swiftly flowing rapids where no movement exists save that of the moving particles that lie within the fixed contour of the whole body.

As there can be no movement of the air produced by such fixed undulations, I am unable to find in his supposition any cause of the phenomenon of the hum of armatures. It is this point that I would beg him to elucidate, as, till he does, his speculations are hardly entitled to rank with the less plausible but perhaps more admissible theories already somewhat numerous.

HAROLD BINNEY.

NEW YORK.

THE BURNET ROSETTE AND SWITCH.

IN the early days of the electric light business we learned that the way to invent a dynamo was to take the other fellow's machine and paint it red. This is good doctrine and has been generally accepted and widely followed. Once in a while, however, it happens that the inventor neglects to apply the saving coat of red paint, and I wish to call attention to a very flagrant case of the kind. In the issue of THE ELECTRICAL ENGINEER for December 9th, appears an article with the above heading written by H. W. Burnet, describing a rosette and switch which has been advertised and sold by the Electrical Supply Co. for about a year. As the article referred to does a slight injustice to my company I wish to state the facts as a matter of justice.

The original of the rosette switch in question was designed by me, and the drawing is now before me, bearing date January 18, 1889. It is designated "Ceiling Cut-Out with Off and On Switch," to be operated by one pendant cord. Nothing was done with this until in the summer of 1890 I ordered from Mr. Burnet, for the Electrical Supply Co., two or three models, and later 500 of the cut-outs, which are identical with the half tone shown on page 622 of THE ELECTRICAL ENGINEER of December 9th, 1891. I learn from the *Patent Office Gazette* that Mr. Burnet has applied for and received a patent on this device. This he is entirely welcome to keep for what it is worth, as the particular mechanical action involved has been superseded by a simpler and more satisfactory one.

The whole thing is of the very slightest importance. Sensible inventors are not in the habit of taking out patents on this class of mechanism at all, very much less going out of their way to patent other people's inventions of such small value. I would not waste space and time in calling attention to the matter at all, but for the particularly brazen nature of Mr. Burnet's assumption. In my small experience as an inventor, it has not fallen to my lot before to meet with any one willing to accept orders for models, to build the same according to instructions, to fill an order for goods in quantity built according to such models, and afterwards claim the whole thing and apply for a patent.

CHARLES WIRT.

CHICAGO, Dec. 12, 1891.

Legal Notes.

INCANDESCENT LAMP LITIGATION—THE UNITED STATES ELECTRIC LIGHTING CO. vs. THE EDISON LAMP CO.

ARGUMENT OF FREDERIC H. BETTS FOR THE EDISON COMPANY.

MR. BETTS in opening the case for the defence, remarked that his brother Kerr in his opening as well as in his concluding remarks had made a statement with which he thought he ought to begin; namely, that the case was one of strong equity on the part of complainant. He could not but disagree entirely with that statement. Let us—said Mr. Betts—carry ourselves back and try to appreciate the true status of the several inventors at the time when this invention was made.

About the year 1877 the whole world of electrical thought had been intensely interested in the problem of the production of electric light by incandescence. Many inventors, both in this country and abroad, had been struggling with this problem for more than 30 years. The whole atmosphere of thought had now been quickened by a sense of some impending discovery, which should render practical the dreams of inventors and scientists. Fontaine had in many respects fairly stated the condition of the affairs existing at the time he wrote. He said :—

> Lighting by incandescence has been studied for a long time; but its application generally presents so great difficulties that at the present day it may be considered as within a purely scientific domain, although a certain number of apparatus exists working moderately well.

That had been the condition of affairs in 1877. The best result which had been attained, according to Fontaine, had been an average duration of the carbon of 21 minutes, but in no case had its length of life been greater than two hours. It would seem, therefore, that had anybody really invented anything tending to materially increase the life of the incandescent lamp he would not have been slow to have communicated that momentous discovery to those who were able to appreciate the importance of such an invention. Weston, the patentee in this case, was a well-known electrician, who is and has been for many years an expert. He had been equipped even at that time, with all the requisite facilities for construction and experimentation. He was an expert in words too, with a remarkable facility of stating in the most favorable way to himself any claims which he might put forward. Upon the face of this case there stood out one most important fact. There was no contemporaneous record of the experiments which Weston is alleged to have made. On the contrary, the evidence of the witnesses who have testified in support of his contention wholly fails to corroborate him in respect to the most vital points. He contended that Weston stood wholly alone in his endeavor to prove that he had perfected a process of treating carbon conductors, or that he had applied that process to the making of conductors of incandescent lamps, at the early date assigned by him, the summer of 1877; or that he had then in fact acquired any knowledge or made any discovery in advance of that which the world previously possessed.

Very different was the way in which other inventors had acted in regard to this same invention. Sawyer and Man had been proved without contradiction to have practised this process of making carbon as early as the 6th of March, 1878. They had filed an application for a patent accompanied by a model which contained a treated carbon. Their patent had been issued June 25, 1878. October 15, 1878, they had filed an application for the process of treating carbons, which had been granted January 7, 1879. Weston's application had not been filed until two years and four months afterwards. Sawyer and Man had exhibited their lamps in the most public manner. Large numbers had been invited to see them. The process of hydrocarbon treatment had been employed in their factory. It had been fully described and illustrated in publications more than two years before Weston had applied for his patent. Another inventor, Maxim, testified that he had also practiced this process, that he had made such a lamp as early as June, 1878, and that he had filed an application for a patent in October, 1878. It was idle for complainant to contend that Maxim had not appreciated what he was doing. Maxim had been the electrician of the United States Electric Lighting Company. They had prosecuted his application. They had asserted him to be the first inventor. An interference had been declared between Maxim and Sawyer and Man, in which Sawyer and Man had been successful and had been declared the prior inventors. Maxim had thereupon dropped the contested claim. In June, 1880, the United States Company commenced making lamps. All through 1880 they had made lamps at Bridgeport and late in that year they started up a plant of lamps, lamps made by Maxim and not by Weston. The United States Company were then exploiting Maxim's invention, as appears by an article in the record from the *Evening Post*. Not until the spring of 1881 was Weston first heard of in this connection. Mr. Curtis in his testimony has said that it was in February or March, 1881, that he first formed the acquaintance of Weston. Mr. Betts then read from the testimony the history of the unsuccessful negotiations with Sawyer and Man in relation to this invention. This was in the spring of 1881. Weston had done nothing to get his invention into public notice, while Sawyer and Man had done everything they could do, by patenting, publishing, and manufacturing lamps as well as they could manufacture them. The United States Company had tried to get a license from them and it was only after it had failed to do so that Weston had first been heard of. In a conference in 1881 between Curtis and Weston, Weston had made the claim that he was the inventor. In 1881, after the public had for two years been in possession of the full knowledge of this invention an application had been filed in behalf of Weston. Subsequently, it did not appear when, the Sawyer and Man patents had also come into the control of the Westinghouse Company, which also now controlled the United States Company. Now it had become very important to belittle everything that Sawyer and Man had done, for by means of a patent granted in 1885, this complainant company would obtain control of the invention for a much longer term. There was nothing to show that the application of Weston had ever been thought of by him or by anybody else, until the exigencies of this complainant had compelled it to have an application for a patent made in the name of Weston.

His brother Kerr has contended that the work of Maxim had eventuated in nothing practical, but he did not think that the facts would sustain him in his contention. The first commercial plant had not been made by Weston, nor did he have anything to do with it. He (Mr. Betts), asserted that the public derived a practical knowledge of this invention, not from Weston, but from somebody else. By way of emphasizing this state of facts he would refer to the stipulation in the record. Depositions taken in a suit on the Sawyer and Man patent had been stipulated into a suit on the Weston patent and the suit had been brought on that patent, because it had the longest time to run. It had been admitted by Mr. Pope, the complainant's own expert, that no less than four prior patents—two English and two United States patents—contained a full disclosure of the invention, or sufficiently full at least, to enable a person skilled in the art to practice the invention.

Such a state of facts—continued Mr. Betts—puts upon the complainant the burden of proving, with the utmost certainty and beyond all reasonable doubt, that Edward Weston had completed the invention before any of these others inventors.

Another feature which he should refer to showed that there was no great equity in this case. The Edison Lamp Company did not use this invention in commercial practice. There was proof of a course of experimentation, of a few weeks, or a few months; the making of a few thousand carbons at the lamp factory in 1884 and 1885. There was not one particle of proof that they had ever put one of these carbons into a lamp. The process had been abandoned; it had never been used in a single commercial lamp from the beginning down to the present time. The Edison lamp was made of bamboo, carbonized in a furnace and then electrically heated in a vacuum to drive out occluded gases. It was sealed up by electrically heating, not in a carbonaceous atmosphere, but in a vacuum. The witnesses had testified as to the number of carbons treated; some 20,000 others 9,000, and so on, figures which might sound large, but which were wholly insignificant in view of the fact that at the present time 25,000 lamps per day were being manufactured with untreated carbons, so that the whole amount testified about actually did not amount to one day's commercial production. The defendant had been prosecuted for a mere experimental use of a process which had never been used in its commercial manufacture.

There were three propositions of law to which he should ask his Honor's assent as applied to the facts of the present case.

First.—He is the first inventor, in the eye of the law, who reduces the invention to a fixed, positive and practical form; for until he has done this he is not in a position to give to the public what it has a right to demand. In a race of diligence between two inventors, he is not the inventor who first conceives the possibility of producing a certain result, but he who so perfects the invention that its utility, practicability and success, for the purpose for which it is intended, is actually demonstrated, or is capable of being demonstrated to those who see it. *Second*, if the party first to conceive and subsequently to reduce the invention to practice. does not use reasonable diligence in asserting his rights, and in the meantime the public derives a knowledge of the invention from other sources, or if by other inventors the public have been put in possession of the invention by public use or sale, he loses his rights. *Third*, when the burden of proof is upon a defendant to establish the date of his invention and patent, his proof must be of such a character as to be beyond all reasonable doubt. The rule is the same as against the plaintiff, when once the defendant, as in this case, has succeeded in shifting the burden of proof, by establishing beyond a reasonable doubt that some party other than the plaintiff's patentee, had, prior to the date of the patent, made the same invention. The burden of proof being thereby shifted, it becomes incumbent upon Weston and those claiming under him to adduce the most positive proof in support of his contention. Mr. Betts read from the opinion in *Thayer* vs. *Hart* (22 Blatchf., 229) which, he contended, applied precisely to the present case. He contended also that the evidence in behalf of Weston had proved nothing more, at most, than the performance of some abortive, inconclusive, and uninstructive experiment.

Mr. Betts next proceeded to analyze the patent in suit. He said that the preamble was almost exactly plagiarized from Sawyer and Man's English patent. Weston had nevertheless recognized the state of the art as shown in Despretz's experiments. He then read an account of Despretz's experiments, as published in the *Chemist* in 1849-1850, in which carbon rods had been electrically heated in a hydrocarbon atmosphere, and said that the statements of the experimenter showed precisely what the effect would be in all cases.

A careful perusal of the specification showed that it drew a distinction in the result or stated two different results; first, the filling up of the pores, rendering the carbon more dense and reducing its resistance, and second, building up the surface, or if irregular in diameter or resistance every part of the carbon is made of equal resistance or diameter. His Honor would find that the claim of the patent had been carefully limited to the process of "building up", and had moreover been so limited by the Patent Office. It was not for a general, but for a particular use of the process for building up the carbon. Next he would refer to the file-wrapper and contents and see what Weston's original claim was:—

The method of preparing carbon and conductor for incandescent lamps, by electrically heating them while surrounded by or saturated with a carbonaceous substance, as described.

His Honor would note that this was much broader than the claim which had afterwards been substituted, and had been made so in view of the publication of Despretz, which had been cited against it as an anticipation. He contended that this change materially narrowed the scope of the claim. Apparently the attorney had become satisfied that it was so broad he would not like to risk it, and so he had limited it to a process of building up imperfect carbons. The significance of that point was, that there was not one particle of proof that the defendant had ever utilized the process for building up imperfect carbons. All the witnesses had said it had been used "for drawing down resistance." The carbons were perfect—so perfect that the Edison Company to-day made all their carbons in this way without any treatment whatever.

The claim was for the treatment of carbon conductors *for incandescent lamps*. What force ought to be given to those last three words? The Despretz patents had been cited against Sawyer and Man. The English court had said:—"Yes, perhaps Despretz had described the same process; but it having been proved that Sawyer and Man had made a lamp, and had placed the carbon in it, had they not done something more?" Those three words must either be erased as superfious, or they must be left in and a limiting effect given to them. If the patentee had never succeeded in making an incandescent lamp, how could be be said to have made a discovery or invention in incandescent lamps? He must show that he had successfully applied it in that way, yet the evidence had shown that he had not invented a practical lamp until 1881, and meanwhile Sawyer and Man had made lamps, and Maxim had made lamps, which were perfectly successful. It was not Weston who had done it. Those three words therefore "for incandescent lamps" had placed Weston in this dilemma:—If he claimed to have made the invention when he electrically heated the carbon in oil, he had made no advance on Despretz; or if he claimed to have been first in the use of the process as applied to incandescent lamps, then he was not the inventor, because in that respect Sawyer and Man and Maxim had both preceded him. The Sawyer and Man lamp had been fully described and illustrated at the time in the *Scientific American*. The difficulty with this lamp had been twofold. First it had not a filamentary carbon, which was necessary in order to achieve commercial success, and second, it was not an all-glass lamp. It had a metal base, which was subject to leakage. Nevertheless a test made by Stowell of the Sawyer-Man lamp had shown a life of 36 hours. This had been a reduction to practice, although the lamp had broken down from too much current. Mr. Betts then read from the *Scientifi American* of March 8th, 1879, an article which, he contended, was a full disclosure of the process, two or two and half years before Weston had made his application. On the 14th of October 1878, Sawyer and Man had sold to the Electro-Dynamic Company a considerable number of patents together with the process in controversy, and the patent for the process had been assigned to the same company on February 3, 1879. What better evidence could there have been of the "sale" of the process more than two years prior to Weston's application? Mr. Betts read from the statute as to the effect of a prior sale, and asked what better evidence there could be of the "sale" of the thing patented than the fact that it had been sold. It was not material that they had not sold lamps. To manufacture and sell lamps required a large amount of capital. Newspaper articles had been published virtually offering the invention for sale. In connection with an invention of this class he knew of no better evidence that it had been "on sale".

The invention of Sawyer and Man had been embodied in a lamp so early that a patent had been granted in June, 1878. The defendants had met the obligation placed upon them by the rule of law and had shifted the burden of proof upon the complainants. Weston must now prove that he had made the invention in a fixed, positive and practical form, at an earlier date than Sawyer and Man. He would call attention to the fact that the complainant's evidence upon this point was exceedingly weak. Quimby was a patent solicitor and an expert, but there was not one word in his evidence about the making of an incandescent lamp. He had only said that the invention was useful for an incandescent lamp. Weston had never suggested to Quimby, so far as the record showed, that the invention was useful for incandescent lamps, nor had Mr. Quimby ever seen an incandescent lamp. Despretz thirty years before had done everything that Quimby saw. What was there that had advanced the sum of human knowledge one iota, in what Weston had shown Quimby? Then there was the evidence of Broadbent. Weston had not said to him that it had to do with incandescent lamps. Another significant fact:—Page, now one of the attorneys for the complainant had acted as Weston's attorney. In 1881 Page had only known him as connected with dynamo machines, arc lamps and plating apparatus. He would submit that Weston's contention was not consistent with the probabilities of the case. If Weston had ever done anything that he had regarded as of importance why should he not have communicated it to Quimby or to Page? Now they could appreciate the importance of the testimony of the witnesses which defendant had called in rebuttal. Huber, a man of great intelligence employed in the same establishment, had testified that he had seen nothing of the alleged invention nor had he seen any incandescent lamps. It was possible and even probable that he might not have seen a temporary or casual experiment, but his testimony had shown conclusively that there could have been no continuous experimentation nor diligent effort to reduce the invention to practice. The evidence had shown that Weston could not have made any invention which he himself had regarded as of any importance, for if he had done so his people all around him must have seen something of it. If he had done what he now says he had done, it was a matter too important to have been hidden under a bushel.

Again the dates were of great importance. There was no dispute as to what Sawyer and Man had done in March, 1878. It wouldn't do for Weston to say in a vague way: "I did the same thing in 1877." He must satisfy the court that there were good reasons for his saying that he had done this in 1877. A critical examination showed that he came very far from sustaining such an allegation, either by his own or by corroborative evidence.

As to the question of infringement it had not been proved that the invention had ever been used or had ever been sold by the defendant company. Mr. Betts read from Robinson on Patents, patent and other authorities, in support of the position that experimentation, merely in order to ascertain whether the process would really reduce the resistance of carbons, was not an infringement. No case of infringement had been made out.

Mr. Betts then reviewed the proof adduced in behalf of Sawyer and Man, and contended that it clearly showed that the public had been put in full possession of the invention and of full information in respect to the invention. Referring to the contention of the complainants that the exhibitions made by Sawyer and Man for purposes of display or for exploiting their electrical enterprises did not constitute the public use, Mr. Betts said that such a criticism came with peculiarly bad grace from those who sought to uphold Weston's invention. Surely Sawyer and Man had proceeded much farther than ever Weston had, for Weston had admitted that he had never made a lamp that lasted two hours. Sawyer and Man's lamp was very far from being as perfect as modern lamps, but it nevertheless was a great improvement upon its predecessors. The criticism that Sawyer and

Man's lamp never went into practical use, also came with bad grace from complainants. There had not been a particle of proof that Weston ever made a practical lamp until after it had been done by others. Maxim had commercial lamps in use in 1880. Sawyer and Man had long before that put the public in possession of the invention. The more the beauty and utility of the process became apparent, the greater became the improbability that Weston had made the invention. During the period referred to he had taken out 16 patents relating to other electrical inventions, and there was in them not one hint of a discovery of this kind. The testimony of three witnesses, his intimate associates, had been such as to preclude the possibility of any continued experimentation. It was impossible that these people should not have seen some evidence of such a discovery as complainants now claim.

Mr. Weston does not fix any date by himself or witnesses with sufficient accuracy to satisfy the courts of his priority. He has entirely failed to meet the requirements of the statute in that respect. Mr. Quimby's testimony that he saw the experiment in the basement of the "church" building, renders it important to know when Weston had his laboratory in that building. Weston fixes the date some time between the organization of the Dynamo Electric Company and his removal, and his memory, induced perhaps by his wishes, made him fix the date of his removal in 1878. The rent receipt, in the absence of any statement to the contrary, may be fairly assumed to have been for rent paid in advance, so that the date for removal cannot positively be put prior to October 1, 1878. The testimony of Quimby was very vague. He was favorable to Weston and he tried to fix the date in 1877, but was it reasonable to suppose that Quimby had any accurate recollection of the date when he saw the experiment? Would such evidence as his satisfy the obligation on the part of the complainant? He would submit that complainant had wholly failed to meet the burden of proof which had been laid upon them in this respect.

Mr. Weston had not regarded the invention as solely applicable to incandescent lamps. If he had been experimenting as a matter of scientific curiosity he had not gone beyond Despretz, for if there was any invention it must have lain in the application of the discovery to a practical purpose. Mr. Weston in 1877, had been a large manufacturer of arc light carbons. How was it that an invention useful in the very line of his business had never been so used, if he had actually made it? There was no explanation other than the explanation that Weston had never done anything at that time which he had regarded as important. Complainant must stand wholly on Weston's uncorroborated statement.

This process of treating carbons in oil or in gas evolved from oil, had never been practiced in a commercial way. The thing that was done in many incandescent lamp factories was the treating of the carbons in attenuated hydrocarbon gas, and this was found in Maxim's patent. The testimony of Vandegrift, or Shallenberger, and of Smith, all prove that carbons were always commercially treated by gas, so that it appeared that if the invention had been left where Weston has it nobody would have ever used it. It lacked the details which would render it of commercial utility. But Weston had described no apparatus for treating carbons in gas, much less in attenuated gas; on the contrary he had described a process which never had been used and was of no commercial value. Mr. Betts then commented further upon the evidence of Mr. Weston, and contended that he had wholly failed to make out a case entitling him to the favorable consideration of the court. Edison had patented a carbon filament lamp in January, 1880, and the court had declared him to be the inventor of the practical incandescent lamp. If Weston had made an incandescent lamp in 1877, why had he not been called as a witness in these important cases?

As to the question of what constituted "public use and sale," Mr. Betts said that he did not think what Maxim had done amounted to a public use and sale within two years. But as to Sawyer and Man, it was another matter. The cases which had been referred to by the other side were those in which the courts had dealt leniently with an inventor who had made his best efforts to put his invention in the market. But in the present case Sawyer and Man had certainly given to the public the fullest information in respect to their process There had been no secrecy about it. When the invention was a process, it was certain that nothing could more fully put the public in possession of it than the publication of a full description of it in the scientific journals.

Mr. Betts contended that the evidence showed conclusively that in his opinion awarding priority to Weston over Sawyer and Man, Commissioner Butterworth had overlooked the question of public use No such question had arisen as between Weston and Maxim, but he thought there was ground for holding that there had been abandonment on the part of Weston. All the time in which he had been doing nothing, other inventors had been at work, and had repeatedly described the invention in patents and in publications, and this he thought was sufficient to show that intervening rights had accrued. Despretz had certainly published what the result would be upon a carbon thread or rod heated to incandescence in a hydrocarbon atmosphere. He submitted that it made no difference what relation this had to the subsequent invention of others. The results of Despretz were in all substantial respects the results described by Weston. He certainly did not think that Weston was legally entitled to any patent for this invention.

RIGHT OF NEW STREET RAILWAYS TO USE EXISTING TRACKS.

THE Supreme Court of California, has disposed of the well-known case of the Pacific Railway Company et al. against Judge Wade of Los Angeles in an elaborate opinion. The public interest was incited by an argument for a writ of prohibition against Judge Wade to prevent him from assessing the amount of damages for and granting the right of way over the street cable road of the petitioners to the Los Angeles Consolidated Electric Railway Company. The gist of the decision is embodied in the following: "There can be no private property in a street, except the fee of the owner, which is held subject to the easement as long as the public continue to use the street as a highway. The maintenance of horse railroads and running of cars upon public streets of the city of Los Angeles for the carriage of passengers is a mere special mode of using the highway, nothing more. The right to maintain such a railroad does not exclude the public from using the street. The opinion therefore sustained the action of Judge Wade and held that the property of the petitioners is in custodia legis, and therefore the court can grant a right of way to any person or corporation and assess damages and compensation to be paid therefor, without citing or consulting the corporation, but simply upon the application of the receiver in possession of its property. The writ of prohibition against Judge Wade therefore was dismissed."

Literature.

Modern Practice of the Electric Telegraph: A Technical Handbook for Electricians, Managers and Operators. By Franklin Leonard Pope. Fourteenth edition. *New York. D. Van Nostrand Company*, 1891. *8vo. pp. xii*, 234. Price, $1.50,

THE first edition of Mr. Pope's useful and popular manual is dated 1869; a somewhat remote antiquity in electrical history. Telegraphy was then almost the sole electrical art of public significance, and some of its finer achievements were yet to come. The duplex was not yet commercially available, and the quadruplex had not arrived. In successive editions the author has kept "Modern Practice" fairly abreast with telegraphic progress, and in the case of this last edition the book is virtually rewritten and much expanded. The first edition had 128 pages; the thirteenth 160; while the book now has 234. In its original form it is familiar to most telegraphers of twenty years' standing; as recast and enlarged it well repays perusal by old acquaintances as well as by the younger men of the telegraph service. The well-ordered arrangement of numbered paragraphs and of chapters, characteristic of the first edition, has been preserved so far as the necessary introduction of new matter would permit. As before, the author has limited the scope of the handbook to the Morse signaling system, excluding type-printing, synchronous-multiplex, automatic, submarine and other methods. The duplex and quadruplex systems, now so widely employed, are amply and very lucidly described and explained; their principles of action are set forth with great clearness. A number of pages in chapter viii (Equipment of American Telegraph Lines) are given to the application of dynamos to telegraphy, a method of supplying current that has transformed the old-time battery-room of such a station as that of the Western Union Company in New York—with its endless rows and shelves of blue-stone batteries—into the semblance of a compact machine shop.

In no instance is the amplification of Mr. Pope's book more noticeable than in chapters iv, v and vi of the new edition, which treat upon the theory of electrical measurements, the laws and conditions of electrical action and of electro-magnetism. These topics, which scarcely entered the thoughts of American telegraphers a generation ago, and which were allowed but a meagre space in the early editions of "Modern Practice" (the first of which appeared but a year or two after the introduction in America in a small and tentative way of systematic line testing), are here treated with a fulness quite adequate to the requirements of those engaged in our now greatly improved telegraph service. The theoretical and technical points are perspicuously set forth in relatively simple but accurate language, the nomenclature being adapted to the best existing usage. There is also included due reference to the more recent views and speculations as to the nature of electricity. The author's cleverness in illustrating his descriptions and expositions is manifest in the many drawings and diagrams employed throughout the book. They are not only truly illustrative of the text, but in appearance are quite worthy of the fine typography and handsome make-up of the book.

A special word should be said in praise of the consideration for readers shown by an author who takes pains to provide so ample and useful an index as that given by Mr. Pope in his last edition

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED DECEMBER 15, 1891.

Alarms and Signals:—

Electric Signaling Apparatus, G. E. Miller, 464,979. Filed Apr. 3, 1891.
An electric signaling apparatus for railway trains.

Conductors, Conduits and Insulators:—

Electric Conductor, W. E. Oehrle, 464,986. Filed Sept. 14, 1891.
An insulated conductor for electric light wires.

Coupling for Electric Conductors, W. C. Preston, 465,202. Filed Apr. 27, 1891.
Consists of a short tube adapted to hold the ends of the conductors snugly, the conductor being held in place by wedges driven into an opening in said tube.

Electric Connector, W. F. Z. Desant, 465.430. Filed May 20, 1890.

Dynamos and Motors:—

Dynamo-Electric Machine, W. P. Wiemann, 465,104. Filed Dec. 30, 1890.
A dynamo comprising metallic end plates carrying rigid field-magnet cores, a magnetizable iron mass carried by the shaft extending through said field cores, the exciting coils wound on the field-magnet cores and the armature having its cores provided with pole pieces which form multiples of the polar projections on the iron mass.

Commutator Connection for Dynamo-Electric Machines, C. O. C. Billberg, 465,233. Filed Oct. 7, 1890.
Provides means for readily detaching the armature wires from their commutator strips for purposes of repair, etc.

Brush Holder for Dynamo-Electric Machines or Motors, C. O. C. Billberg, 465,234. Filed April 25, 1891.
Has for its object to maintain a proper bearing of the brush at all times upon the commutator.

Switch-Actuating Mechanism for Electric Motors, C. G. Armstrong, 465,404. Filed May 11, 1891.
Relates to construction of devices for stopping and starting electric motors.

Electric Motor Switch, E. W. Rice, Jr., 465,292. Filed Mar. 28, 1889.
Has for its object to prevent damage to the electrical apparatus from a sudden heavy flow of current.

Electric Motor, H. Groswith, Reissue 11,210. Filed Oct. 26, 1891.
An electric motor having a duplicate set of elements, a common external connection to one brush of each commutator and a pair of contacts connected respectively to the two other brushes for external connection.

Galvanic and Thermo-Electric Batteries:—

Packet or Pad for Electric Batteries, L. H. Rogers, 465,206. Filed Feb. 20, 1891.
Consists in enclosing an electrolytic chemical within an envelope of porous material.

Lamps and Appurtenances:—

Portable Electric-Lamp Holder, J. Baker and H. S. Graham, 465,039. Filed Mar. 5, 1891.
Provides means for lengthening or shortening the conducting wires of an incandescent lamp.

Measurement:—

Electrical Indicating-Instrument, E. Weston, 465,442. Filed Mar. 11, 1891.
An ampere meter in which the fixed coil is eliminated and the movable coil is closed in the annular field produced between the poles as a permanent magnet.

Metallurgical:—

Process of Extracting Copper Pyrites, T. A. Edison, 465,250. Filed Feb. 17, 1890.
Claim 1 follows:
The method of concentrating chalco-pyrites ores by eliminating magnetically any magnetic material therein, while the copper and iron pyrites are non-magnetic, and then heating the remainder to such a temperature as to render the chalco-pyrites magnetic and separating the reduced chalco-pyrites magnetically.

Magnetic Ore Separator, C. M. Ball, 465,349. Filed Dec. 11, 1890.

Medical and Surgical:—

Electric Belt, A. Erikson, 465,093. Filed June 25, 1891.

Miscellaneous:—

Means for Propelling Boats by Electricity, O. Büsser, 464,955. Filed Feb. 10, 1891.
Relates to a method of towing canal boats by means of an electric motor on the deck of the boat, acting on a stationary cable sunk in the canal, and a trolley wire strung along the bank of the canal.

Automatic Circuit-Breaker, W. R. McLain, 465,046. Filed Sept. 18, 1890.
Has for its object a method of automatically increasing the break in the circuit at the instant of the melting of the fuse wire.

Riveting by Electricity, E. E. Ries, 465,089. Filed Sept. 15, 1888.
See Patent Notes.

Feed-Water Regulator, G. W. Schilling, 465,212. Filed Jan. 27, 1891.

Method of Controlling Alternating-Current Induction, E. Thomson, 465,-078. Filed Apr. 17, 1889.
Consists in varying the angle of the magnetic axis of two coils in inductive relation to a closed magnetic circuit.

Adjustable Rheostat, F. J. Sprague and C. R. Pratt, 465,218. Filed Aug. 25, 1891.
A rheostat having a large number of contact plates in the switch by means of which the resistance is varied, said plates being so mounted as to occupy a small space and provide a rapidly-moving co-operating contact.

Electrical Sewer-Gas Indicator, J. J. Lawlef, 465,278. Filed Mar. 4, 1891.
An electric signal for sewerage systems.

Electric Fan, P. Diehl and E. H. Bennett, Jr., 465,360. Filed Apr. 4, 1891.

Electric Fan, P. Diehl and E. H. Bennett, Jr., 465,361. Filed Apr. 8, 1891.
A novel arrangement of suspended ceiling fan.

Bracket for Supporting Electric Conductors, J. A. Duggan, 465,365. Filed July 15, 1891.

Production of Insulating Coatings or Linings in Electrolytic Apparatus, L. Grabau, 465,369. Filed Aug. 9, 1887.
A melting pot having a cell surrounding an electrode, the cell being open at the bottom and having double walls forming a chamber provided with a feed and exhaust port and a discharge passage connected with the neck of the cell for the discharge of the matter.

Electric Heater, W. H. Boles, 465,428. Filed Mar. 21, 1891.

Electric Switch and Case for the Same, C. P. Chappell, 465,425. Filed Nov. 4, 1891.
Method of protecting the contact plates of switches from exposure to the weather.

Mining Machine, J. C. Werner, 465,150. Filed May 11, 1891.
Claim 1 follows:
The combination of two rotary cutter bars and an intermediate rotary clearing-worm, the cutter bars operating independently of each other and of the worm.

Railways and Appliances:—

Electric Car-Brake, E. Verstraete, 465,084. Filed Feb. 5, 1891.

Converter System for Electric Railways, M. W. Dewey, 465,359. Filed May 11, 1891.
Provides cores for the primary or road-bed coils that will form and maintain closed magnetic circuits.

Train-Signaling Apparatus, P. Synnestvedt, 465,396. Filed April 27, 1891.
An electrically operated compressed air or steam train signal.

Electric Railway, G. F. Green, 465,407. Filed Sept. 15, 1879.

Electrical Railway, G. F. Greene, 465,432. Filed May 15, 1886.
See Patent Notes this issue.

Telephones and Apparatus:—

Telephone, C. Cuttriss, 464,959. Filed July 22, 1891.
A telephone receiver without electrodes. See The Electrical Engineer Dec. 16th.

Patent Notes.

E. E. RIES' PATENT ON RIVETING BY ELECTRICITY.

On Dec. 15 a patent was issued to Mr. E. E. Ries, of Baltimore, entitled "Electric Riveting," No. 465,089. This patent describes the process in which the rivets are inserted in the holes in a cold state, which are then heated to incandescence by the passage of an electric current through the same and are maintained at incandescence during the operation of heading, by which the operation of riveting is greatly facilitated. The patent contains seven claims, of which we give the three following:

1. The method or process of riveting which consists in heating the rivet when inserted in the rivet hole or holes by the passage of an electric current through the same and then heading the rivet, substantially as described.

3. The method or process of riveting which consists in heating the rivet when inserted in the rivet hole or holes to the required degree of incandescence by the passage through the same of an electric current of suitable quantity and tension, then heading the rivet and maintaining the same in the desired state of incandescence by suitably regulating the current during the heading operation, substantially as described.

5. The method or process of riveting metal structures together, which consists in first inserting a rivet into the rivet-hole, then making electrical contact between the ends of the rivet and an anvil and the heading-die, respectively, which constitute the terminals of an electric circuit, then charging said circuit with an electric current or currents until the rivet is heated to the desired degree of incandescence, and then forcing the heading-die upon the rivet until the heading operation is completed, substantially as described.

GREEN'S ELECTRIC RAILWAY PATENTS.

Considerable interest has been manifested in the issuance of two patents to George F. Green, of Kalamazoo, Mich., as they date back to the early days of electric railroading and were the subject of prolonged interference proceedings. The patents are entitled "Electric Railway," Nos. 465,407 and 465,432, December 15, 1891, and were filed respectively September 15, 1879, and May 15, 1886.

Claim 4 of the first patent is follows:

The combination of a railway track, one or more stationary means of electric supply, electrical conductors extending from said means of electric supply along the lines of said track, and consisting wholly or in part of the rails thereof, vehicles moving along said track, rotating electro-dynamic motors fixed upon said vehicles for imparting motion thereto, and wheels supporting said vehicles upon the track, and also serving to maintain continuous electrical connection between said means of electric supply and said rotating motors, substantially as described.

Claim 3 of the second patent is as follows:

The combination of one or more sources of electric supply, a railway track, a wheeled vehicle moving upon or along said track, a conducting circuit composed wholly or in part of insulated conductors extending along the line of travel of said vehicle, one or more rotating electric motors mounted upon said vehicle for propelling the same and included in said circuit of conductors, and a circuit controller placed on said vehicle, and also included in said circuit of conductors, substantially as described.

It is claimed that Mr. Green conceived his invention long prior to the filing of his patent, and that he built and operated a small model as far back as 1874, for the purpose of exhibiting his invention to capitalists and demonstrating its practicability.

ELECTRIC SMELTING—COWLES CO. vs. PITTSBURGH REDUCTION CO.

The Cowles Electric Smelting Company has filed a bill in equity in the United States Court, Cleveland, O., against the Pittsburgh Reduction Company. The bill asks for an injunction preventing the defendant company from using certain patents for smelting ores by electric currents, claiming priority for the invention and patent. It is similar to a suit filed by the Pittsburgh Reduction Company against the Cowles Company in the Cleveland courts, and is only another chapter of the bitter fight which the two companies are waging against each other.

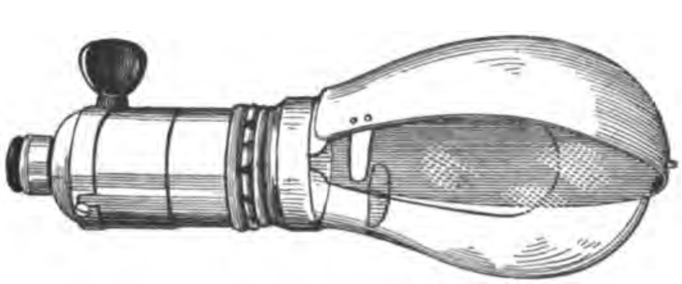
TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

Interest the public in your business by advertising its facts.

THE NOVELTY ELECTRIC CO.'S HALF REFLECTOR.

A NUMBER of interesting novelties and new designs in electric light fixtures and supplies have recently been brought out by the Novelty Electric Co., 50, 52, 54 North Fourth Street, Philadelphia. One of these, illustrated herewith, is their "No. 1 Half Reflector." It is a simple and efficient device, and very reasonable in price. The half-round reflector springs at once into position on the glass



NOVELTY ELECTRIC CO.'S HALF REFLECTOR.

bulb of any incandescent lamp, and a small hole at the lower end of the reflector engages with the little projection or "nipple" at the tip of the lamp. These reflectors are made in a variety of forms and admit the use of the ordinary shade at the same time.

BURTON ELECTRIC HEATERS.

THE Electric Merchandise Co., Chicago, has received this week an order for four sets of Burton electric heaters from the Aspen Mining Company, Aspen, Col., to be used in the company's motor stations. The Benson & Halcyon Heights Railroad Company, Omaha, Neb.; Edison General Electric Company, Portland, Ore.; Maschinenfabrik Oerlikon, Oerlikon bei Zurich, Switzerland; Newburyport & Amesbury Horse Railroad Company, Newburyport, Mass.; Warrensburg Electric Light Company, Warrensburg, Mo., are among the number of companies placing recent orders for heaters. The following letter has been received:

ALLENTOWN AND BETHLEHEM RAPID TRANSIT CO.
Allentown, Pa., Dec. 10, 1891.

BURTON ELECTRIC CO.,
Richmond, Va.

DEAR SIRS: Please ship eight more electric heaters with switches, being the equipment for two cars same as we had before. They are giving excellent satisfaction and are liked by the patrons of the road much better than the stoves.

Yours truly,
(Signed) A. H. HAYWARD, Sup't.

WALDO & STOUT.

THIS firm has just been organized at Bridgeport, Conn., for the purpose of embarking in the business of founders in aluminum, silicon and manganese bronze. The firm consists of Dr. Leonard E. Waldo, who is well known to the electrical profession from his work in the perfection of aluminum and silicon bronzes. Mr. Newton E. Stout will have the care of the business management.

The new foundries of the firm will be located on Railroad avenue extension, near the Wilmot & Hobbs factories, and a new road will at once be opened to that thoroughfare. The foundries will be devoted to making new alloys of copper with aluminum, silicon and manganese in the shape of bronze and brass castings.

The design of the furnaces is the Swedish patent furnace for casting wrought iron, and oil will be used as fuel. It has also been decided to erect very complete facilities for the proper testing, both chemical and physical, of the metal for engineering or other purposes. Among other things a contract has been made for the construction of a testing machine to break bars up to a tensile strength of 200,000 pounds.

The new company hope to get their first building completed by early summer. Their structures will be spread over an acre of land, and additions will be erected over the rest of the site as the work extends. The buildings will be constructed of brick, and on account of the use of oil as fuel the roof in the centre will be about fifty feet from the ground. Two acres more are held in reserve for future buildings. Mr. Erwin S. Sperry will act as superintendant of the factory.

ALEXANDER, BARNEY & CHAPIN.

THIS enterprising firm have been compelled for the third time since the establishment of their business, to enlarge their store to keep pace with their ever-increasing trade. They had to abandon the "Exchange" and tear down the offices formerly used by the purchasing agent and general sales agent, and add all that part to their store. New shelves and counters have been put up, and they have thereby not only gained a great deal of room, but the appearance of the store seems to be improved.

Among the many novelties shown at their establishment for the holiday season is a Christmas tree lighted by miniature incandescent lamps, which is attracting a great deal of attention in their window. It is seldom that a handsomer show is made during the holidays than that displayed by the A. B. C. Co. at the present time.

GAS ENGINES AND DYNAMOS FOR ISOLATED PLANTS.

ONE of the exhibits that attracted a great deal of attention at the American Institute Fair was a complete isolated plant composed of a 2 h. p. Hartig improved gas engine and a 16-light Riker low speed dynamo. The gas engine having two cylinders gets an impulse at each revolution, thus obviating any flicker in the electric light. The dynamo is compound wound and has a 10-inch pulley driven from the 44-inch fly-wheel on the gas engine. It runs at the low speed of 810 revolutions per minute, the gas engine making 185 revolutions per minute. The extremely low speed of the dynamo has also a great deal to do with the steadiness of the lights.

Below will be seen a table showing the actual amount of gas consumed per hour and cost for a specified number of lamps. This plant took the award of excellence at the fair.

Mr. Hartig does not claim the highest efficiency for his engine, but guarantees it to run at a more uniform speed than any other machine in the market.

Num. of 16 c. p. 110 volt lamps.	Volts.	Speed.	Gas consumed in cubic feet.	Cost per hour gas @ 1.25 per M.
16	110	810	80	10 cts.
12	110	820	60	7.5 cts.
8	110	830	52	6.5 "
4	110	840	44	5.5 "

Running free the engine consumed 20 cubic feet of gas.

THE UNITED STATES PORTELECTRIC CO.

ARTICLES of incorporation of the United States Portelectric Company, with a capital of $5,000,000, were forwarded from New York to West Virginia last week, the company having been organized under the laws of that State. The following are the incorporators: Thomas L. James, ex-Postmaster General; ex-Judge A. J. Dittenhoefer, John Straiton, Charles F. James, Percival Knauth, William James, John T. Williams, Colonel Henry Huss, Frank Lawton, and Whipple V. Phillips. The company controls a device for the transportation of mail and express packages at a high rate of speed, which, it has been reported, will probably be utilized by the Post Office Department. There has been an experimental plant in operation in Dorchester, Mass., for the past year. The *modus operandi* was illustrated and described in THE ELECTRICAL ENGINEER, May 27, 1891.

A CHRISTMAS TREE TWIG.

THE American Electrical Works have long had the reputation for taste and ingenuity in the little souvenirs they send their friends from time to time. The latest of their productions in this line is a pretty Christmas card, bearing a twig from their Christmas tree, associated with the usual good wishes of the season and the sentiment: "Heaven give you many, many merry days."

TO MANUFACTURE THE FIBROUS BATTERIES.

We have received information that the Fibrous dry battery and the disque Leclanché porous cup are hereafter to be manufactured exclusively by Messrs. Thompson & Robertson, 258 Broadway. This battery and cup, it will be remembered, have been manufactured for some time past by Messrs. Taylor & Walsh, of this city, whose interest the firm of Thompson & Robertson have purchased. The first-named member of this firm is the Hon. Roscoe H. Thompson, formerly of Boston, and the late treasurer of the Fibrone Manufacturing Company, of this city. Mr. J. Hart Robertson, under whose supervision the batteries will be manufactured, is a member of the New York Electric Club, and a well-known electrician, the most prominent of his inventions probably being the writing telegraph. Mr. Robertson, however, considers the fibrous battery the most promising of his inventions, and will give all his time to its manufacture at the company's factory in Bloomfield, N. J. Mr. Louis Walsh will be the manager of the sales department. Mr. Walsh is probably best known to the electrical trade through his connection with the Crosby Electric Company, of this city. The Fibrous dry battery is adapted for all open-circuit work, is small, being only 4¾ x 8 inches, and cylindrical in shape, and is said to be the only dry battery in the market that is not sealed. The company have already received many flattering testimonials in regard to this battery.

E. T. BIRDSALL, M. E.

Mr. E. T. Birdsall, of 115 Broadway, has been retained as the consulting engineer for the new Hotel Grenoble, a fine building to be put up by the well-known builder Noble. Mr. Birdsall will have charge of all the mechanical and engineering details, and will put in a fine electric light plant of about 1,200 lights. He has also been retained for the big new Municipal Building on Centre street, which will be at least two years before it is completed. Mr. Birdsall has of late had many calls of this nature upon his time.

PHILADELPHIA NOTES.

Mr. Chas. K. Westbrook, manager of the Isolated Light and Power Department of the Thomson-Houston Electric Light Co., announces the following recent sales and installations, viz.: Philadelphia and Reading Coal and Iron Co., Pottsville, Pa., 35 arc; Pencoyd Iron Co., Pencoyd, Pa., 50 arc; H. C. Hamilton & Son, Manayunk, 500 incandescent; So. Baltimore Car Works, Baltimore, Md., 85 arc; B. and O. Railroad Co., Brunswick, Md., 25 arc; Delaware Hosiery Co., Dover, Del., 250 incandescent; Penn. Supply Co., Wilkesbarre, Pa., 90 incandescent; Stinson Bros., Philadelphia, 45 arc; Cayuta Wheel Foundry Co., Sayer, Pa., 125 incandescent: Boyd, White & Co., Philadelphia, 18 arc; Shoneman & Bros., Eighth street, 6 arc; and a 75 incandescent plant for use on the boat of the Board of Police Commissioners at Baltimore, Md.

The Car Shops of the Bristol (Tenn.) Belt Line Railway Co., of which Mr. W. A. Stadelman of this city is general manager, were completely destroyed by fire last week, together with cars, motors, tools, etc., and are supposed to have been set on fire by tramps after having killed the watchman, Mr. John Overstreets, whose body was found in the ruins burned to a crisp and surrounded by four iron barrel hoops. The company has placed an order with the J. G. Brill Co. for new cars, and the road will soon be put in operation again. The road was of the Short system and had only been in operation about two months.

Vallee Bros. & Co. have this week completed the contract for wiring the Williamson Free School, which has been progressing for over a year. This firm have for several months confined themselves strictly to the electrical supply business, but the above contract was taken before the construction work was abandoned. They are agents for the Buckeye incandescent lamp, of which they have sold over ten thousand this fall. The agency for the Russell mast-arms has recently been awarded this firm.

La Roche Electric Co.—At a meeting of the board of directors of the La Roche Electric Works, last week, it was decided to build a factory for the manufacture of their electrical apparatus. A committee was appointed to select a desirable site which will be suitable for shipping facilities. This move was made in order to meet the large increase of business, which has outgrown the capacity of their present quarters.

The Century Electric Club has just been organized in this city for the advancement of its members in the electrical field, in which they are all engaged. The work will consist in reading papers, etc., discussions, and a regular review of periodicals.

"Star Electrix." The irresistible Mr. D. C. Spruance, of the Star Electrix Co., is home for the holidays from the West and reports the largest crop of orders ever known by the oldest inhabitants.

Curtis Bay, Md.—I was in error last week in stating that Mr. W. A. Stadelman had closed a contract with the Curtis Bay Railway Co. of Baltimore. It should have read Mr. W. A. Stearns, of the Edison Co.

Mr. M. S. Shapleigh, agent for the Electrical Supply Co., reports a large increase in business over last year. They have just put upon the market several new specialties which have merit.

Mr. S. Ashton Hand, vice-president of the Equitable Engineering and Construction Co., has gone to Chicago and other points West on a business trip.

Mr. C. A. Benton, of the Detroit Electric Works, was in the city last week on business, and took wing northward for New York.

WESTERN NOTES.

The Electric Appliance Company, as general Western agents of the Consolidated Electric Manufacturing Company, of Boston, are putting in a very large stock of their celebrated goods. Their sockets, wall sockets and receptacles are samples of the manufacturer's art. Their Davis arc light cut-out has been demonstrated as being a wonderfully practical article, and is used exclusively throughout Boston by the Boston Electric Light Company. Their arc light hanger boards, switches, etc., are very desirable articles at attractive prices. Their telescope switchboard plug and socket, with auxiliary transfer plug, fills a long-felt want. The Electric Appliance Company is certainly to be congratulated upon securing control of so valuable a line of specialties.

The Laclede Gas Light Co., St. Louis, will double the capacity of its incandescent electric lighting plant, and has ordered of the Pond Engineering Company, two 250 h. p. compound condensing Armington & Sims engines, with Blake pumps, and independent condensing apparatus. This work was awarded, after strong competition from all the leading high-speed engines, to the Pond Engineering Co., who will put in the foundations, and superintend the installation and starting of the plant. It is expected that one of these engines will be in operation by Jan. 1st, 1892, and the other shortly thereafter. The first engine will be belted direct to a 2,500 light alternator. The foundations will be carried to solid rock.

The Electrical Supply Co., Chicago, have converted the front end of their large store into an elegantly finished sample-room. This is separated from the sales department by a combination of handsome upright display cases and a beautifully patterned grille reaching to the high ceiling. All the woodwork is oak, finished in hard oil. The floor is of the same material, laid in mosaic figures, oiled and polished. Displayed in the cases and arranged about the room are samples of every conceivable article for electrical use. To such an extent has this been carried that the display amounts to a small exposition in itself. No visitor to Chicago should fail to see it.

The Patton Motor & Mfg. Co. are receiving inquiries from street railway men from all over the country in regard to their street railway system, recently described in The Electrical Engineer, some of which are highly interesting. They are building two complete outfits with the utmost dispatch, and which will be shipped to their respective destinations in a short time. Their car at Pullman is still running day in and day out with the same persistent regularity and refusal to break down under all the severe tests to which it has been subjected.

Mr. J. K. Pumpelly is busily employed in developing his new mechanical form of storage battery, in which he has not only made important changes from any heretofore made, but which, it is stated, does not infringe on any of the storage battery patents. His plant is located at No. 205 Springer Building, and he will shortly place these new cells on the market.

Mr. C. O. Harris, of Dallas, was in town last week looking after a number of standard articles which he will handle in Texas and the neighboring States. As a member of the late firm of Clower, Harris & Co. he built up quite a trade for supplies, and will no doubt find a ready market for the class of goods which he will offer.

The Chas. Munson Belting Co., through Mr. H. B. Morgan, have secured the order for the belting for the L. Z. Leiter Building, comprising two 48 inch, seven 10 inch, two 12 inch and one 6 inch belts. This is the largest private electric plant in the city of Chicago.

☞ ***Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Miscellaneous, etc., will be found in the advertising pages.***

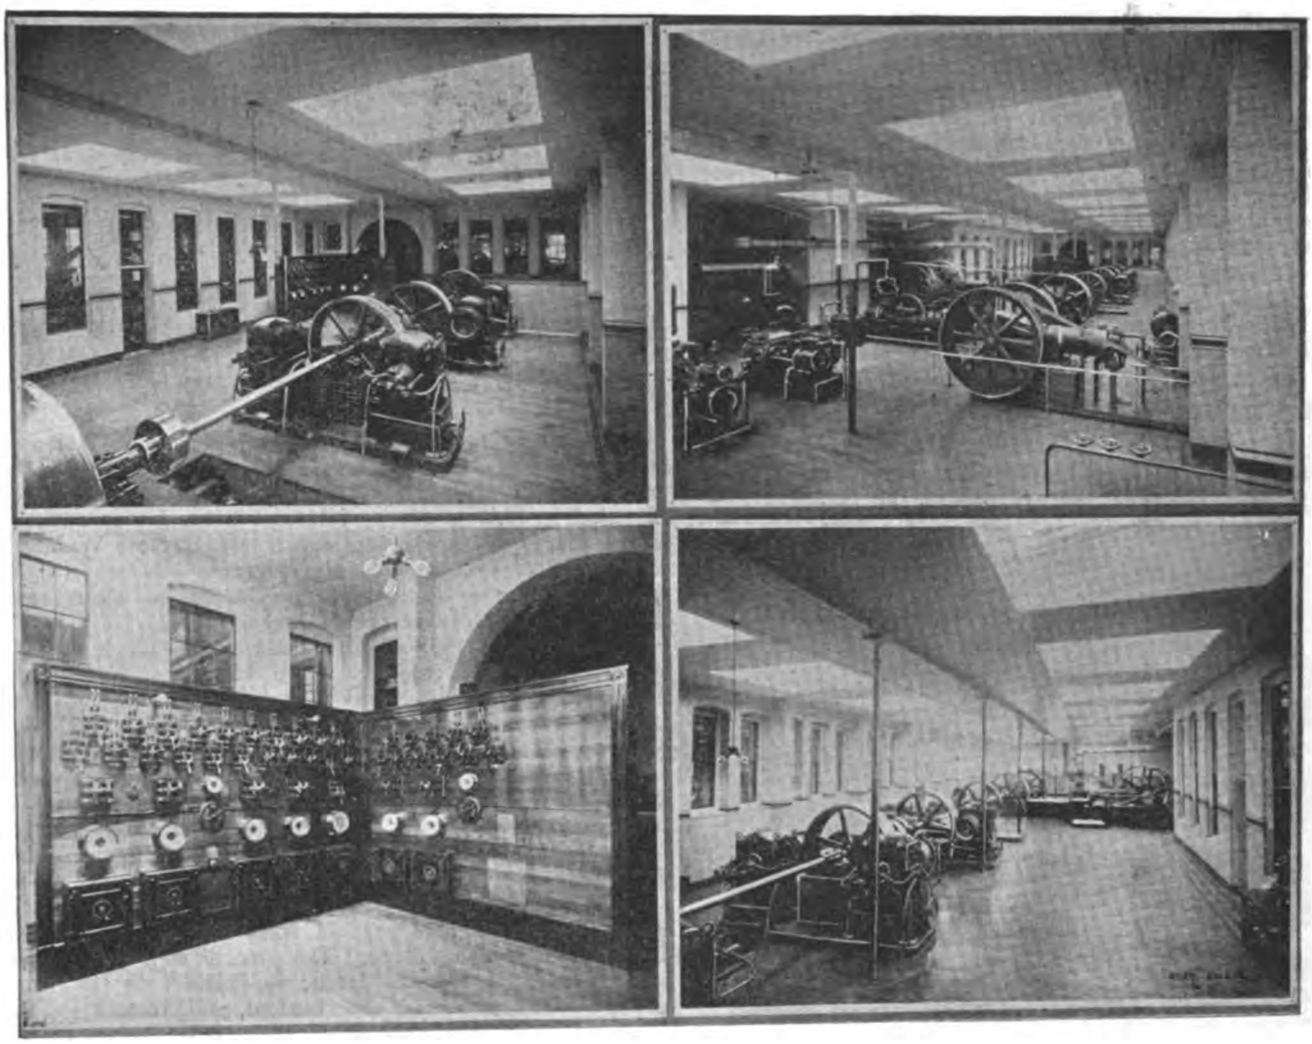
THE
Electrical Engineer.

VOL. XII. DECEMBER 30, 1891. No. 191.

LIGHTING THE WALTHAM WATCH FACTORY.

SOME three years ago the Waltham watch factory, at Waltham, Mass., after having experimented with several systems of electric lighting, concluded to put in a large isolated plant, and upon careful investigation placed the order with the Mather Electric Company, through Claflin & Kimball, their New England agents, for a plant of 2,000 lights. This plant, Figs. 1, 2, 3 and 4, was installed originally in the summer and fall of 1888, and has since been increased by the further addition of 1,250 lights dynamo capacity. They have already connected nearly 5,000 lights through the various departments of their extensive works.

The dynamos supplied by the Mather Company are of the Anthony type, whose special feature lies in the construction of the field magnets, which are constructed of laminated wrought iron of very thin plates, the magnet being stamped out of wrought iron, and thus composing a field without any joints in the entire magnetic circuit. In this way the high efficiency of the Mather dynamo is retained, together with a gain in decreased weight of the machines and slow speed of the dynamos. The dynamos have a capacity of from five to six hundred lights each, running at a speed of about eight hundred revolutions per minute.



FIGS. 1, 2, 3 AND 4.—MATHER ELECTRIC LIGHT PLANT, DRIVEN BY EVANS FRICTION SYSTEM, WALTHAM WATCH CO., WALTHAM, MASS.

The switchboard arrangements of the plant, Fig. 3, are very complete, and include a full set of instruments for each dynamo, the whole being so arranged that the dynamos are run in multiple, the dynamos being switched into circuit as the current is called for throughout the building. Each department of the building, thirty-two in number, is supplied by an entirely separate circuit from the dynamo-room, thus placing the lights of any of the departments of the building under the control of the electrician in the dynamo-room.

It was the original intention when the plant was installed to use storage batteries as an auxiliary to the dynamos, and a storage battery plant of a capacity of 500 lights was originally installed, but its use has been gradually superseded by the use of dynamos, as the batteries do not appear to be entirely suitable for the purpose for which they were used.

As will be seen from the cuts, the dynamos are driven by the Evans friction system, driving direct from the main shaft. This system gives easy control of the individual dynamos, allowing them to be started and stopped at will without the use of friction clutches. The dynamos are so arranged that they may be driven either from the main shaft from the main engine of the Corliss type, or they may be driven direct by means of a Ball compound engine of 300 h. p., which is shown in Fig. 3.

As an auxiliary to the regular dynamo plant, a small dynamo of 250 lights capacity has been installed for the purpose of furnishing light during the night for watchmen purposes and for sweeping the factory, every foot of the immense establishment being swept every night.

This plant has been very satisfactory to the Waltham Watch Company, and has reflected great credit on the work of the Mather Electric Company and its agents, Claflin & Kimball. When it is remembered what a particularly perfect service is required in the delicate work of watchmaking, it can be easily understood that a system that is satisfactory for such work must be entirely satisfactory for any of the ordinary classes of manufacturing. This we believe to be one of the best, if not the best, and largest isolated plants for manufacturing purposes run as a plant from one point. It has operated now some three years without a single breakdown or interruption of service of any kind.

THE WADDELL-ENTZ ELECTRIC MOTORS AND DYNAMOS.

There was a time, not many years ago, when the designing of dynamos and motors was in the hands of that class known by the generic term of "inventor," whose chief aim seemed to lie in the direction of constructing machines not with the view, particularly, of obtaining the highest results, but of working out a design which should differ as far as possible from that of all other existing machines. This practice has fortunately gone very largely out of fashion, and in its place we find the efforts of designers bent in the direction of constructing machines which shall be not only of very high electrical efficiency, but in which the design is such that the machine can be produced with the least possible cost. A good example of this modern tendency is to be found in the design adopted in the machines now being constructed by the Waddell-Entz Electric Co., of this city, and our readers will be interested in the description of the means which have been employed to effect the desired purpose.

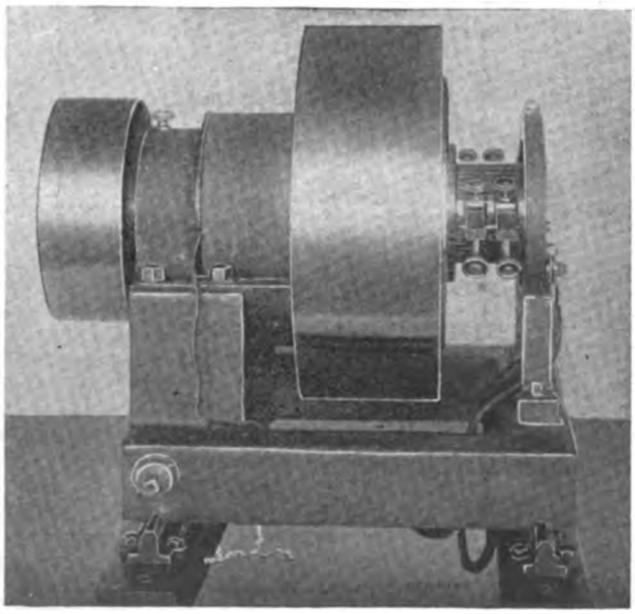


Fig. 1.—The Waddell-Entz Dynamo.

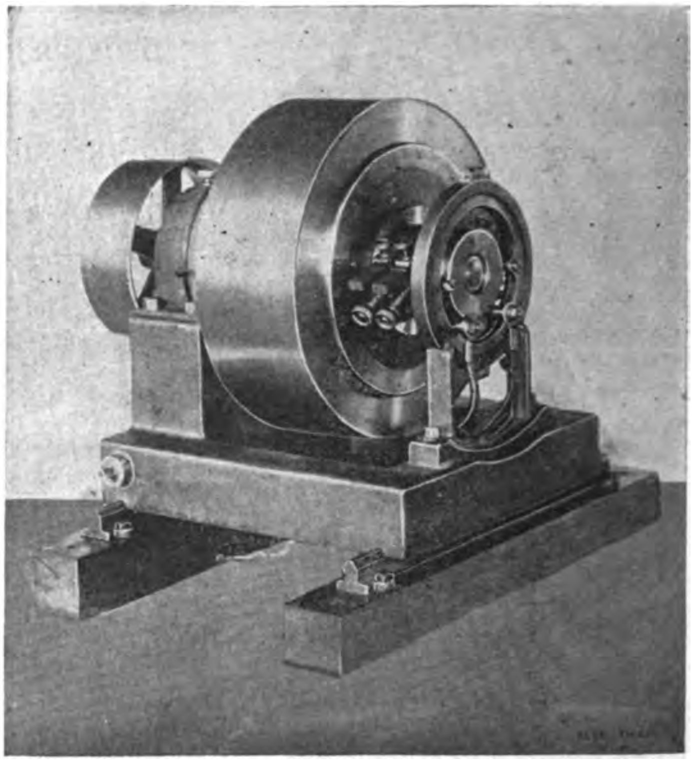

Fig. 2.—The Waddell-Entz Dynamo.

The machine which we illustrate in the accompanying engravings has a capacity of 2 kilowatts, and in its design Messrs. Waddell and Entz have had in mind constantly, first, the securing of high electrical efficiency with a mechanical construction such that the parts should be subject to the least manipulation and machine work. It was for these reasons that the type of field and armature shown was adopted. As will be noted, the field magnets are energized by a single coil wound upon a core which has a projecting horn which forms the upper pole piece. This core is let into a hub, which has a low projecting flange running parallel with the core, and which forms the lower pole-piece. The core, as well as the outside surface of the pole itself, is finished on the same mandrel, and is bored and bushed, and turned at the end. The energizing coil is slipped on to the core, which is held in place securely by two screws which prevent it from turning and at the same time from slipping in and out. The core is of malleable iron, and, as already stated, is bushed, and forms the bearing for the armature shaft. In order to provide for ample oiling the magnet is cored, thus providing an oil chamber; at each end of this core a ring passes over the shaft and dips down into the oil below, so that as the shaft revolves a continual supply of oil is fed to the bearing. As a result, the machine requires no attention in this regard for weeks at a time. In the larger machines having four or more poles a second bearing is provided, but in the two-pole machines, as stated above, the armature is entirely supported by a single long bearing passing through the centre of the magnet core.

The construction of the armature adopted in this machine has been very carefully worked out, and a somewhat striking feature of the machine is the fact that no wire whatever is visible, the armature being inclosed in a brass cover. The armature is built up of soft iron rings stamped in a press, and one of its principal characteristics lies in the fact that it is built up and held in position without the employment of bolt holes passing through the armature. By this design the full section of the iron is utilized, which is particularly desirable in multipolar machines. The rings, insulated by paper, are perfectly smooth, and require no turning in the lathe after they come from the stamping press. For the purpose of building up into an armature they are put into a press between two outside rings of brass, and are then screwed up under pressure.

spider is bolted to the armature ring by means of the same bolts which serve to bind the armature plates together, and the brass cover is then slipped over the armature and held in place by screws. By the employment of the bolts on the outside of the armature not only is the reduction of the magnetic circuit obviated, but, in addition, the insulation of the plates from one another is not destroyed, as has frequently been proved to be the case of the bolts passing through, and which therefore require to be insulated and thus serve to still further increase the size of the hole and thus reduce the iron section.

As the pole-pieces are situated entirely on the inside of the ring, all trouble due to shifting of the wires by centrifugal force is avoided, as the revolution of the armature merely tends to keep the inside of the wire more firmly in place; besides, the action of the magnetic lines is such as to make the wire hug the armature more closely.

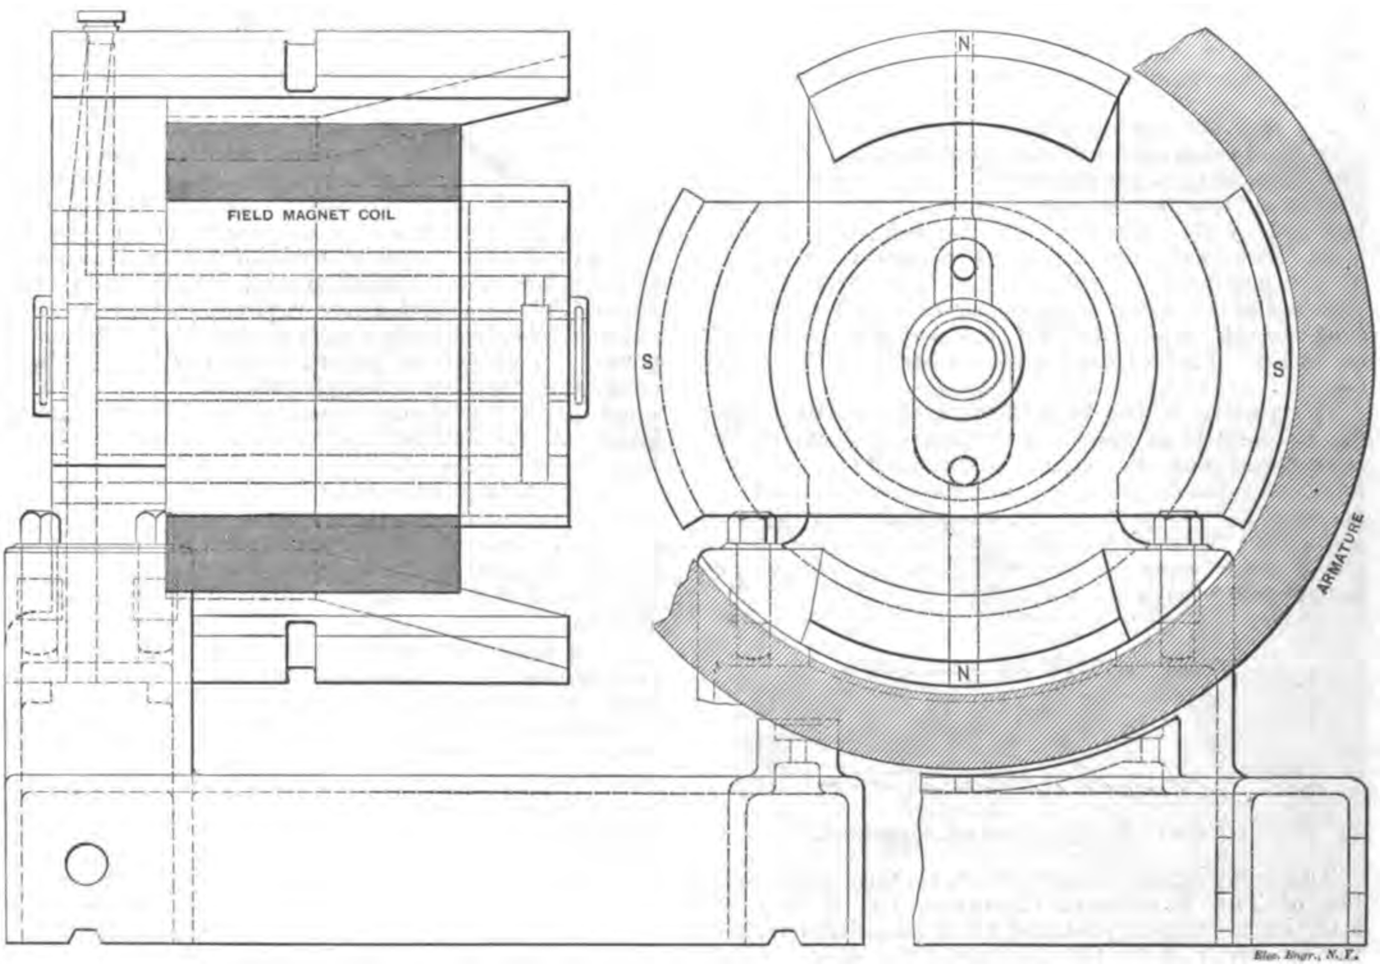

FIG. 3.—MAGNETIC FRAME OF WADDELL-ENTZ 4-POLE MACHINE.

The outer brass rings are then clamped together by a series of bolts spaced evenly around the armature and screwed up by nuts while the plates are under pressure, so that when the pressure is released the armature comes out as a solid ring.

The bolts encircling the armature are placed on the outside circumference, leaving the inner entirely smooth, and are of small diameter, being so spaced that they form grooves for the winding. They thus afford a positive driving and take the place of teeth without, however, introducing disturbing reactions. They also avoid the slotting of the armature and thus can be stamped out with a smooth, round die. The armature is therefore practically ready to wind as soon as it comes out of the press, so that the least possible time is lost. While this operation is going on, the commutator is being built up upon the spider through the center of which passes the shaft. When complete, the

In the two-kilowatt machine illustrated, the brushes are held by a stand encircling the end of the commutator. Each pair of brushes is mounted on a separate ring, these rings being insulated from each and held in position in the frame. The machine is so designed that the brushes, once set, require no shifting, the machine being sparkless at all loads.

The machine, it will be noted, is mounted on a pair of rails, and for the purpose of tightening the belt a screw passes through a threaded eye cast into one of the rails. By this means, while being shifted to and fro, it is at the same time positively held in position and its stability thus increased. The machine work required in the building up of these dynamos, it will thus be noticed, consists almost exclusively of boring and turning, the only planing necessary being that required for the rail grooves. On account of the design adopted, it will be seen that each part of the machine can be separately constructed, the armature being independent of the commutator and spider, and each of the magnetic parts also is capable of separate finishing. The result is that the machine can be constructed in the least possible time as no one part need be delayed while another is being finished, a most desirable feature in the rapid filling of orders.

The design of the frame of the four-pole machine is illustrated in Fig. 3. Here, it will be seen, a single energizing coil is also employed, but an outer bearing is added to give stability to the armature.

These machines are built in sizes varying from 2 to 100 kilowatts. In the two-kilowatt machine the armature resistance, warm, is .0295 ohm, and it is wound with two No. 15 B. & S. wires. The field resistance, including the regulating box, is 100 ohms. This gives a drop of 5.04 volts in the armature, and an efficiency of 90 per cent. at 1,100 revolutions of the armature. The floor space occupied by this machine is remarkably small, the dimensions of the machine being as follows: Length, 18¼ inches, outside of pulley; width, 19 inches, outside of rails; height, 18 inches.

The 25 K. W. machine has six poles, an armature resistance of .015 ohm, and a field magnet resistance of 30 ohms. The diameter of the armature is 39¼ inches and it runs at a speed of 390 revolutions per minute. The floor space occupied by this machine is 46½ × 46½, and 48 inches high. The 50 K. W. machine has 8 poles and the 100 K. W. 10 poles; the latter running at 200 revolutions per minute and occupying a floor space of 78x82 inches, and standing 82½ inches high, with a diameter of armature of 68 inches. Each of these machines has but a single magnet coil.

The factory of the Waddell-Entz Co. at Bridgeport, Conn., where these machines are now being constructed, is equipped with the most modern machinery, and it is safe to say that by their use, in connection with the simplicity of the design employed, the production of dynamos and motors has been brought down to a degree of simplicity and cheapness which would hardly have been believed possible but a short while ago.

ELECTRICITY AT THE PLOW.

BY

A. A. Denton

Of the U. S. Department of Agriculture.

The following statements are not, perhaps, in the regular line of The Electrical Engineer, but if they turn attention to practical problems which immediately concern the prosperity of the Great Plains of the West, they will be well worth space in its columns.

In the States which occupy the Great Plains there is an immense area, nearly level, free from stones, trees, or other impediments to cultivation of the soil by power machines. The sole power now available for the cultivation of this almost boundless farm, is animal power. Western farmers wisely, perhaps, certainly necessarily, discard hand implements, so far as possible, and depend almost wholly upon animal power machines in the production of immense crops of grain. The use of animal power always has been, and always will be subject to limitations. Manufactures made comparatively little improvement until the adoption of efficient prime motors. Disconnect engines and motors and turn the shafting of a manufactory by flexion of muscle, and see how essential to modern manufactures are modern motors. So long as commerce was dependent upon galley slaves or upon slow-moving caravans, so long it was necessarily limited. Agriculture is now where Manufactures and Commerce were before the adoption of efficient motors, and like them it will make wonderful progress when it substitutes tireless motors for animal power.

As a consequence of this limitation of power in agriculture, a very large part of the Great West lies fallow and unproductive. The annual prairie fires harvest the natural crop of grass. The useless smoke of these prairie fires should take the form of food supply for the hungry millions of the earth. They should be replaced by wheat fields of vast extent. The rapid extension of agriculture in the Great West is simply a matter of the application of efficient motors equal to the demand of agricultural work in that section.

There has been very great improvement in agricultural work in the last half century, and all of that improvement is due to the substitution of animal power, or of steam power, for manual labor. The application of animal power to the reaper performs the labor of 30 men. The application of power to the threshing machine saves two-thirds of the manual labor formerly required. The application of steam power in the locomotive renders the carriage of farm products easy. It is in consequence of these comparatively recent applications of power that the Western States have developed production to a degree which would have been impossible in previous centuries. And it is in this line, the adoption of efficient motors, that agriculture will make still more wonderful progress. Only a beginning has yet been made in the application of power to agricultural work. Agriculture is inferior to manufacture, as its prime motor, animal power, is inferior to steam power. Western agriculture requires to take a step in advance, by substituting a more powerful motor for animal power. In agriculture proper, that is, in the growing of crops, invention has accomplished but little, and that is simply in the line of substituting animal power for manual labor. At the dawn of civilization, the barbarian farmer, with his rude plow drawn by bullocks, was not so greatly inferior in accomplishment to the Western farmer with his steel plow drawn by his overworked team. In the saving of crops, after they are produced, invention has done much. We harvest 20 acres of grain per day, we thresh 20 acres per day, we carry the grain 500 miles per day to market, but by the inefficiency of its motive power the plow is limited to two acres per day. Our reapers can reap more grain, our threshers can thresh more grain, our locomotives can pull longer trains, loaded with grain, but Western agriculture is held back by the inability of animal motors to plow faster and deeper and more cheaply. It is thwarted, in a measure, by plowing done out of season, done badly, and expensively. It is limited by the amount of work which can be got out of its tired motors.

There is cruelty to animals in our Western system of agriculture. With immense work and with feeble motors the result is the destruction of the motor. With limitless power in the earth, in the air, and in the sea, we drive helpless animal motors to death. Invention has placed the burden of agriculture upon them, and they are broken down when they should be in their prime.

It appears useless to exploit steam as a motor in agriculture. The steam engine has apparently been improved nearly to its limit. The difficulties in the way of applying it to agricultural work appear to be inherent and unavoidable. On foundation or on rails it is indeed a giant; when it touches earth it is powerless.

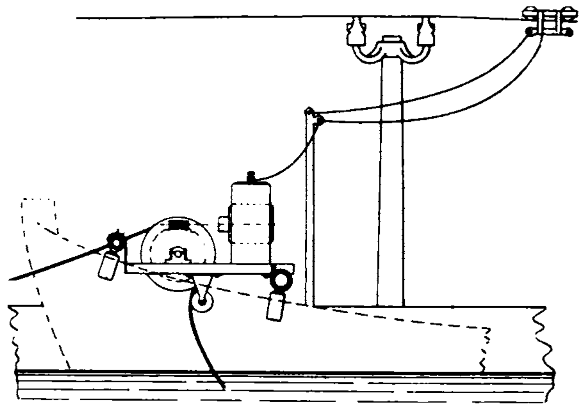
It appears otherwise with the electric motor. It is simple, its few wearing parts can be protected from dust, it has ample power, it has not excessive weight, it carries neither fuel nor water.

In its simplest expression, the problem is the dragging a plow, a harrow, a seeding machine, a reaper or a wagon loaded with grain, half a mile, in a straight line, reversing, and dragging it back again, simply passing to and fro, until the entire field is worked.

In the many applications of electrical work, this, the most important and the extensive application of all appears to have been entirely overlooked. This shall lighten human labor, shall relieve suffering animals, shall increase production, decrease cost and cheapen food. We will wonder, a few years hence, how men produced food for all mankind by use of the whip. And we will point to the old-fashioned plowman, urging his tired and slow-moving team, as we point to the old-fashioned man who swings the old-fashioned cradle in grain. There is urgent demand in agriculture for electrical engineering.

TOWING CANAL BOATS BY ELECTRICITY.

The fact that a vast amount of freight is still transported by means of canal boats, and that these boats are



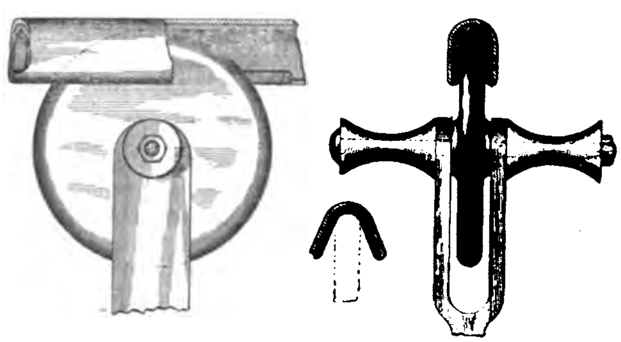
Towing Canal Boats by Electricity.

still drawn by horses or mules, as in the days of Rameses or Tiglathpileser, lends especial interest to a recent invention of a German engineer, Mr. Otto Büsser which is well illustrated in the accompanying drawing. As will be seen, a stationary cable is laid at the bottom of the canal and is grasped by a set of sheaves on the deck of the boat, actuated by an electric motor. The current is supplied to the latter by means of trolley wires strung along the bank, the trolley making contact on the upper side of the wires and being towed along by the flexible conductors.

A peculiar feature of this arrangement is that the whole installation is portable, and is readily fixed to the gunwales of the boat as it enters the canal, and removed at the further end. This is accomplished by fastening the motor upon a bed-plate resting upon adjustable cross-rods at whose ends are pivoted vertically clamps which fit over the gunwales and are firmly held by set-screws.

THE SARGENT INSULATED TROLLEY WIRE.

In order to obviate the necessity of guard wires in overhead electric railway construction, and to remove, at the



Figs. 1 and 2.—Sargent's Insulated Trolley Wire.

the same time, a serious source of trouble in the management of such roads, Mr. Charles E. Sargent, of Chicago, has devised the novel form of trolley wire shown in the accompanying illustrations.

As will be seen, the conductor is ∩-shaped in section, and has its upper and outer side covered with insulation, the trolley wheel being without flanges, and traveling in the uninsulated groove formed by the inside of the ∩.

The two spools of insulating material seen on opposite sides of the wheel, Fig. 2, are for the purpose of striking against the lower surface of the wire and limiting the upward movement of the free end of the trolley-arm when the trolley-wheel misses the wire.

This form of wire, has of course, considerably more rigidity than the ordinary cylindrical wire in use now, but this, it is claimed, is not sufficient to prevent its being coiled readily on rollers for transportion.

THE MOORE TROLLEY AND AUTOMATIC DEVICE FOR CONDUIT RAILWAY WORK.

BY

D. McFarlan Moore

The partial success of a number of conduit electric railways in Europe has led many to believe that the solution of the electric railway problem lies in some form of

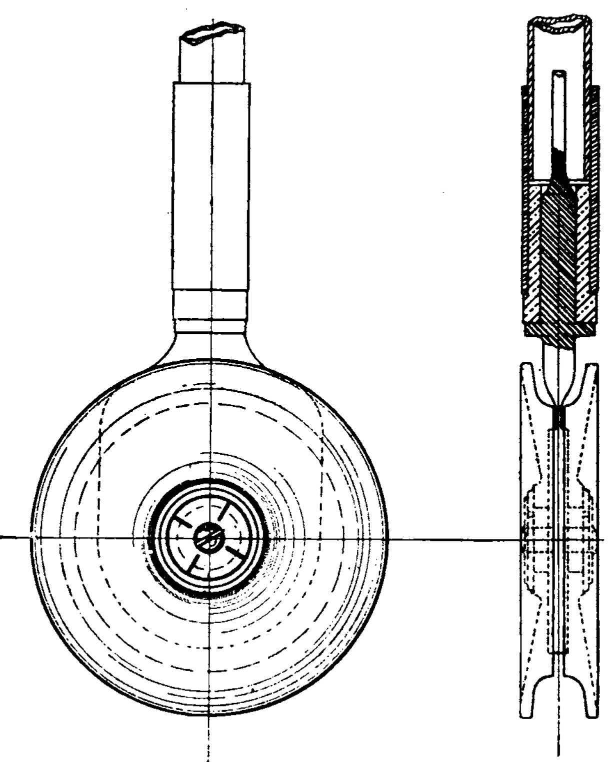


Fig. 1.—Moore's Conduit Trolley.

the conduit system, and particularly as the use of the overhead wire is absolutely prohibited in many large cities, such as New York and Chicago. It seems also to be well recognized that in the ideal conduit system of electric railways the trolley or contact device should be permanently attached to the motor truck, and not be detachable from it.

This result can be successfully accomplished by the use of the trolley illustrated in the engraving, Fig. 1. It is designed to be lifted from the conduit at any point on the line, and as such is the narrowest trolley that can possibly be constructed, being a trolley wheel without a yoke. As each half of the trolley has its own bearing, it may be termed a split trolley wheel. Each half of the wheel runs independently of the other half; this is advantageous in rounding curves, as it makes the contact more perfect. The principle involved in this trolley is by no means confined to railway work, as it can be applied in many instances for moving contacts in general, and especially when large working conductors are used. Its construction is simple and cheap, and its various parts can easily be replaced. Its design is such that the slot in the conduit need be only three-quarters of an inch, or less, in width.

The application of electric power for operating tramcars, transfer tables, etc., in machine shops, foundries, mills and manufacturing establishments of all kinds is rapidly becoming an important part of electrical engineering railway work. In every case it is desirable, and in many cases absolutely necessary, that the trolley wire or working conductor should be beneath the ground or floor of the shop. This is necessitated in many instances by the use of traveling cranes, which preclude the possibility of employing an overhead trolley wire. In many large manufacturing establishments it is desirable also to have the tramway run not only inside of the various buildings, but also from building to building, and if the buildings are widely separated it may be required to connect them with the overhead system.

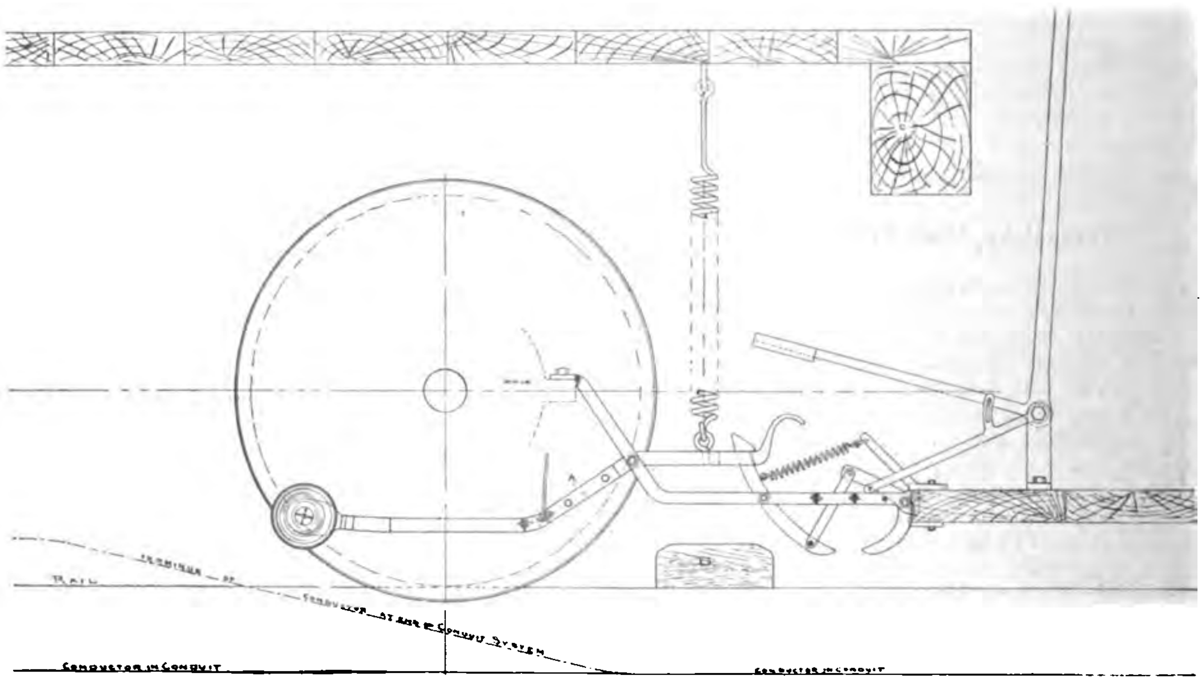

Fig. 2.—The Moore Automatic Device for Railway Conduits.

Fig. 2 shows an automatic arrangement for raising and lowering the trolley when necessary to change from the underground to the overhead system, and vice versa. As will be readily seen the levers are operated automatically by means of the block, B, placed in the centre of the track. The trolley is raised from the conduit by simply placing the conduit conductor on an incline, the inclined portion of course being "dead." The cheapest and best forms of conductors for conduit work when using this trolley are iron or copper bars or angle iron. The lever, C, is provided only as a positive arrangement in case the automatic device should not act, owing to the removal of a block or for some other like reason. In case a return conductor is required the main trolley lever can be forked at the point marked A, so that two trolleys can run in two conduit slots separated by about six inches.

L'Industrie Electrique, a new Parsian electrical journal, will be published from the beginning the year under the able editorship of M. E. Hospitalier.

HOW TO INVENT THE SUCCESSFUL COMPETING TELEPHONE.

BY

Edward P. Thompson

A point of valuable knowledge, among other matters, with which the would-be inventor of the successful competing telephone should be equipped, is the gist of each class of telephone, which has been invented thus far. It is almost safe to say that the successful competing transmitter will consist of some slight improvement over some existing improvement or original invention. The most powerful example, which presents itself, is the very transmitter which suggests the present problem. Although the result is far inferior, the Reis transmitter of musical sounds is exactly like the Berliner transmitter, except to those who know the gist of both. In each case two terminals of an electric circuit are normally in contact. However, when the device is in operation, the contacts separate in the one, and remain together in the other with variable pressure. It is found that all the telephones at present known are divisible into a comparatively few classes, and that a short sentence will give the pith of each. They are treated, not in any chronological order, but in the order in which they naturally appear in the mind. Even if read, not for the purpose of assisting in inventing, the classified knowledge may be useful in other ways.

The State of the Art.—In one or more transmitters at present known, electrical undulations, corresponding to air vibrations, are produced by causing the mechanical energy of the condensations and rarefactions of the air.

To vibrate a diaphragm of iron before the poles of a magnet.

To vibrate the diaphragm of iron before the poles of a magnet in which the core is partly or wholly of steel.

To vibrate a steel diaphragm before the poles of a magnet with or without a core.

To vibrate a magnet before the poles of a second magnet.

To vibrate an iron sheet *between* the poles of a magnet.

To vary the temperature of a heated conductor of very small diameter, such as a platinum wire, the condensations and rarefactions of the air causing the alternate heating and cooling of the conductor (comparatively) whereby its resistance is similarly varied.

To vary the temperature upon the face of a thermopile, the condensations and rarefactions of the air causing an alternate heating and cooling of the thermopile, whereby electrical undulations are produced (theoretical).

To vary the length of a continual spark between the two electrodes, the electromotive force of the current being sufficient to maintain the spark (theoretical).

To vary the linear resistance of a ligature, such as a carbon filament, the air vibrations causing a conducting liquid to rise and fall alternately along a part of the length of the wire.

Same as above, the air vibrations causing a second conductor to intermittently touch or short circuit variable portions of the first conductor.

To vary the amount of light falling upon a conductor, such as selenium, which is sensitive to light in such a manner, that for variable light, its resistance varies.

Same, except that a substance sensitive to heat rays is employed.

To vibrate a card board, supporting iron filings, before the poles of a magnet.

To circularly vibrate the armature of a minute dynamo, before the poles of the field magnet.

To vary the pressure existing between the two carbon or metallic or conducting liquid electrodes normally and abnormally in contact with each other.

Same, the number of the electrodes of one or both polarities, being increased.

Same, one of the electrodes, when metallic or carbon, being pulverized.

Same, in which one of the electrodes is a valve, loosely located upon the end of a tube which is the other electrode.

To vary the pressure upon the plates of a voltaic pile, an alternate increase and decrease of distance between the plates causing variable amounts of current generated.

To vary the shape of a globule of mercury balanced in a conducting liquid, the vibrations of the better conductor, mercury, varying the resistance of the circuit.

To vary the static charge of condenser plates, whereby the electric current of the line becomes varied as to its electromotive force.

Conditions of the Problem.—It is needless to mention that these are very severe. The transmitter must possess novelty over all those at present known, and further, it must be equal and if possible, superior, to the carbon transmitter. It should be applicable to long lines, and in such a manner that the receiver will give forth the words clearly and loud enough to be heard intelligently. It should serve the test of transmitting the ticks of a watch and whispering, when two or three feet away from itself not simply over a small distance, but for a mile or so. For a short distances it should transmit the sound of heavy breathing. It is assumed that a good Bell receiver is used, such as that on which the patent expires in March, 1893. One of the difficulties, in order to be as profitable, commercially as the carbon transmitter, is the cost of construction. The latter consists substantially of two pieces of compressed carbon powder, a diaphragm of tin-type metal, and the frame, the carbons being supported in a relatively yielding position, and means of adjustment being provided. It is one of the cheapest electrical devices manufacturable.

ELECTRIC LOCOMOTIVES IN FRANCE.

The French Northern Company will shortly make some trials with an electric locomotive between Paris and St. Denis, and afterwards, if these prove satisfactory, between Paris and Calais. On falling gradients the *vis viva* of the train will be utilized for recharging the accumulators.

IS IT NECESSARY TO BOND ELECTRIC RAILWAY TRACKS?

In an article on the Gibbon duplex rail that was published in The Electrical Engineer of Oct. 29, 1890, the suggestion was made editorially that with such a continuous rail it should no longer be necessary to "bond" electric railway tracks. Rail bonds are at present a necessary evil, and while many improvements have been made in them, very few electric railway managers would care to go on using them if they could be dispensed with. Not only do they often introduce seriously wasteful resistance, but very frequently they disappear altogether, leaving merely a stain in the earth to signify that they once were there, very much as Dickens represented one of his characters to have vanished, leaving only a grease spot behind. It therefore occurred to us that the Gibbon rail, altogether aside from its qualities as a rail, might offer an effective remedy for the "bonding" trouble. Learning recently that a section of this track had been furnished to the Brooklyn street railway companies, we obtained permission for a test of it by Mr. Townsend Wolcott, who has now submitted the following report to us under date of December 24:

> I have examined, according to your request, the section of track furnished to the Atlantic Avenue Railway Co., Atlantic and Third Avenues, Brooklyn, by the Duplex Street Railway Track Company.
>
> The track is so keyed together for the purpose of securing mechanical continuity and strength, that electrical continuity is at the same time secured, thus rendering the track a good electrical return for trolley or conduit roads, without any other bonding than that which is a part of the system and which does not involve extra expense as do the ordinary methods of bonding.
>
> I made a bridge test of the above-mentioned section and found the resistance too small to give an indication on the bridge, although the latter showed .001 ohm very plainly. The test current had to pass through two keys and around one complete joint.
>
> I think this track when properly laid, will be found practically equal to a continuous rail both mechanically and electrically.
>
> Townsend Wolcott.

This seems to confirm our opinion very thoroughly, and we print his report as one of interest to our readers in the railway field. We have now suggested to Mr. Wolcott the desirability of a direct comparison, electrically, between this track and that of some electric road with "bonded" tracks lately finished. Such a comparison has now been undertaken, and we hope soon to give the results. In the meantime, we shall be glad to hear from any of our readers on this important subject.

INFLUENCE OF STEAM ON PERMANENT MAGNETS.

The influence of steam on magnets is the subject of an interesting note in the *Schweizerische Bauzeitung* in which reference is made to the researches of Strouhal and Barus. These have shown that with long-continued heating in steam, magnets lose from 28 to 67 per cent. of their power. If, after this, the magnets are remagnetized and again exposed to the action of steam, only a very slight loss of magnetic power is found to take place. The experiments which have been made would seem to warrant the conclusion also that after such treatment a magnet is less liable to deterioration from mechanical vibration as well as heat. In one of the experiments, a short magnet was boiled in water for four hours. It was then magnetized and held in an atmosphere of steam for two hours more, after which its magnetic moment was measured. It was then subjected to 50 blows from a piece of wood, both transversely and longitudinally. Again measuring its magnetic moment, showed a loss of $\frac{1}{800}$, and on repeating the hammering with the wooden bar the loss was $\frac{1}{400}$ of the original moment. In view of all this, repeated steaming and magnetizing is recommended as a good means of securing permanent magnetism in pieces of hard steel.

ELECTRIC ICE-HARVESTING MACHINERY.

BY

F. E. Kinsman.

In 1805 Mr. Frederick Tudor, of Boston, began the exportation of ice. In 1832 the entire quantity exported was less than 5,000 tons, all of which was taken from a pond in Cambridge, Mass. In 1846 there were 65,000 tons exported; in 1856 it reached 146,000 tons, while in 1875 the shipment of ice to southern cities and ports exceeded 1,000,000 tons. To-day we are shipping large quantities to European ports in addition to an extensive Southern trade; even in view of the fact that Norway is supplying large quantities, we are able to sell ice in Great Britain, in competition with nearby countries, and this notwithstanding the fact that our method of cutting and harvesting has not been materially altered since Mr. Tudor's first effort in 1805. Many efforts had been made to improve the process of cutting and handling ice, but with the exception of the improved form of the old-fashioned ice-plow, drawn by horses. which requires two men each, one to lead the horse, and the other to guide the plow—and the method of hoisting the ice into the storage building by steam power, practically nothing had been accomplished, until the year 1890, when the writer brought out his self propelling electrical ice-cutting machine, which can be made to do the work of any number of horses, and the necessary detail of laborers to manage them.

No branch of industry of any importance, has suffered such neglect, and at the same time assumed such enormous commercial importance as the ice business of the United States. Its importance to our every-day life, was clearly brought out by the great outcry that was raised by the press during the winter of 1889-1890, when it was found that there was likely to be an ice famine, and its domestic and sanitary value was even more clearly demonstrated by the comparatively high prices which the public were compelled to pay for that which was consumed, most of which was brought from the extreme northern sections of the United States. The difficulties of securing the crop from such points, and the high price consequent thereon, greatly stimulated the introduction of artificial ice-making apparatus. This was done to such an extent that, naturally, ice men began to realize the important character of their new competitor and to look about them for means of reducing the cost of harvesting and handling their product. They found that the principal points to be considered were, first, the matter of reducing first cost; second, the securing of locations where an unfailing supply could be had near the market. The first item, that of first cost is largely made up of the price paid for labor and teams. Owing to the knowledge on the part of the workmen of the fact that frequently but few days were vouchsafed the companies in which to secure their crop, they could practically place their own figures upon their services and for the use of their teams, where such were required.

Another item of grave importance, in the aggregate, was the loss of horses by drowning (one company is reported to have lost 27 in the winter of 1891 from this cause); another source of loss is from influenza contracted by exposure on the ice fields. The drawing of an ice plow being an absolutely dead weight, requires a constant drag, and those acquainted with the business well know how quickly a horse begins to perspire, even in the coldest weather. It only requires a stop of a few minutes for rest, or any other cause, to give them a severe chill and cold, which is likely to develop into lung fever or pulmonary diseases, which is said to be one of the largest indirect items of cost in the harvesting of natural ice.

Another important item, is the trimming of irregularly shaped cakes of ice, when they reach the foot of the hoisting apparatus. This irregularity is due to the fact that the plow now in use cuts but from three to four inches the first trip, and from two to three inches the second trip, and approximately two inches the third trip, a total of from six to nine inches, leaving, with 18 inch ice, from one-half to two-thirds to be split, and any irregularity in splitting has to be corrected before it is passed into the storage house. It has also been found that the old method of packing ice with layers of straw or sawdust between each tier, was troublesome and expensive. They therefore adopted the method of corrugating the cakes of ice, as they passed into the ice-house by a special attachment connected with the hoisting apparatus. This permitted the putting of the corrugated faces together, which answered the same purpose as straw or sawdust, namely, prevented the cakes from freezing together in a solid mass. This corrugating and trimming of the cakes of ice left around large houses a troublesome accumulation of refuse ice, the removal of which was not an insignificant item of cost. These matters are however to a certain extent governed by circumstances within the control of the companies themselves.

The second point, however, that of an unfailing supply, is one over which the companies have had no control in the past, and one in which the writer proposes to come to their assistance, by the use of apparatus with which they will in a measure be able to overcome the unfavorable condition of the season, and to harvest ice that is thinner than it is possible to harvest with horses.

It is well known that the temperature of the water under the ice is higher by from six to eight degrees than the ice. As it is impractical to remove the snows which fall upon the ice before it is thick enough to bear a horse, the thickness of the ice is somewhat reduced by having a comparatively warm body of water beneath it and a protecting blanket of snow upon it, which would not be the case if the snow could be economically removed as fast as it falls, thus exposing it to the lowest possible temperature.

This can be accomplished by the electrical self-propelling snow-removing apparatus, devised by the writer, with but comparatively little trouble and expense. The planing and cleaning machine is equipped with a scooping chamber, which can be dumped when once filled or upon approaching the shore limit of the ice field, while the planers can be raised or lowered sufficiently to remove the unevenness of the upper surface caused by rough and windy weather, when the ice first begins to make. These planers are detatchable at will; they are furnished either rotary on a plane with the ice, or revolving before the saws. The cutter or groover is so constructed as to admit of the easy adjustment of the knives for cutting between the thickness of ice, where, if it is desired, the shafts upon which the knives are mounted in gangs are also supplied with corrugators which corrugate the upper surface of the ice as it is cut. This corrugating upon the field is a decided improvement over doing the work at the ice-house, as all the refuse ice made or produced by cutting and corrugating is floated off on the water when the cakes are split from the main body, and become submerged in the water. Here it is well to mention the fact that, on account of the greater depth to which the main grooves are cut which divide the cakes, a much more even side is obtained, as the shorter the splitting space, the less divergence from a true line.

The electric ice-cutting machine designed by the writer is shown in side and end elevation respectively, in the accompanying engravings, Figs. 1 and 2. The illustrations are so clear as hardly to require a detailed explanaiion. The cutters are driven direct by the armature which has an elongated shaft upon which the cutters are mounted, thus obviating the necessity of using belting or gearing. The depth of the groove to be cut can be regulated by a hand-wheel under the control of the attendant, the cutters being raised by a worm-and-tooth segment. The same shaft that carries the cutters is provide with two worms which, acting through shafts and bevel gears, propel the wheels upon which the machine is mounted. By this means an exact ratio is obtained between the travel of the machine and the speed of the cutters. The direction of the machine is controlled by the hand-wheel and sprocket chain passing around the pivot of the rear wheel; but the machine may also be guided by a special "guide" running in the groove last cut.

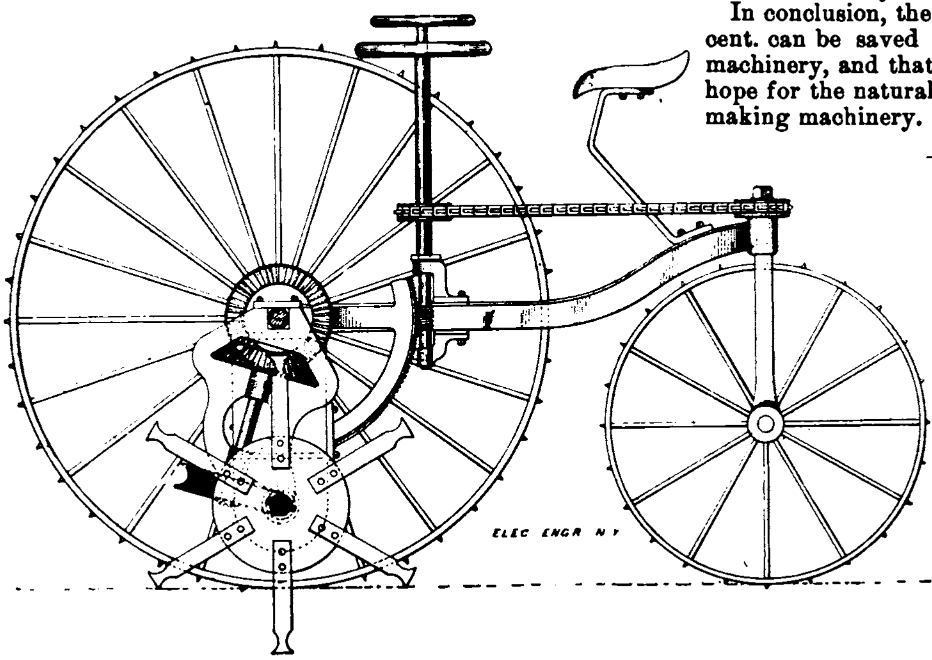

Fig. 1.—Kinsman Electric Ice Harvester.

With this cutter it is possible to groove ordinary ice almost through to the water, as the machine produces no shock or jar upon the ice, and its width and length is sufficient to give it the advantage of a broad bearing surface, while the weight of a No. 2 machine does not exceed that of a fair-sized horse; a No. 4 machine, carrying a gang of four cutters is somewhat heavier but not enough as to prevent cutting very thin ice with it.

The great change secured by the use of electricity in ice cutting is that the apparatus weighs comparatively little, and that the current can be generated at a merely nominal cost by the same power that lifts the ice into the house; while the same engineer who now attends to the lifting apparatus also cares for the generator. It will therefore be seen that the entire cost of grooving ice on the field is reduced to the wages of a man who rides the machine and a few extra pounds of coal used in the furnace, and that the entire force can be concentrated upon the housing of the ice, thus admitting of a full crop, which would otherwise be prevented by a sudden change of weather. As stated, the total weight of a No. 2 machine, with a capacity equal to from fifteen to twenty horses does not exceed that of a fair-sized horse, but, unlike the horse, requires absolutely no attention when not in use. It does not take cold when standing still, nor is it a total loss if it accidentally goes overboard.

As to the method of transmitting the current to the motor on the machine, two methods are available. Use can be made either of a trolley wire supported on sliding stands, or the cutter can be supplied with a reel. In either case no difficulty would be experienced.

In conclusion, the writer believes that from 30 to 50 per cent. can be saved by the use of electric ice-harvesting machinery, and that this method stands to-day as the only hope for the natural ice men against improved modern ice-making machinery.

LENGTH OF ELECTRIC WAVES.

M. Poincaré has announced to the French Académie des Sciences that M. Blondlot has measured by a new method the length of waves of electric oscillations, and that he has found that this length is proportional to the square root of the capacity, and to that of the self-induction, as required by Sir Wm. Thomson's formula. The mean of his experiments has given for the speed of propagation of electric waves in a metallic wire a figure not greatly different from the speed of light—a difference less than can be accounted for by errors of observation. The result is confirmatory of Maxwell's theory that light is due to alternate currents of very short periodicity.

AN ELECTRIC ROAD AT NIAGARA FALLS.

A corps of engineers on the Canadian side are now mapping out the line of an electric road between Chippewa and Queenston. The route through Victoria Park will be located just under the bank, along the western boundary of the reservation. It is likely that the power for this road may be obtained from the Niagara River, and a much bigger scheme is on foot for a power canal cutting across from the river and emptying down the Queenston Heights below the whirlpool.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XII. NEW YORK, DECEMBER 30, 1891. No. 191

As we do not pound on a piano with all our strength to get a sound, but select different keys, so by using those components of light which we require, we may avoid wasting the other parts of the spectrum.—Prof. J. B. de Motte.

AGRICULTURAL ELECTRICAL ENGINEERING.

WE have from time to time printed notes on experiments which had been made looking to the influence of electricity on the growth of plants. These experiments may be divided into two classes; first, those involving the influence of the electric light directly upon vegetation; and, secondly, those in which the current was made to act directly upon the seed of the plant until its maturity. The experiments of Siemens some years ago and the more recent ones carried on in the Agricultural Department of Cornell University ought to show in some degree what can be expected by the first method, while the recent investigations by Specnew, in Russia, and others, give a fair indication of the value of the second method But electricity is capable of still further applications in agriculture in a direction which promises immediate results, and which cannot fail to secure for it the attention of agriculturists. The field still open to the electrical engineer is pointed out very forcibly by Mr. A. A. Denton, assistant in charge of the U. S. Department of Agriculture at Sterling, Kan., and consists in nothing less than the application of electric power to plowing. Mr. Denton points out that while we apply steam to the harvesting, threshing and transportation of grain, we are practically still pursuing the methods of thousands of years ago in the manipulation of the earth preparatory to the reception of the seed. As he puts it, while we can harvest and thresh 20 acres of grain per day, we can, by the method at present in vogue, in which animal power alone is employed, only plow up two acres a day. The problem to be solved, then, consists merely in providing a motor which shall be able to drag whatever appliance is necessary either for the tillage of the soil and the harvesting of the crop, in a straight line half a mile, reversing and dragging it back again until the entire field is worked. Mr. Denton considers the steam engine as unsuitable for this purpose and sees in the electric motor the ideal machine for this purpose. While the suggestion of the application of electric motors to the tilling of the soil was actually put in practice some 10 years ago in France, at Sermaize, it seems to have gone no further than the experimental stage. Mr. Denton's suggestion is, therefore, an eminently timely one and appears to involve no serious difficulties in its application. Nearly all the Western States have coal measures from which fuel can be drawn, so that the substitution of electric for animal power can be carried out with a large saving in time and cost. Many readers of THE ELECTRICAL ENGINEER will remember, too, that Mr. W. Forman Collins, of the staff of this paper, had an excellent article some months ago on the relation of electricity to the irrigation of the Western plains.

THE ARGUMENTS ON THE "HYDROCARBON" PATENTS.

THE argument of Mr. Christy, in behalf of the complainant in the recent trial of the suit of the United States Electric Lighting Co. against the Edison Lamp Co., involving the question of the validity of Weston's patent for the hydrocarbon treatment of incandescent lamp filaments, of which we give a full synopsis in another column, brings to a close the proceedings in this interesting and important case. In pursuance of a policy which has been consistently adhered to by the conductors of THE ELECTRICAL ENGINEER, that of placing upon record in its columns every matter of permanent interest affecting the leading electrical industries, no trouble or expense has been spared to present a full and adequate report of the arguments of counsel in each of the three great legal controversies, the final results of which must practically determine the ownership or control for some years to come, of the incandescent lamp manufacture of the United States. The first of these legal contests was the McKeesport case, so called, involving the Sawyer-Man patent for a fibrous carbon, and decided by Justice Bradley adversely to the patent; the second was the New York case, involving the Edison patent for the carbon filament, in which the patent was sustained by Justice Wallace; and the third is the New Jersey case recently tried in Philadelphia and now awaiting the decision of Justice Acheson, on Weston's hydrocarbon patent. Not only has no other journal attempted to give a report of the proceedings in these cases, but it may not be out of place to add that THE ELECTRICAL ENGINEER has received the highest commendation from eminent counsel engaged on both sides for the completeness, accuracy and impartiality of its reports of these trials. It is to the summary of the testimony of witnesses as given in the arguments of counsel, and to the opinions of the learned jurists with whom the ultimate decision of these controversies rests, that the future historian of the art of electric lighting must look for the greater part of his material, and this consideration must be our apology, if any be needed, for having devoted so large a space to matters which may seem to some of our readers of scarcely sufficient immediate interest to justify it.

ELECTRIC TRACTION FOR BROOKLYN.

A LONG fight at last is drawing to its close, and the great city of Brooklyn falls in line with the others that have already adopted electric traction. The common council has given permission to the Brooklyn City, Coney Island and Brooklyn, Brooklyn City and Newtown, and the Atlantic Avenue lines to change their motive power from horses to the overhead trolley system, and it is understood that Mayor Chapin will promptly approve the ordinance; while there is not the slightest reason to expect that the State Railroad Commissioners will change from their favorable attitude toward electric traction. This action by the Brooklyn city council means that about $12,000,000 will be spent there in the next two years in making the change, the Brooklyn City road spending alone at least half that amount.

The opposition to the change has been wild and absurd as usual, with the familiar stories of plague, nuisance and sudden death, and without a single fact in support of the allegations. The *Brooklyn Eagle* in an admirable editorial on the subject congratulates the citizens on the coming addition to the means of rapid transit, and points out that in like manner, though more vigorously, other boons were fought against in the City of Churches, such as the introduction of the water supply, the horse railroads, paid firemen, elevated roads, and uniformed police. All these things though bitterly opposed have come, and now everybody rejoices in their existence. So it will be with the trolley system. We are heartily glad to see that the street railway companies have made so successful a fight for themselves and for the public they serve.

ICE HARVESTING BY ELECTRICITY.

ON the preceding page we have referred to the adoption of the electric motor in agricultural operations, and the benefits which, it is shown, could be derived thereby. The arguments followed in that case are quite applicable to another case which, also, has thus far not received the attention that its importance would seem to merit. The methods pursued in ice harvesting have undergone no change in years, the horse being still the motive power employed. The manner in which the electric motor can be applied for the purpose and the saving in the cost of harvesting ice which can be effected by its use, furnish the subject of an interesting essay by Mr. F. E. Kinsman in this issue. As he points out, it permits not only of greater economy in the harvesting of thick ice, but it even permits of harvesting ice of such a thickness that it could not be attempted with horses; and thus admits of the profitable utilization of thin ice, which is now allowed to go to waste, although in mild winters it forms the only source of natural ice supply. It is not difficult to conceive, also, that a profitable business might be developed in the operation of portable ice-harvesting plants, so that the itinerant grain-threshing machine will find its counterpart in the traveling ice-harvesting machine.

THE SUCCESSFUL COMPETING TELEPHONE.

FOR several years subsequent to the invention of the Bell telephone and its successful application, a large percentage of the applications for patents filed in the Patent Office, in the Electrical Department, consisted of telephonic devices of one form or another, not a few of these relating to new forms of transmitters. Now that the transmitter in present use appears to be endowed with prolonged life by the recent issuance of the Berliner patent, we shall probably note a large increase in the number of telephonic inventions submitted to the Patent Office. Every intelligent inventor ought to know the state of the art in which he is seeking to effect improvement, and for those who have not followed the telephonic art with a view to its improvement, a résumé of the various methods of obtaining telephonic effects in an electric circuit will at this time prove of value. The admirable résumé of Mr. E. P. Thompson, on another page, shows that not a little ingenuity has been already expended in this direction. The experience of the past would seem to indicate that the demand for any invention has always been met when sufficient inducement has been offered to inventors, and in this case certainly the inducement is as great as that ever offered to an inventor. Mr. Thompson suggests a great many ways in which the goal may be reached.

"AMERICA'S GREATEST RAILROAD."

THE series of disastrous collisions which has accompanied the efforts of the management of "America's Greatest Railroad" to operate "the fastest and most perfect through train service in the world," provokes the very natural inquiry why it is, that on what is alleged to be "the only four-track railroad in the world," the passenger tracks should be incessantly blockaded by broken-down freight trains, and why in such case resort must necessarily be had to the archaic and futile expedient of sending a man back with a flag or lantern, who may go or may not, as may happen, and who may be seen or may not, as may happen, by the engineer of the approaching "flyer." The truth is, that two of the tracks of the "only" being one side of the North river and the other two the other side, it is somewhat difficult to separate effectually passenger and freight traffic; while the management seem to be as yet in a state of the most deplorable ignorance in respect to the utility, for signaling purposes, of an agent popularly known as electricity. We would by all means advise these ambitious people to take a course of elementary lessons in the modern art of conducting transportation, which might be done in the kindergarten department of the railway university at Altoona, or some other institution of the kind which is not hopelessly wedded to the outgrown traditions of the days of small things.

ISOLATED ELECTRIC LIGHTING BY LOW-TENSION ALTERNATING CURRENTS.

BY

William Smith Horry

It may seem curious to old-time electricians to hear any one seriously propose to revert to old and discarded methods of electric lighting and under a new name to flaunt them again before the public as something quite new and improved, yet this is precisely what is suggested in this paper. The development of the converter has totally changed the original "alternate current dynamo-electric machine" into the high-tension "alternator" of to-day which seems capable of anything—lighting, heating, welding, metal working, tempering, soldering or of twirling armatures hundreds of miles away. So, too, the development of the choking coil may lead us to revert to the original machine in all its simplicity, and to evolve, thereby, a more perfect method of isolated lighting than has ever existed before.

When the electric incandescent lamp was first invented it was said that the life it had was much increased by the use of the alternating current. I think this was conclusively proved at the time with such lamps as we had in 1880, though it does not apply so forcibly now, with the greatly improved vacuum and the hard and durable filaments such as are now made. Still the lamps *do* wear out slowly even now, the direct current attacking the ends of the horseshoe and the alternating wearing away the filament more evenly, but still surely, until it finally succumbs at the bend.

Electricians will remember, too, the alternating dynamo of 1880 of low tension and large quantity, and the installation of lamps in parallel or two or three in series. Before the days of compound winding for direct-current machines this system had its advantages in the steadiness of the electromotive force curve for all loads. All this is history now; we had no E. M. F. curves in those days. But this style of dynamo is gone. It was considered more expensive to construct than the newly discovered compound-wound, direct-current dynamo; it required too, a separate exciter and there was no advantage to compensate for the extra cost that such a machine entails. So it fell into disuse for several years until the converter was developed; then it assumed a new garb and new sphere of usefulness.

I propose to use again this style of machine connected, as of old, directly to the mains of the building to be lighted. The difficulties attending the installation of an alternating machine have been now overcome, and the dynamo of this pattern is now infinitely simple and little liable to derangement. Moreover, the commutator of the direct-current machine is generally in a neglected condition in isolated plants, and it soon wears out because the average attendant does not acquire the knack of keeping it in condition. In this new system the lamps are placed in parallel across the mains, and the Ries regulating socket is used. With this arrangement each lamp can be turned high or low just like gas, and the whole system then presents the appearance of being unique. The system is especially useful for the lighting of our large hotels which can now be fitted up from cellar to garret bedrooms, and all with absolute safety.

At present there is no electric light system that lends itself completely to this work. In the cities, gas is used in the bedrooms, and in the country, candles to help out the electric light plant downstairs. I have heard it stated by people ignorant of electricity that the electric light will not ascend above the first story. I am inclined to think the statement is correct of the several systems with which I am acquainted.

Extended experience with the Ries regulating socket has brought out very clearly the fact that there is great economy in systematically turning down the incandescent lamp when all its light is not required, although I am perfectly aware that theory conclusively proves the opposite to be true. There is economy in the life of the lamps themselves, and economy of power also; the lamp will last thousands of hours turned down this way, and still work out its 500 hours of good efficiency when turned on full. And then the current; the energy required to light up one corridor in a hotel would light up three or four well enough if the lamps were controllable and were adjusted to the requirements of the guests. If the light be wanted it is there; it indicates its own location and invites one to turn it on.

It is therefore contended that the low-tension alternator with the Ries regulating socket and lamps as described, introduce a combination which is an advance upon the usual practice of installing isolated plants, and that it will be found both on the score of economy and adaptability, greatly superior to any direct-current non-controllable system. It is, moreover, the only plan yet suggested for isolated lighting which is completely adapted to all the varied requirements of artificial illumination.

REACTIVE COILS IN PRACTICAL WORK.

BY

S. G. Neiler

In The Electrical Engineer of Dec. 9, under the title of "Reactive Coils," Mr. Otis K. Stuart explains the principle underlying the action of the coils, by giving a very clear explanation of what takes place in a transformer, but does not take up the reactive coil as it is used commercially. In reading over Mr. Stuart's article it struck me that it would not be amiss to go a step further and explain just how the current flowing in a circuit is controlled by the reactive coil and it is with that idea in view that I have written the following, hoping the same might be of some benefit to those not already familiar with the subject.

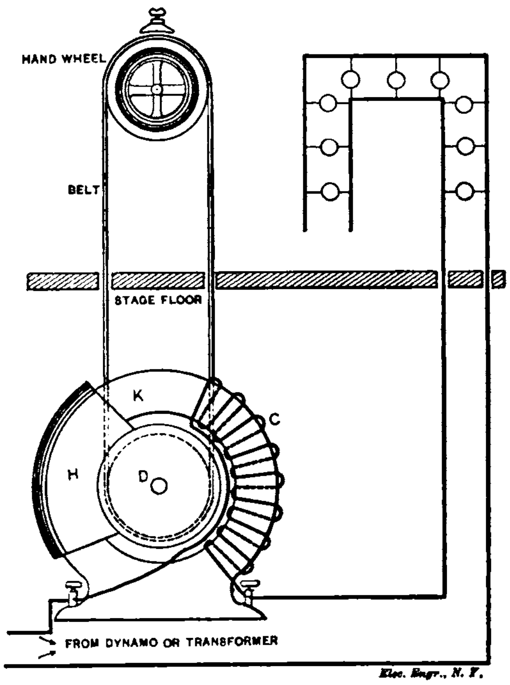
Mr. Stuart says: "A reactive coil placed directly in the circuit of an alternating system, therefore, can be made to control the amount of current going over the system. * * * Probably the most interesting application has recently been made use of by Mr. Elias E. Ries." He then gives a description of the socket, and says, "A very small reactive coil is so connected to a series of contacts that, by means of a movable arm * * * a relatively small or large amount of current may be admitted to the filament."

I think that one not familiar with the action of a reactive coil would be led to the conclusion that the only method of varying the strength of current would be by making a number of connections or "loops" into the coil and cutting out, or in, more turns which, of course, would accomplish the object, as exemplified in the Ries socket. But I think by far the most beautiful manner is that designed by Prof. Elihu Thomson and used by the Thomson-Houston Electric Company in their apparatus.

To explain clearly it will be necessary to understand that by placing a closed coil around an alternating magnetic field a current is induced in the coil forming the closed circuit, exactly similar to a transformer whose secondary is short-circuited. Now we may consider the action taking place in a Thomson-Houston reactive coil as illustrated in the accompanying diagram. This consists, primarily of a laminated iron core in the form of a closed ring K, about one part of which is wound a comparatively few turns of fine insulated wire C, covering about one-third of the circumference. Inside of this ring is a laminated iron drum D, fastened to which, and passing around the outer ring, is a copper hood H of large area, forming a closed coil about the ring and which fits closely, leaving a very small air space between it and the ring. This hood is fastened rigidly to the inner core and is provided with a handle or a pulley and belt so that it can be moved to occupy any position relatively to the winding on the ring.

When this hood is furthest away from the winding, the action is such as to increase the magnetizing effect of the coils by closing the magnetic circuit through the drum and hence to increase the number of lines flowing in the iron ring, so that the self-induction of the coil is very great and enough to nearly overcome the impressed electromotive force, thereby reducing the current flowing through the lamps.

By moving the hood so that it covers the winding, the current flowing in the hood would tend to counteract the magnetizing effect of the coils and by so doing lessen the self-induction of the same. When so placed, the relation



THE THOMSON REACTIVE COIL.

between the hood and the coils is the same as would exist in a transformer whose secondary was short-circuited and hence the coil offers but little resistance to the passage of the current. In any intermediate position of the hood the effect would be to increase, or decrease, the self-induction of the coil as the hood was moved further from, or nearer to, the winding.

The current used in the lamps is nearly in direct proportion to the brilliancy of the light; such being the case it is seen that in these reactive coils there is comparatively little loss of energy. The arrangement is such that when the hood completely envelops the winding, the coil is short-circuited, the hood completing the circuit across the terminals, and by so doing avoiding the loss due to the resistance of the coil and allowing the lamps to take their full amount of current. In the Ries socket the object is accomplished by cutting out sections of the winding and thereby reducing the self-induction in the wire and allowing a correspondingly greater current to flow.

The above, together with Mr. Stuart's article, will, I think, help to make the action of the reactive coil clear to those not already acquainted with the same. The illustration shows the arrangement employed for regulating the lights in theatres, the reactive coil being operated by a pulley and belt on the stage floor.

NOTE ON GALVANIZED IRON TELEGRAPH WIRE.

BY

Frederic A. C. Perrine

In the London *Electrician* for December 28, 1888, there was printed an article giving the results of tests, and the requirements of galvanized iron telegraph wire as used by the Postal Telegraph Department of Great Britain. In this article it is stated that two qualities of wire are used, one known as "high-resistance" wire and the other as "low-resistance" wire, the first giving a resistance at 60 degrees F. of 12.7 ohms per mile for a wire of the standard gauge, 171 mils, while the low resistance wire is either of "special blend" iron, 11.3 ohms per mile, or "charcoal" iron, having a resistance under the same conditions of 11.2 ohms per mile. This low-resistance wire is used for circuits exceeding 200 miles and the high-resistance for shorter lines. A tabulation of the qualities of these three grades of wire is also given, together with a mile-ohm comparison with pure iron.

According to this, the breaking strength of the "blend" iron is 3.2 times the weight per mile, of the "charcoal" 2.87 times the weight per mile, and the "high-resistance" 3.5 times the weight per mile; the two "low-resistance" wires give from 16 to 17 per cent. elongation in breaking, and the "high-resistance" 17 to 18 per cent. For a wire from 209 mils in diameter to one of 121 mils in diameter the number of twists in six inches varies in the "blend" iron from 17 to 30, and in the "high-resistance" from 22 to 38. The weight per mile-ohm of pure iron is given as 4,368.94 lbs., of the "blend" iron as 4,520, of the "charcoal as 4,480, and of the "high-resistance" as 5,080.

These are very interesting results, and in some respects remarkable, but the writer has not stated whether they are maximum or minimum figures, or whether they are averages of actual tests; neither does he seem to take into account the alteration in the mile-ohm of pure iron due to galvanizing it, since he says: "The relative resistances of pure copper and Swedish charcoal iron, similar to that used for the best line wire, are as 1 : 6.034; or the resistance of commercial iron is 6.034 times that of pure copper, not 6.558 times, as is usually given in text books. From this it appears that iron wire may now be obtained having a conductivity of 98.44 per cent. of pure iron."

Still, when he gives the mile-ohm weight of the best galvanized "blend" wire it has only the conductivity of 97.51 per cent. of that of pure iron, whereas the effect of galvanizing should be to reduce rather than to increase the weight of the mile-ohm.

In this country there is but one quality of wire at present in use for telegraph service in commercial lines, where a consistent series of tests is maintained. For short local lines and railroad private wires a great deal of steel and puddled iron is employed, but in these cases the only requirement is that it should stay on the poles and conduct. But our great telegraph companies employ for their commercial lines only the quality of iron which is known to the trade as "*Ex. B. B.*," a rather generic term, which is so interpreted by the specifications of the telegraph companies as to exclude all except the best grades of Swedish and Norway irons, which are imported in rolled rods and drawn, annealed and galvanized in this country.

Of this *Ex. B. B.* galvanized iron wire, about two years ago I had averages cast up from a long series of tests made on wire manufactured for the Western Union Telegraph Company, and found that the results varied with the size of the wire to a considerable extent; but that for any one size, the various tests were fairly concordant, and show that one wire is about 4 per cent. poorer in conductivity than the figures given on the English "blend" low-resistance wire, while the figures given on the "high-resistance" wire would not fill the specifications of our telegraph companies.

The exact averages on our wire are:

Date of test.	Size, B. W. G.	Quantity tested.	Resistance per mile.	Weight per mile.	Weight per mile-ohm.	Breaking weight.	Twists in 6 inches.	Elongation, per cent.
Feb., '88, to Jan., '89..	4	85 miles	6.51	716.7	4,664	3,016	18.5	13.83
Jan., '88, to Dec., '88..	6	650 "	8.55	544.96	4,663.5	1,454	18.9	13.82
Sept., '88, to Jan., '89..	8	3,500 "	12.18	379.8	4,629.5	980.5	21.4	15.16
Sept., '87, to Nov., '89..	9	8,300 "	14.008	331.9	4,620.5	877	24.3	14.21

The gradual decrease in the weight of the mile-ohm here to be observed is partially due to the greater proportionate amount of zinc on the smaller wires, though from the decreased elongation as well as the increased tensile strength of the heavier wires there seems to be an indication of more perfect annealing in the case of the smaller wire.

These tests upon a given number of miles are obtained by inspection of the wire in lots of from 50 to 100 miles, out of which are selected at random a certain number of coils,—about 10 per cent.,—from which test pieces are cut and carefully measured. These may, therefore, be taken as fair averages of the wire as it is produced for stringing on the poles in service. In experimenting with various grades of iron before finally selecting that which has been taken as the standard, remarkable results were obtained, and irons were found of much better quality, but, unfortunately, of which the price, when brought to this country, was prohibitory.

I have before me the result of a test of three samples made September 26, 1881, of which the weight per mile-ohm was 4,259.5. One of No. 12 galvanized wire manufactured by the Palmer Wire Company, tested March 31, 1884, giving a mile-ohm weight of 4,226.25, as well as quite a large number of samples giving better results than 4,350 pounds per mile-ohm. A number of tests have also been taken at various times on the same wire, both before and after galvanizing, and in every case there is a reduction in the weight of the mile-ohm by at least 5 per cent., due to the greater conductivity of the zinc.

While the results given above would indicate that in this country our telegraph companies do not use as high a grade of iron as the British Postal Department, yet I should judge from the method in which the English figures are given that our averages are fully as high as theirs, while in neither case is the highest obtainable grade of iron used.

HEYL ACCUMULATOR.

In the accumulator recently introduced by M. G. E. Heyl, the electrodes are composed of combinations of plumbic, chromic or tungstic acids with calcium, barium or strontium. To increase the coefficient of output and capacity, the inventor uses more particularly compounds of calcium and lead for the reason that these are easily oxidizable. The combination $CaPbO_4$ corresponding to 68 per cent. of peroxide of lead, contains 4.56 per cent. of active oxygen. The other alkaline earths, or of baryta, or strontium, furnish analogous compounds applicable to the purpose. Besides the advantage resulting from the chemical nature, the compound $CaPbO_4$ would offer a further valuable property in its porosity; it might replace the diaphragm employed to separate the elements of cells. The analogous compounds of chromium and tungsten can be employed in the same manner.

ELECTROMOTIVE FORCE, WITH SPECIAL REFERENCE TO THE EXTENSION OF OHM'S LAW.—II.

BY

Maurice Oudin, M.S.

The measurements of E. M. F. have in all cases been made in air. The result cannot with certainty be considered the true contact force. What is measured is not the Volta effect of zinc and copper, but zinc, air and copper, which may be something quite different. With the object of finding out what influence atmosphere had upon E. M. F., Von Zahn placed a pair of metallic plates in a vacuum. The E. M. F. of the two elements was considerably lower than that in air. The impossibility of obtaining a perfect vacuum prevents any conclusion from this test. For the E. M. F. depends not at all on the quantity of the active material present. Though only a few molecules of oxygen remained in the vessel, the effect would not be materially changed. Clerk Maxwell suggested measuring the E. M. F. of two substances by the Peltier effect. Speaking of the Volta force in the first volume of his classical work, he says: "The greater part must be sought for not at the junction of the two metals, but at one or both surfaces which separate the metals from the air or other medium which forms the third element in the circuit." Oliver Lodge, who is at the head of what we may call the modern school of electricians, agrees with Maxwell's views as far as they go. The contact-force not being sufficient, we have seen, to account for the whole E. M. F., the question naturally arises, where is the true source? Prof. Lodge locates it at the junction of the zinc and electrolyte. He regards the air as a dielectric bath of oxygen. Metals immersed in it are attacked by the oxygen molecules If they do not succeed in combining with the metal, the effort to do so, the chemical strain, as it were, produces certain physical effects. Oxygen being an electro-negative element, attacks the metals with different degrees of intensity. Hence the difference of potential. The medium, air, may be replaced by a fluid. In the case of a gas the dielectric is in a state of strain. If an electrolyte be the medium a current flows on connecting the metals.

It is well known that the entire heat developed in any battery is exactly equal to the heat that would be obtained by burning or consuming the elements of which the battery is composed, in some chemical capable of acting upon these elements. Accordingly the energy of such a battery bears a direct relation to the chemical changes taking place. It would naturally follow that such dependency should exist between the transfer of energy in the battery and the E. M. F. developed. This relation calculated from the heat of combustion of the elements composing various batteries has been found to exist in some cases. But up to the present, whether from errors in our data or the omission of some necessary constant, this dependency has not been found to be universally true.

There seems now to be no doubt about the presence of a true contact force at the junction of two metals. It is scarcely appreciable, being, under the best conditions, less than the E. M. F. of a single voltaic cell. It is dependent, apparently, upon the unequal vibration of the molecules of the dissimilar substances. There is an impingement and a constraint of molecules having different velocities. The molecules of one metal fail to accommodate themselves to the time of vibration of the opposing molecules, and a flow is set up in the direction of greatest impact.

The so-called thermo E. M. F. discovered by Seebeck is a variety of contact force, produced when the junctions of a circuit formed of different metals are brought to different temperatures.

It has been found that for the production of a contact-force, it is not essential that the circuit should consist of different metals. A lack of homogeneity in two conductors of the same metal also gives rise to an E. M. F. when one juncture is heated.

Frictional electricity, or electricity in equilibrium, is the manifestation of contact-force. The specific resistance of substances that are good generators of static electricity is well nigh infinitely great compared with that of metals. In metallic bodies the excitation is at once propagated throughout the entire mass. In non-conductors it remains at the surface of contact, which is increased by the rubbing, and there accumulates. Consequently, while in metals the true contact-force is almost inappreciable, in non-conductors the same force may become very great.

One of the earliest known electrical phenomena was the property that certain crystalline bodies possess of acquiring opposite states of electrification at opposite ends, when subject to a variation of temperature. Tourmaline displays this property in a marked degree. It retains its charge for a considerable time, and if suspended in the presence of electrified bodies, it behaves much as a needle in a magnetic field. Certain crystals also become charged with electricity when subject to a mechanical strain or deformation. Quartz crystals, from their size and purity, show strong electrification under such conditions.

Another source of E. M. F. is the action of light on selenium, that rare element generally found associated with sulphur. The cell is usually made of two metals coated with selenium. Mr. Fritts used brass and gold plates. W. Siemens found the E. M. F. set up in diffused day-light proportional to the intensity of light, while Von Uljamn, using platinum plates thin to transparency, found it proportional to the square root of the intensity of the light. As the generation of a current requires energy, the question arises, Whence does it come? It is generally conceded not to be due to thermal action. It is either a chemical change resulting from the action of light, or a direct conversion of light waves into electrical energy. There is good ground for giving the preference to the latter explanation.

An E. M. F. is set up when a thin cross-shaped metallic strip conveying a current is placed in an intense magnetic field. If the terminals of a sensitive galvanometer and of a battery be connected to opposite arms, and the strip be placed so that its plane is at right angles to the direction of the magnetic field, the presence of a current will be indicated by a slight deflection of the galvanometer needle. This is the Hall effect.

A year ago there appeared in the technical press, an article on the generation of a magneto-optical E. M. F. It is well known that a ray of polarized light traversing a magnetic field in a direction parallel to the lines of force, will have its plane of polarization twisted an amount depending on the strength of field. Conversely, if by any means a polarized beam of light can be made to oscillate it ought to generate an alternating E. M. F. Prof. Sheldon claims to have reached such a result. It was shown however, by Prof. Brackett, of Princeton, that the E. M. F. detected could not have been due to the ascribed cause. We might expect from the reversibility of most physical phenomena that some effect would be produced. However, as a scientific authority suggests, since polarized light passing through a solution of sugar has its plane rotated it would follow that if polarized light fell on one side of a glass beaker containing water and its plane be rotated, sugar might be expected to fall out at the other.

The various sources of E. M. F. that have been described above are capable of evoking a continuous current. In such circuits the galvanic constants are related according to Ohm's law. Now there is another order of phenomena, where Ohm's law fails to apply. It was found early in the history of telegraphy, that when the key of the transmitting instrument was opened and shut many times in a minute, the effect upon the receiving magnet at the other end of the line was much diminished. The current for some reason did not attain its maximum value during the make and break of the circuit. With a given number of cells and a line of known resistance, the current in practice was less than it ought to have been by Ohm's law. Evidently the element of time, which did not enter into Ohm's law, had to be considered. It was not long before it was proved that the retardation of the full value of the current and its diminution when the circuit was rapidly made and broken was due to the electromagnetic induction of the circuit on itself, or, as it is briefly called, self-induction. To understand the modification of Ohm's law through self-induction, we must study the nature of induction and how this quality of a circuit gives rise to a counter E M. F.

The phenomena of induction were discovered by Faraday in 1831. Oersted had 11 years previous observed how a current affected an adjacent compass, causing it to deflect from its position in the magnetic meridian. This proved as a fundamental fact the existence of a magnetic field surrounding a wire conveying a current. Faraday took up the line of experimental investigation at this point, and by a series of brilliant and remarkable experiments brought out all the facts of electromagnetic induction. He found that when a wire was moved in the vicinity of a magnet, or when a wire conveying a current was moved relatively to another wire, a temporary E. M. F. was set up. He found this to vary in strength with the velocity with which the wire was moved. The same result was obtained when the conductors remained stationary and the current in one was increased or diminished. Although the phenomena of induction are many and complex, they arrange themselves under the heads of electromagnetic, self and mutual induction. The E. M. F. due to electromagnetic induction constitutes Faraday's principal discovery. Its general conditions have been stated. The name is restricted to that E. M. F. induced by the movement of a conductor near a magnet, or a wire conveying a current.

Both Henry and Faraday were early and indefatigable workers in the field of induction, and it is not so very strange that they independently discovered magnetic and self-induction. Priority of discovery of self-induction is given to Henry. He observed that when the current in a long wire was interrupted, a spark of some brightness appeared at the break, showing an increase in the strength of the original current. This is the so-called extra current. Henry explained the phenomenon, and gave it its present name. It is well worth while to notice here the insight Henry had at that early day into phenomena that only recently have assumed importance. In 1832 he discovered the oscillatory character of the lightning flash and also the discharge of Leyden jars. Years later Sir Wm. Thomson proved the same mathematically.

To properly understand induction, and more particularly self-induction, we must remember that a current traversing a wire produces a commotion in the medium surrounding it. We know that if such a wire be made to pass through a surface on which are sprinkled iron filings, the filings will arrange themselves in concentric rings around the wire. The circles thus formed show the direction in which the force of the current acts. When a current is started, the lines of force spread out on all sides like the ring waves in a pool of water from a central point of disturbance. When the current is broken, the lines of force collapse and fall back upon the wire. By the general theory of induction the springing up or dying away of magnetic lines produces an instantaneous E. M. F., always in such a direction as to oppose the change in the current. Hence self-induction prevents the current from immediately arriving at its maximum value on making the circuit, and causes it to persist a while after the break. It would appear as if a current of electricity possessed a quantity of the nature of inertia. A fly-wheel absorbs energy in passing from a condition of rest to a definite velocity, and then gives it all up again as work in some form on slowing down. To maintain its velocity uniform, if we neglect friction, no work need be done upon it. The analogy can be applied to the case of a wire carrying a current. Starting a current implies work done in the medium which is derived from the electrical energy of the current. Stopping the current restores the energy to the system. No expenditure of work is required to maintain its magnetic field when the current has assumed a steady regime. Faraday called that condition of the medium produced by a current the electro-tonic state. He lacked sufficient mathematical training to deduce the ultimate consequences of his experiments; but he recognized that induction depends on a change in the medium, and that in this operation work is involved.

Mutual induction is the third division of the general phenomena of induction. As self-induction is the flux of magnetic force produced around a circuit by any change in itself, so mutual induction is the magnetic flow set up in a circuit by any change in the current of an adjacent circuit. It is then the number of lines of force linked in two circuits when one circuit contains a varying current.

The current resulting from inductive E. M. F., or influenced by it, such as at the make or break of a circuit, or during any variable period, cannot, as we have seen, be calculated from Ohm's law. It is invariably less than it would be if it obeyed that law. The element of time has to be considered, that is, the delay in the current behind the E. M. F., and further, that any variation of the current implies work which, according to the sense of the change, is taken from, or added to, the energy of the current. The law of Ohm has to be modified to meet these cases by the introduction into the expression of a factor whose value depends on the conditions of the circuit and on the time. We apply this factor to Ohm's formula. It is then no longer a simple expression, but Ohm's law extended, or as Dr. J. A. Fleming calls it, when the factor becomes complex and troublesome "Ohm's law glorified." In circuits in which there exists a varying E. M. F., we have in place of Ohm's law, Helmholtz's well-known equation:

$$i = \frac{E}{R}\left((l - e - \frac{t}{T} \right)$$

In words this equation means that the current at any instant is equal to the current which would flow if there was no self-induction, less a quantity depending on the induction and resistance of the circuit, and also on the time from the instant when the circuit was made. A final solution of this equation when the E. M. F. varies periodically is:

$$i = \frac{E}{\sqrt{R^2 + p^2 l^2}} (\sin p\, t - \theta)$$

where p is 2π times the frequency of the current, and θ an angle, whose tangent is the ratio of $p\, L$ to R. To account for the diminution of the current in the variable state, the factor introduced into Ohm's law may be regarded as diminishing the impressed E. M. F. as in Helmholtz's expression, or as increasing the resistance in some way, as in the second equation. In practice the last form is more convenient, and we have in the denomination of the mathematical expression of Ohm's law thus modified a quantity to which the name impedance has been given, composed of the ordinary Ohmic resistance and a term inductive in character called the inductive resistance. As Helmholtz's equation shows an induction E. M. F. acts in opposition to the impressed E. M. F. As work is involved we might expect this result from conservation of energy. Such an opposing reaction is a counter E. M. F. Hence any work done in a circuit, such as electrolytic action, heating or cooling a junction, or moving a magnet, is a counter E. M. F., since it gives rise to an E. M. F. that opposes the original.

It follows that Ohm's law must be modified not only when there exists an induction E. M. F., but also when there is interposed in the circuit a counter E. M. F. due to any cause.

Whatever be the nature of the current, we find that the expression for its value, no matter how complex, retains the general features of Ohm's law. In all cases it may be resolved into two factors, one representing the value the current would have were the instantaneous conditions to continue—Ohm's law pure and simple—the other dependent upon the conditions under which the changes are taking place, and properly considered as modifying the first.

ON POLYPHASAL GENERATORS.—II.[1]

BY M. I. PUPIN, PH. D., COLUMBIA COLLEGE.

Consider now n iron ring cores of exactly the same dimensions and made of the same material. Let ρ be the reluctance of each ring. Let each of the n coils be interlinked with one of the iron rings; we shall have n homogeneous magnetic circuits, and as long as the magnetization of these rings is considerably below the saturation point we shall have

$$\frac{4\pi\, s\, c_1{}^1}{\rho} + \frac{4\pi\, s\, c_2{}^1}{\rho} + \ldots\ldots\ldots\ldots + \frac{4\pi\, s\, c^1{}_n}{\rho} = 0$$

That is to say, the magnetic induction in the n magnetic circuits obeys the same law as the n electric currents; we can therefore employ the method of polyphasal connection for the magnetic circuits also and we obtain what the Germans call a Verkettung der Magnetischen Ströme, which may be translated into English by a more accurate expression: Polyphasal *coupling* of magnetic circuits. A transformer constructed on this principle may be called a *coupled transformer.*

A simple consideration will show that the field rotates around the axis of the ring B synchronously with the rotation in the generator which produces the impressed E. M. forces. Consider the armature of the generator. Since the ampere turns on one side of the neutral plane are always equal and opposite in sign to the ampere turns on the other side of this plane it is evident that the magnetic field due to the ampere turns in the armature is fixed in space and perfectly symmetrical with respect to the plane of symmetry PP[1]. We can therefore say that this field, though *fixed in space, rotates with respect to the armature* with the *same angular* velocity with which the armature rotates in space. The distribution of the ampere turns over the stationary ring B being at any moment the same as that over the armature ring, it follows that the magnetic field of B also rotates with respect to B synchronously with the rotation in the armature. An inspection of the diagram in Fig. 4 will show that when the rotation in the generator is reversed the rotation of the field B will also be reversed.

The strength of the rotating magnetic field will vary in strength because the strength of the two equal magneto-motive forces which are working in multiple arc will vary. The following simple consideration will show us the law of this variation. Two cases must be considered separately. First, when n is an odd number; secondly, when n is an even number.

Case 1.

A simple definition will save me the tedious repetitions of long sentences. I define the sum of all the electromotive forces generated in all the turns which are at any moment on the same side of the neutral plane of the generator as the resultant impressed E. M. F. at that moment. The magnetomotive force of the rotating field will evidently vary according to the same law as the resultant impressed E. M. F. To find the law of variation of the resultant impressed E. M. F., consider the armature of the generator when the angle θ of coil 1 is zero. To make the reasoning shorter, I make now the angular width of each coil equal to $\frac{2\pi}{n}$, so that the n coils completely cover the ring, which makes $\alpha = \frac{\pi}{n}$. If this angular width is smaller, then a simple consideration will show that the law of variation which I am about to deduce will be exactly the same. In the position just mentioned, the coils 1, 2, 3, ... $\frac{n-1}{2}$ will all be on the same side of the neutral plane, whereas coil $\frac{n+1}{2}$ will be just half on one side and half on the other side of this plane. There is no electromotive force generated in this coil. As the above-mentioned angle θ begins to increase from zero, coil $\frac{n+1}{2}$ begins to contribute to

---

1. Read at the sixty-second meeting of the American Institute of Electrical Engineers, New York, December 16th, 1891.

the resultant impressed E. M. F., but this contribution is just counterbalanced by the loss due to the entrance of coil n into the opposite region of the neutral plane. The variation in the resultant impressed E. M. F. is therefore due solely to the change of position of the turns in the coils 1, 2, 3, ... $\frac{n+1}{2}$, or on one side and the corresponding turns on the other side of the neutral plane. This will be the case until coil $\frac{n-1}{2}$ has completely passed to one side of the neutral plane and coil n is just bisected by it. During this interval Θ has increased from zero to $\frac{1}{2}\frac{2\pi}{n} = \frac{\pi}{n}$. The value of the resultant impressed E. M. F. at any moment during this interval is easily found. Denote it by E, then

$$E = e_1 + e_2 + \ldots\ldots e_{\frac{n-1}{2}}$$

$$= K\left\{\sin\left(\theta + \frac{\pi}{n}\right) + \sin\left(\theta + \frac{\pi}{n} + \frac{2\pi}{n}\right) + \ldots\ldots + \sin\left\{\theta + \frac{\pi}{n} + \left(\frac{(n-1)}{2} - 1\right)\frac{2\pi}{n}\right\}\right\}$$

$$= K\left\{\sin\left(\theta + \frac{\pi}{n}\right) + \sin\left(\theta + \frac{\pi}{n} + \frac{2\pi}{n}\right) + \ldots\ldots + \sin\left\{\theta + \frac{\pi}{n} + \left(\frac{n-3}{2}\right)\frac{2\pi}{n}\right\}\right\}$$

$$= \left\{\frac{K_1 \sin\left(\theta + \frac{\pi}{n} + \frac{n-3}{4}\frac{2\pi}{n}\right)}{\sin\frac{\pi}{n}}\right\} = K_2 \sin\left(\frac{\pi}{2} + \theta - \frac{\pi}{2n}\right)$$

$$= K_2 \cos\left(\theta - \frac{\pi}{2n}\right)$$

It is evident that the resultant impressed E. M. F. E varies during the interval from $\theta = 0$ to $\theta = \frac{\pi}{n}$ just like $\cos\left(\theta - \frac{\pi}{2n}\right)$; that is to say it varies just like a simple harmonic. When $\theta = \frac{\pi}{2n}$, E reaches a maximum which is equal to K_2, it has a minimum both when $\theta = 0$ and when $\theta = \frac{\pi}{n}$; each of these minima equals $K_2 \cos\frac{\pi}{2n}$. The ratio of the minimum to the maximum value equals $\cos\frac{\pi}{2n}$. For a three-phase system this ratio is .866, and it diminishes very rapidly as n increases. It is evident that after θ has reached the value $\frac{\pi}{n}$ the armature is, as far as concerns the resultant impressed E. M. F. in exactly the same position as at the start when $\theta = 0$. We conclude therefore that E has $2n$ equal

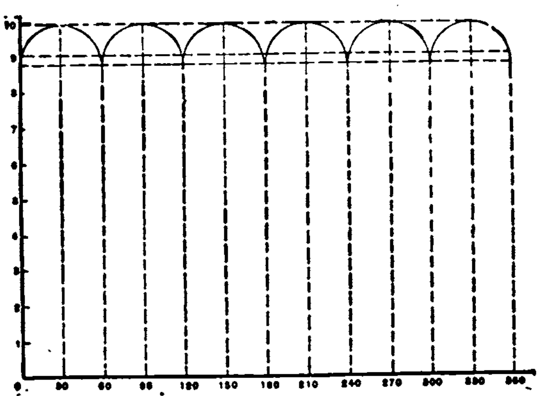


Fig. 5.

maxima and $2n$ equal minima during each revolution of the armature. In diagram Fig. 5 these fluctuations of E for a three-phase system are represented graphically.

CASE 2.

The same relations hold good when n is even. The maxima take place when $\theta = 0, \frac{2\pi}{n}, \frac{4\pi}{n}, \ldots\ldots$, The minima when $\theta = \frac{\pi}{n}, \frac{3\pi}{n}, \frac{5\pi}{n}, \ldots\ldots$ and the ratio of any minimum to any maximum is $\cos\frac{\pi}{n}$. Since the magneto-motive force varies according to the same law as the resultant impressed E. M. F., it follows that the strength of the rotary magnetic field fluctuates periodically, having $2n$ equal maxima and $2n$ equal minima during each revolution and the ratio of any minimum to any maximum equals $\cos\frac{\pi}{2n}$. That is, when n is odd, but when n is even then there are n maxima and n minima and the ratio of any minimum equals $\cos\frac{\pi}{n}$.

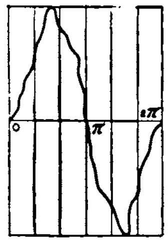

Fig. 6.

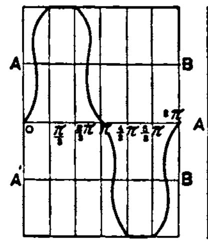

Fig. 7.

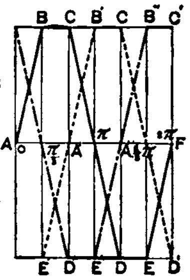

Fig. 8.

A polyphasal generator of this kind would produce a rotary magnetic field of constant strength only when $n = \infty$. For a three phase system the maximum variation would be nearly 14 per cent. of the maximum value. This agrees perfectly with Mr. Dobrowolsky's calculations, but I fail to see how these calculations could justify any one to assume that they hold good for all types of polyphasal generators[1]. The generator which we have considered could be actually constructed but its output would be so small in proportion to its size that we may dismiss it at once as an impracticable machine. We can make it practicable by substituting for the non-magnetizable ring which carries the armature coils a laminated iron ring and for the uniform magnetic field the magnetic field of a well made field magnet with its pole-pieces placed with respect to the armature coils in any one of the various ways sanctioned by practical experience. But in a generator of this kind the resultant impressed E. M. F. will no longer vary according to the law which I have pointed out a little while ago. To be sure, we shall still have the same number of maxima and minima, as may be inferred readily from our knowledge of the shape of the E. M. F. curve of a continuous current dynamo. We all know that this curve is not in general a straight line, but a wave line having as many maxima and as many minima as there are sections in the commutator. But the ratio of the maxima to the minima is no longer an a priori calculable quantity. If we knew the mathematical relation between the intensity of the field at any point of the armature surface and the co-ordinates of this point with respect to the neutral plane then we could calculate that ratio, but the amount of experimental and practical work involved in this problem would be very great. A much easier and practically much more important problem is to determine the conditions which must be fulfilled in the construction of a polyphasal generator, in order that it may be capable of producing a rotary magnetic field of constant intensity in the simplest possible way, that is, without the application of brushes and commutators. Mr. v. Dolivo-Dobrowolsky seems to think that the three-phasal generator is incapable of doing that, for he distinctly says that such a generator necessarily produces a rotary magnetic field whose strength varies 14 per cent. He also states that (evidently to obviate these fluctuations) the Allgemeine Elektricitaets Gesellschaft employ a method of transmitting currents of smaller differences of phase than one-third of the period through three wires. In this point they claim to be ahead of Tesla, Bradley, Haselwander and Wenstrom. In fact if one is not exceedingly careful in the perusal of Dobrowolsky's discussions of this subject he will be lead to believe that the rotary field in some of Tesla's motors varied as much as 40 per cent. and certainly not less than 14 per cent. I do not think that Mr. Dobrowolsky wishes to be understood as holding that opinion; for neither he nor anybody else excepting Tesla himself can know what these variations were. The number of phases employed tell us nothing definite about the range of these variations.

A polyphasal dynamo which is capable of producing a rotary magnetic field of constant intensity must be constructed in such a way that its resultant magneto-motive force must remain constant as long as speed and the magnetic field of the field magnets remain constant. As long as the variable electromotive force developed in each coil follows the law of a simple harmonic that result can never be accomplished by a finite number of phases,

1. M. v. Dolivo-Dobrowolsky: Der Drehstrom und seine Entwickelung; Officielle Austellungs Zeitung, Electricitaet, Heft 12.

but it may, perhaps, be accomplished by producing in each coil of the generator a variable electromotive force which varies according to some definite complex harmonic law. In a well-made commercial machine the electromotive forces developed in the various turns of the armature always vary according to some such a law. *The form of this complex harmonic law depends on the form of the magnetic field of the field magnets and also on the distribution of the coils over the armature.* The problem that remains to be investigated consists therefore of three parts: 1st. What must be the particular form of the complex harmonic E. M. F. developed in each coil of a polyphasal generator, in order that both the condition of continuity be fulfilled and also that the resultant impressed E. M. F. be continually constant. 2d. What form of the magnetic field of the field magnets will be capable of producing such an E. M. F. 3d. Can a continually constant resultant E. M. F. produce a rotary field of constant strength.

1st. The first part of this problem is purely mathematical. In a paper read before the New York Mathematical Society I indicated a method of discussing this part in a general way, and worked out completely two particular cases, namely, the cases of a three and four phasal system. The paper is given in the appendix.

2d. For a three-phasal system the form of the complex harmonic E. M. F. given in Fig. 7, will satisfy all the conditions. The form A, B, C, D, E, F, given in Fig. 8, is only a particular case and ought to be aimed at in the construction of the machine.

When there are only three turns within a space through which the armature moves with respect to the field during the time that corresponds to a complete period as in the case of the Lauffen generator (see Figs. 11 and 12), then the field of the field-magnets must be constant in intensity during an angle which corresponds to one-sixth of the period. I have indicated that in the diagram Fig. 9. In the case of bipolar three-phasal generators as indicated in the diagram Fig. 10, where we have six coils, the diametrically opposite pairs being connected in series, the pole faces must have an angular width of 120 degrees and the field must be constant in intensity within the region bounded at any moment by the armature and the pole faces. This is a practical problem offering no serious difficulties judging from the experimental results obtained by S. Thompson, Isenbeck, Mordey and others, and also from the experimental results obtained lately by a graduate of our school, Mr. Freedman, John Tyndall Fellow of Columbia College.

The curve of impressed E. M. F., which must be produced in the case of a four-phasal generator is given in Fig. 13, and needs no further commentary. Larger number of phases offer no special advantages whereas the disadvantages arising from employing a large number of phases are self-evident.

3d. When a coil in which a simple harmonic E. M. F. is developed is closed by a resistance, whether self-inductive or non-self-inductive, the current which is set up in the closed circuit will be a simple harmonic, having therefore all the characteristics of the impressed E. M. F. This, however, is not necessarily the case when the impressed E. M. F. is a complex harmonic. A complex harmonic E. M. F. is composed of a large number of simple harmonic E. M. forces of different frequencies, all the higher frequencies being multiples of the fundamental frequency. When, therefore, a coil in which a complex E. M. F. is generated, is closed by a conductor, and the current is started, the current will be also

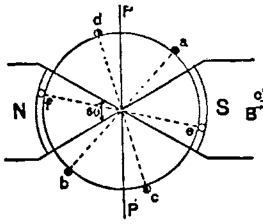

Fig. 9

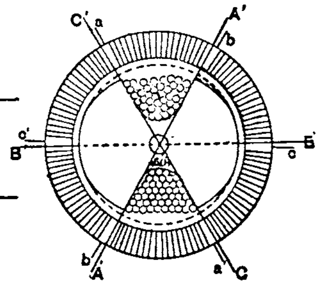

Fig. 10.

a complex harmonic, each simple harmonic component of the complex harmonic E. M. F. producing its own simple harmonic current which is a component of the resultant complex harmonic current. But since the component simple harmonic E. M. forces have each a different frequency, it follows that they will have a different impedance and the shifting of phase will be also different for each component current, currents of higher frequency having a larger shifting in phase and also the ratio of the amplitude of any one of the component currents to the amplitude of any other component of lower frequency, being smaller than the ratio of the amplitudes of the corresponding component E. M. forces. In this respect the propagation of the complex harmonic current-wave resembles very much the propagation of a complex harmonic sound-wave or a complex harmonic light-wave through an absorptive medium like air. The component simple harmonic waves of light and sound will in general suffer the less through the transmission, the longer their wave-length. Just as the sound and light-waves, after such a transmission, lose a great many characteristics of the original vibration which produced them, so an electric wave in its transmission through a conductor possessing ohmic resistance and electromagnetic, not to speak of the

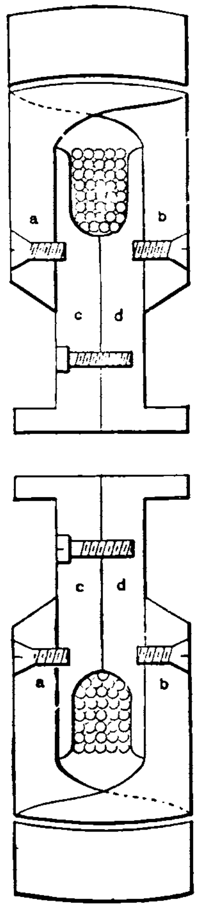

Fig. 11.

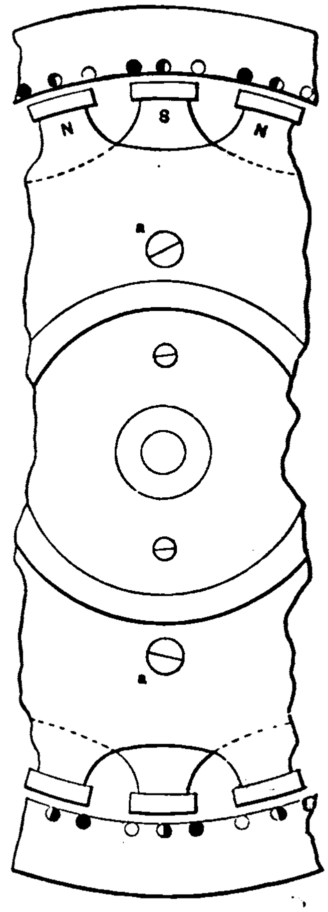

Fig. 12.

electrostatic, inductance will lose a great many characteristics of the impressed E. M. F.

To put this into simple symbolic language of mathematics,

Let L be the coefficient of self-induction of the circuit,
" R be the total resistance,
" $K \sum_{1}^{\infty}{}_m a_m \sin m\,p\,t$ be the complex harmonic impressed E. M. F. where $p = 2\,\pi \times$ fundamental frequency,
" x be the value of the current at any moment t.

We shall have, then,

$$L\frac{d\,x}{d\,t} + R\,x = K\sum_{1}^{\infty}{}_m\, a_m \sin m\,p\,t.$$

The solution of this differential equation gives

$$x = K\sum_{1}^{\infty}{}_m \frac{a_m}{\sqrt{R^2 + m^2\,p^2\,L^2}} \sin\,(m\,p\,t - \varphi_m)$$

$$\text{where } \tan\varphi_m = \frac{m\,p\,L}{R}$$

The current x is a complex harmonic, its component simple harmonic currents being

$$x = x_1 + x_2 + \ldots\ldots + x_m + \ldots\ldots \textit{ ad infin.}$$

$$\text{The current } x_\alpha = \frac{K\,a_\alpha}{\sqrt{R^2 + a^2\,p^2\,L^2}} \sin\,(a\,p\,t - \varphi_\alpha)$$

$$\tan\varphi_\alpha = \frac{a\,p\,L}{R}$$

Let E be the impressed E. M. F., then

$$E = e_1 + e_2 + e_3 + \ldots\ldots + e_m + \ldots\ldots \textit{ ad infin.}$$

The component simple harmonic E. M. F. e_α is given by

$$e_\alpha = a_\alpha \sin a\,p\,t$$

These relations give an exact quantitative expression to the preceding physical description.

These considerations made me hesitate at first in taking as granted that a polyphasal generator producing complex E. M. forces, such as I deduced mathematically in the course of my paper, would be capable of producing a rotary magnetic field of constant intensity. But I was glad to find out that my hesitation was groundless, at any rate in certain particular cases.

Consider the three-phasal generator whose diagram is given in Fig. 10. Take, now, another *well-laminated* armature wound in a similar way as the armature of the generator. Connect the three pairs of coils of the generator to the three sets of coils in armature 2. We shall have three separate circuits, the ohmic resistance and the self and mutual inductance in each circuit being the same. Denote by E_1 E_2 E_3 the three complex harmonic E. M. forces in the three circuits. Let x, y, z be the currents at any moment. Then we shall have

$$L\frac{d\,x}{d\,t}+M\frac{d\,y}{d\,t}+M\frac{d\,z}{d\,t}+R\,x=E_1,$$

$$L\frac{dy}{d\,t}+M\frac{d\,x}{d\,t}+M\frac{d\,z}{d\,t}+R\,y=E_2;$$

$$L\frac{d\,z}{d\,t}+M\frac{d\,x}{d\,t}+M\frac{d\,y}{d\,t}+R\,z=E_3.$$

But since $E_1+E_2+E_3=0$ for all values of t it follows that

$$L\,\frac{d}{dt}\,(x+y+z)+2\,M\,\frac{d}{dt}\,(x+y+z)+R\,(x+y+z)$$

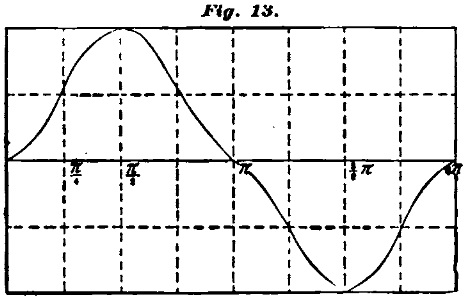
$= 0$ for all values of t. This can be true only if

$$x+y+z=0$$

for all values of t. That is to say, the currents fulfill the condition of continuity. We can therefore employ the method of polyphasal connection. Substitute now in the first of the three differential equations

$$z=-(x+y)$$

Fig. 13.



and we obtain

$$(L-M)\,\frac{d\,x}{d\,t}+R\,x=E_1=K\sum_1^{\infty}{}_m\;a_m\sin m\,p\,t$$

The solution of this equation gives

$$x=K\sum_1^{\infty}{}_m\frac{a_m}{\sqrt{R^2+m^2\,p^2\,(L-M)^2}}\sin\,(m\,p\,t-\varphi_m)$$

Similarly,

$$y=K\sum_1^{\infty}{}_m\frac{a_m}{\sqrt{R^2+m^2\,p^2\,(L-M)^2}}\sin\left\{m\,(p\,t+\frac{2\,\pi}{3})-\varphi_m\right\}$$

$$z=K\sum_1^{\infty}{}_m\frac{a_m}{\sqrt{R^2+m^2\,p^2\,(L-M)^2}}\sin\left\{m\,(p\,t+\frac{4\,\pi}{3})-\varphi_m\right\}$$

In the case under consideration both L and M are pretty small when the metallic parts of the magnetic circuits are near the saturation point, so that $L-M$ is exceedingly small, and $m^2\,p^2\,(L-M)^2$ will be very small in comparison to R^2 even for large values of m, unless the frequency is very high. Also, since

$$\tan\varphi_m=\frac{m\,p\,(L-M)}{R}$$

φ_m is exceedingly small unless p is very large, we shall have for moderate frequency generators

$$x=\frac{K}{R}\sum_1^{\infty}{}_m\,a_m\sin m\,p\,t$$

and similarly for y and z. The same method of reasoning may be easily applied to any number of phases. The mathematical operations will be considerably larger, but still the same results will be deduced without much difficulty.

That is to say, the curves for the currents are the same complex harmonics as those of the impressed E. M. F. The currents therefore produced a rotary magnetic field of nearly constant intensity; this is evidently true even if these currents produce a saturation in the iron part of the magnetic circuits.

The resemblance between a polyphasal generator and a continuous current dynamo, which these relations bring into view, is exceedingly striking and instructive.

The advantages gained from a polyphasal generator capable of producing a rotary magnetic field of constant intensity would be very much diminished indeed if it should turn out that it is impossible to devise a simple and efficient method of transformation[1] by means of which the polyphasal system of currents producing a rotary field of constant intensity (a constant rotary field system) can be transformed any number of times without losing its distinguishing characteristic. I intended to discuss this problem also this evening, but having been disappointed by the mechanician who is constructing several pieces of apparatus illustrating this problem, I decided to postpone this discussion to some other time.

To sum up:

1st. The consideration of simple harmonic impressed E. M. forces does tell the whole story of the polyphasal generators.

2nd. The law of variation of the strength of the rotary magnetic field which a polyhasal generator can produce is not as simple as Mr. v. D. Dobrowolsky thinks.

3rd. Polyphasal coupled transformers must be worked at *low magnetizations* and *low frequencies*, otherwise they will not satisfy the condition of continuity. It follows, therefore, that they will *probably be very large for the output which they can give.*

4th. It is very probable that nearly constant rotary magnetic fields can be produced in practice by a small number of phases (not more than three) by properly shaping the curve of the impressed E. M. F.

Letters to the Editor.

THE "JEWEL" INCANDESCENT LAMP TRADE-MARK.

In looking over the list of new incorporations, in a recent issue of the *Chicago Evening Post*, I noticed that certain parties, wholly unauthorized by me, have made application to the Secretary of State for the incorporation of a company for the manufacture of incandescent lamps, this company to be known as the "Jewel Incandescent Lamp Company."

The purpose of these parties, whoever they may be, is evidently to appropriate the name "Jewel" as applied to incandescent electric lamps; and for the purpose of defrauding me of my trade-mark, which I have extensively advertised and introduced, and which name has become very valuable.

The name or trade-mark "Jewel" as applied to incandescent lamps, originated with me, and is my personal property. Any attempts by other parties to pirate this name, is not only an injustice to me, but to users of the "Jewel" incandescent lamp.

By kindly giving this publication in your valuable paper, you will greatly oblige.

WM. HOOD.

CHICAGO Dec. 24, 1891.

A TELEPHONE TRANSMITTER WITH METAL SPRINGS.

In THE ELECTRICAL ENGINEER of Dec. 19th, a telephone transmitter without electrodes is illustrated and described.

In June, 1889, I constructed and operated transmitters based on this principle.

The springs used by me were metal; sometimes a round wire was employed; at other times a ribbon was coiled into a spiral and used.

Transmission was perfect, but not as loud as I hoped for. Carbon was suggested to me, but I had at that time no facilities for working it and abandoned it after repeatedly failing to construct a helix of it.

B. C. W.

ELMIRA, N. Y., Dec. 21, 1891.

MR. MACKAY AS SANTA CLAUS AGAIN.

A FEW days before Christmas Mr. J. W. Mackay, president of the Commercial Cable Company, instructed Vice-president Ward to pay to each and every employé of the company half a month's salary as a Christmas bonus to mark his appreciation of their cheerful and co-operative efforts during the year. He also sent the following cable to the boys: "I want the staff to aid me in keeping the 'Commercial' to the front. Let it always retain its reputation as the 'leading cable company—leading in accuracy, leading in speed, leading in staff.'

"I wish you and your families a Merry Christmas and a Happy New Year."

1. Not only transformation of the power supplied by the generator into electrical power of higher or lower potential, but also transformation of this power into mechanical power. This, of course, leads into the discussion of rotary fields produced under practical conditions.

Legal Notes.

INCANDESCENT LAMP LITIGATION—THE UNITED STATES ELECTRIC LIGHTING CO. vs. THE EDISON LAMP CO.—III.

ARGUMENT OF GEORGE H. CHRISTY FOR THE UNITED STATES COMPANY.

THE closing argument for the complainant was made by George H. Christy, Esq., of Pittsburgh. Mr. Christy said he would commence with a word in reference to the general equities of the case. He understood his brother Betts to allege that the invention in question had been given to the public; first by Sawyer and Man and second by Maxim, and that this had been done at a date such that Weston was barred from procuring a valid patent, and therefore stood in no position of equity in this court. Moreover, he thought his brother Betts clearly implied that his clients were entitled to the benefit of any equity asserted on behalf of Sawyer and Man or of Maxim, but in that opinion he apprehended that his brother had made a serious mistake as regarded the doctrine of equity. Assuming for the present that he was correct in what he had said of Sawyer and Man, it merely proved that they had made something known to the public in the assertion of an adverse right belonging to themselves. Could the public take anything by such a disclosure? or could this defendant take anything as a matter of equity? So also in the case of Maxim; the defendant was in no position to assert any equity as regards this invention. It did not claim under either of those parties. It could only assert an equity as part of the general public; but the general public could be entitled to no equity in view of anything that had been done by Sawyer and Man, or by Maxim, for what they had done had been under a claim of title and exclusive right of their own. Moreover, the party who was claiming this equitable right was the party charged with being the infringer, but an infringer (if it could be shown that defendants did infringe), was in no position to assert equities by virtue of anybody else's title.

The claim of complainant's patent was for "building up said core with carbon obtained and deposited upon the same by and during the operation of electrically heating said core." Mr. Christy showed by extracts from the specification that the term "building up" included any result whereby the carbon which was separated from the surrounding liquid, vapor or atmosphere, was put on, or into, or anywhere with reference to the conductor so as to impart to it the qualities desired for a burner for an incandescent lamp. His brother Betts had said that the words "for incandescent lamps" in the claim must be rejected as surplusage, or used as a term of limitation; if surplusage, then it was anticipated by Despretz; if, on the other hand, it was a limiting phrase, then the invention had not been complete until Weston had found out, by actually trying a treated carbon in a lamp, that it was suitable for that purpose. He (Mr. Christy), believed the latter meaning to be correct; but his brother Betts had been in error in his conclusion that the invention could not be completed until Weston had found out that it might be used as a commercial success in an incandescent lamp. That was not the standard of invention at all. The standard by which it was to be judged was this: Was the carbon pencil, thread, filament, stick, whatever it was, in better condition for that use after treatment than it was before? If so, the conditions of invention had been practically fulfilled, and it had been so because Weston had progressed far enough to ascertain that fact. Mr. Christy then read from Fontaine's book of 1877, a statement that the examination of incandescent carbons through a strongly colored glass had rendered their defects visible. That test was a part of the state of the art as it then existed. Would Mr. Weston then have had any difficulty, looking at his carbon, before and after treatment, through a smoked glass, to ascertain whether the carbon had been improved? And if he had found—as his testimony had said that he did—that such was the case, the invention had then, if he (Mr. Christy) correctly understood the law, been complete and perfect at that time. The testimony of Mr. Vandergrift was that the test of visual inspection was the one used to-day, and the only reliable one known in the art.

His brother Betts had contended that there had been no sufficient proof of infringement, and that the Weston process, so far as it had related to the use of oil, had never been commercially used. "Why,"—said Mr. Christy,—"his own client had used it." That use had been the very infringement complained of. He then read from the testimony of defendant's employees in confirmation of his statement, and said that it did not lie in the mouth of defendant to say anything about defects of a patent based upon the use of oil, or based on the use of red heat, for it had used both. Defendant had said there was no proof of sale or use. It was not necessary. Defendant was engaged in the business of manufacturing lamps; presumptively, when it had been proven to have made use of a process in its factory, by its workmen, and apparently in the ordinary course of business, it was fair to infer that it had been done for a purpose. Under the law the construction of a thing in a commercial way was a commercial use, but the proofs were that defendant's workmen had put the carbons into lamps. It seemed to him that that testimony made out a clear case of infringement. Defendant contends that it made but a few, but for present purposes the number made was immaterial. When complainant had made out a *prima facie* case, all that was necessary was to prove one act of infringement, and then in case the bill was sustained, to ascertain the extent of infringement.

But the testimony of defendant's employees had shown that the infringing had continued off an on at intervals for months; that carbons not in conformity with the standard had been treated, while those of the proper or desired resistance had not been treated. He would say here parenthetically, that he understood Mr. Edison claimed to have discovered a new material for a filament made from bamboo and to have invented a process for carbonizing his bamboo carbons so perfectly that they did not need this treatment. He then read from an affidavit of Mr. Edison in certain proceedings in Canada, introduced by stipulation into this case, setting forth at length the great difficulties attending the commercial process of carbonizing filaments. It was fair to infer, continued Mr. Christy, from what had been said by Mr. Edison and by his witnesses, that some carbons were made not good enough for use, and that to the extent of those carbons defendant had employed this process. Defendant had said that it had quit using the process, but it had not promised that it would not use it any more. His Honor was aware that a defendant could not take anything by such a pretension as that, unless it appeared that it had gone permanently out of the business and intended to stay out.

Again defendant had said that all that had been done had been experimental, but the testimony had shown that Mr. Holtzer, the superintendent of the works, had directed the electrician to continue the process as to all carbons not up to the standard. Yet defendant contended that the whole thing was an experiment; that they had only done a few, and that there was no proof that any of them ever went into a lamp that was sold.

Turning to another point, Mr. Clarke defendant's alleged expert—he said "alleged," because Mr. Clarke, had admitted that he had had no experience in the treatment of carbon—had been asked whether or not from the testimony of Broadbent and Quimby, a man skilled in the art as it existed in 1877 and 1878, could have manufactured a successful commercial lamp. That was not a correct standard by which to judge of that testimony. It had been taken simply as to certain facts within the knowledge of the witesses, and was not required by any rule of law or practice to be in the nature of a specification; hence the inquiry made of Mr. Clarke was immaterial and irrelevant. Again Clarke had said that Quimby did not say that Weston had told him he was going to put those carbons into electric lamps. It was not necessary to tell a painter that a picture represented a sunset nor to so label it. It was not necessary for Quimby to be told that the thing which he saw done in a glass globe had been intended for an incandescent lamp; he would have known that by seeing the experiment.

Defendants had said that Mr. Edison was entitled to the credit of the successful commercial lamp; that he had made it by getting rid of gases, and by the use of a vacuum, etc., but there were one or two very singular things in this case. His Honor would understand as complainant's view, that Weston was not bound to proceed with his application for a patent until a reasonable probability appeared that he could get some reward by the sale or use of a commercial lamp. So long as no commercial lamp was known in the art, in which his invention could have been used, he had done perfectly right in delaying his application and he had done it for good reasons. Defendants on that statement of facts, had been challenged to prove, if they could, that their inventor, Edison, or anybody else, had had a commercially successful lamp in such a way as to get some equity to it themselves as distinguished from Weston. If Mr. Edison had been the inventor that they claim, or if he had solved this problem in the fall of 1879, did it not seem probable that the fact would have been proven in this case? To whom had they gone for that credit? Not to Edison, but to Maxim; to the use made by him and the present complainant in November, 1880, and they had tried to bring themselves in as entitled to any benefit which might possibly have arisen in behalf of Mr. Maxim.

(*To be continued.*)

Appointments, Etc.

MR. B. L. FREEDY, who has been manager of the telephone exchange in St. Paul, has gone to Fargo, Dak., to assume management of the exchange there, while Mr. W. F. Burns, of Fargo, removes to St. Paul.

MR. ALEX. CHURCHWARD, the assistant electrician of the Riker Electric Motor Co. during the past year, has now been appointed general superintendent and electrician of that company.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED DECEMBER 22, 1891.

Alarms and Signals :—

Low-Water Alarm, F. St. Clair, 465,767. Filed April 11, 1891.
A steam low-water alarm, electrically actuated.

Train-Signaling Apparatus, P. Synnestvedt, 465,501. Filed Oct. 13, 1890.
An electric signal, by means of which the conductor of a railway train may readily communicate with the engineer.

Combined Signal and Telephone System, T. W. O'Brien, 465,648. Filed July 20, 1891.
Comprises an organization of electric circuits and appliances enabling a speaking instrument to be employed as a useful auxiliary to the ordinary system of arbitrary bell signals.

Electric Circuit Closer for Burglar Alarms, W. C. Thompson, 465,602. Filed Oct. 19, 1889.
A window sash burglar alarm.

Annunciator for the Supposed Dead, W. H. White, 465,548. Filed Nov. 24, 1890.

Clocks :—

Independent Electric Clock, W. J. Dudley, 465,655. Filed July 11, 1891.

Conductors, Conduits and Insulators :—

Conduit for Electric Wires, H. W. Jones, 465,564. Filed April 1, 1891.
Claim 1 follows:
A conduit for electric wires composed of strips of compacted asbestos fibre, wound in opposite directions, and waterproofing material, and cementing material.

Distribution :—

System of Electrical Distribution, F. A. La Roche, 465,594. Filed Oct. 9, 1890.
Has for its object the equalization of the difference of potential between the leads of an electric light or power circuit.

Means for Turning On and Off Electric Currents, T. C. Smith and B. D. Acker, 465,805. Filed Oct. 1, 1890.
A method of locally controlling an electric light circuit.

Dynamos and Motors :—

Dynamo-Electric Machine, R. Thury, 465,808. Filed Aug. 4, 1891.
A multipolar dynamo having two concentric rows of field magnets with the unlike poles of each series in juxtaposition, a rotatable armature compos-d of a divided hollow thin iron cylinder covered on the inner face with internal conductors and on the outer face with external conductors, and connections at the respective faces of the armature.

Lamps and Appurtenances :—

Globe-Holder for Electric-Arc Lamps, H. A. Foster, 465,470. Filed Nov. 3, 1890.
A clamping device for attaching globes to arc lamps.

Hanging Device for Arc Lamps, W. K. Howard, Jr., 465,665. Filed Oct. 30, 1890.
An automatic catch for arc lamps.

Electric Arc Lamp, H. C. Waldecker, 465,685. Filed Apr. 8, 1891.
Method of regulating the feed of arc lamp carbons by means of a piston loosely fitted into a tube containing liquid, which checks any sudden movement of the carbon.

Incandescent Electric Lamp Fixture, G. E. Villaret and V. E. Rondel, 465,-684. Filed May 23, 1891.

Electric Arc Lamp, H. P. Ball, 465,514. Filed June 13, 1891.
A cut-out for arc lamps, provided with a mechanical lock for holding the circuit closed.

Cut-Out for Incandescent Lamps, H. C. Wirt, 465,508. Filed Mar. 28, 1890.
An automatic short-circuting device for series incandescent lamps.

Measurement :—

Electrical Testing Instrument, R. Varley, Jr., 465,809. Filed Jan. 15, 1891.
A testing instrument for the purpose of locating very minute insulation faults in electric wires.

Metallurgical :—

Electrolytic Apparatus for Treating Metals, E. S. Hayden, 465,525. Filed Nov. 5, 1887.
Claim 1 follows:
In an electrolytic bath having a number of plates unconnected electrolytically excepting through a solution in the bath, and having narrow partitions extending from opposite sides of the bath adapted to hold the plates in a vertical position and out of contact with each other, and stops wholly between the partitions supporting the plates above the bottom of the bath.

Miscellaneous :—

Electric Switch, G. E. Painter, 465,618. Filed Apr. 16, 1891.
A small, compact, and inconspicuous switch for residences, etc.

Rheostat, W. S. Andrews and A. K. Warren, 465,512. Filed Aug. 26, 1891.
A rheostat for electric fan motors.

Electric Snap-Switch, W. S. Andrews, 465,511. Filed May 7, 1891.
A simple and inexpensive construction for the snap-switches.

Electric Switch, H. Barton, 465,444. Filed Dec. 15, 1890.
An electric switch in which, when the connections are made, the contact-piece is locked in position, and can only be released by pressure properly applied at the handle.

Railways and Appliances :—

Electric Railway Trolley, F. J. Sprague and P. O'Shaughnessy, 465,806. Filed Jan. 22, 1889.
A trolley employing a single horizontally-placed spiral spring, for the purpose of keeping an even pressure against the trolley wire.

Electric Railway, W. H. Applegate, 465,613. Filed Nov. 10, 1890.
A conduit railway in which a traveling conductor maintains electrical contact with the main lead without exposing the entire length thereof.

Gearing for Electric-Motor Cars, O. F. Evans, 465,593. Filed Jan. 24, 1891.
A worm-gear for use in connection with high-speed motors on electric cars.

Electric-Railwy Trolley, C. S. Foster, 465,469. Filed May 31, 1890.
A mechanism for securing the trolley on the trolley-wire so that it cannot become accidentally detached.

Guard for Trolley-Wire Insulators, F. O. Blackwell, 465,447. Filed May 29, 1891.
The guard for preventing the trolley from striking the insulator, when thrown from the wire.

Telephones and Apparatus :—

Adjustable Support for Telephones, C. H. Gatchell, 465,778. Filed Aug. 26 1891.
An adjustable bracket for telephone receivers.

Society and Club Notes.

THE THOMPSON SCIENTIFIC CLUB, LYNN, MASS.

At the regular meeting of the club the annual election of officers was held. The following were elected: President, J. B. Cahoon; 1st vice-president, H. G. Reist; 2d vice-president, F. C. Bates; secretary, F. Sheible; treasurer, J. B. Barr; librarian, E. D. Priest. Reviewers: Engineering, H. G. Reist; physics, H. S. Rodgers; natural science, J. E. Randall. Executive Committee: Messrs. Randall, Cahoon, Reist, Bates, Barr, Towner, Priest.

The rapid growth of the club is apparent when we consider that it was organized in May, 1889, and moved into its present extensive quarters last February. The reports of officers for the past year showed the club entirely out of debt, with quite a balance in the treasury. At present there are about 100 books and pamphlets in the library, together with 24 subscriptions to current scientific and popular periodicals, the latest addition being the *Century Dictionary*.

The club now numbers 134 members. At the last meeting Prof. Chas. R. Cross was elected an honorary member of the club.

The course of public scientific lectures now being held is in every way a success. The proceeds of this course will go towards fitting up the library of the club.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

The subjoined resolution, passed by the international congress committee and the council of the American Institute of Electrical Engineers, is the outcome of the recent visit to New York city of Dr. Elisha Gray of Chicago, chairman of the Committee on the World's Electrical Congress.

Dr. Gray, after several informal interviews with officers and members of the institute, was invited to attend a meeting of the congress committee on December 16, where a mutual exchange of views upon the subject was had, and the result is entirely satisfactory to all parties interested.

Resolved, That the American Institute of Electrical Engineers, having already taken action during the past three years, by correspondence and otherwise, towards the holding of an International Electrical Congress in connection with the Columbian World's Fair, hereby expresses its desire and intention to co-operate, by all means in its power with the World's Congress Auxiliary of the World's Columbian Exposition, through its Electrical Congress Committee, in furthering the gathering of such a congress at Chicago in 1893, and in making it a successful and worthy representation of the best electrical science and practice in all parts of the world.

THE ELECTRIC CLUB.

On New Year's Eve (Thusday) Mr. Joseph Howard, the celebrated journalist and member of the club, will deliver a lecture at the club house entitled "A Plain Talk about Journalism." It may be counted upon as one of his most brilliant efforts, and will be heard by a large audience. The lecture will be followed by a high class musical programme.

THE NEW YORK ELECTRICAL SOCIETY.

At Columbia College, on Wednesday, Dec. 30, before the New York Electrical Society, Mr. A. A. Knudson will read a paper on 'Electrical Fakes." Such a subject is full of interest and amusement, and it will lose nothing at Mr. Knudson's hands.

THE MAGNETIC CLUB.

The annual meeting of the Magnetic Club of New York will be held January 14, at 195 Broadway, for the election of officers and four members of the governing committee.

DID NOT RECEIVE THE ITEM.

An electrical concern recently sent out some lamps with the note that the lamps shipped were "3.6 watts No. 3 base." The shipping list came back with the statement that the lamps had arrived but that the above item had not come to hand.

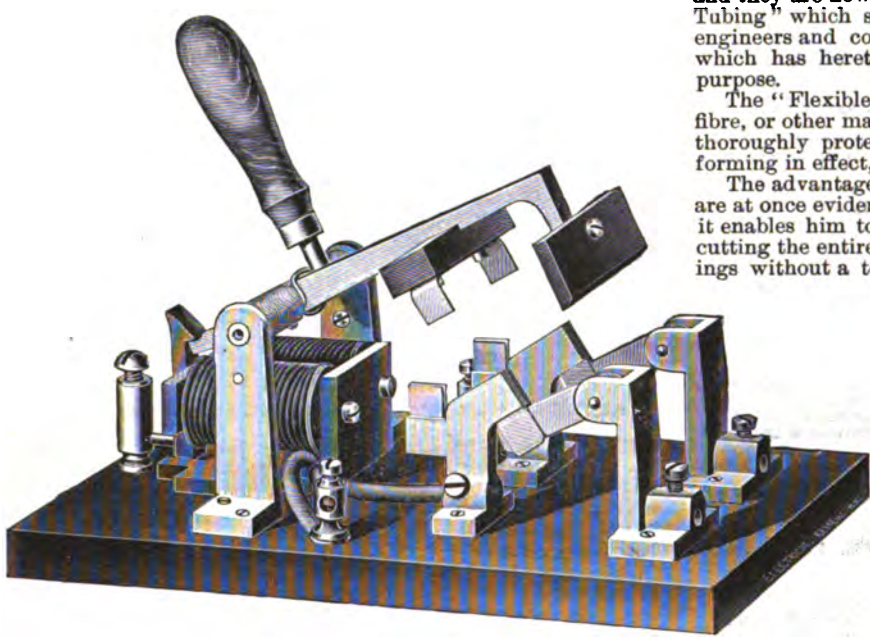
TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

The best way to get a happy and prosperous New Year is to advertise for it.

HILL'S SELF-ACTING SWITCH FOR CHARGING STORAGE BATTERIES.

THE switch shown in the above illustration was designed by Mr. W. S. Hill to be used when charging storage batteries from arc lighting circuits, to prevent the circuit from being opened and the streets being left in darkness, should any accident happen to the batteries, or any of the battery connections, by which the circuit would be broken.



HILL'S SELF-ACTING STORAGE BATTERY SWITCH.

The switch has four contacts, an electromagnet, and a lever actuated by a spring. When the lever is raised, as shown in the cut, the magnet, the four contacts and the batteries to be charged are all connected in series between the two binding posts. The latch that holds the lever up, is held by the pull of the magnet on an armature. Should anything occur to open the circuit for an instant, the magnet will be discharged and the latch be drawn back by a spring, releasing the lever, which will then drop and close the circuit between the two main line contacts, thus restor ing the circuit. At the same time the connection between the main and the battery contacts is broken, thereby disconnecting both ends of the battery circuit and preventing its being short-circuited on itself. With slight modification the same device is used to cut out the batteries when they have been sufficiently charged.

In this case the position of the magnet is reversed and it is made to release the latch, when a predetermined amount of current is passing through the magnet, the circuit through the magnet being connected to the terminals of the batteries, and in shunt thereto.

These switches are manufactured by the W. S. Hill Electric Co., of No. 54 Devonshire street, Boston, Mass., and are guaranteed to do all that is claimed for them in a satisfactory manner.

NOYE ENGINES FOR THE JAMESTOWN (N. Y.) ELECTRIC ROAD.

A NOTABLE addition will be made to the plant of the Jamestown Street Railway Co., Jamestown, N. Y., and the John T. Noye Mfg. Co., of Buffalo, N. Y., have secured the contract. There will be added two of the Noye Co.'s "B" style, heavy duty, compound condensing engines of about 400 horse power each, to operate two Short generators having a capacity of 250 horse power each, and it is expected that the enlarged plant will be in operation at the opening of the excursion season next spring. Provision has been made in the plant for another engine like the foregoing, which may be added later on. The present plant consists of three Dick & Church engines of 125 horse power each.

THE "FLEXIBLE CONDUIT."

MANY and various have been the devices for insulated tubing for the installation of electrical conductors in interiors, but, so far, all experiments seem to have been carried out on one line, that of a short, rigid tube, connected at intervals by joint sleeves or other similar devices and with rigid moulded bends, or elbows. Some of the devices, have been practically waterproof, some partially fireproof, and others in a measure flexible, but all have lacked one or the other of these highly necessary adjuncts.

It has remained for Mr. Charles H. Herrick, of Boston, Mass., to strike a happy combination of these three very important factors of a successful insulated tubing for interior wiring, and for the well-known American Circular Loom Co., of the same city, to carry out his ideas to a successful issue, in the manufacture of "The Flexible Conduit," which forms the subject of this article.

Their justly celebrated "Canvas Jacket" covering so successfully used by them in the manufacture of line wires, has enabled them to manufacture a strong, flexible, thoroughly waterproof cover, for the insulated flexible core, designed by Mr. Herrick, and they are now placing on the market, an insulated "Flexible Tubing" which seems destined to take the place, with electrical engineers and constructors, of much of the short, stiff tubing, which has heretofore been the only article obtainable for the purpose.

The "Flexible Conduit" is formed of a spiral lining of linen fibre, or other material, heavily taped with the best Para tape, and thoroughly protected and insulated by a heavy woven jacket, forming in effect, an insulated flexible hose.

The advantages of such a system of tubing for interior wiring, are at once evident to the practical electrical constructor, in that it enables him to install it in buildings already finished, without cutting the entire surface of the wall or ceiling and in new buildings without a tenth of the cost, as the "runs" can be made,

THE "FLEXIBLE CONDUIT."

owing to the long lengths of the "Flexible Tubing" without the use of joint sleeves.

The turns can also be made without the application of *elbows*, for the flexibility of the tube makes any curve, and even a complete circle of small diameter, possible. Being flexible, the tube will stand almost any amount of rough handling, making the waste generally arising from this source, practically nothing. The cost of joint sleeves and moulded elbows, is also done away with, as is the cost of the labor in the application of the same, which is really the prime factor in the expense of the conduit system of electrical wiring.

There is also an extended field for this manufacture, for the purpose of speaking tubes. It answers the purpose admirably, and is much cheaper and more lasting than anything now used for the purpose.

From the tests seen by the writer it is his opinion that the flexible tubing is thoroughly waterproof, highly non-inflammable, and thoroughly flexible, and there seems no reason why the field for the sale of it is not almost unlimited.

NEW YORK INSULATED WIRE CO.

IN ORDER to keep in closer touch with their business, which has so greatly developed during the last few years, the New York Insulated Wire Co. have decided to move down-town into the electrical district. They have now taken a suite of offices at 13, 15 and 17 Cortlandt street, Smith Building, on the third floor, and will enter upon occupancy January 1. The company will be duly represented there by Messrs. Gallaher, Godfrey and Olsen, and by Mr. Augustus Noll, its electrical engineer and expert. The company have also taken commodious storage on Warren street, and will there carry a very large stock of their celebrated wires and cables. They will thus be in excellent shape to handle the largest orders for "Grimshaw" white core wires, "Vulca" duct, and their street specialties. They report a very active business in "Vulca" duct, in Canada as well as in this country, and have a number of large buildings on their list for which Grimshaw has been specified.

WESTON ELECTRICAL MEASURING INSTRUMENTS AND APPLIANCES AT THE FRANKFORT ELECTRICAL EXHIBITION.

It may be remembered that the Weston Electrical Instrument Company, Newark, N. J., decided at the last moment to exhibit the Weston standard portable ammeters and voltmeters, and other electrical measuring instruments at the Frankfort Electrical Exhibition. In taking this course the company was well aware that its instruments would be subjected to close scrutiny by many of the most competent and eminent electricians and electrical engineers of Europe, and would be brought into direct competition with those made by such prominent firms as Siemens & Halske, Hartmann & Braun, and other makers of high-grade instruments. The Weston Electrical Instrument Company, however, felt great confidence in the merits of its goods, and was certain that if the instruments were thoroughly examined and tested, their great accuracy, permanency, portability and convenience would commend them to the favorable notice of the European electricians and engineers, and that it would be able to secure many orders for them.

Recent developments show that the confidence of the manufacturers in the merits of the Weston instruments was not too great. The company has received most favorable notice in many of the German scientific journals, and, what is more important, numerous orders for its voltmeters and ammeters from many of the best electrical engineering firms in Germany and other countries, including Siemens & Halske, Ganz & Co., Shuckert & Co., Lahmeyer & Co., Allgemeine Electricitats-Gesellschaft, the Societa Generale Italiana di Elettricita and the Brush Electrical Engineering Company. It has also received orders from many of the most distinguished electricians of Europe, notable among whom are Prof. H. F. Weber of Zurich, Prof. Kittler, Prof. Kohlrausch, Prof. Perret and Prof. Lichtheim. Prof. Weber was a member of the Testing Commission of the Frankfort Exhibition, and had an opportunity of thoroughly examining the merits of the Weston instruments.

We understand from the Weston Company that the instruments sent to Frankfort were not especially made for exhibition purposes, and that, as a matter of fact, were not equal to those sent out daily in the regular course of its business. Indeed, they were much inferior to the regular product, and would not have been passed for sale. This arose from the fact already stated, that the company did not decide to exhibit in Frankfort until about the time the Exhibition was to open and all the available space had by that time been taken by other exhibitors.

The Exhibition Committee, however, built an annex expressly for the company. The time required to prepare for so extensive an exhibit of the many varieties and ranges of its instruments, and the numerous parts entering into their construction, was necessarily very short. In addition to this, the Weston Company was greatly pressed with orders at the time, and was engaged in largely extending its facilities for manufacturing and standardizing the instruments. It was, therefore, extremely difficult to get out a sufficient number of the instruments to properly represent the work of the company. Under these circumstances it was impossible to spend the time necessary to secure close adjustment of the instruments intended for exhibition without greatly interfering with regular commercial work.

The Weston Electrical Instrument Company feel justified in expecting a still more favorable reception of its instruments after the filling of the numerous orders already received, arguing that, if the relatively poor ones sent as an exhibit were so favorably received, it is fair to suppose that those of its usual standard quality will be still more appreciated.

LARGE SALES OF PAGE BELTING.

The Page Belting Co., Concord, N. H., with stores in New York, Boston, Chicago and San Francisco, are moving on with their business in the usual manner, increasing in all departments and report that among the large belts which they have recently shipped is one to Richmond, one to Madison, Me., one to the Natick Electric Light Co., Natick, Mass.

Of their Acme link belts, among those shipped during the past month, have been the following:

A 15 inch belt to the Chattanooga Electric Railroad Co., Chattanooga, Tenn.; Pottstown Light, Heat and Power Co., Pottstown, Pa.; Shamokin Electric Street Railway Co., Shamokin, Pa.; Edison Electric Illuminating Co., Easton, Pa.; People's Street Railway Co., Scranton, Pa.; Huntingdon Electric Light Co., Huntingdon, Pa.

In their export business, they have shipped to Havana, Russia, Brazil and Caraccas. Of their Eureka dynamo belts, which are of double leather, slotted, they have shipped, among others, the following: Austin Water, Light and Power Co., Austin, Texas; Forest Mill Co., Clearfield, Me.; Xenia Electric Light Co., Xenia, Ohio; Danbury and Bethel Gas and Electric Light Co., Danbury, Ct., West End Street Car Co., San Antonio, Texas; Home Electric Light and Steam Heating Co., Tyrone, Pa.; Shamokin Street Railway Co., Shamokin, Pa.; Johnstown Electric Light Co., Johnstown, Pa.; Elmira Woolen Mills, Elmira, N. Y.

CROCKER-WHEELER CO. EXTENDING THEIR WORKS.

The large and increasing business done by the Crocker-Wheeler Electric Motor Company, New York, has several times made it necessary, during the year just closing, for them to secure more room for manufacturing purposes. The company report that they have again taken additional space in the buildings occupied by them at 430 and 432 West Fourteenth street, and will put in a lot of new machinery.

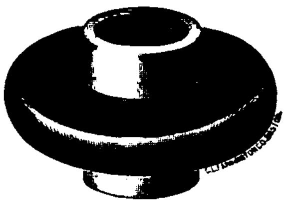
We note that the Augusta, Ga., *Chronicle* makes a very complimentary note on the Crocker-Wheeler exhibit at the local exposition, in care of Mr. George C. Field and Mr. W. E. Platt.

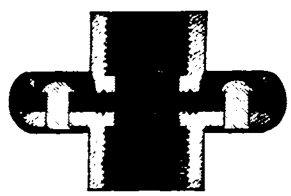
THE VIADUCT ELECTRIC CO.

The Viaduct Electric Co., of Baltimore, Md., has sent out as a seasonable souvenir a neat little box of lead pencils for its friends and customers. Each of the pencils is stamped with the name and compliments of the company.

THE McCARTHY INSULATED JOINT FOR ELECTRIC FIXTURES.

We illustrate this week a new form of insulated joint for use on electric and gas fixtures, manufactured by the W. T. C. Macallen Company, of 161 High Street, Boston, and the invention of Mr. Louis McCarthy, the manager of the company. Fig. 1





Figs. 1 and 2.—McCarthy Insulated Joint.

represents the joint as ready for use, and Fig. 2 is a section, showing in detail its construction. The joint consists of two halves of brass, with screwed ends for reception of gas pipe and fixtures insulated from each other by pressed mica washers. The flanges are riveted together, the rivet being in metallic contact with one flange and insulated from the other by mica. After the two flanges of the joints are thoroughly riveted together they are covered with a special insulating compound to prevent any danger of moisture on the outside forming a contact between the two halves. The use of pure mica sheet is new, is claimed to be entirely impervious to any acid or gas, and is, as is well known, perfectly fireproof. There are many well-known joints on the market, all more or less subject to the influence of gas tar or heat, and as this joint uses only pure mica, which is impervious to gas tar as an insulating material, and depends upon metallic parts for its strength, it is sure to at once become a favorite with electrical engineers. In appearance it is extremely neat, well finished and of first-class workmanship.

EUREKA TEMPERED COPPER.

The Eureka Tempered Copper Co., of North East, Pa., have got out a new circular entitled, "Long Stories Boiled Down to Suit Busy Men." It is full of pithy extracts from letters commendatory of their admirable specialty. These testimonials constitute a body of evidence that must carry conviction and lead to larger sales than ever.

THE BALL AND WOOD CO.

Those present at the station of the Edison Elec. Illg. Co., Patterson, on Dec. 19 witnessed a very pretty sight when the new compound engine of 250 h. p., built by the Ball & Wood Co., was started. Little Elizabeth Brock, four-year-old daughter of the general manager of the company, after some climbing, successfully reaching the throttle valve, and exerting all her strength gave it a twist which threw 2,500 more lights into the dark places of the city.

NEW YORK NOTES.

W. R. FLEMING & Co., 174 Fulton street, representing the Harrisburg Foundry and Machine Works, are installing the "Harrisburg" Ide and Ideal engines, as well as complete plants. The following are a few of the recent orders they have taken: For the H. W. Johns Mfg. Co.'s new factory, South Brooklyn, two 125 h. p. horizontal, steel single return-tubular boilers; Philip Daly's Pennsylvania Club House, West End, N. J., a complete plant of 60 h. p.; Dunellin Electric Light Co., Bound Brook, N. J., complete plant of 35 h. p.; Mr. Luther C. White, Waterbury, Conn., one 25 h. p. Ideal engine; Hotel "Marlborough," New York City, one 100 h. p. Ideal engine; Mr Jacob Rothchild, Fourteenth street, city, one 35 h. p. Ideal; Hotel "Endicott," Ninth avenue and Eighty-first street, two 100 h. p. Ideal engines. All of these contracts for engines were made with most rigid guarantees that the engines would run noiselessly and without vibrations. The firm are making a specialty of this class of work, appreciating how important it is that there should be no noise or vibration whatever in plants for hotel and apartment house service.

THE INTERNATIONAL ELECTRIC SUPPLY CO., through Mr. W. H. Fleming, E. E., the general manager of this company, Times Building, New York, has issued the following circular:—

This company has been organized to furnish at lowest market prices, every description of electrical apparatus and supplies required for arc and incandescent lighting, electric railways, electric plants for mining and power purposes, telegraph materials and telephones, house and hotel electrical supplies in foreign countries; more especially will its trade be devoted to the needs of our neighbors in Latin-America. The company is also in a position to furnish complete electric light installations, whether for central station work or isolated plants, for factories and plantations.

We understand that some large lighting contracts have already been closed for Mexico and Central America.

Mr. W. H. Fleming, the general manager of the new organization, is well known in this city, and from his extended practice in this country, as well as in the East and West Indies, in the installation of electric lighting stations, has gained an experience which will be of inestimable value in steering the company through the "quicksands" that others have fallen into in attempting to exploit and obtain the foreign electrical trade.

THE EASTON ELECTRIC COMPANY, Brooklyn, N. Y., has just installed another fifty-five arc light dynamo in the store of Wechsler & Abraham, on Fulton street, that city. This makes the fifth dynamo the Easton Company have sold to this well-known firm, and the order being given after eighteen months' trial of the other four dynamos, speaks well for the Easton system.

MR. J. L. SOMOFF, successor to the Union Electric Co., 1 Ann street, New York, has issued a neat four-page circular of his small incandescent lamps and appliances in connection with which they can be used. It gives full information as to sizes, prices, voltages, etc., and introduces some novel and useful designs to notice.

MR. F. NAPIER DENISON, of the Edison General Electric Company, Toronto, Can., leaves this week for an extended tour through the southern part of Europe and England, on account of ill health. He will combine business with pleasure and visit some of the principal electrical plants on the Continent.

NEW ENGLAND NOTES.

WHITMORE AND ROBINSON, of Boston, consulting electrical engineers, have issued another circular stating the object of their business. They have a well-appointed laboratory on Essex street, and are prepared to calibrate all kinds of instruments and test insulation, dynamos, motors, converters, fuses, primary or secondary batteries, etc. They make a speciality of testing iron and steel for induction, magnetic permeability or hysteresis properties, which are extremely important in the construction of dynamos, motors and converters. Whitmore and Robinson also act generally as consulting engineers and will aid purchasers in an intelligent purchase of electrical goods, charging for such work a percentage on the cost of the goods.

THE EVANS FRICTION CONE COMPANY, of Boston, are issuing their new catalogue for 1892, in which there are a number of new engravings showing some of their most recent applications of the Evans system to driving dynamos. For the larger sizes of dynamos the Evans Company are showing the application of extended bases with outboard bearings, in order to get a more perfect alignment and less vibration on the armature shaft, with a more perfect bearing between the fly-wheel of the engine or counter-shaft and the dynamo pulley. They also show the application of their system in driving four dynamos from one large upright engine, two dynamos being driven from each fly-wheel of the engine.

THE BEACON VACUUM PUMP AND ELECTRICAL COMPANY, of Boston, have made a decided success of their incandescent lamps, which are the only lamps in the market which are exhausted exclusively by means of a mechanical pump, and entirely without the aid of mercurial pumps, as used by other lamp companies. The Beacon pump is working to the entire satisfaction of the manufacturers and produces a vacuum in any quantity of lamps at the same time in a very few minutes, and is especially adapted for exhausting the larger sizes of incandescent lamps up to 150 candle-power. The Beacon pump is well worth the careful investigation of all incandescent lamp companies.

THE MATHER ELECTRIC COMPANY, of Manchester, Conn., have just published a very interesting little pamphlet descriptive of their new type of motor and power generator. The pamphlet contains a quantity of valuable information regarding the safe and economical working of motors and generators in general, and has some interesting diagrams showing the best methods of connecting up to the mains. It also contains valuable instructione upon starting and stopping motors and upon the necessary cars required for their successful and satisfactory working. The pamphlet is well worth reading and every engineer ought to procure one for his guidance in operating generators and motors.

THE AMERICAN ELECTRIC COMPANY, of Boston, proprietors of the New Era electric gas-lighting burner, have achieved quite a success. It is entirely different from anything on the market, the gas being lit by the mere turning of the gas-cock in the usual manner, without the intervention of any other piece of apparatus. The key of the gas-cock is thus always a true index of whether the gas is turned on or off, and thus prevents any possibility of accident by leaving unwittingly the gas turned on during the night. The American Company are full of orders and a very large business is anticipated.

THE W. S. HILL ELECTRIC COMPANY have made rapid strides since the organization of their company, and are now busy manufacturing small dynamos, motors and all kinds of electric switches. All the goods are made under the patents of Mr. W. S. Hill, who personally superintends their manufacture, while Mr. Poor attends to the general management of the company, and is succeeding in placing the company in a first-class condition to do a large business. The factory facilities have been doubled, and it looks as if more commodious quarters would soon be required.

THE JOHN BECKER MANUFACTURING CO., of Boston, makers of name plates, milling machines, etc., have moved to their new building, Water street, Fitchburg, Mass., where they will enjoy greatly increased facilities for their large business.

PHILADELPHIA NOTES.

MR. G. A. WILBUR, the Philadelphia agent for the Fort Wayne Electric Co., is rounding up the year with an excellent record. His latest installations are an additional plant for the Frankfort Avenue Merchants' Electric Light Co., consisting of four 60 Wood arc light dynamos; also an addition to each, the Southern Electric Light & Power Co. and the Allentown (Pa.) Electric Light & Power Co. of one 60 Wood arc light dynamo. The Edison Electric Illuminating Co., of Bellefonte, Pa., have also purchased a 40 Wood arc light dynamo.

MR. T. J. COPE, of the Cope Electric Pilot Line Co., has just returned from Washington, where he put about twenty miles of draw wires in the Lynch and Lake conduits of the Chesapeake & Potomac Telephone Co. successfully. There was some doubt expressed as to the ability of the machine to adhere to the vitrified surface of the terra cotta, but it ran full as well as in ducts of any other material, having run 450 feet in two minutes.

THE DIAMOND ELECTRIC LIGHT, HEAT & POWER CO., of Seventeenth and Somerset streets, whose plant was started some two weeks ago, are erecting poles and supplying arc and incandescent lights in the northern part of the city.

MR. BENJ. W. TINGLEY, secretary of the Heisler Electric Co., is just recovering from a severe attack of the grippe, this being his first sickness for over twenty years.

ST. LOUIS NOTES.

J. H. SIEGRIST, JR., & CO., St. Louis, just placed an "Ideal" engine in the new works of the Central Distillery Co., this city. They also sold this company one of the Bristol recording pressure gauges for making an accurate record of the pressure carried on their boilers.

WASHINGTON.—The Lynch and Lake terra cotta conduits lately reported favorably by the commission appointed by President Harrison, are giving entire satisfaction to the parties now wiring them in the District of Columbia, there being no breaks or unevenness to abrade the cables, which are easily drawn in.

☞ Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Miscellaneous, etc., will be found in the advertising pages.
