A NEW METHOD OF REGULATING ARC, OR CONSTANT CURRENT, DYNAMOS.

BY

F. Tischendörfer

THE writer, in designing the method of regulation described below, set about to fulfill the two following conditions: 1. The current in the armature must be constant, while the ampere turns of the field magnets may vary. The brushes are to remain fixed in position without causing sparking, under all conditions of load in the working circuit.

These conditions have been met in a system of regulation whereby the area of the inducing magnetic field is made variable, increasing the area of the magnetic fields in the direction of the rotation of the armature, by an increase of the load in the working circuit, and by decreasing this area in the reverse direction upon a decrease in the load.

The accompanying engraving, Fig. 1, shows the dynamo, one designed for 12 arc-lamps at 12 amperes, and Fig. 2 shows the automatic regulator employed.

The operation of the machine will be clearly understood from the diagram, Fig. 3. Here L represents the line circuit, connected at one end to one of the commutator-brushes, B^1, and including a series of arc-lamps, the return circuit being connected through the magnet M^3 and field-magnets M^2 of a regulating electric motor M', and ultimately through the regulator G, and one of the circuits

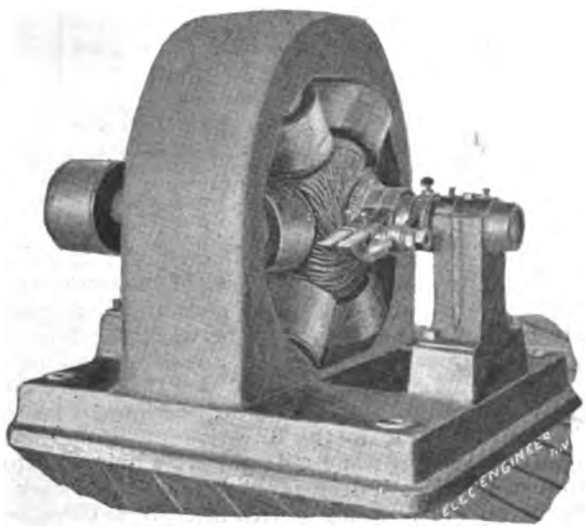

FIG. 1.—TISCHENDOERFER ARC DYNAMO.

w to w^{12} and field-magnets N to N^2 and S to S^2 to the other commutator-brush B.

The field-magnets are constructed with re-entrant poles N N' N^2 S S' S^2. Each of the field-magnet coils is divided into sections or layers connected in sequence at the points 1, 2, 3, &c., to 12, with branch conductors w to w^{12}, running to insulated conducting-segments C to C^{12}, arranged in circular order around a shaft D, which carries also a geared regulating-wheel J, meshing with a worm W on the armature-shaft of the regulating-motor M', the commutator T of which is connected on one side by stationary brushes K through a conductor e' with one of the coils of the field-magnet coil N at a point t'.

K' represents a pair of movable commutator-brushes carried by a pivoted armature-lever A', provided with an adjusting-spring s, this armature being located in the mag-

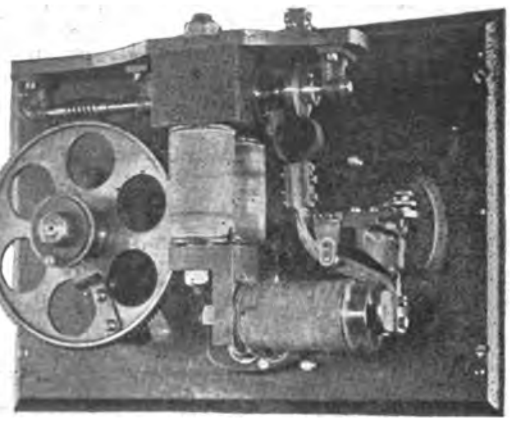

FIG. 2.—TISCHENDOERFER AUTOMATIC REGULATOR.

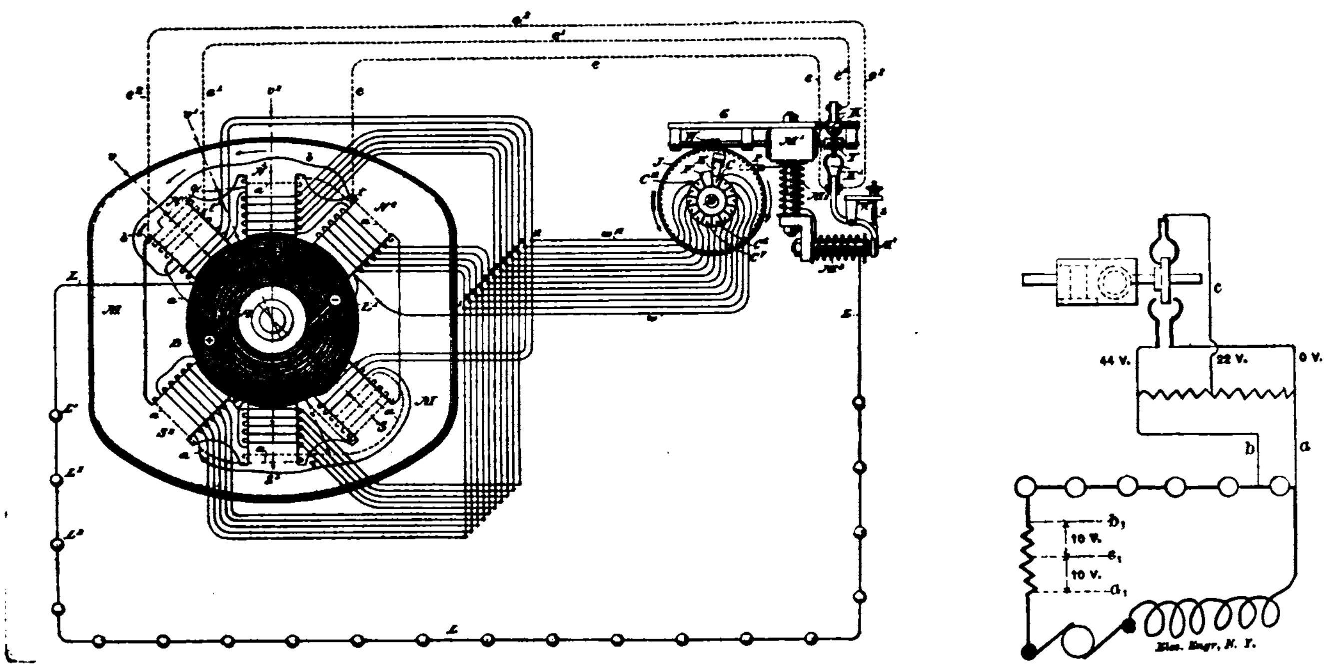
netic fields of the regulating-magnets M^3, the coils of which are connected directly to the exterior or working circuit and in series with the field-coils M^2 of the regulating motor M'. These two brushes K', which are insulated from each other, are connected, respectively, by wires e and e^2 with the coils of the field-magnets N^2 and N at points t and t^2, the former being connected to the field-coil N at the point of greatest potential of the machine—that is to say, near the plus commutator-brush B—while the latter is connected to the field-coil N^2 at a point t of much lower potential, the conductor e' being connected to the coil N at a point t' of intermediate potential, as shown.

The operation of the apparatus is as follows: Suppose the lamps to be all in circuit and the machine to be working with a full load. Under this condition of affairs the retractile spring s of the armature A' is so adjusted that the brushes K' are held out of contact with the ends of the commutator-strips of the commutator T, and the motor, therefore, is inert. The current then flowing magnetizes all of the field-magnets N to N^2 to the necessary point of saturation, and S to S^2 to a similar point of saturation, and circuit may be traced as follows, the circuit being in parallel from the plus commutator-brush through the layers of the north and south field-magnet poles respectively. Passing by the dotted lines a from the brush B to field-magnets N and S around the several layers of dotted windings, thence to field-magnets N' and S', (shown each as one layer of dotted winding,) thence to field-magnets N^2 and S^2, (shown each as one layer of dotted winding,) and thence by the full-line conductors b to the first field-magnets N and S through two sections, giving the same polarities as before, thence to field-magnets N' and S' through five sections, giving the same polarities as before; thence to field-magnets N^2 and S^2 through five sections, giving the same polarities as before, the conductors being connected ultimately to the wires w to w^{12}, running to the conducting-segments c to c^{12} on the regulator G. As long as this state of affairs continues the field-magnets will be energized to the desired point of saturation.

Suppose, now, one or more of the lamps are removed from the circuit, or short-circuited. The armature A' is immediately drawn forward by the increase of current, thereby causing the left-hand brush K' to come into contact with the commutator T, carried by the armature of the motor M', thereby connecting the brush with the field-magnet circuit at the point t. Immediately, therefore, a derived circuit is formed from the field-magnets through the conductors e and e', the current passing from the point t' of higher to the point t of lower potential through the armature of motor M' in such direction as to impart to the gear-wheel J, through the worm W, a motion in the direction of the tailless arrow, shown on the right of the wheel J, causing the sliding contact E to pass from the segment C to the succeeding segment C', whereby the first layer or section of the field-magnet N^2 is cut out of circuit, and the corresponding section of the south field-magnet S^2 is similarly cut out of circuit, thereby diminishing the magnetic effect of the field-magnets upon the armature, without, however, decreasing or in any manner affecting the magnetic effect of the remaining field-magnets N N' and S S'. As soon, therefore, as this decrease in the magnetic condition of the field-magnets N^2 and S^2 is effected, a decrease of the current on the line will result and the armature A' will assume its normal position, which it will maintain for a given quantity of current in neutral position, as shown in the diagram.

As this action is repeated, therefore, and lamps are successively removed from the circuit successive sections of the field-magnet coils N^2 and S^2 will be cut out, until finally all of the sections indicated in heavy lines will be removed from the circuit, and so on in succession the various sections of the field-coils N' S' will be continuously removed until all of the sections indicated by heavy lines have been cut out. In like manner, also, the two successive sections in the field-coils N and S will be removed when the E. M. F. required upon the line is a minimum. It will be noticed, however, that those coils indicated upon the field-magnets in dotted lines are never removed from the circuit, and that this dotted-line circuit is made to include a greater proportion of the field-coils in the magnets N and S and only one section in each of the coils N' and S' and N S^2. This arrangement of coils is designed for the purpose of always leaving the machine in such a condition that it will act upon the self-exciting principle, no matter what may be the resistance or condition of the exterior circuit, and also with diminished effect upon the field-cores N' S' and N^2 S^2 under all conditions of resistance in the exterior circuit, it being necessary to always maintain a certain proportion of north magnetism in the cores N' N^2 and south magnetism in the cores S' S^2 in order to prevent a magnetic short-circuit through the same inner-end field-poles and the armature.

With this method of regulation it is possible to maintain the commutator-brushes always in a fixed position and to avoid sparking under all conditions of load, inasmuch as no change is made in what is known as the "magnetic lead," by virtue of the fact that the magnetic lines of force are always maintained at the proper degree in the various field-cores in proportion to the demands of the exterior circuit. In other words, when the machine is working with a full load the resultant of all of the magnetic lines of force will be through the centre of the field magnet cores N' S', as shown by the line of arrows v^2.



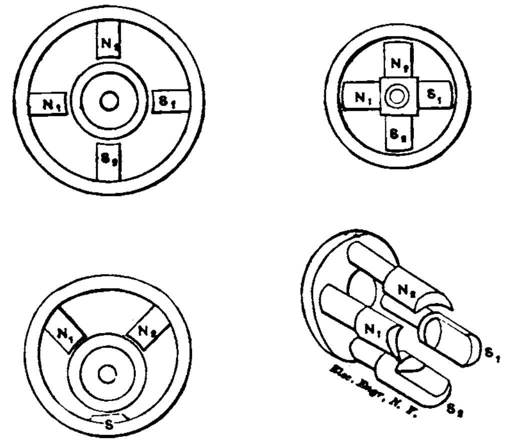
FIGS. 3 AND 4.—TISCHENDOERFER'S METHOD OF CONSTANT CURRENT REGULATION.

When the magnetism of the field-cores N^2 S^2 is reduced to a minimum by the cutting out of all of the sections of its winding, the resultant effect of the lines of force remaining will be felt at a point midway between the field-cores N N' and S S', as shown by the arrows v' and in like manner when the magnetic effect of the two sets of coils N' S' N^2 S^2 is removed, the resultant of the lines of force remaining will be found in the direction of the arrows v through the field-cores N and S. It will be readily understood, therefore, that for each decrease in the load in the working-circuit the lines of force are shifted in a reverse direction to the direction of rotation of the armature, and vice versa, on increasing the load in the circuit.

In the diagram, Fig. 3, the magnet coils N N^1 and N^2 are connected in parallel to the magnet coils S S^1 and S^2, but it is desirable to connect all coils N and S in series. This series connection is made in the dynamo shown in Fig. 1 in such a manner that first two layers of N^2, then two layers of S^2 and so on are cut out. The tests of the dynamo also shows that the remaining layers in the coils S^1 and S^2 and N^1 and N^2 which are shown in Fig. 3 by the dotted lines and which were employed to avoid magnetic shunt-circuits between like poles, and the adjoining part of the armature core, are not necessary.

The tests demonstrated the remarkable fact that all layers of the coils N^1 and N^2 and S^1 and S^2 can be cut out entirely without any signs of sparking at the brushes, even when the coils N and S alone are in circuit, these being necessary to operate only one lamp. The small dynamo constructed gives 700 volts and 12 amperes at 1350 revolutions per minute, and no sparks are visible with the brushes fixed, although the voltage varies from 700 down to 60.

It is not necessary in a large dynamo to have as many



FIGS. 5, 6, 7 AND 8.

magnet coils or branch of conductors as there are lamps in the working circuit, because a not too large variation of current will be equalized through the reaction of the armature on the magnetic field.

The small armature of the motor of the automatic regulator is in shunt to the main circuit in the regulator shown in Fig. 2, but it can also be operated as shown in Fig. 4, in which a high resistance is connected in parallel to the first lamp, and from this resistance there are taken off the three potentials a, b, and c (0, 22 and 44 $v.$); or there can be placed in the main circuit before it reaches the lamps a small resistance of about 2 ohms, and the armature brushes connected with the three potential a_1 b_1 c_1.

The new method of regulation by diminishing or increasing the induction area can be carried out with more or fewer re-entrant poles. A few examples of such cases are shown in Figs. 5, 6, 7, and 8.

It will also be evident this system of regulation can be applied to constant potential dynamos and motors, and also to constant current motors.

THE DETERMINATION OF SPECIFIC HEATS BY THE ELECTRIC CURRENT.

A METHOD of determining specific heats by the electric current was published by Prof. J. Pfaundler in 1869. It depended on Joule's law, and was one in which the same current develops quantities of heat, in coils of wire arranged in series. This method has hitherto found but few applications from the circumstance that it only applies to non-conducting liquids. According to an article in the *Wiener Berichte*, Prof. Pfaundler has got rid of this drawback by substituting for the coils of wire spiral glass tubes filled with mercury. He has also given the method far greater accuracy and certainty by inserting three mercury resistances in the branches of a Wheatstone bridge, by which it is possible to control and keep constant the ratio of the resistances during the passage of the heating-current. Small variations in resistance are compensated by introducing glass threads in the straight ends of the tubes which contained the mercury. In other cases these changes are measured by displacing the contact-key, and in this way the result is corrected. The comparative measurement of the rise of temperature is made more delicate by means of a thermopile.

NEW METHOD OF REPORTING GAMES AND RACES.

BY

PROBABLY no one thing tends more to popularize recurring events, such as amusements of all kinds, than the wide dissemination of detail reports of such amusements by the newspapers, telegraph ticker, etc., and no less is this the case with sporting events than it is with amusements in general.

Undoubtedly the more ornamental, attractive, and pleasing the instruments placed before the public eye, provided the methods employed are reliable, the wider becomes the field of its operation, and to the extent of this field of operation does any particular sport become advertised, or, what amounts to the same thing, substantially in this case, popularized.

An apparent demand exists for some means to supply the public resorts with just the news that they want, omitting the general financial and stock market reports, which they do not want and will not pay for at such rentals as will enable the ticker companies to profitably supply them, and for this statement there is no better proof than the

FIG. 1.—RACE DIAL, MOTT SYSTEM.

fact that only one saloon or public resort in a hundred of all grades is supplied to-day with tickers in New York.

To meet this demand inventors have endeavored for years to improve the present stock ticker; to simplify it, cheapen it, get rid of its delicate adjustment, operate it over one-line wire instead of two and three lines, force its working over long distances, exceeding at least the present limit of about 15 miles, and other minor disabilities. But so far there has been no improvement to overcome these defects, nor is there likely to be on the lines of the present stock ticker, and the perversion of its legitimate field as an instrument of commerce to the reporting of athletic sports does not come up to the requirements of the athletic community nor supply the demands of this market at popular or unpopular prices.

The conservative estimate that $5,000,000 changed hands last season in the racing of horses, and that $2,000,000 does not cover the transactions incident to the game of baseball,

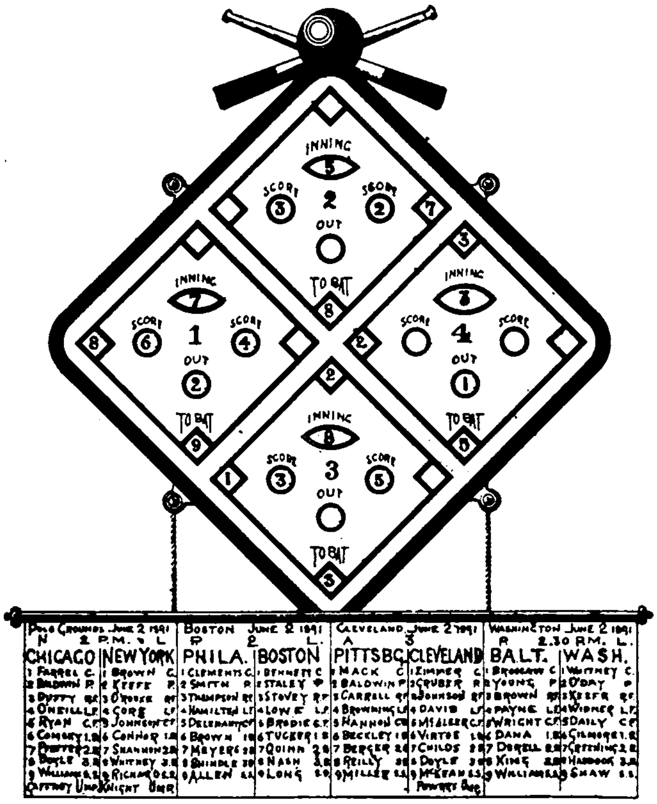


FIG. 2.—BASEBALL DIAL, MOTT SYSTEM.

goes to show the commercial status these sports are taking with the American public, and emphasizes the demand for a simple bulletin visible to all the persons in a room, indicating the various points of a game concurrently with the play, as plainly as a clock indicates the time of day. Numerically considered, the market for such an instrument is as much greater than the market for the stock tickers in its legitimate sphere, as the public resorts in a city exceed in number the brokers' offices.

Such an electric system of visually indicating the concurrent report of a game or race I have devised and they are illustrated in the accompanying engravings. Fig. 1 shows a race dial reporting the Brooklyn Jockey Club races at Gravesend track, May 30 last. The entries, purses, length of race, character, whether sweepstake or handicap, best record, weights, ages, jockeys, etc., is placed on the entry slip and held by a clip in juxtaposition to the bulletin. The face of the dial, which is electrically operated, shows the field in each race, the scratches, if any, the winner, second and third, and the time. For instance, the third race was one mile, purse $2,500. Winner, Longfellow; second, Airplant; third, Spinalong; time 1.18¼. The fifth race is about to start. Guilty and Billet Doux are scratched.

Fig. 2 shows a dial reporting four games of baseball simultaneously, or in any order, illustrating the main features of the game in either case. The Chicago and New York teams, of the National League, are playing at the Polo Grounds, N. Y., June 2, 1891, at 2 p. m. The score is 6 to 4, in favor of the former; the 7th inning is being played; two are out; Williamson at the bat, Doyle on 3d base. Philadelphia and Boston at Boston, same date, 2 o'clock; score, 3 to 5 in favor of Boston; 5th inning. Pittsburgh and Cleveland at Cleveland, score 3 to 5, 8th inning. Baltimore and Washington at latter place same date, 2.30 p. m., score 0; 3d inning; one out; Young on 3d base; Wright to bat; Brown on 2d base.

Fig. 3 shows the electrical organization, which is so plain that no detail description will be necessary. Its main features are the segment circle or selector, with trailing lever, the local and transmitting battery, the latter being thrown on the line in positive and negative impulses by the keys *k' k* respectively. The problem, simply stated, is to enable an operator to select any one of any number of magnets at a distant point or a number of distant points, and when so selected to cause the one selected to operate. The instrument A, which is used for relaying and repeating in this case, controls two separate and independent locals from the battery B', the one selecting the magnet and the other energizing the magnet selected. The number of local magnets is determined by the number of features to be shown on the face of the dial and is limited by the number of segments or in the selector. The addition of more magnets being a mere duplication of parts.

Because of its simplicity and few working parts this instrument costs less than one-fifth of the cost of tickers; many instruments may be operated over single-line circuits to any distance, as the system may be relayed and repeated ad infinitum; it requires no delicate adjustments, no winding or supplying with ink or tape. All indications on the face of the dials are brought to blank spaces by the operator after the day's events have been reported, or in case a mistake has been made by the operator. The expense of operation is minimized, as no receiving operator is required, as with telegraphy.

A relay may be interpolated in the main line for inter-

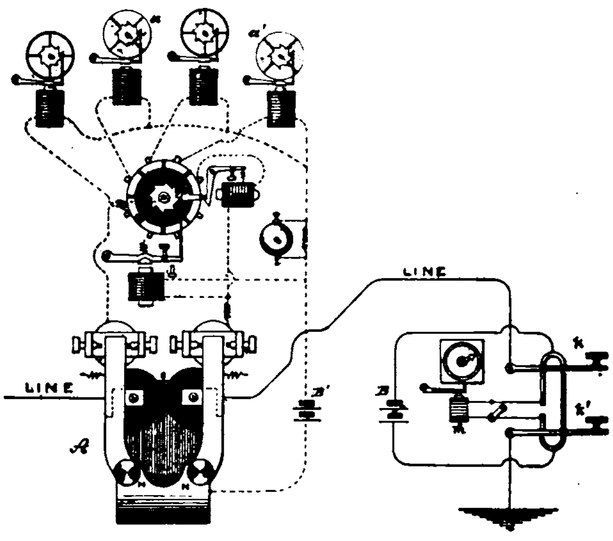

FIG. 3.—DIAGRAM OF THE MOTT SYSTEM.

mediate working of 20 to 25 dials in locals so arranged that *no* resistance nor even a disturbing influence is apparent on the main line. Unlike the tickers, it may be operated from the grounds of play or race track, or, like the ticker, locally. It can be easily operated by a transmitter which may be carried in the pocket, requiring no skill, but good judgment on the part of the operator. A feature of no little consequence is the fact that all signals are unintelligible if the line is surreptitiously tapped.

ELECTRICAL ENGINEERS.

FRANCIS W. JONES.

SOME time or other it will be worth the while of the historian to investigate the facts in connection with the Loyalist emigration from this country at the time of the Revolution, to British North America and the West Indies, and then the subsequent inflow of the descendants of those political exiles as new settlers. There are to-day a large number of people in this country who are regarded as Canadians or West Indians, when in truth they are more distinctively American than any whose fathers came here after 1776; and they are not a little proud of a fact that lies at the bottom of much of the tendency to closer political relationship between the various portions of this continent.

It was of such interesting Loyalist ancestry, exiled from New England, that Francis Wiley Jones was born, at Weymouth, Nova Scotia, in the old family homestead, one of the first in those primeval forests. At Weymouth, Mr. Jones spent his youth, and in 1859, when only thirteen years of age, he entered the Post Office, at Kentville, N. S., as a clerk. There, without any help or advice, he learned telegraphy, and in about three months began telegraph work also. He continued in this dual capacity, varying the monotony by issuing marriage licenses and recording vital statistics, until 1867. It may be mentioned that Mr. J. F. Morrison, of Baltimore, the first president of the National Electric Light Association, was an operator at Aylesford, on the same line. Mr. Jones then removed to St. John, New Brunswick, where he accepted a position as operator under Mr. R. T. Clinch, the superintendent of the Western Union Telegraph Co. He was soon given full care of the batteries in addition. The office was then the repeater station for the Atlantic cables, just put in operation, and was one of the most important of the company, besides being a nursery of talent from which came such well-known men as J. Ranney, B. S. Black, E. T. Barberie and the two Dorans. During 1868–9 severe electric storms occurred, stopping many of the circuits. On several occasions the batteries were disconnected and the wires were worked entirely by auroral currents. At Mr. Jones' suggestion, two wires between St. John and Plaister Cove, the eastern repeater point, and two between St. John and Boston, the western repeater point, were looped into metallic circuits, and the St. John-Milliken repeater spanned the two loops in such a way as to eliminate all earth connections. Signals were immediately exchanged free from atmospheric disturbances. A similar plan was afterwards adopted by Mr. Geo. B. Prescott between New York and Boston.

Mr. Jones thinks that St. John was perhaps the first American city that saw a public exhibition of the electric light. About this time, the city being visited by a member of the royal family, he connected two battery carbons to a Grove battery of 80 cells, fed them by hand, and from the Western Union windows made a fitful but very brilliant display to an immense crowd of puzzled and dazzled sight-seers on Prince William street.

Thinking that the United States would afford him more elbow-room in the electrical field, and being full of youthful energy, Mr. Jones left St. John for Chicago, arrived there in May, 1872, and was at once enrolled on the night force. He now saw a galvanometer and a Stearns duplex for the first time, and at once made their intimate acquaintance. In 1873 he was appointed Sunday manager, and was entrusted with onerous work in moving the office to its present position on La Salle street. In 1875 the American Electrical Society was organized in Chicago, and upon Mr. Jones as its corresponding secretary and librarian fell the work of issuing, with Mr. William Henry Smith, the valuable and now rare transactions of that body. In No. 3, vol. 2, is an able discussion by him on the nature, effects, and telegraphic remedies for electric storms.

In September, 1874, Mr. Edison put the quadruplex in operation on the Wheatstone Bridge principle between New York and Boston. As arranged, the quad was then barely successful on short circuits and not much better than a duplex on long circuits. In August, 1875, Mr. Jones reduced it to the differential form between Chicago and Buffalo, with repeaters at Detroit, with such marked benefit that the latter method was adopted throughout the Western division, and two years after throughout the country; and the New York-Chicago quad circuits were for the first time put into use for business, and with but one or two slight changes, the quadruplex as used by the Western Union to-day is substantially as modified by Mr. Jones in 1875. The same year Mr. Jones was appointed assistant manager of the Chicago office with care of the operating department and the circuits.

In 1880, on the resignation of Mr. G. B. Prescott, as electrician of the Western Union Telegraph Co., the new position of general circuit manager was created for Mr. Jones, under Mr. John Van Horne, vice-president, Mr. George A. Hamilton becoming electrician to the company. Mr. Jones continued as general circuit manager in New York until the spring of 1882 when he resigned to get rest and recover his health. He now became general manager of the Union Electric Mfg. Co., where he remained for two years, acquiring a valuable experience in processes of electrical manufacture. In 1884, however, his old tastes led him back into the telegraphic field, and he became electrician of the Bankers' and Merchants' Telegraph Co. For this corporation, then in its heyday, he arranged a duplex with an induction coil to obviate the static troubles, and it is said to be the only one that can successfully compete with the Stearns condenser duplex on long lines.

When the financial crisis of 1884 forced the B. & M. into the hands of a receiver, Mr. Jones was asked to assume the general management of a seemingly hopeless wreck, falling daily into deeper debt. Mr. Jones took up this cheerful task, and in 1885 Mr. A. B. Chandler, president of the Postal Telegraph Co., came to his assistance with mental and financial help of the most encouraging nature. Mr. Jones gladly resigned in Mr. Chandler's favor, and became the assistant general manager and electrician of both concerns. Since that time affairs have assumed a wonderfully different aspect, and as the result of their conjoint labors, the Postal has the reputation to-day of being one of the best-run telegraph companies this country has ever seen. With Mr. Chandler's approval, the New York, Chicago, Boston and Pittsburgh Postal offices have been entirely equipped with dynamos for supplying current to all their wires, and the New York office is the first in the world where dynamo current was used for both the main and the local circuits. Mr. Jones has displayed much inventive skill and ingenuity in this work, and the Postal methods, which have been patented, yield results that are most satisfactory.

Since 1877 Mr. Jones has been a citizen of the United States. He is a life member of the New York Press Club, the New York Telegraph Club, and the American Institute of Electrical Engineers. Of the latter body he is a charter member and was one of its first officers. Mr. Jones, on his removal to New York from Chicago, proposed the formation of the New York Electrical Society—now the oldest electrical body of its class in the country—and was elected its first president. Mr. Jones has also taken an active interest in the welfare of operators and was largely instrumental in the starting of the Electric Building, Loan and Savings Association, formed by Postal Telegraph employees, and is vice-president of the organization.

THE WILLSON ELECTRIC ALUMINUM PROCESS.

In the production of aluminum and its alloys, or other metals of equally refractory character, by means of the electric current, the ore is fused and decomposed, and the oxygen thus liberated attacks the containing crucible and the electrodes, which are usually made of carbon, by means

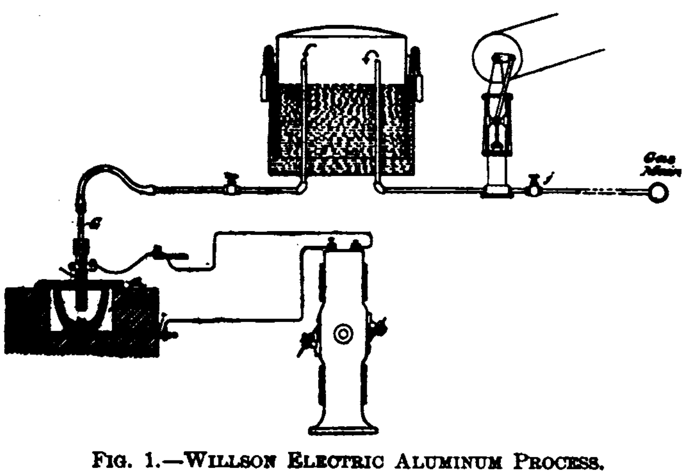

FIG. 1.—WILLSON ELECTRIC ALUMINUM PROCESS.

of which the current is introduced and rapidly wastes them away. The material of the electrodes and crucible is thus made to act as a reducing agent, and the process of electric smelting is rendered expensive.

In order to avoid this loss, Mr. Thomas L. Willson, of Brooklyn, the electrical engineer of the Willson Aluminum Co., of this city, has devised a method of introducing a deoxidizing agent in the form of a hydrocarbon gas, so that it shall be interposed between the liberated oxygen, and the surfaces of the crucible and electrodes.

In the accompanying engravings, Fig. 1 shows a diagrammatic elevation of the general apparatus, and Fig. 2 a detail sectional view of the furnace and electrodes employed in carrying out the process.

As will be seen, A is a hearth of brick-work having an opening within which the crucible is set resting upon a carbon plate built into the hearth, and forming the bottom of the opening. The positive and negative terminals of the dynamo are connected, respectively, with the carbon plate, and the carbon pencil E. The connection with the

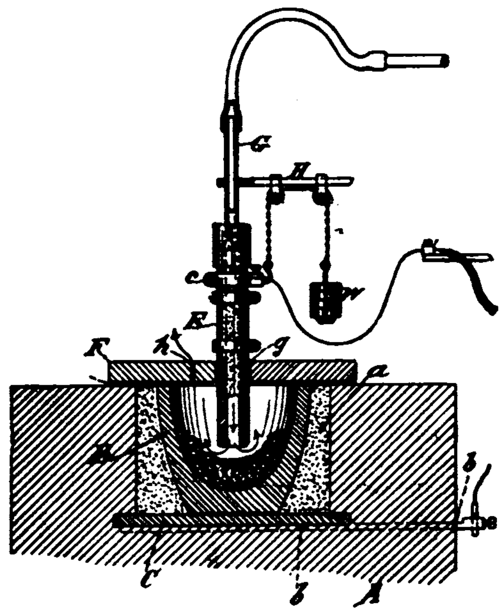

FIG. 2.—WILLSON ELECTRIC ALUMINUM PROCESS.

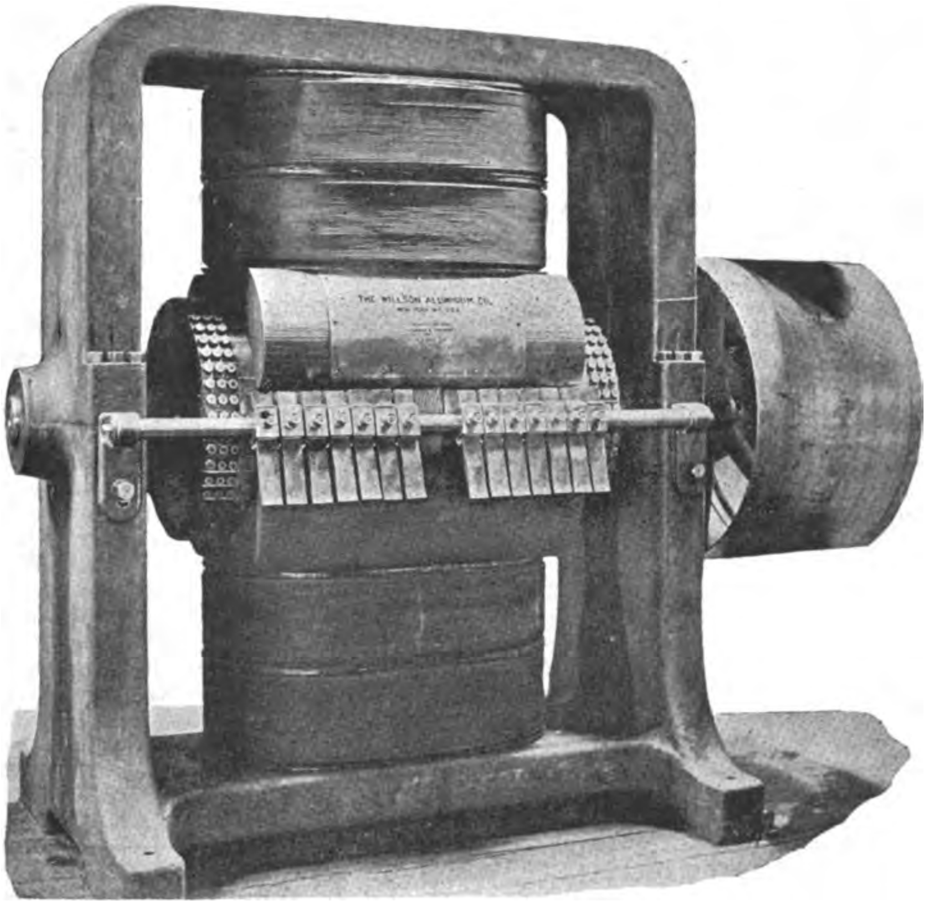
carbon plate is made through the medium of the metal bar *b*.

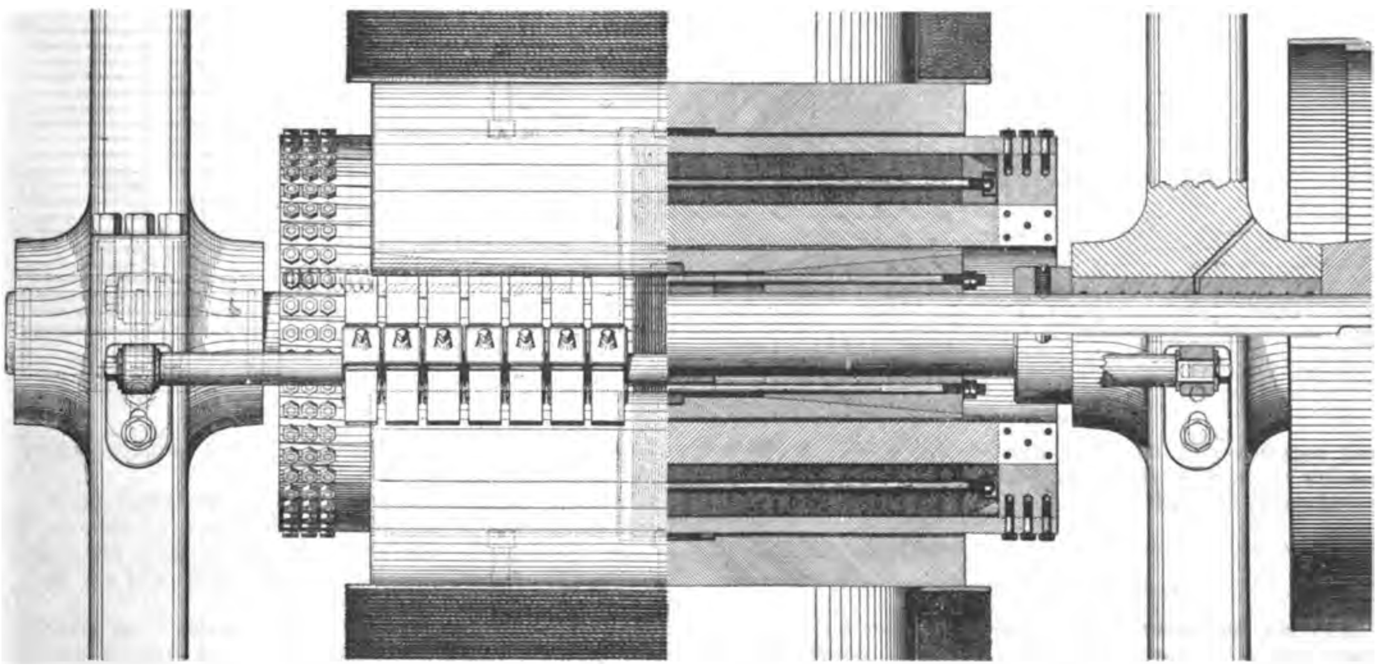
The carbon electrode E is made tubular, as shown in Fig. 2, the duct through it constituting a gas-passage. The upper end of the carbon-rod has united to it an iron pipe G, which extends upward in line with the corbon-rod, and is connected to the supply of gas. A gas holder, shown in Fig. 1, is provided to equalize the pressure of the gas.

The operation will now be readily understood. In the bottom of the crucible is placed a quantity of broken copper, and, on top of this a layer of alumina in the form of a nearly pure corundum.

The cover is then placed over the crucible and luted down, and the carbon pencil thrust through it and pressed down through the layer of corundum until its tip touches the copper. After the current has been started by bringing the carbon pencil in contact with the copper, the carbon pencil is lifted slightly to strike the arc, and as the copper fuses it is lifted still higher until the maximum arc is formed. This arc is then maintained stationary. At the same time the gas is turned on, and during the operation the pump is kept running at sufficient speed to supply the desired quantity of gas at the proper pressure. This pressure should be sufficient to overcome any pressure existing in the furnace, and to cause a slight blowing out of the gaseous products of combustion through the vent.

The heat of the arc first fuses the copper and sets it into ebullition, partially vaporizing it. As the heat becomes more intense the alumina is also fused, and is decomposed, its oxygen being set free and immediately combining with the hydrocarbon gas pumped in and forming carbonic acid, carbonic oxide, and steam, which escape through the vent. The aluminum, which is freed from its combination with oxygen, at once combines with the copper, forming an aluminum bronze. Throughout the operation the copper is vaporized by the intense heat and the copper vapors circulate within the crucible, becoming condensed against the comparatively cool sides and streaming down as liquid copper through the mass of corundum, whereby a circulation is created through the latter, and as rapidly as the corundum is fused and its oxygen driven off, the copper combines with the aluminum. The operation consumes from fifteen minutes to two hours, depending upon the character of the corundum, the proportions of the ingredients, and the strength of the current.





Figs. 3 and 4.—The Willson 750,000 Watt Generator and Armature.

When the corundum has been wholly fused and melted down, and its oxygen eliminated, there remains in the crucible a bath of molten aluminum bronze, which is poured or tapped out of the crucible. A special type of dynamo to be used in connection with this process has been designed and built by Mr. Willson, and is shown in the engraving, Fig. 3. This machine weighs 25,442 lbs. It has a 24-inch Gramme armature, weighing 6,163 lbs., mounted upon a 5-inch hammered steel shaft. The shaft bearings are of composition brass, 15 inches long. There are over 11,000 pounds of cast iron in the frame of the machine, and 7,000 pounds of forged iron in the pole pieces, etc.; and altogether it contains 7,456 pounds of copper in the fields and armature. The capacity of the dynamo is 750,000 watts at 530 revolutions per minute, and it is designed to run at 50 volts.

One of the special features of this machine is the arrangement of the brushes, which, as will be noted, are placed directly against the outer surface of the armature bars; the commutator as such is thus done away with. The armature bars, which are $1\frac{1}{2}$ sq. in. in section, are thoroughly insulated with asbestos and with mica where the brushes bear, and are practically indestructible. One armature of this type, after four years of constant operation, shows not more than $\frac{1}{32}$ inch reduction of size. As will be seen by reference to Fig. 4, no spiders are used, and the shaft is gripped by an expansion hub, the friction being automatically taken up by means of a constant spring pressure. Tests of the machine have shown it to run remarkably cool and to possess a high efficiency.

The machine illustrated has been constructed by Mr. Willson for the Willson Aluminum Co., and will shortly be put in operation at Leaksville, N. C., for the extraction of pure aluminum and its alloys by the Willson process as described above. A large water power is available for driving the dynamo, and it is believed that, with the new process, together with the cheapness of the power, it will be possible to produce aluminum both pure in quality and at a considerably reduced cost.

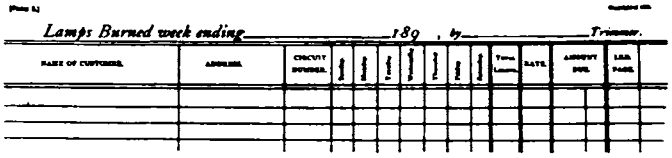
CENTRAL STATION MANAGEMENT AND FINANCE.—IX.

BY

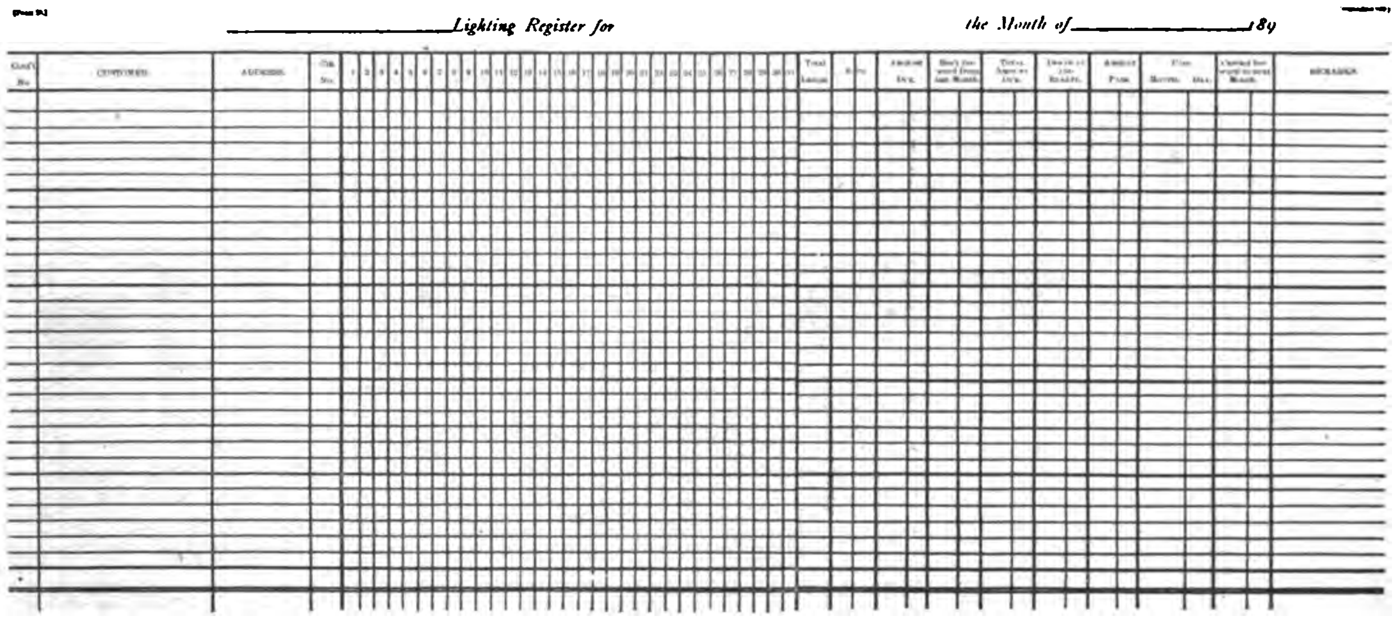
Horatio A. Foster

Department of Accounts.

For convenience of reference it is well to have a contract book with all the proper headings, giving all necessary items and index for reference. If a separate ledger account is kept with each customer, all such data can be put in under the page heading, and is easier of reference than if in a separate book. It will be noticed that the lighting register, form No. 28, has columns for all data necessary to record from installation orders. When the installation is completed the order is returned to the office and filed until the lights are started; then the time of starting is recorded on the slip and all items of record entered in the proper books, such as the lighting register or ledger, the trimmer's book or meter book, circuit register, form No. 28, and posted on the bulletin board, so that inspectors may know where to find it.



Form No. 5.—Inspector's and Trimmer's Blank.



Form No. 28.—Lighting Register.

In respect to methods of reporting arc lamps burned, there are probably as many as there are of running a station. It must be admitted that most of them are negative reports in that only those lamps which did not burn are mentioned, and those not surely.

The writer considers it much better to use what may be called the positive method, and report every lamp trimmed, with the customer's name and location, and for such method advances blank No. 5. It is thought best to make this report on loose sheets which will be written up by the clerk and placed in loose covers, where the trimmer can fill in for the week, and then fresh sheets can be inserted and

THE FISKE RANGE FINDERS.

A naval officer writing from Europe says that while the "Baltimore" was at Toulon nothing aboard the ship excited so much favorable comment from foreigners as the Fiske range finders. "Just now," says the writer, "when our growing navy is accused everywhere of being simply a copy of foreign navies, it is worth while to be able to point out something in which foreign navies admittedly copy us."

the completed ones entered by the clerk in tho lighting register or ledger.

Where stations are full and a load of good, steady customers is connected the sheets can be furnished with the customers' names, all printed in, so as to save a great deal of tedious writing by the clerk every week.

If the old negative method is considered good enough, then form No. 28 for a lighting register is put forward as embodying all the points necessary for either weekly, biweekly, or monthly accounts, and any lamps reported as not burning either by the trimmer or inspector, or both, can be checked off every day and the rest be entered as O. K.

Form No. 5 is also used by the incandescent inspector to record the number of lamps burned daily by customers having monthly or contract rates.

TESLA'S SYSTEM OF ELECTRIC LIGHTING WITH CURRENTS OF HIGH FREQUENCY.

In his lecture delivered before the American Institute of Electrical Engineers,[1] Mr. Nikola Tesla dwelt at length upon the fact that the direct application of electro-magnetic waves to the production of luminous effects was impracticable and that for this purpose electro-static waves or thrusts must be employed. To make these effects available in practice, however, it is necessary to employ currents of very high frequency and of very high potential.

In a patent just issued to Mr. Tesla on this method of electric illumination, he draws attention to the mechanical difficulty of obtaining the necessary high frequency of alternations, and hence he avails himself of the principle of the disruptive discharge. The current of high frequency is produced by the disruptive discharge of the accumulated energy of a condenser maintained by continuously charging the condenser and discharging it disruptively, in connection with an induction coil which generates the high potentials required.

The accompanying diagram, Fig. 1, illustrates the method employed by Mr. Tesla, the generator in this case

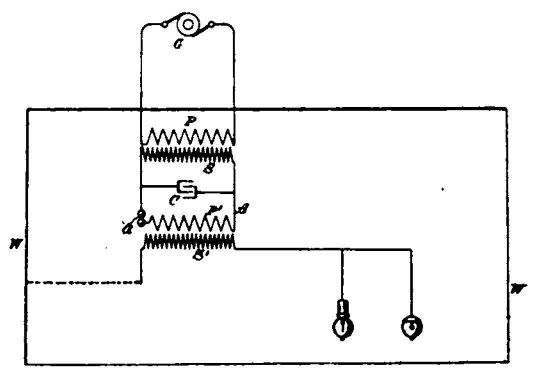


FIG. 1.—TESLA'S NEW SYSTEM OF ELECTRIC LIGHTING.

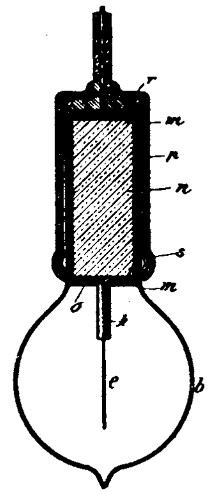
being one delivering alternate currents of comparatively low potential. The potential of the current is raised by means of an induction-coil having a primary P and a secondary S. Then by the current developed in this secondary a condenser C is charged and this condenser discharged into a circuit A, having an air-gap *a*. By the means above described, a current of enormous frequency is produced. It is next necessary to convert this into a working-circuit of very high potential, for which purpose there is connected up in the circuit A the primary P′ of an induction-coil having a long fine wire secondary S′. The current in the primary P′ develops in the secondary S′ a current or electrical effect of corresponding frequency, but of enormous difference of potential, and the secondary S′ thus becomes the source of the energy to be applied to the purpose of producing light.

The light-giving devices may be connected to either terminal of the secondary S′. If desired, one terminal may be connected to a conducting-wall W of the room to be lighted and the other arranged for connection of the lamps therewith. In such case the walls should be coated with some metallic or conducting substance in order that they may have sufficient conductivity.

Mr. Tesla has devised several forms of lamps to be used



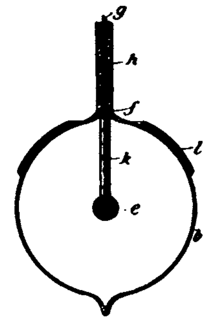


FIG. 2.—TESLA'S LAMP WITH STRAIGHT FILAMENT, ONE INSIDE AND ONE OUTSIDE CONDENSER COATING, AND ONE CONDUCTOR.

FIG. 3.—TESLA'S LAMP WITH INCANDESCENT BALL AND ONE CONDUCTOR.

in connection with his system, two forms of which are shown in the engravings Figs. 2 and 3. In the former the globe *b* is formed with a cylindrical neck, within which is a tube or sheet *m* of conducting material on the side and over the end of a cylinder or plug *n* of insulating material. The lower edges of this tube are in electrical contact with a metallic plate *o*, secured to the cylinder *n*, all the exposed surfaces of the plate and of the other conductors being carefully coated and protected by insulation. The light-giving body *e*, a straight stem of carbon, is electrically connected with the plate by a conductor *f*, which is coated with a refractory insulating material *k*. The neck of the globe fits into a socket composed of an insulating tube or cylinder *p*, with a more or less complete metallic lining *s*, electrically connected by a metallic plate *r* with a conductor *g*, that is attached to one pole of the source of current. The metallic lining *s* and the sheet *m* thus compose the plates of a condenser.

Fig. 3 shows a lamp containing an incandescent body *e* which is connected to one pole of the source of current. Outside of the globe the conducting-wires are protected by a coating of insulation *h*, and inside the globe the supporting-wire is inclosed in and insulated by a coating *k* of a refractory insulating substance, such as pipe-clay. A reflecting-plate *l* is shown applied to the outside of the globe *b*. This form of lamp is a type of those designed for direct electrical connection with one terminal of the source of current; but, as in the case of the lamp, Fig. 2, there need not be a direct connection, for the carbon or other illuminating body may be rendered luminous by inductive action of the current thereon.

ELECTRICITY THE THING.—Discussing the work of the electric car, the Minneapolis *Tribune* says: "Here it is heartily welcomed as a convenience, a civilizer, and a boomer of real estate values."

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers*

VOL. XII. NEW YORK, JULY 1, 1891. No. 165.

The scientific principles which at one period appear of no practical value, and are far removed from popular appreciation, at a later time, in the further development of the subject, become the means of individual prosperity and national wealth.—Joseph Henry.

IS THE DYNAMO A PERFECTED MECHANISM?

IN a recent paper, "On some Points Connected with Mains for Electric Lighting," read by Mr. W. H. Preece, the able electrician in charge of the British postal telegraph system, before the London Institution of Electrical Engineers, he remarked that "it is a pity that some of that redundant mental energy which is endeavoring to raise the efficiency of dynamos and transformers from 94 to 95 per cent. could not be transferred to the question of mains, where real advancement and true economy on a considerable scale are much required."

Taken literally, we are certainly inclined to agree with Mr. Preece that any attempt to further increase the efficiency of the best-constructed dynamos of to-day is hardly worth the time and energy, but, we may ask, are the efforts of inventors to-day directed with this object in view? If we may judge from the work which has been done during the past few years, it can hardly be justly held that such has been the case. On the contrary, we think that an analysis of this work will show that the attempts of dynamo builders have been more in the direction of the improvement of mechanical and electrical design with the view of reaching greater simplicity and cheapening of construction. Indeed, in not a few instances these attempts have been accompanied by a decrease in the efficiency of the machine; but though the dynamo may justly be regarded as one of the most perfect converters of energy, it would be rash to assume that on this account it had reached a condition such that any further modification would be a waste of time and energy. There is still much to be done in both the dynamo and its twin, the converter. In the dynamo, simplicity of construction is still to be striven for, and although the difficulties once experienced with the commutator are now largely overcome, the continuous current machine without the commutator is an object certainly worth striving for. Then again in the case of transformers, their design is still subject to improvement in the direction of increasing the efficiency at light loads. Their low efficiency with light loads has up to the present day been found to detract seriously from their value. Taking all these points into consideration, we believe it would be safe to assume that the final types of dynamo and transformer have not yet been evolved, and that, indeed, they are things in the future. We might even go further and state that, considering the rapid advances and the changes which are becoming manifest in our methods and systems of illumination, it will not take much to render the present types of both the dynamo and transformer obsolete in a very few years.

"GOOD FAN WEATHER."

WE have all of us long been accustomed to hear that it is an ill wind that blows nobody good, and electricians have come to think that it is the best weather for them when there is no wind at all. During the past two or three weeks the country at large has enjoyed its first taste of what has come to be known in electrical circles as "good fan weather," and the result is that the demand for fan motors has been something enormous. People have come to a realizing sense of the fact that it is easy to substitute a fan motor for the little lamp in their office, and the consequence is that without any drumming at all, the orders for these fans have poured in upon the local companies so fast that, to our own knowledge, it has been some days before they could be filled, the customer meanwhile panting and gasping and mopping himself. Some of the companies have not yet bestirred themselves as they should to cultivate this business, thinking it, perhaps, too small to bother about; but we think that with even a little canvassing they would find it very large and very profitable. The addition to the day load of an ordinary station, even if 1,200 or 1,500 fans were running at a time, would not be great enough to require any additional men in the station and there would be the profit not only on the current, but probably on the sale of all the motors too. Moreover, many a man, too, would become familiar with the idea of using electric power and would follow up the little fan motor with something larger for heavier work. We hope to see central stations paying all possible attention to this new business.

As a general thing, the fans give great satisfaction to those who buy them. Some of the complaints made are idle; others are well founded. It seems to us that the fans are very often too large, and create too great a breeze. This is easy to remedy, and might perhaps be helped by having a wider range of sizes. A great many offices are small, and are hot because small, and the customer does not want to run his fan at half speed with the help of a lamp or else run it at full speed and be subjected to a miniature cyclone. Another complaint we have heard from laymen is that the fans are sometimes too noisy and that their insistent hum is trying to nervous people. Here again is a defect that can be remedied. It has also been criticised that the switches are sometimes crude and difficult to get at. This also can be improved upon. All these are minor defects and do not offset the great fact that the electric fan has become as great a boon in hot weather as ice cream or the morning bath. There is no reason why electric fans should not be as plentiful in the land as sewing machines.

THE SUCCESS OF ELECTRIC RAILWAYS.

BECAUSE electricity has been proposed as the motive power for the coming underground rapid transit system of New York, the *Sun* goes out of its way to sneer at what electric roads actually have done in America. Thus, for example, in a paragraph about the old electric road at Asbury Park, whose power-house was visited by fire, it says that electricity did not pay and that the company will go back to horses. It suggests that this might be said of many another road. Well, even if true, what of it? Is steam locomotion a failure because hundreds of roads in this country do not pay, and never have paid? The reason why the visitors to Asbury Park will have to endure horse-car travel this summer is that the company would lose a large part of its season and income while rebuilding its power plant. It may be, also, that the company, while able to put on a few horse teams, would find it very difficult in these close times to raise the money it wanted. But the *Sun* may as well know that if there is one fact it cannot gainsay it is that electric traction is cheaper and better than horse traction. There are some roads that even electricity cannot make pay, but there are a good many more whose only hope and salvation has been found to lie in resort to electric motors. We venture to predict that Asbury Park will soon have a good, modern electric road, replacing the unfortunate pioneer one now destroyed, a road, which for all its crudeness, did very good work.

ALUMINUM PROCESSES.

THE history of the commercial production of the metal aluminum is probably as interesting as that of any metal now employed in the arts. Obtained first by the chemical method, it passed through various modifications from the time of St. Clair Deville until the advent of the electric method of production has within a comparatively short time placed the chemical methods outside the pale of competition. But the attentive observer in the field of electric production of aluminum cannot fail to discern that this method is likely to follow somewhat the chemical methods, in so far as the variety of processes is concerned. Thus when the Messrs. Cowles first drew attention to the possibility of extracting aluminum by the electric method, they employed a process of reduction by means of electric heat in the presence of carbon. In the Héroult process, and in one or two others, the electrolytic action of the current is employed; and the carbon electrode is made the positive and the molten bath the negative electrode.

In this issue we describe still another process, due to Mr. Thomas L. Willson, for which he claims a number of advantages based, no doubt, on good arguments. By employing a hydro-carbon gas as a reducing agent instead of carbon in the solid form, Mr. Willson argues that the reducing agent in the first place is in a perfect form for chemical union with the oxygen of the alumina, and, being already in the gaseous state, no heat is absorbed in the conversion of the solid to the gas before it can act upon the oxygen. Thus a greater heat is obtained for a given expenditure of electrical energy. Besides, according to Mr. Willson, by introducing the hydro-carbon gas under pressure, the reaction and hence the reduction can be effected with any desired rapidity, and, above all, the product may be made pure, on account, evidently, of the purity of the gaseous reducing agent. We are glad to note that the process will be put in commercial operation at an early date and will thus be able to demonstrate on a large scale what has been successfully carried out experimentally.

Mr. Tesla's New System of Illumination.

PENDING the publication of the full report of Mr. Tesla's lecture before the American Institute of Electrical Engineers, we give this week the essential principles embodied in a new system of illumination as embodied in a patent which has just been issued to him. It will be noted that what Mr. Tesla had set before him was to obtain in the first place, alternations of very high frequency by charging and disruptively discharging a condenser, and then raising the potential enormously by means of an induction coil. In other words, Mr. Tesla accomplishes the desired results by exalting the effects which have heretofore been produced in but a feeble manner. It will be noted that though employing alternations in the primary generating apparatus far exceeding those at present in vogue, Mr. Tesla does not depend upon even this high frequency to effect the desired purpose, but introduces the disruptive discharge of the Leyden jar with its well-known enormous frequency as the means for obtaining the required rapidity of alternation. With the method now clearly pointed out, we believe that it will take but a comparatively short time to work out and present to the public the practical details necessary for the general application of such a system.

A New Constant Current Machine.

THE method of regulating constant current arc machines by the shifting of the brushes has become so general that of late comparatively few attempts have been made to vary this method. The simplicity of the plan is no doubt largely accountable for this, and it has been indeed no small problem to beat or better it by an arrangement in which the brushes shall remain stationary. A very ingenious solution, however, has been effected by Mr. F. Tischendoerfer, whose machine and method of regulation are described on another page. At first sight, Mr. Tischendoerfer's machine might appear to be a multipolar dynamo, but it will be evident on closer examination that it is a bi-polar machine in which the pole pieces have been divided into sections with independent windings, by means of which the area of induction can be varied. By cutting out the coils of the field magnets in succession, Mr. Tischendoerfer maintains the neutral point at a fixed position in space, and hence the brushes may also remain fixed. The operation of the machine has shown the method to be one of practical value.

ELEMENTARY GEOMETRICAL THEORY OF THE ALTERNATE-CURRENT TRANSFORMER.—V.

BY

Chas. Steinmetz.

IV. *Power or Effect.*

The *power*, or the *effect*, of the different E. M. F.'s and currents in the transformer, measured in watts, can be also represented in this polar diagram in a very simple way.

In Fig. 9, as explained in the foregoing, let
$\overline{O E_0}$ = the maximum impressed primary E. M. F.,
$\overline{O E_i}$ = the maximum induced primary E. M. F.,
$\overline{O E}$ = the maximum resulting, or heating, primary E. M. F.,
$\overline{O E_1}$ = the maximum secondary E. M. F.,
$\overline{O C}$ = the maximum primary current,
$\overline{O C_1}$ = the maximum secondary current,
and draw the circles with these lines as diameters, which intersect any ray $\overline{O x}$, representing a certain moment of time, in the instantaneous values of these electric quantities, $\overline{o e_0}$, $\overline{o e_i}$, $\overline{o e}$, $\overline{o e_1}$, $\overline{o c}$, $\overline{o c_1}$.

Then the *effect* of the primary impressed E. M. F. at the time t, that is, at the angle $\vartheta = A O x = \frac{2 \pi t}{T}$, is, $p_0 = o c \times o e_0$.

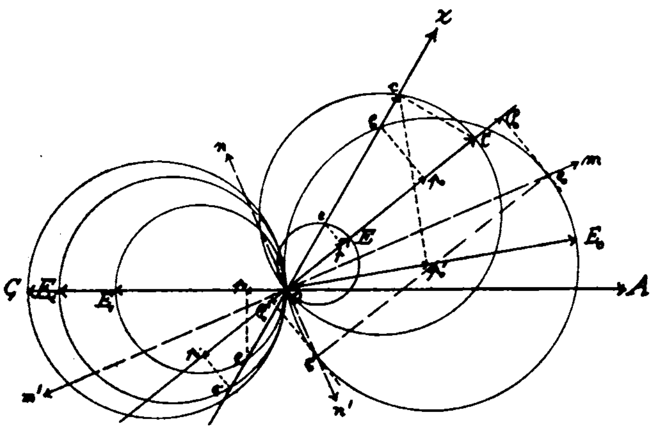

FIG. 9.

Now, connecting c with C, and producing $\overline{e_0 p_0}$ perpendicular to $\overline{O C}$, we get two similar triangles, $o c C \sim o p_0 e_0$. Hence, by the well-known relations of similarity, we get, $\overline{o c} : \overline{O C} = \overline{o p_0} : \overline{o e_0}$; or, $\overline{o c} \times \overline{o e_0} = \overline{o p_0} \times \overline{O C}$, whence:

"*The instantaneous value of the effect of impressed primary* E. M. F., $e_0 = \overline{o e_0}$, *at any time is given by its projection* $p_0 = \overline{o p_0}$ *upon the maximum value of the primary current* $C = \overline{O C}$, *multiplied into this primary current.*"

Or, in the same way:

"*By the projection of the instantaneous value of the primary current,* $p_0{}^1 = \overline{o p_0{}^1}$ *upon the maximum primary impressed* E. M. F.: $E_0 = \overline{O E_0}$, *multiplied into this primary* E. M. F."

The first representation will be more conveniently used, when the power of the different E. M. F.'s, acting in the same circuit, that is, with the same current, is to be compared; the latter representation, when the same E. M. F. produces several currents. The *effect of the induced primary* E. M. F. e_i is given by the length: $p_i = \overline{o p_i}$, multiplied into $C = \overline{O C}$. The *effect of the heatiug* E. M. F.: e is: $\overline{o p} \times C$.

In the same way, we derive the instantaneous *power-value of the secondary circuit* by the projection $o p_1$ of the secondary E. M. F. $\overline{o e_1}$ upon the maximum secondary current, $\overline{O C_1}$, multiplied into $C = \overline{O C_1}$.

For instance, in the transformer treated as an example, for the time $t = \frac{T}{6}$, that is at the angle $\vartheta = A O x = 60°$, the *whole effect of the primary circuit* is given by $o p_0$ = 1.035 inch, and $O C$ = 1.44 inch; hence, $o p_0 \times O C$ = 1.49 square inch.

Now, 1 ampere = .03 inch, and 1 volt = .01 inch; hence, 1 watt = .0003 square inch, and, therefore, 1.49 square inch = 4962 watts. That is: $p_0 = \overline{o p_0} \times \overline{O C}$ = 4962 watts.

In the same way, the effect of the *induced primary* E. M. F., $\overline{o p_i}$ = —.618 inch, $\overline{O C}$ = 1.44 inch, $o p_i \times \overline{O C}$ = —.889 square inch, p_i = — 2962 watts, therefore negative. That is: the induced primary E. M. F. consumes energy in the primary circuit, and gives it back in the secondary circuit.

Heating effect of the primary current, $\overline{o p}$ =.417 inch. $\overline{O C}$ =1.44 inch, $\overline{o p} \times \overline{O C}$ =.60 square inch, p = 2,000 ampere turns.

The heating effect is the only one, which must always be positive, that is, must consume energy, just as in mechanical engineering, the effect of frictional resistance must always be positive.[1]

From this we get the equation, $p = p_0 + p_i$, or, 2,000 = 4962 — 2962, the *law of conservation of energy*, derived from the *parallelogram-law* of *sine waves.*

Or inversely, when starting from the equation, $p = p_0 + p_i$, we derive the *parallelogram-law* of sine waves from the law of *conservation of energy*, as pointed out before.

The *effect of the secondary circuit* is, $\overline{o p_1}$ =.25 inch, $\overline{O C_1}$ =1.5 inch, $o p_1 \times O C_1$ =.375 square inch, p_1 = 1250 watts, always *positive*, so long as no self-induction is acting.

From this we derive the *magnetizing effect*, that is, the energy converted into magnetism, $p_m = -p_i - p_1$ = 2962 — 1250 = 1712 watts; that is, at this moment electric energy is transformed into magnetic potential energy; and the magnetism rises.

If no self-induction is present, the *effect of the secondary current twice* during each period equals zero, at the angles, $90° = \frac{T}{4}$, and $270° = \frac{3\,T}{4}$.

It is a maximum for the angles 0° and $180° = \frac{T}{2}$, and is then $\overline{O E_1} \times \overline{O C_1}$ = 1.5 square inch = 5000 watts.

The whole *energy of the primary circuit* equals zero *four times* per period, for the angles $90° + \varphi = 128.7°$ and $270° + \varphi = 308.7°$, where the current = 0, and $90° + \psi = 100°$, and $270° + \psi = 280°$, where the impressed E. M. F. = 0, and is always positive except between the angles $90° + \psi = 100°$ and $90° + \varphi = 128.7°$, and $270° + \psi = 280°$ and $270° + \varphi = 308.7°$, where it becomes negative. Hence:

Twice during each period the transformer gives back energy to the line and to the dynamo.

The effect of the secondary current always being positive, meaning *consumption* of energy, the energy given back by the transformer to the primary circuit is converted from magnetic potential energy into electric energy. Four times during each period the effect of the primary impressed E. M. F. reaches a maximum.

We find these maxima, by laying off a tangent on the circle e_0, perpendicular to C.

Two tangents: $P_0 e_0$ and $P_0' e_0'$ being possible, we derive two points P_0 and P_0', the one P_0 giving the two *positive* maxima of the *impressed energy:*

$P_0 = \overline{O P_0} \times \overline{O C}$ = 1.624 × 1.44 = 2.34 square inch = 7800 watts for the angles, 24.35° and 204.35°.

1. Or always negative, when counting *production* of energy positive.

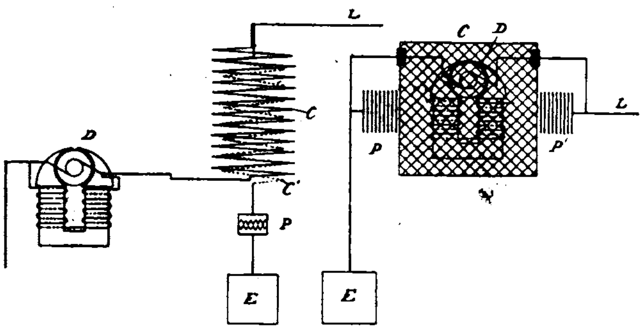
The other, P_0', gives the two *negative* maxima of the impressed energy: $P_0' = \overline{o\,p_0'} \times \overline{o\,c} = -.104 \times 1.44 = -.15$ square inch, $= -500$ watts for the angles 114.35° and 294.35°; that is, perpendicular to the positive maxima. These four maxima lie in the middle between the four zero-values of the impressed energy.

In the same manner we find for the *induced primary* E. M. F., 2 positive and 2 smaller negative maxima, in the middle between the 4 zero values, but for the primary resulting, or heating E. M. F. only 2 positive maxima and 2 zero values exist. In the same way, by using the diagram, Fig. 8, containing the working of the hysteresis and the eddies also, we derive the effect for this more complete diagram.

But Fig. 8 allows us also to estimate the energy consumed by hysteresis and by eddies. This offering no new difficulties, we may be allowed to suppress it here.

THOMSON'S NEW LIGHTNING ARRESTER.

A METHOD of supplementing the action of the ordinary lightning arrester in protecting dynamos, motors, and other apparatus from lightning or other high potential discharges has recently been devised by Prof. Elihu Thomson, and is illustrated in the accompanying engravings. It consists, briefly, in causing the discharge, when passing to earth, to generate, by induction, a counter-electromotive force which opposes its passage through the apparatus to be protected. In the illustrations, Figs. 1 and 2, L represents a line circuit, in which is included the dynamo D, generating either direct or alternating current, as the case may be, the protector being equally applicable to all systems of distribution. The line-wire is connected to ground at one end of the circuit, and at the other end there are two conducting paths to ground, one, the ordinary lightning-discharge path, shunting the generator by way of arrester-plates P and ground-plate E and including also a few turns of wire C′, while the second comprises a corresponding coil C, which may be interior or exterior to the coil C′ and passes through the generator to ground. These two coils are arranged in inductive relation to one another, but are well insulated. Their effect is to cause a lightning or other static discharge when passing directly to ground through the path of comparatively low self-induction and coil C′ to generate an opposing counter-electromotive force from the generator



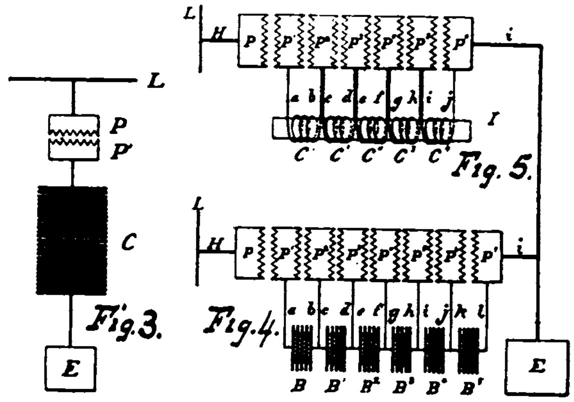
FIGS. 1 AND 2.—THOMSON'S COUNTER E. M. F. LIGHTNING ARRESTER.

to the line in the other coil C, and in this way to balance the inductive effects.

In Fig. 2 the coil C in the direct lightning-discharge path is, in effect, an exterior casing or basket-work of metal, which surrounds the dynamo, while the windings of the machine itself serve as the second coil, corresponding to C in Fig. 1. The connection from the line and earth-plate to the casing C may be made either directly or through a series of insulated plates PP′, which are separated by a small interval, enabling a static discharge to pass throughout the series and preventing the continuance of an arc between individual plates on account of the number of spark-gaps in series. The passage of an inductive discharge from the line by way of the cage C, shunting the generator, will set up a counter-induction effect in the windings of the dynamo itself, and these two will oppose one another, so that the dynamo will be thoroughly protected.

Figs. 3, 4 and 5 show other forms of lightning arrester, embodying the same principle, also invented by Prof. Thomson, in which are placed a number of polarizing cells in series with the discharge-plates and divided into sections, each section being shunted by the plates.

In Fig. 3 the generator C is arranged between the arrester-plate P′ and earth-plate E, while in Fig. 4 the successive sets or sections of polarizing-cells B B′ B², &c., are placed in series with the discharge-plates P P′, and each set or section



FIGS. 3, 4 AND 5.—THOMSON'S COUNTER E. M. F. LIGHTNING ARRESTER.

is connected in shunt by connections *a b c*, &c., with the discharge-plates P′ P² P³, &c., which are arranged in series with one another and also in series with the discharge or jumping space between P P′. The counter-electromotive force generated by each set or section of the polarizing-cells is made insufficient to sustain an arc between the arrester-plates in shunt, so that the discharge goes to earth either wholly or partly through the cells; but a sufficient kick or back electromotive force is generated by the polarization of the cells to extinguish the arc between the plates P P′.

In case alternating currents are employed, counter-inductive devices C C′ C², &c., are substituted for the polarizing-cells in the manner shown in Fig. 5.

THE USE OF LEAD AMALGAM IN ACCUMULATORS.

MONS. NÉZEREAU has recently been again directing his attention to the subject of accumulators. It will be remembered that his earliest work referred to the use of juxtaposed amalgams. The active material of this modified accumulator consisted of spongy lead, which was obtained by eliminating mercury from an amalgam of lead (Hg : Pb : : 1 : 2); this was fused and the cold crystalline mass was then powdered and compressed into a grating set in a frame, and after being hardened by immersion in dilute sulphuric acid and subsequent exposure to the air the prepared plates were then ready for the action of the forming current. These early accumulators of Nézereau, it may be remembered, had a capacity reaching as high as 25 ampere hours per kilogramme of plates, but they were costly to make. Nézereau has observed that in the case of accumulators in which spongy lead is the active material, this material in the positive electrodes, especially in the neighborhood of the supports, is very rapidly acted upon chemically, moreover the agglomerated materials do not form with the metal a sufficiently intimate and conducting layer. He finds that it is only necessary to cover the polar surfaces with a spongy layer of 4 millimetres thickness, for this distance appears to be the limit of the destructive action of the charging current.

ELECTRIC DISCHARGE IN VACUUM TUBES.

BY

Nikola Tesla

In THE ELECTRICAL ENGINEER of June 10, I have noted the description of some experiments of Prof. J. J. Thomson, on the "Electric Discharge in Vacuum Tubes," and in your issue of June 24 Prof. Elihu Thomson describes an experiment of the same kind. The fundamental idea in these experiments is to set up an electromotive force in a vacuum tube—preferably devoid of any electrodes—by means of electro-magnetic induction, and to excite the tube in this manner.

As I view the subject, I should think that to any experimenter who has carefully studied the problem confronting us and who has attempted to find a solution of it, this idea must present itself as naturally, as, for instance, the idea of replacing the tinfoil coatings of a Leyden jar by rarefied gas and exciting luminosity in the condenser thus obtained by repeatedly charging and discharging it. The idea being

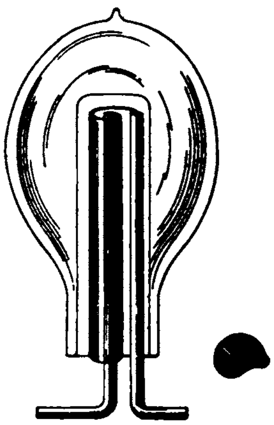


FIG. 1.

obvious, whatever merit there is in this line of investigation must depend upon the completeness of the study of the subject and the correctness of the observations. The following lines are not penned with any desire on my part to put myself on record as one who has performed similar experiments, but with a desire to assist other experimenters by pointing out certain peculiarities of the phenomena observed, which, to all appearances, have not been noted by Prof. J. J. Thomson, who, however, seems to have gone about systematically in his investigations and who has been the first to make his results known. These peculiarities noted by me would seem to be at variance with the views of Prof. J. J. Thomson, and present the phenomena in a different light.

My investigations in his line occupied me principally during the winter and spring of the past year. During this time many different experiments were performed, and in my exchanges of ideas on this subject with Mr. Alfred S. Brown, of the Western Union Telegraph Company, various different dispositions were suggested which were carried out by me in practice. Fig. 1 may serve as an example of one of the many forms of apparatus used. This consisted of a large glass tube sealed at one end and projecting into an ordinary incandescent lamp bulb. The primary, usually consisting of a few turns of thick, well-insulated copper sheet was inserted within the tube, the inside space of the bulb furnishing the secondary. This form of apparatus was arrived at after some experimenting and was used principally with the view of enabling me to place a polished reflecting surface in the inside of the tube, and for this purpose the last turn of the primary was covered with a thin silver sheet. In all forms of apparatus used there was no special difficulty in exciting a luminous circle or cylinder in proximity to the primary.

As to the number of turns, I cannot quite understand why Prof. J. J. Thomson should think that a few turns were "quite sufficient," but lest I should impute to him an opinion he may not have, I will add that I have gained

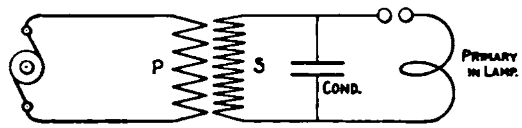

FIG. 2.

this impression from the reading of the published abstracts of his lecture. Clearly, the number of turns which gives the best result in any case, is dependent on the dimensions of the apparatus, and, were it not for various considerations, one turn would always give the best result.

I have found that it is preferable to use in these experiments an alternate current machine giving a moderate number of alternations per second to excite the induction coil for charging the Leyden jar which discharges through the primary—shown diagrammatically in Fig. 2,—as in such case, before the disruptive discharge takes place the tube or bulb is slightly excited and the formation of the luminous circle is decidedly facilitated. But I have also used a Wimshurst machine in some experiments.

Prof. J. J. Thomson's view of the phenomena under consideration seems to be that they are wholly due to electro-magnetic action. I was, at one time, of the same opinion, but upon carefully investigating the subject I was led to the conviction that they are more of an electrostatic nature. It must be remembered that in these experiments we have to deal with primary currents of an enormous frequency or rate of change and of a high potential, and that the secondary conductor consists of a rarefied gas, and that under such conditions electrostatic effects must play an important part.

In support of my view I will describe a few experiments made by me. To excite luminosity in the tube it is not

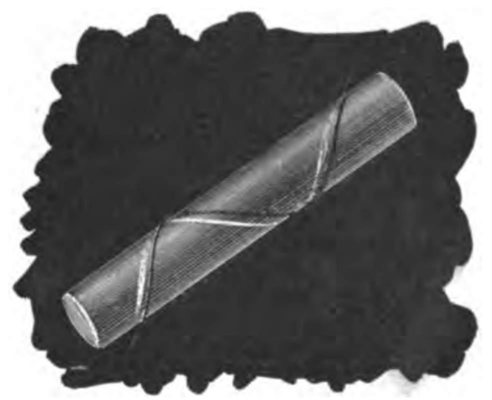

FIG. 3.

absolutely necessary that the conductor should be closed. For instance, if an ordinary exhausted tube (preferably of large diameter) be surrounded by a spiral of thick copper wire serving as the primary, a feebly luminous spiral may be induced in the tube, roughly shown in Fig. 3. In one of these experiments a curious phenomenon was observed; namely, two intensely luminous circles, each of them close to a turn of the primary spiral, were formed inside of the tube, and I attributed this phenomenon to the existence of nodes on the primary. The circles were connected by a faint luminous spiral parallel to the primary and in close proximity to it. To produce this effect I have found it necessary to strain the jar to the utmost. The turns of the spiral tend to close and form circles, but this, of course, would be expected, and does not necessarily indicate an electro-magnetic effect; whereas the fact that a glow can be produced along the primary in the form of an open spiral argues for an electrostatic effect.

In using Dr. Lodge's recoil circuit, the electrostatic action is likewise apparent. The arrangement is illustrated

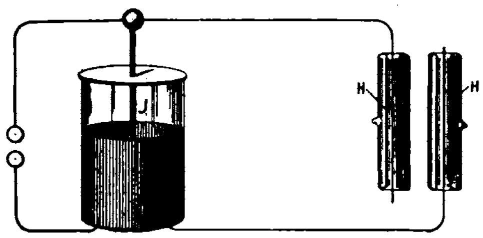

FIG. 4.

in Fig. 4. In his experiment two hollow exhausted tubes H H were slipped over the wires of the recoil circuit and upon discharging the jar in the usual manner luminosity was excited in the tubes.

Another experiment performed is illustrated in Fig. 5. In this case an ordinary lamp-bulb was surrounded by one or two turns of thick copper wire P and a luminous circle L excited in the bulb by discharging the jar through the primary. The lamp-bulb was provided with a tinfoil coating on the side opposite to the primary and each time the tinfoil coating was connected to the ground or to a large object the luminosity of the circle was considerably increased. This was evidently due to electrostatic action.

In other experiments I have noted that when the primary touches the glass the luminous circle is easier produced and is more sharply defined; but I have not noted that, generally speaking, the circles induced were very sharply defined, as Prof. J. J. Thomson has observed; on the contrary, in my experiments they were broad and often the whole of the bulb or tube was illuminated; and in one case I have observed an intensely purplish glow, to which Prof. J. J. Thomson refers. But the circles were always in close proximity to the primary and were considerably easier pro-

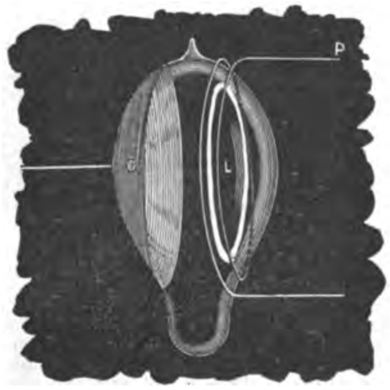

FIG. 5.

duced when the latter was very close to the glass, much more so than would be expected assuming the action to be electromagnetic and considering the distance; and these facts speak for an electrostatic effect.

Furthermore I have observed that there is a molecular bombardment in the plane of the luminous circle at right angles to the glass—supposing the circle to be in the plane of the primary—this bombardment being evident from the rapid heating of the glass near the primary. Were the bombardment not at right angles to the glass the heating could not be so rapid. If there is a circumferential movement of the molecules constituting the luminous circle, I have thought that it might be rendered manifest by placing within the tube or bulb, radially to the circle, a thin plate of mica coated with some phosphorescent material, and another such plate tangentially to the circle. If the molecules would move circumferentially, the former plate would be rendered more intensely phosphorescent. For want of time I have, however, not been able to perform the experiment.

Another observation made by me was that when the specific inductive capacity of the medium between the primary and secondary is increased, the inductive effect is augmented. This is roughly illustrated in Fig. 6. In this case luminosity was excited in an exhausted tube or bulb B and a glass tube T slipped between the primary and the bulb, when the effect pointed out was noted. Were the action wholly electromagnetic no change could possibly have been observed.

I have likewise noted that when a bulb is surrounded by a wire closed upon itself and in the plane of the primary, the formation of the luminous circle within the bulb is not prevented. But if instead of the wire a broad strip of tinfoil is glued upon the bulb, the formation of the luminous band was prevented because then the action was distributed over a greater surface. The effect of the closed tinfoil was no doubt of an electrostatic nature, for it pre-

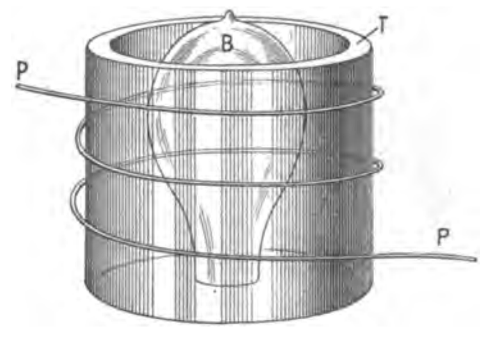

FIG. 6.

sented a much greater resistance than the closed wire and produced therefore a much smaller electromagnetic effect.

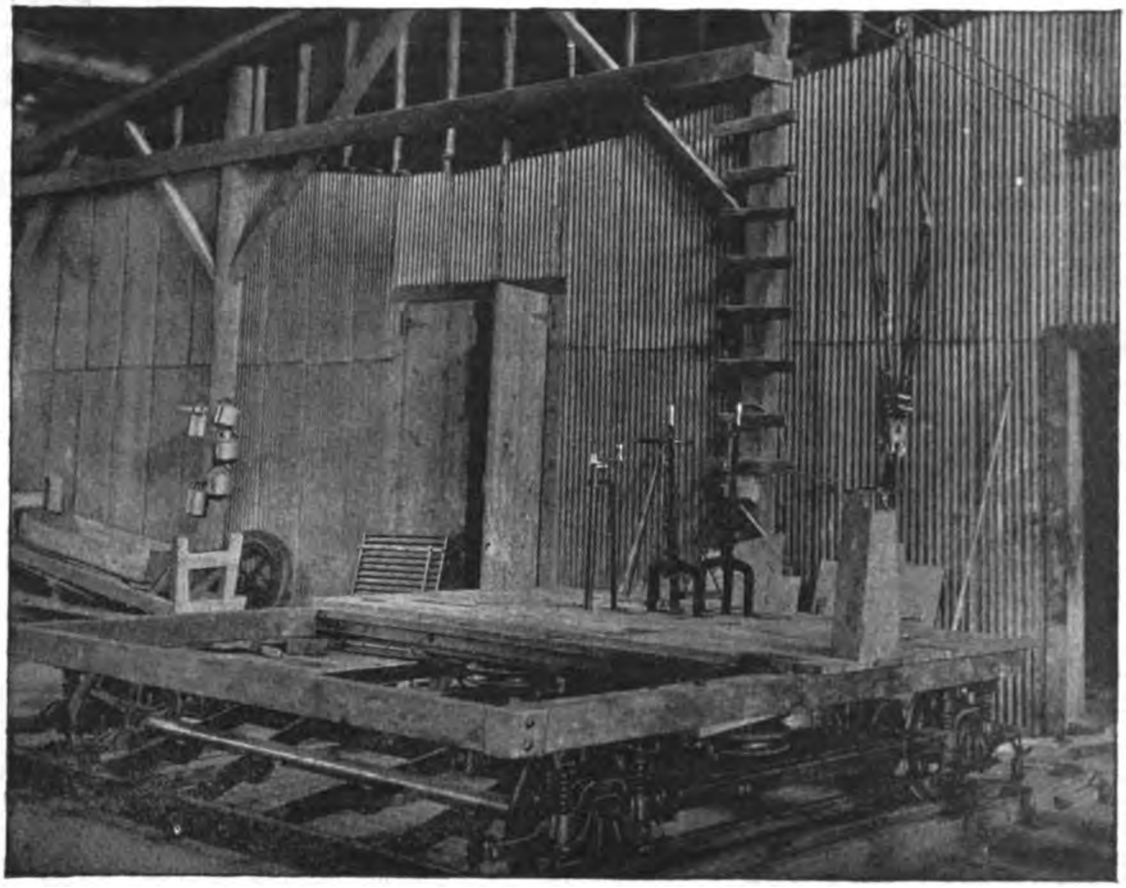
Some of the experiments of Prof. J. J. Thomson also would seem to show some electrostatic action. For instance, in the experiment with the bulb enclosed in a bell jar, I should think that when the latter is exhausted so far that the gas enclosed reaches the maximum conductivity, the formation of the circle in the bulb and jar is prevented because of the space surrounding the primary being highly conducting; when the jar is further exhausted the conductivity of the space around the primary diminshes and the circles appear necessarily first in the bell jar as the rarefied gas is nearer to the primary. But were the inductive effect very powerful they would probably appear in the bulb also. If, however, the bell jar were exhausted to the highest degree they would very likely show themselves in the bulb only, that is, supposing the vacuous space to be non-conducting. On the assumption that in these phenomena electrostatic actions are concerned we find it easily explicable why the introduction of mercury or the heating of the bulb prevents the formation of the luminous band or shorten the after-glow; and also why in some cases a platinum wire may prevent the excitation of the tube. Nevertheless some of the experiments of Prof. J. J. Thomson would seem to indicate an electro-magnetic effect. I may add that in one of my experiments in which a vacuum was produced in the Toricellian method, I was unable to produce the luminous band, but this may have been due to the weak exciting current employed.

My principal argument is the following: I have experimentally proved that if the same discharge which is barely sufficient to excite a luminous band in the bulb when passed through the primary circuit be so directed as to exalt the electrostatic inductive effect—namely, by converting upwards—an exhausted tube, devoid of electrodes, may be excited at a distance of several feet.

ELECTRIC MOTORS IN A GLASS FACTORY.

THE demand of mills and manufactories for a safe, reliable and economical method of transporting raw materials and manufactured products about the works or to and from the railway station has led to the adoption of the electric tramway. The Thomson-Houston Motor Co., of Boston, have recently installed such a tramway at the works of the Pittsburgh Plate Glass Co., of Ford City, Pa. This installation is especially interesting owing to the peculiar conditions under which it is working, and furnishes a good example of the wonderful possibilities of the application of electric power The purpose for which the tramway is used is transferring the immense plates of glass in process of manufacture from one part of the works to another.

Four locomotives, one of which forms the subject of the accompanying illustration, are in use, each being equipped with a twenty horse-power Thomson-Houston motor. This motor is used not only to propel the locomotive, but also to drive a hoisting drum, which by means of special gearing is thrown in or out at will.



ELECTRIC MOTOR, FORD CITY, PA., GLASS WORKS.

Glass is loaded on cars which run on tracks at right angles to the main track, and the hoisting apparatus above mentioned is used to pull these cars up to the tow-cars, which run on the main track and are hauled by the locomotives. The tow-cars are ordinary platform trucks. The grade of the main track is such that the platforms of the trucks are on a level with the side track, and the cars when loaded are placed on the trucks and then transferred to any desired point.

There are two lines of main track, both of which are entirely inside the works, and each of which is about 700 feet in length. The guage of the road is nine feet and ten inches (9′ 10″), which is probably the broadest gauge ever used in tramway work. The overhead single wire construction is used and the current for the operation of the motor car is generated by a 500 volt Thomson-Houston generator of the class known as M. P. 75.

MR. HENRY HARMON NEILL, a journalist well known in electrical circles and a member of the *Commercial Advertiser* editorial staff for some time past, has now become editor-in-charge of the editorial page of that excellent and time honored evening journal.

Literature.

Electricity and Its Recent Applications. By Edward Trevert. *D. Van Nostrand Co.* New York, 1891. Illus., 346 pages, cloth. Price, $2.

This book, issued by the Bubier Publishing Co. of Lynn, and published by the D. Van Nostrand Co., is an excellent addition to the books treating electricity in a popular way. It is intended more particularly for students and amateurs, and hits their needs pretty closely. Mr. Trevert has made other successful essays in this line, and has a great knack of stating the essential facts in a simple, lucid manner. He greatly prefers fact to theory, and might even be said to slight the latter, yet he gives enough to furnish an intelligent idea of the principles lying at the bottom of the science and art.

The book is divided into twenty chapters, which range through the whole field of applied electricity. Some of the chapters will be read with great avidity, especially those which tell how to make things, such as bells, motors, induction coils, &c. Many of the chapters are new also in the subjects of which they treat, including electric mining, electric welding, the electric railway, &c. There are several valuable chapters telling just how to handle electric gas-lighting circuits, how to test, how to make measuring instruments, &c. Wherever possible, Mr. Trevert has introduced cuts of the newest apparatus of all kinds, so that the reader must feel that he is put abreast of the very last work and invention of the day. Here and there a better or more correct phraseology might be employed, but the general treatment is well designed and thoroughly meritorious.

At the end of the book is a brief glossary, but one cannot help regretting the absence of a good index. The book is too useful altogether to be issued without one, and we do hope the lack will be supplied hereafter. The book is well printed in large type, on good paper, and is strongly bound. There will be a great many readers to appreciate Mr. Trevert's plain, honest treatment of his subject.

MR. PETER CLAUS has just been appointed New York representative of the Germania Electric Co., of Boston, for their incandescent lamps, with headquarters in New York.

CARE AND MAINTENANCE OF ELECTRIC BLOCK SIGNALS.[1]

BY C. L. LANG.

ELECTRIC signals for keeping trains a certain distance apart, commonly called "block signals," are slowly but surely coming into use. No argument is necessary to demonstrate the value of such appliances, so the matter settles itself into a question of cost. Ordinarily not a word has been said about the cost of maintenance, so the railroad official gets the idea that to once equip his road with signals the cost stops; that they will run themselves, so to speak, displaying automatically, and continuously, with almost the intelligence of a human being. The signals are ordered, placed in position, and are found to work splendidly.

Soon, engineers begin to report signals out of order; standing at "danger" improperly. The road master is probably notified, who knows no more about it than a child, except that it is "electric"; so he hunts up the telegraph lineman, who knows but little more. The result soon is, that all the signals are at "danger," and the company putting them in is notified that the signals are a failure. Upon investigation the signal company usually finds the whole trouble to be *want of care*. Thus we see the signals have got a bad reputation through no fault of their own, while the general manager discovers that the first cost is but the beginning of the expense.

As my experience has been mainly with a battery signal, what I say will more particularly have reference to the systems using a battery.

First of all, select an intelligent man to take care of your signals, and impress upon him that eternal vigilance is the price of a perfect working signal. He should clean his battery zincs very often to keep the internal resistance at the minimum, the external resistance being merely nominal. A point not generally understood by battery men is, that a battery that will work a 4 ohm sounder for two weeks will only work a signal circuit of half an ohm resistance one week.

When the zinc becomes reduced one-half in size we do not notice it in a circuit of high resistance, but it is fatal to a circuit of very low resistance. In our service we have two circuits of different resistance; one from one-half to two ohms; the other from ten to twenty ohms. We transfer the half-consumed zincs from the low to the higher resistance circuits, keeping up the efficiency of both batteries. Before leaving the subject of batteries I want to say that fully nine-tenths of the failures recorded on block signals can be legitimately charged to the battery, showing that this is the main point to watch.

Another point that, if carefully and intelligently watched will save much anxiety and search for cause of trouble, is the relay. Every relay should be hermetically sealed so no dust can prevent the points from making sure and perfect connection. Every relay should be protected by a lightning arrester of some kind, as, strange as it may appear, relays in a circuit made up of the steel rails of the track and underground wires with no line wire whatever, are often burned by lightning. Where the track is used as the circuit the joints are usually bridged by wires fastened to the rails by rivets driven into holes drilled for the purpose. Here is something that requires very close watching. The track workmen are often ignorant, careless, or both, breaking the wires or loosening the wires on the rivets. A detecting galvanometer is a very valuable help in locating faults of this nature.

In systems using the tracks for the circuit, insulations are necessary to divide the track into suitable signal sections, as well as for other purposes. These require great care in first introducing, as well as careful watching from day to day. The insulating material may be of wood, vulcanized fibre, leatheroid, laminar fibre or other suitable material. The exact manner of introducing these insulations varies on different roads.

The cost per signal for maintenance of double track block signals is not far from $40.00 per annum, varying somewhat according to the traffic. Notwithstanding the expense of installing a complete signal system, and expense of care, I believe their use to be an economy when the traffic is as heavy as is the case on some parts of most of our leading railroads.

By the aid of these automatic signals trains are run into, and out of, our cities safely at intervals of one, two or three minutes, regardless of fog or weather. Without signals this could not be safely accomplished. As I remarked in the beginning, the perfect working signal displays intelligence little short of human; never sleeps on duty, and never gets drunk.

THE WRITING TELEGRAPH.

A test of the writing telegraph between New York and Chicago was made recently, and, allowing for atmospheric disturbances, was fairly successful. A message of sixty words was transmitted without a break, and was recorded automatically by a pen attached to the transmitting instrument.

1. Abstract of a paper read at the 10th Annual Meeting of the Association of Railway Telegraph Superintendents, Cincinnati, O., June 18, 1891.

Society and Club Notes.

ASSOCIATION OF RAILWAY TELEGRAPH SUPERINTENDENTS.

THE Tenth Annual Meeting of this Association was called to order by President G. T. Williams, at the Grand Hotel, Cincinnati, Wednesday, June 17th, at 10:30 A. M. The following members were present:

G. T. Williams, President, Cleveland, O.; P. W. Drew, Secretary and Treasurer, Chicago, Ill.; C. Selden, B. & O. R. R., Baltimore, Md.; A. R. Swift, C., R. I. & P. R. R., Chicago, Ill.; C. W. Hammond, Mo. Pac. R. R., St. Louis, Mo.; M. B. Leonard, C. & O. R. R., Richmond, Va.; C. S. Jones, Ill. Cen. R. R., Chicago, Ill.; E. A. Darlton, R. & D. R. R., Washington, D. C.; G. L. Lang, N. Y. & N. E. R. R., Boston, Mass.; G. M. Dugan, Ill. Central R. R., Jackson, Tenn.; T. J. Higgins, C., C., C. & St. L. R. R., Cleveland, O.; S. K. Bullard, M., K. & T. R. R., Sedalia, Mo.; H. C. Sprague, K. C., Ft. S. & M. R. R., Kansas City, Mo.; U. J. Fry, C. M. & St. P. R'y, Milwaukee, Wis.; C. H. Smith, I., I. & I. R. R., Kankakee, Ill.; A. R. Lingafelt, C., R. I. & P. R. R., Topeka, Kan.; Robert Stewart, C. R. R. of N. J., Elizabeth, N. J.; H. C. Reed, M., L. S. & W. R. R., Milwaukee, Wis.; J. B. Stewart, West Shore R. R., Weehawken, N. J.; J. W. Stacey, Tex. & Pac. R. R., Marshall, Tex.; W. C. Walstrum, N. & W. R. R., Roanoke, Va.; T. W. Parks, I. & G. N., Tyler, Tex.; S. S. Bogart, (Honorary Member), New York, N. Y.; R. J. M. Danley, C., S. & H. Ry., Columbus, O.; F. M. Duncan, D. & R. G., Denver, Col.; F. W. Wilson, G. R. & I. R. R., Fort Wayne, Ind.; A. Hayward, O. & M., Cincinnati, O.; K. McKenzie, M. & O., Jackson, Tenn.; E. R. Adams, P. & R. R. R., Reading, Pa.; W. D. Vincent, B. & O. R. R., Pittsburgh, Pa.; W. P. McFarlane, F. E. & M. V., Omaha, Nev.; G. R. Kimball, B. & O., Newark, O.; J. L. Orbison, C., H. & D. R. R., Cincinnati, O.; H. C. Hope, C., St. P., M. & O R. R., St. Paul, Minn.; Horace Johnson, C., W. & B. R. R., Chillicothe, O.; W. P. Ward, B., C. R. & N., Cedar Rapids, Ia.

Twenty-one new members were elected as follows:

H. J. Adams, B. & M. R. R., Alliance, Neb.; J. H. Jacoby, Lehigh Valley R. R., Bethlehem, Pa.; W. P. Ward, B., C. R. & N. R. R., Cedar Rapids, Ia.; A. D. Halliday, D. & I. R. R. R., Two Harbors, Minn.; J. P. Boyle, K. & W. R. R., Centreville, Ia.; W. P. Mc Farlane, F., E. & M. V. R. R., Omaha, Neb.; G. E. Evans, L. & N. R. R., Louisville, Ky.; E. R. Adams, P. & R. R. R., Reading, Pa.; C. G. Sholes, A., T. & S. F. R. R., Chicago, Ill.; K. McKenzie, M. & O. R. R., Jackson, Tenn.; W. D. Vincent, B. & O. R. R., Pittsburgh, Pa.; J. M. Eagan, St. L. & S. F. R. R., Springfield, Mo.; R. J. M. Danley, C., S. & H. Ry., Columbus, O.; G. R. Kimball, B. & O. R. R., Newark, O.; E. R. Scoville, B. O. & S. W. R. R., Chillicothe, O.; H. G. Johnston, I., I. & I. R. R., Kankakee, Ill.; W. W. Jackson, N. Y. & N. E. R. R., Providence, R. I.; J. W. Dawson, K. & M. Ry., Charleston, W. Va.; F. Peters, S. P. R. R., New Orleans.

Mr. Chas. S. Jones, Ill. Central R. R., Chicago Ill., was elected President, and L. H. Korty, U. P. R. R., Omaha., Vice-President for the ensuing year. P. W. Drew, of Chicago, was re-elected Secretary and Treasurer.

It was voted unanimously to hold the 11th meeting of the Association at Denver, on June 15th, 1892.

In discussing Mr. Lang's paper,[1] MR. ROBERT STEWART said that on the Central R. R. of N. J. trains were started out from ¼ to ½ minute apart, some of the blocks being comparatively short.

In reply to an inquiry regarding damage from lightning, MR. LANG said that during an electrical storm in May seven relays were burned out which were connected with a track circuit, and had not more than ten feet of line wire. Previous to this storm they had not used lightning arresters for track circuits, but did so now. The form adopted was made of two plates of copper separated by paraffined paper.

MR. WILLIAMS stated that several years ago on the Pan Handle Road near Dalton, Ill., he saw 18 poles which had been struck and destroyed by lightning, although no wires were on them, it being a new line of poles. On the other side of the track the poles having wires on them were not disturbed.

MR. M. B. LEONARD, of the Chesapeake and Ohio Railroad, read a paper on the "Phonoplex for Railway Telegraph Lines." He said that with the increase of traffic there was a corresponding growth in the use of the railway telegraph, but it was frequently difficult for a superintendent to obtain additional facilities. It had therefore been necessary in many cases to adopt devices used by commercial telegraph companies to increase the carrying capacity of the wires. The phonoplex, besides increasing the capacity of existing lines, possessed several distinct advantages over the Morse apparatus. Its operation was not affected by the weather. In most instances it would work over a break in the wire where parallel wires existed, the induced current jumping over to the companion wire and thus bridging the break. The phonoplex

1. See this page.

formed a never-failing means of communication with all offices. The battery now used in connection with it is the Edison-Lalande. On the Chesapeake and Ohio line during the December blizzard all the wires were down between Clinton Forge and Richmond. The Phonoplex worked steadily until the other wires were cleared up. The Kansas City and Fort Scott Railway had had a similar experience. He believed that in the Chesapeake and Ohio service the system had paid for itself several times over.

In response to an inquiry as to the nature of the damage to the line referred to, MR. LEONARD said that the wire was broken, crossed and grounded. They worked through the break by the induced current, but could not say which wire it was on. There were four stations between Clinton Forge and Richmond. The operation of the phonoplex could only be stopped by an absolute break where there was no other wire for the current to pass over.

MR. ROBERT STEWART inquired if it would work through a leaky wire in a 7-conductor cable a mile in length; if so, it would be valuable, as cables were expensive. No positive reply was elicited to this inquiry. MR. LANG stated that it could not be worked on two wires strung on the same set of poles.

MR. SELDEN stated that the B. & O. R. R. Co. has a wire 120 miles long with 30 stations which they wished to have equipped with the phonoplex, but after several months experimenting, the attempt was abandoned as impracticable. He confirmed Mr. Leonard's statement that it would work over a break under the conditions stated. The B. & O. R. R. has a set working between Philadelphia and Baltimore, and several sets in N. Y. City. Their longest circuit was 91 miles, but circuits 30 miles long were worked on other roads.

MR. LANG stated that between Hartford and Boston the phonoplex worked admirably up to within 40 rods of the Boston office, where the wire entered a cable 75 feet in length, which contained a W. U. ticker wire. That made it practically useless.

MR. U. J. FRY, of the Chicago Milwaukee & St. Paul Railway, read a paper on the "Quadruplex."

After a brief explanation of the apparatus, he referred to various applications which could be made besides its use between two stations. In their service they quadruplexed one wire between Chicago and Marion, Iowa, 225 miles, and worked a single wire from Marion to Omaha, 80 miles, into one side and another from Marion to Kansas City, 306 miles, into the other side. This enabled the Chicago office to work with any or all offices from Marion to Omaha inclusive. Another wire between Chicago and Milwaukee is quadruplexed. They work a single wire from Milwaukee to Minneapolis, 345 miles, on one side, and on the other side is worked a single wire from Milwaukee to Prairie du Chien, to Canton, South Dakota, 80 miles, during the night, and in the daytime this circuit is disconnected and that side of the quadruplex is worked duplex. With this arrangement at Milwaukee, they are enabled to close the night offices, allowing the wires to work through, giving the general office at Chicago access to the entire system through other night offices. With the aid of these combination and automatic repeaters at junction points they can, during the daytime, place their general manager's office in direct communication with any division superintendent's office on the system at very short notice. They run two wires from the telegraph office to the general manager's office; one to a key and sounder for transmitting, the other to a sounder for receiving; thence to ground, and with the aid of four switches they can extend the local circuits of either quad set down to his office on these two wires. The repeating sounder was placed on No. 2 side in search of trouble. They have now dispensed entirely with this sounder by putting the reading local circuit in place of the repeating local circuit on the neutral relay and allowing that relay to close the local on the back stop as before, then exchanging the tap wire and long end, which places the short end of battery to line with key closed. They give signal on back stroke at the distant end, and the whole battery to line with key open, breaking the local at the distant end. The change is found very beneficial in working single into quadruplex circuits where it is necessary to keep keys closed, so that when circuits are idle the short end is to line, preventing the heating of rheostat which otherwise would occur, and require continual watching. This he believed to be the proper and most economical way of operating a quad, because overcoming the danger of operators who worked on both quad and single wires from leaving single wire keys open. This change necessitated closing the key on quadruplex wires as well as single wires rendering the use of keys uniform. Mr. Fry also submitted a plan by which they expect to operate several quadruplex sets from one battery.

In the course of the discussion of Mr. Fry's paper, Mr. C. Selden described the events in connection with the first steps taken by Dr. Nicholson in the invention of his quadruplex in 1869, at Cincinnati.

Thursday, at 10 a. m., the Association visited and inspected officially the various exhibits of electrical apparatus, reference to which was made in our last issue.

Mr. J. W. UPP, of the Franklin Motor Works, Peabody, Mass., has joined the forces of the Thomson-Houston Co.

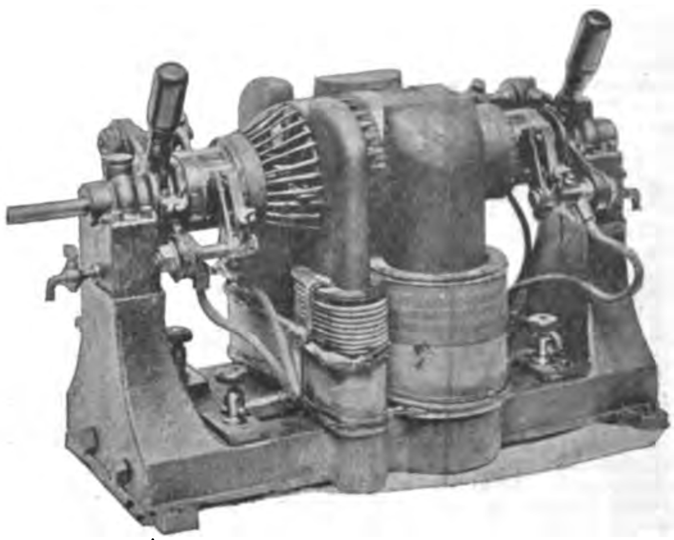
Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents.
Anonymous communications cannot be noticed.
The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.
In order to facilitate reference, correspondents, when referring to any letter previously inserted, will oblige by mentioning the page on which it appears.
Sketches and drawings for illustrations should be on separate pieces of paper.
All communications should be addressed EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

CONSTANT CURRENT TRANSFORMERS.

In a recent number of *Engineering* under the title of "Lahmeyer Constant Current Transformer," there is described a machine now being exhibited at the Frankfort, Germany, Electrical Exhibition which is in all respects the same as one which I invented a considerable time ago. The peculiarity of my machine (and this peculiarity agrees with the Lahmeyer machine) is that one of the windings on the armature passes over a supplemental portion of the core influenced by a separate magnetic field in such a way as to cause a regulation for drop to take place.

My machine was designed and constructed for use in systems of distribution with continuous currents, and the machine is a continuous current transformer compounded for drop in the machine itself, for drop in the secondary, and for drop in the high



THOMSON'S CONSTANT CURRENT TRANSFORMER.

potential or main line leading to the machine. The machine also admits of ready compounding for the combined drop.

Such machines will readily enable a large station to be built, furnishing continuous currents which are transmitted to substations with the compounded transformers feeding local mains at low potential. The machines are efficient and require very little care in running. They may be compounded by the primary or the secondary current, or both, acting on the accessory field. The machines may also be made to use continuous currents for driving and produce alternating currents in the secondary system, or they may be run by alternating currents and produce continuous currents.

I herewith enclose a photograph of one of such machines (shown in the accompanying engraving) which I have had in use for a considerable time past. It is adapted to charge storage batteries at low potential by one of its windings, taking in current at comparatively high potential on the other winding. It will be seen that the field is divided into a large and small field magnet, the large one being energized in shunt and affecting both windings, while the small field is wound, in the present instance, differentially, and affects only one of the windings, in this case the low potential winding. The similarity of this machine to the Lahmeyer machine is evident.

I have worked out the principle in a variety of ways and of course it is impossible to say to whom priority belongs in this instance. It is another curious instance of the independent working out of the same invention by different workers in the field.

In this connection I may remark that the inventors here in the United States labor under a disadvantage as to publication which is not always present with foreign inventors. Our applications for patents in the United States require that a system of examination be had which often consumes months and sometimes years, especially if the inventor is strenuous in obtaining claims which are broad enough to cover his invention, and is not satisfied with the most limited claims, and especially, also, if the examiner, as is sometimes the case, makes renewed objections on technical grounds. The judgment of the courts has been that, should the United States applicant apply for foreign patents before the issue of his United States case his United States patents will be limited to expire with the date of the shortest foreign patent. He is therefore restrained from publishing any new invention or discovery at the time it is made, simply because if he does so he loses his rights to foreign patents; in accordance with the requirements of foreign countries that prior publication must defeat a patent. On the other hand, if he applies for foreign patents before his United States case issues, he must sacrifice so many years of the term of the United States patent as expresses the difference between the shortest term foreign patent and the seventeen years granted in the United States. It is within my knowledge that a considerable number of valuable electrical inventions which have been first published abroad have been made in the United States in the course of our more extended electrical work as a consequence of the conditions mentioned above.

ELIHU THOMSON.

LYNN, MASS.

HOW LIGHTNING DOES ITS WORK.

In Anderson's "Lightning Conductors," the Hotel de Ville at Brussels is referred to as being the building best protected against lightning of any in Europe, and the method of protection is described as the wire-cage system, which Professor Elihu Thomson points out as the most perfect in an article referred to in an editorial in THE ELECTRICAL ENGINEER of June 24. Unfortunately for Anderson and Professor Thomson, the Hotel de Ville at Brussels was damaged by lightning in the spring of 1888.

My system of lightning protection is based simply on experience. A dissipated conductor has never failed to protect, so far as I know, and, in this connection, I would state that Franklin made the same observation (see his letter to Peter Collinson, September, 1753), as did Wm. Watson, F. R. S. (see Vol. 52, p. 634, "Philosophical Transactions," 1761-62).

I can merely claim that I have put to use this physical law, which was at least partially enunciated by those old philosophers. I do not claim that my way is the only way of protecting buildings from lightning. I should not think, for instance, of suggesting the placing of one of my dispellers on a building largely made of metal; such a building can generally take care of itself. I do not claim that it is not an objection that the dissipation of my dispeller leaves the house for the time being unprotected, for this is too obvious to need mention, only suggesting that experience shows that houses (not ships) have been seldom, if ever struck twice in the same storm. I believe that I have added a new method of lightning protection to those already known, and that my method is based on experience—and not on *a priori* reasoning.

I agree with Prof. Thomson, in the main, in his ideas about the nature of lightning discharge and of the flash being the visible dissipation of the electrical energy as light and heat, but when he states that I do not consider the portion of the electrical energy dissipated in the air between the top of the house and the cloud, I can only think that he has not read my paper read before the American Institute of Electrical Engineers, April 21.

N. D. C. HODGES.

New York, June 26, 1891.

College Notes.

HARVARD ELECTRIC CLUB NOTES.

At the annual election of the Harvard Electric Club the following officers were chosen for 1891–92:—President, G. S. Curtis, '92; vice-president, C. H. Arnold, '92, and P. L. Spaulding, '92; secretary, T. Hopkin, '93; treasurer, H. C. Smith, '93; librarian, P. W. Davis, '93; members at large of executive committee, G. T. Page, '92; C. H. Arnold, '92, and H. Gregory, '92.

AUBURN COLLEGE, ALABAMA.

The Agricultural and Mechanical College of Alabama, at Auburn, will show its appreciation of the importance of electricity by establishing, this fall, an electrical department. Mr. A. F. McKissick, of Pittsburgh, and more recently of Cornell University, has been elected professor in charge of the new course. This institution at Auburn is one of the leading colleges in the South. It is situated in the iron regions near Birmingham, Decatur, Bessemer and Florence, and shares in every way in their modern and progressive spirit.

Metal and Supply Market.

THE INCANDESCENT LAMP MANUFACTURERS' ASSOCIATION.

The exclusive news published in THE ELECTRICAL ENGINEER last week as to the formation of the above Association was received with much interest by the whole electrical community, and has elicited much comment. The Association itself gave out no news, but refused to do so, and has denied all current reports as to its proceedings. On this point we have received the following from Mr. Otis K. Stuart, who was elected secretary:

"On page 716 of your issue of June 24 there is a notice of a meeting of the incandescent lamp manufacturers of this country, which was held at the Astor House, New York City, on Wednesday June 17th. There is hardly a statement in this notice which is correct, and either the party who gave you the information was not at the meeting or he has a very poor recollection of the results of the same. The officers who were elected at the meeting are permanent officers. As secretary and corresponding secretary of this Association, I feel authorized to state that any information not coming from me is unofficial, and I take this opportunity to so inform the electrical public. When we are ready to publish the results of our proceedings you will receive the proper official notification."

Whatever Mr. Stuart says "goes," but we can only say that our informant affirms the substantial accuracy of his statements and asks for a categorical contradiction of them.

To what was stated by us last week, it may be added that at the meeting to be held on July 17, a committee is to report as to the attitude and intentions of the lamp manufacturers still outside the Association; and there is much guessing as to the course to be taken by the Sawyer-Man, Thomson-Houston and Edison Companies. The first named has always strenously maintained the controlling nature of its patent, and its great licensee, the Thomson-Houston Co., has manufactured almost wholly for its own numerous sub-companies and isolated plants. Mr. Insull, who as second vice-president of the Edison General Co. is in charge of its manufacturing interests, says that the Edison patents have had hundreds of thousands of dollars spent on their legal supremacy, and that on no possible consideration would there be any change in the attitude of uncompromising hostility to infringers. It being suggested that probably the Edison lamp patents might now be adjudged as narrow or void, he replied, that even in that unlikely event the company would prefer to stand alone, and to follow the lines of active manufacturing competition that had kept it to the front for the past ten years.

It will be seen that the situation in the lamp industry, now growing so rapidly, is most interesting and critical.

Financial Market.

QUOTATIONS ON ELECTRICAL STOCKS.

F. Z. Maguire & Co., Electrical Securities, of 18 Wall street, this city, report the following quotations of June 27, 1891, from New York, Boston and Washington:

Legal Notes.

EDISON INCANDESCENT LAMP LITIGATION.—IV.

ARGUMENT OF GEN. S. A. DUNCAN (CONTINUED).

The following morning, Tuesday, June 2, Mr. Betts resumed his argument as follows: He desired his Honor to take note of the Adams lamp of 1865, which seemed to him to be a very important step in the prior art. He thought that his brother Dyer in opening the case had visibly weakened when he came to the Adams lamp, and had run over it as gingerly as possible. Dr. Adams was a graduate of Harvard and a well-known inventor. As early as 1865 to 1869 he made a number of incandescent lamps with carbon conductors. He had applied the practical knowledge that he had as a manufacturer of Geissler tubes, to the making of incandescent lamps. His lamp had a carbon incandescent conductor, leading wires of platinum sealed into the glass, and an all-glass globe in which a high vacuum was maintained. It had contained everything described in the Edison patent, except the incandescent conductor of carbon was not of as small cross-section as that of Edison.

The complainants having substantially abandoned—he did not say in their argument, but the evidence of their experts had abandoned it—the two features of novelty relied upon in the English case, they now sought to rely upon a new feature; the supposed discovery by Edison of the stability of carbon in a vacuum.

Complainants' whole case stood on that position so far as any broad claim of novelty was concerned; everything else was old in the art. A comparison of Edison's platinum lamp with that of the patent in suit, showed that they were substantially alike, with the exception that in the platinum lamp there was a fine wire or filament of platinum, and in the lamp of the patent a wire or "filament"—so-called—of carbon. Now, was that Mr. Edison's discovery, that carbon was stable in a vacuum, and could he therefore claim that the substitution of carbon for platinum was an invention and involved discovery? He did not suppose it could be successfully contended that the attenuated form of the carbon had anything to do with its stability. It was not the attenuated form that made it less destructible; it was the fact that it was enclosed in a vacuum, and that there was no access of oxygen with its destructive action. His Honor would notice that there had been no hint of this supposed discovery in the English cases, and the plaintiffs' attempt to sustain the patent on that theory seemed to him to be due to a conviction that the basis on which the English case had proceeded was slipping from underneath them. Several of the prior patents had said that the vacuum should be made as high as possible; with the Sprengel pump a better vacuum could be obtained than with the appliances of earlier days, but the use of the earliest appliances had been just as much to render carbon stable, to the extent to which the vacuum had been produced, as in the most improved appliances of modern times. Mr. Edison had rather overstated the matter when he said he had discovered that carbon did not deteriorate at all. It did not deteriorate *as much* in a high vacuum as in a low vacuum, and yet Mr. Edison has stated in a later patent that there is a limit to a high vacuum beyond which one must not go. The same claim appeared to have been advanced in connection with the Sawyer and Man patent, but Mr. Justice Bradley in his finding in that case seemed to have disposed of that contention. If that discovery was as Mr. Justice Bradley says, not new, what was there left in the art to discover? A general statement that a carbon with small cross-section was the proper thing to use in incandescent lamps, did not advance the art; it did not tend to its preservation. What was needed was specific directions as to *how* to make and *out of what* to make an incandescent carbon conductor. The first man who had pointed out the particular kind of carbonaceous material, and how to carbonize it, could have made an invention and could have had a patent for a mode of producing carbon for use in incandescent lamps; but a mere general statement in reference to carbon in an attenuated form, or modes of preparing carbon which did not result in a commercially successful conductor did not advance the art at all. The world had not been taught how to select nor how to treat the incandescent conductor so as to make it a commercial success.

His Honor would find general statements in the patent, that Edison had "properly" carbonized cotton and linen threads, paper and wood splints. That had added nothing to the art. The thing was to know *how* to "properly" carbonize the proper materials. The tar-putty filament was the only one described in such detail that it could be followed with any accuracy. Mr. Batchelor, Mr. Edison's associate, had testified that there was nothing generally known in the art of carbonizing on January 9th, 1880 (long after the date of the application of this patent), which was now being used in a commercial Edison lamp. He had also testified that their methods of carbonization were known only to themselves. Now, unless the patent in suit had pointed out some method of carbonization which had taught the world what it did not know on January 9th, 1880, what had it added to the practical information of the public? Mr. Edison and the Edison Company were entitled to great credit for having made the bamboo lamp; so far as he knew, it was the first successful commercial lamp; but there was the distinct testimony of Mr. Batchelor that the merits found in the bamboo conductor did not exist at all in other fibrous materials. A similar contention had been passed upon by Mr. Justice Kay in the English case, in words which he thought were difficult to answer. He (the justice) says that it is somewhat difficult to make out that the lamps of the specification are commercially successful, if none were ever brought into the market, and that the success of the lamp made under a subsequent patent, like the bamboo lamp, which has been largely used, could hardly support a previous patent which had not described it.

On the construction which was sought to be made by the complainants, the claim, if constructed to cover any carbon of attenuated cross-section, was broad enough to include anything that had been done, but that was not what the art had needed. It needed a specific description how to make it, what to use, and what to select. There was another difference between the English cases and the present case, and that was the proof in this case, that a peculiar method of carbonization was necessary to the making of a practically successful lamp, namely, electrical carbonization in a vacuum. The specification did not give—whether it was an intentional suppression or whether Edison did not know it—that description of the way of making a commercially successful lamp.

(Mr. Duncan observed that Mr. Edison had testified that in the very first lamp he made in 1879 he used the process of carbonization described by him which included electrical carbonization on the pump.)

Mr. Betts said that besides those general statements that were to be found in the patent in suit, they were confronted by another difficulty, and that was that Edison had been practically anticipated in those general statements. His Honor would find a stipulation as to the date of publication of copies of the Lane-Fox patents. That was important, because one of these patents was relied upon as a printed publication. The stipulation gives the date of October 18, 1879, as the date when it had been published and put on sale; that was three days before Edison claims to have made his invention. It was a very narrow margin, but he supposed three days was as good as three years. Mr. Betts then read a number of extracts from the patents and publications of Lane-Fox, which he contended anticipated Edison in pointing out that an incandescent lamp could be made of a carbon conductor of high resistance, and of small radiating surface, enclosed in an all-glass vacuum chamber.

He would submit, therefore, that the result of all these inquiries was, that the present invention ought to be limited to the specific thing made as described, and not extended to all successful carbon conductors. Such a view was in harmony with the final decision of the German court, and in harmony also with the position the Edison Company had taken in connection with their other pending application. They had maintained for years the position that the patent in suit did not claim broadly what it was now asserted to claim, but that the broad invention had been contained in another application. He submitted that these views were sufficient to satisfy the defendants that the patent should not have the construction which had been contended for.

ARGUMENT OF MR. EDMUND WETMORE FOR THE UNITED STATES ELECTRIC LIGHTING COMPANY.

Mr. Wetmore said that in closing the argument for the defendant, he should only endeavor, very briefly, to recapitulate the principal points which were relied upon to support the proposition, that under the legal construction of the patent involved in the suit the defendants had not infringed it. To this end he should recall some of the leading facts in the prior state of the art and should once more ask his Honor to take a final inspection of the language of the specification, in view of all the facts elicited during this long discussion. Referring to the prior state of the art, they had two facts to start with:—first, that the date of the invention in this case had been fixed beyond controversy on October 21, 1879. Upon that date, and not until that date, did Mr. Edison first put a carbon conductor, claimed to fall within the terms of this patent, into a hermetically sealed globe; and upon that date and not until that date, by his own testimony, does he allege that he discovered the fact of the high degree of stability which that conductor possessed under those conditions; a discovery which had been urged by his friends on the other side as the very gist of the invention. The other fact was that the invention or discovery disclosed in Mr. Edison's American platinum patent had passed into the prior state of the art. That had been established beyond contradiction, first by the fact that a French patent containing the description of the alleged discovery, in the fullest possible terms, had been issued before the invention in suit had been made, and second, that it was the law established by authorities that he need not stop to cite, that when a patentee had described in a patent a broad invention and had claimed it, or not claimed it, he cannot make that invention the subject of a subsequent patent, unless at the time of applying for his first patent he had either announced his intention to do so on the face of the instrument, or had accompanied it by an application for a broad claim in another patent. Neither had taken place in this case.

Mr. Wetmore said he would next refer to some of the general facts which had been brought forward in regard to the prior state of the art. He then entered at some length into a discussion of the technical considerations involved in the distinction between lighting in multiple arc and lighting in series, which is omitted as not being necessary to the understanding of his argument. In the course of this explanation Mr. Wetmore showed conclusively that multiple-arc lighting, though a large and important branch of electric lighting, was not the whole of it and never had been. Hence, he said, the man who discovered the proper way of making a lamp for multiple arc lighting did not solve the whole problem, though he solved the most important part of it; and moreover, he might say that the problem, so-called, of house-to-house lighting had not yet been solved. With all the inventions and improvement that have been brought to bear, it could not yet be produced cheaply enough to supply the place of gas in the ordinary household. He said this, not in the slightest to depreciate the value of the discovery, whoever made it, of the use of high resistance lamps in multiple arc. It was a discovery of very great value, but for reasons which have already been stated to his Honor, the defendants' position was that it was absolutely and utterly out of this case. Mr. Edison may have been first; Lane-Fox may have been first. He hoped it was Mr. Edison, because he was an American; he was entitled to whatever credit belonged to him; he had claimed that credit in his earlier patents; there let his claim rest. The subject-matter of the present controversy did not depend upon the value, or character, or even the existence of that discovery, except so far as the patent might be an improvement upon the means of lighting which that discovery gave.

Before leaving this subject he would call attention once more to the first claim of the platinum patent:—

"In an electric light, the combination with a hermetically sealed vacuum chamber made entirely of glass, of metallic conductors passing through the glass, and an incandescent conductor placed in an electric circuit, substantially as set forth."

The word *metallic*, originally in the claim, had been stricken out by Mr. Edison, so that he might stand on that broad claim of a conductor *of any material*, having the properties of high resistance, enclosure in a vacuum and means to enable it to be used in multiple arc. He would recall a few of the facts that were known at the date of Mr. Edison's invention here in controversy. It was known that the resistance of a conductor depended, first upon its specific resistance and second upon its shape; now, as to the materials of which those conductors could be made, and indeed, up to the present time, there were substantially but two materials known in the world; one was platinum and the other carbon, and carbon had been recognized for years as the superior material because of its high infusibility. It was known that carbon was the most stable material in nature; if a stable conductor could not be got with carbon it could not be got with anything in the universe; that was the reason carbon had been used in all the early lamps.

His friends upon the other side had contended that the Adams lamp was an abandoned experiment; it was in fact merely a premature invention; he had referred to it merely as showing a striking instance of the fact that it was known to those who worked at such apparatus, that a conductor of extreme tenuity could be enclosed in a vacuum, carrying the current to it by platinum wires, and that it had a high degree of stability. Here was an instance where a man, a worker in the art, had actually applied it.

After recapitulating at some length Edison's course of experimentation with platinum and carbon, as shown in the evidence, Mr. Wetmore said that in regard to the efficiency of the platinum wire as compared with that of the lamp of the patent, Mr. Edison himself had given important testimony. In a paper read before the American Association at Saratoga, after he had made the platinum lamp, Edison had stated that he had obtained eight 16-candle lights per horse-power, while in the tests made by Rowland and Barker on the lamp in suit, it appeared that its value was only about six lamps per horse power. Mr. Clarke had testified that the efficiency of the carbon lamp of the patent was about eight per horse-power; in other words, the efficiencies of the two lamps were practically the same. It was perfectly true that the platinum lamp did not go into commercial use, but neither did that of the patent. They were both superseded by a lamp which was cheaper, better and more available for the purposes of the market. If he apprehended the argument of the complainants, the invention claimed was the discovery that carbon, reduced to the attenuated form necessary to give it high resistance, had stability enough to make it practically useful in an incandescent light. Upon that discovery, and upon that alone, must they base their claim for a broad interpretation of this patent. It was worth while to consider that contention more closely; first, it could not be claimed that stability was not a known property of carbon; it was not only a known property but was its characteristic and best known property. It was also known, and indeed was a matter of necessary inference, that the more thoroughly the destructive gases were removed from the bulb, other things being equal, the longer would be the life of the carbon; such being the fact, as he understood the law, it could not make any difference whether anybody by actual trial had ascertained to precisely what point of tenuity a carbon conductor could be carried. It was merely a question of degree. Everybody knew for example, that if a hempen rope were run over a metal pulley, it would be worn out by friction; and a slender rope would be worn out more quickly than a thick one; everybody knew that by reducing friction, the rope, whether thick or thin, would last longer than it would otherwise; but if a man by the ordinary methods of removing friction, got a pulley over which he could run a more slender rope that he thought he could—use a filamentary rope, in fact—he had discovered a new property in ropes, he had made an invention. Mr. Wetmore then cited the decision of the Supreme Court in the case of the *Comminuted Glue Company* vs. *Upton*, to show that complainants could not stand upon the alleged discovery that carbon had a high degree of stability, but that they must go a step further in order to enter the field of invention; that was what Mr. Edison had done in this patent and had got a patent for. It might have been an invention to so carbonize the carbon as to give it a very high specific resistance. Another point was the making of the spiral. In short Mr. Edison could only have a patent for his method of manufacturing that particular carbon, so as to have one that could be practically used in an incandescent lamp.

Mr. Wetmore then proceeded to read the statement of invention as set forth in the preamble of the Edison patent, and observed that the statement of the prior state of the art was incorrect because it ignored much that was known, as for example the King lamp. The reversal of the previous practice of inventors, referred to in the patent, and upon which much stress had been laid, was inaccurate and misleading, because the reversing of that process was in fact, not what was contained in this patent, but what had already been given to the world in his preceding patent. The remainder of the patent was ill drawn, because that instead of containing explicit directions, so that a person skilled in the art could follow it, it consisted of a number of disjointed statements of what Mr. Edison had discovered, the whole making a description, defective, if any person wanted to carry it out; but to show what had been intended to be covered by the patent the description was intelligent enough. The discovery that cotton thread properly carbonized will give a very high resistance was not a discovery because it depends upon the length the thread which is cut off. Mr. Wetmore then proceeded to make a detailed analysis sentence by sentence of the specification and claims, and in summing up his conclusions, said that however indefinite the term "filament" might be as designating any particular length or any particular degree of fineness, it did give a definite claim in reference to the body of the specification, if it had the meaning which he insisted upon that it did have, to wit:—a piece of fine high resistance carbon, coiled into the spiral conductor of the patent. Whether or not there was any invention, in view of the prior platinum patent, in adopting this form, Mr. Edison had chosen to make it essential by his description. He could not come in now and say, "Here I have described a conductor of a particular sort; one of its characteristics is that its radiating surface is reduced to three-sixteenths of an inch instead of the whole surface," and then say to a man—"Well you don't use that; you have got a conductor in which you use the whole amount of radiating surface, and I don't consider that which I said was so essential, after all, to be of any importance."

In that connection he wished to state his position in regard to those most significant admissions that had been made in the divisional application which had been pressed by the plaintiffs. They had gone into the Patent Office, after this patent had been granted, and asked that another patent be given to them on the ground that the one here in suit was expressly limited to the very construction for which he (Mr. Wetmore) had contended. Now if their present construction of the patent was right, they could not have that claim, because the conductor sought to be patented was precisely the one which they here claimed to be an infringement of the patent in suit. If the patent which they are now seeking should be granted, and if their construction of the present patent was correct, the former would be absolutely void. They were endeavoring to pursue this suit and to pursue that application; these were inconsistent grounds. If they lost this suit they would have a patent, and if they won the suit they would not need it. It appeared to him that a party could not be heard, in a court of equity, to take those inconsistent positions.

Mr. Wetmore said he would refer to one more point, and that was the extreme injustice on the part of the plaintiffs, in view of the facts, in making the almost appalling claim which they had based upon this specification. The defendant, as appears from the record, had been in this business since early in 1880; the first incandescent lights which appeared in the city of New York, had been put up by that company, in the Equitable Building. A million and a half of dollars had been put into the business; they had sold over 36,000 lamps the first year; they had gone on rapidly increasing until they were now selling more than a million per annum. They had pursued that course for five years, right under the nose of the Edison Company, and during the whole of that time they had certainly never heard anything of such a claim as had been presented in this suit. The only explanation of that five year's delay was to be found in what the plaintiffs had been seeking to obtain in the Patent Office on that pending application, and they had never been able to offer any other possible solution of the question. Finally when they found that that was their best chance, they had unmasked this battery and said, "Here is the claim on which we seek to embrace the whole of this field." They had taken the cork out of this narrow bottle, and the afrite had come out of it, like the character in the Arabian Nights. Could these plaintiffs be entitled to this discovery, and to uphold that patent upon that broad theory against $20,000,000 of capital invested in the Thomson-Houston and in the Westinghouse companies, and ask the court to prohibit the sale of these lamps by all these establishments; so that it would wreck private fortunes; so that it would depreciate stock to the extent of millions; so that it would throw large corporations into bankruptcy; and if they were right, they could have the full power of this court extended to throw into the hands of this single company a monopoly so vast, that in any other country except one with an all-abiding sense of law, the result would be a revolution. That was their position, and they say now after the language of that specification which he had word by word read to his Honor:—"We ask the court to construe that, against our own solemn admissions," more broadly than any of the famed electricians within the sound of his voice would ever think of construing it, and they are the parties to whom it was addressed. He did not believe that their claim was well founded, and in that belief, he should leave the defendants' rights and the protection of the public as well, with the utmost confidence, in the wisdom and experience of his Honor.

(Here the court adjourned for the day.)

SUIT ON FIXTURE PATENTS.

A suit has been commenced by Mr. George Maitland, owner of alleged controlling patents on electric and combination gas and electric fixtures, through his counsel, Messrs. Philipp, Munson, Phelps & Hovey, of this city, in the United States Circuit Court at Philadelphia, against Alfred C. Gibson, doing business as the Gibson Gas Fixture Works, of Philadelphia, Pa. Mr. Gibson has appeared through his counsel, Theodore F. Jenkins.

Reports of Companies.

WESTINGHOUSE ELECTRIC & MANUFACTURING CO.

The adjourned meeting of this company was held at Pittsburgh last week, June 23, but was again adjourned until July 15, in order that further assents of stockholders to the scheme of reorganization might be secured. It is understood that nearly 100,000 shares have now assented, leaving but a few thousand shares to come in. The time for assenting is limited to July 8.

DIVIDENDS.

THE COMMERCIAL CABLE CO. have declared a quarterly dividend of 1¾ per cent., payable to shareholders of record on June 20.

THE THOMSON-HOUSTON CO. have declared a dividend of 87½ cents (3½ per cent.) per share on the preferred stock to stockholders of record June 23.

MOUNT VERNON, CONN.—The Mount Vernon Electric Light Co. has declared a quarterly dividend of 1½ per cent.

ELECTIONS.

MILFORD, MASS.—The Milford Electric Light Co. has elected G. M. Greene president and treasurer and A. S. Trowbridge, clerk. The annual report showed net earnings of about $1,000. The company is to look into the subject of storage-battery lighting for houses and factories.

Obituary.

THEO. LARBIG.

The death occurred last Saturday, in Brooklyn, of Mr. Theo. Larbig, who was shot by Mr. J. V. Meserole, son of the City Surveyor, during a quarrel. Mr. Larbig was well known in electrical trade circles from his long and active connection with the supply business.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED JUNE 23, 1891.

Accumulators:—

Electrode for Secondary Batteries, B. Anderson, 454,818. Filed Sept. 29 1890.

Electrode formed of two perforated plates, each having transverse flanges on three edges; corresponding flanges on the plates are secured together to unite them, leaving a central recess open at top to receive active material.

Alarms and Signals:—

Electric Signal-Receiving Instrument, G. L. Foote and W. C. Moore, 454,643. Filed April 14, 1891.

Relates to the class of signals known as "individual call apparatus" for central station service.

Electrical Fire-Alarm, B. W. Leonard, 454,746. Filed March 24, 1891.

A thermostat with a system of circuits and electro-magnetic apparatus for sounding an alarm in a building and in stations of the fire department.

Conductors, Conduits and Insulators:—

Electric Conductor, A. W. Sperry, 454,546. Filed Oct. 27, 1890.

Metallic conductors have tubular ends and plugs to unite one length to the next together with a fire and water-proof covering.

Insulating Material, A. W. Sperry, 454,547. Filed Oct 27, 1890.

Composed of mineral wool and silicate of soda or potash and zinc white.

Compound for the Manufacture of Insulators, Packings, etc., A. W. Sperry, 454,548. Filed Dec. 22, 1890.

Consists of mineral wool, rubber, linseed oil and oxide of iron; in about the proportions of eight pounds of mineral wool, one and one-half pounds of rubber and linseed oil combined, and three pounds of oxide of zinc.

Electric Connection, J. H. Bickford, 454,794. Filed March 6, 1891.

An improved bond or electric connection for joining the rails of a track intended to be used as a conductor.

Distribution:—

Electric Regulator for Constant Potential, C. Hering, 454,475. Filed Dec. 16, 1887.

A rheostatic device actuated by electro-magnetic apparatus. The rheostat acts upon the principle of pressure upon a series of carbon discs or plates to diminish their resistance.

Electric Regulator for Constant Potential, C. Hering, 454,476. Filed May 24, 1889.

Amplification and an improvement on the invention shown in No. 454,475 above.

Regulating Electric Lights and Power, I. and A. Hersberg, 454,650. Filed Dec. 10, 1890.

Relates to apparatus for controlling the length of time during which an electric circuit is held open or closed.

Dynamos and Motors:—

Belt-Controller for Dynamos, W. A. Foote, 454,467. Filed July 31, 1890.

Commutator for Dynamos or Motors, C. A. Lieb, 454,488. Filed Dec. 12, 1890.

Consists in making the commutator sections of aluminum or of an aluminum-alloy; also includes details of construction.

Speed-Regulator for Dynamo-Electric Machines, E. E. Winkley, 454,541. Filed Apr. 15, 1890.

Relates to electro-magnetic devices for controlling the valve-action of the engine or other original source of power.

Electric Motor, F. B. Rae, 454,626. Filed Sept. 5, 1890.

An automatic switch, especially adapted to shunt-wound machines, operating to break contact between the main line and motor in the event of interruption or variation in the circuit.

Electric Motor, A. B. Roney, 454,627. Filed Jan. 3, 1891.

Has one or more auxiliary motors rotating radially around a common axis and means for adjusting such auxiliary motors from the centre to change the speed of the main shaft.

Galvanic and Thermo-Electric Batteries:—

Galvanic Battery, P. Hathaway, 454,598. Filed Sept. 18, 1890.

A chloride of silver battery. A zinc vessel contains the negative element and the exciting fluid and also forms the positive element; the negative element of chloride of silver is in the form of a rod having an indented or corrugated suface.

Galvanic Battery, J. Emmner, Jr., 454,794. Filed Dec. 15, 1890.

Relates to batteries of the Bunsen type. The element outside the porous cup is composed of a series of horizontal plates or sections sufficiently separated from each other to permit a free circulation of the fluid.

Lamps and Appurtenances:—

Electric Arc-Lamp, H. Lemp & M. J. Wightman, 454,485. Filed Oct. 26, 18?6.

Relates to the class of lamps in which the regulating mechanism is under the sole control of a shunt magnet during the normal action of the lamp. The present invention employs the main-circuit magnet to form the arc, after which operation it no longer acts in the operation of the lamp.

Incandescent Electric Lamp, T. A. Edison, 454,558. Filed Aug. 7, 1882.

A conducting wire, passing through the globe socket, is joined to the loop filament, midway of its length, by which arrangement the carbon filament may be used in the ordinary manner or as two conductors in multiple arc; or either half may be used by itself.

Electric Search-Light, G. Sautter, 454,604. Filed Feb. 27, 1891.

Relates particularly to mechanism for directing search-lights from a distance by electrical means.

Lamp Cut-Out and System, E. Thomson, 454,782. Filed Mar. 20, 1886.

Relates to the operation of incandescent lamps in series, and provides for the establishment of a shunt or short-circuit around a lamp upon the interruption of the series circuit by the rupture of a filament.

System of Electric Lighting, N. Tesla, 454,622. Filed Apr. 25, 1891.

Consists, chiefly, in generating, for the operation of lighting devices, currents of enormous frequency and excessively high potential. Employs induction apparatus for transferring such currents to a working circuit. Includes the charging of a condenser and the maintenance of an intermittent or oscillatory discharge of such condenser through or into a primary circuit, to which the secondary or working circuit is in inductiv

Produces incandescent light by connecting a conductor inclosed in a rarefied or exhausted receiver to one only of the poles of a source of electric energy of high frequency and high potential.

Electric-Light Hanger, G. W. Smith, 454,815. Filed Jan. 22, 1891.
For the suspension of arc lamps; includes means for disconnecting so as to keep the circuit closed while the lamp is disconnected.

Medical and Surgical:—

Electrical Pessary, W. N. Sherman, 454,573. Filed Feb. 18, 1891.

Miscellaneous:—

Electric Elevator, R. Eickemeyer, 454,462. Filed May 14, 1890.
Electro-mechanical means, in the control of the elevator attendant, to regulate or reverse the motive power.

Limit-Switch, F. B. Rae, 454,496. Filed Jan. 14, 1890.
For application between a generator and translating devices; adapted to operate when the strength of passing current reaches a dangerous point; automatic in action.

Magnetic Separator for Paper Pulp, C. H. Atkins, 454,555. Filed Aug. 11, 1890.
Improvement upon the invention patented to the same inventor Nov. 27, 1888, No. 393,348.

Walking Automaton, G. R. Moore, 454,570. Filed Jan. 30, 1891.

Switch-Board for Telegraph Lines, F. T. Viles and M. Young, 454,584. Filed Jan. 13, 1891.

Electric Hose-Coupling, J. B. Strauss. 454,669. Filed Mar. 19. 1891.

Lightning Arrester, E. Thomson, 454,671. Filed Oct. 30. 1890.
Claim 1 follows:
The combination, with an electric-line circuit including an apparatus to be protected, of a lightning-discharge path from the line-circuit, shunting such apparatus and electro-responsive means respectively in such line-circuit and shunt and arranged in inductive relation to one another, so that the passage of the discharge through the shunt means generates a counter electromotive force in the line circuit means, opposing the passage of the discharge through the aforesaid apparatus to be protected.

Lightning-Arrester, E. Thomson, 454,672. Filed Nov. 5, 1890.
A lightning-arrester comprising a pair of discharge-plates, a number of sets of polarizing-cells in series therewith, and a plurality of discharge-plates with jumping-spaces in shunt with the sets of polarizing-cells.

Lightning-Arrester, E Thomson. 454,673. Filed Jan. 31. 1891.
Improvements upon the apparatus described in patent 454,671 above.

Method of and Apparatus for Heating Bars by Electricity, E. E. Angell, 454,698. Filed Mar. 16, 1891.
Consists in inserting a bar or blank in an electric circuit, then inserting another in parallel in the same circuit, side by side with the first, and then withdrawing one from the circuit, the other remaining in circuit during the withdrawal of the first.

Insulator for Marine Condensers, P. Decker, 454,717. Filed Feb. 5, 1891.
Seeks to obviate the galvanic action caused between the copper tubes and the iron parts about the keel of a vessel in the method of condensing frequently employed, by interposing a complete non-conductor of electricity between the adjacent portions of the exhaust steam-pipe and the copper condensing tube.

Electric Circuit Closer, J. H. R. Ward, 454,816. Filed Jan 8, 1891.
A circuit closer of the class operated by a suspended cord or chain.

Electro-Magnetic Clutch, E. S. Bennett & H. F. Parshall, 454,832. Filed July 29, 1890.
Employs electro-magnetic attraction to arrest motion, as a brake, or to transmit motion.

Railways and Appliances:—

Brake Mechanism for Street Cars, N. C. Bassett, 454,450. Filed Dec. 29, 1890.
The gearing is so arranged that the tractive power upon the different axles is rendered unequal; means are provided for changing at will the leverages by which the braking power is applied to different wheels so as to keep the braking pressure proportioned with their unequal tractive effects.

Overhead Electric System, C. A. Lieb, 454,486. Filed Nov. 6. 1890.
Relates to the suspension of trolley wires, and consists in the use of springs for keeping the wires at the proper tension automatically.

Car-House Hanger, C. A. Lieb, 454,487. Filed Nov. 18, 1890.
For the attachment of trolley wires to the ceiling.

Trolley-Pole Mechanism, G. H. Larkin and J. Tomkins, 454,522. Filed Feb. 17, 1891.
Relates to mechanism for supporting and controlling trolley rods.

Trolley for Railway-Cars, E. Verstraete, 454,582. Filed July 26, 1890.
Relates to trolley arm and support.

Electric-Car Trolley, W. Duncan. 454,536. Filed June 25, 1890.
Means for balancing trolley poles.

Electric Signal for Railway Trains, F. P. Lenahan, 454,625. Filed Feb. 28, 1891.
Relates to signals for giving warning of the near approach to each other of railway trains upon the same track.

Telegraphs:—

Telegraphy, B. B. Toye, 454,630. Filed Sept. 25, 1890.
Relates to improvements in duplex, quadruplex and sextuplex telegraphs, particularly to the latter.

Telephones and Apparatus:—

Signal Device for Telephone Pay-Stations, W. Gray, 454,470. Filed Apr. 19, 1890.

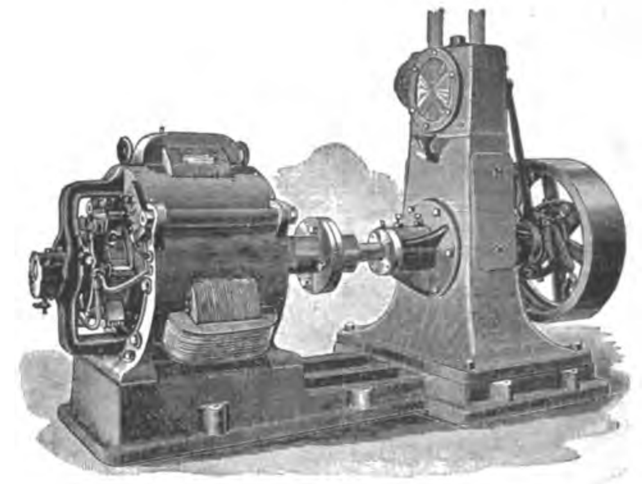
Signal Attachment for Telephones, A. D. Sundeen, S. B. Molander, G. W. Anderson and A. M. Carlsen, 454,503. Filed June 23, 1890.
Devices intended to enable automatic responses from a telephone, in the absence of the operator, signifying that no one is present to reply and when the absent operator will return.

Signal Attachment for Telephones, A. D. Sundeen, S. B. Molander, G. W. Anderson and A. M. Carlsen, 454,504. Filed June 23, 1890.
Similar in purpose to the above, includes a phonograph in connection with a telephone.

MR. CHAS. T. LINDNER, who was formerly connected with Edison interests in New York and more lately with the Edison General Electric Co. in San Francisco has now opened an office at Room 5, No. 316 Pine street, San Francisco, as a consulting electrical engineer.

THE ELEKTRON LIGHTING PLANT ON BOARD THE STEAM YACHT "ROMOLA."

THE accompanying engraving shows the plant recently installed by the Elektron Manufacturing Co., of Brooklyn, N. Y., on the steam yacht "Romola," belonging to Mr. Joseph Pulitzer, proprietor of the New York *World*. The dynamo is an eighty-five light slow-speed Perret machine of the usual construction, waterproofed, and is coupled by a flange coupling to the shaft of a Case steam engine, running 585 revolutions per minute. The combination is placed on a substantial bracket in the side of the engine room, and runs without any appreciable vibration. The yacht, which is 170 feet long, is well lighted by the dynamo direct in the evening,



PERRET SLOW SPEED DYNAMO ON BOARD THE YACHT "ROMOLA."

and by storage batteries during the day-time and when the dynamo is not running.

Where it is desirable to be very economical in floor space, a different style of coupling is used by the Elektron Manufacturing Co., and the space between engine and dynamo shortened up considerably.

AUTOMATON PIANO CO.

A reception was given at the Hotel Brunswick on Thursday, the 25th, by Mr. A. B. de Freece on behalf of the directors of the Automaton Piano Company, and several well-known people were present. The rendering of the various compositions clearly demonstrated the fact that it is possible to produce by a mechanical means all the expression and effect of an accomplished musician. The automaton is an attachment placed on an ordinary piano and run by the means of machinery. In the case of this reception the machinery was run by a C. & C. motor connected to Gibson storage batteries. The attachment does not in any way alter the appearance of the piano, as it is placed out of sight. A roll of perforated music was inserted, the drawer closed, a button was touched, the keys suddenly moved as if touched by an invisible hand and the piano commenced playing Wagner's "Tannhauser," bringing out perfectly the grand melody and full tone of the Steinway piano to which the automaton was attached. The whole affair passed off very pleasantly under the direction of Mr. de Freece, who is well known to the electrical people as having had charge of the Edison exhibit given at the Lenox Lyceum some time ago.

BISHOP GUTTA-PERCHA CO.

After a hard fight, the Bishop Gutta-Percha Co. has, Mr. H. A. Reed informs us, succeeded in convincing some people that good work pays, even though it costs money. The result is the market for their product is an ever widening one. Since January last they have sent to Washington nearly 30 miles of underground cable, over 3 miles of it being equal to No. 00. They have made for the Narragansett Electric Light Co., of Providence, six No. 0 and two No. 6 armored cables to carry the current under the river. They are now making about 10 miles of underground cable, mostly large conductors for incandescent work, for the West End Electric Co., Philadelphia. Another order is for an armored cable, equal to No. 0, and 7,000 feet long, to carry high potential alternating current across the bay at Tacoma, Washington. This cable will weigh about 20,000 lbs., making a full carload.

MR. W. W. COLE is the new superintendent of the Utica Belt Line Street Railroad Co.

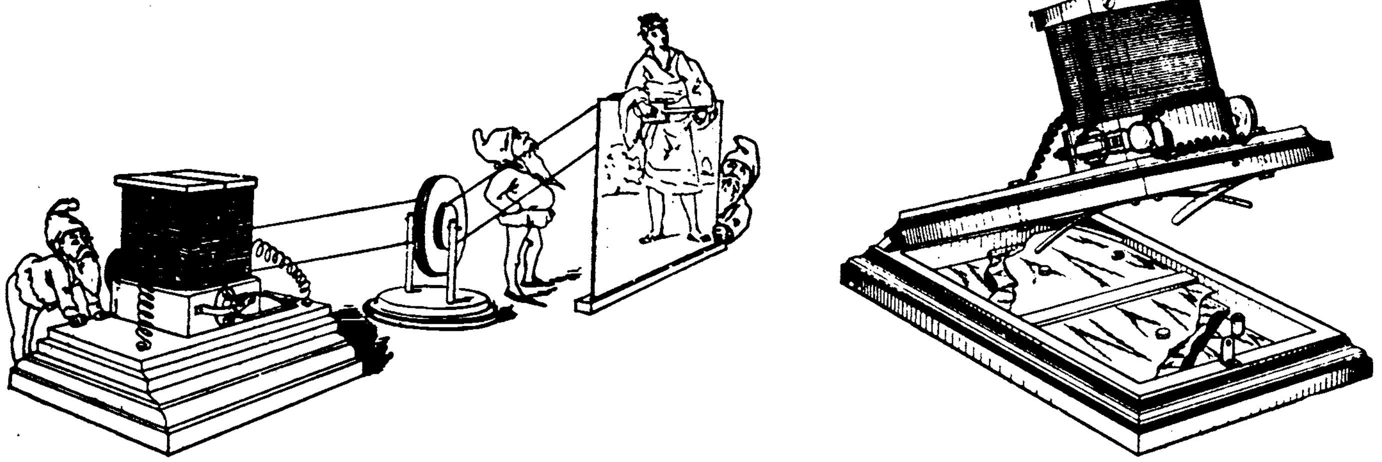
TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

In adverti‸ing, familiarity with the name leads to familiarity with the goods.

THE SIMPLEX ELECTRIC ENGINE.

ELECTRICITY in all its branches has long been a most fascinating study to the boy-student, but since the almost universal adoption of electricity for furnishing light and power, it has become



FIGS. 1 AND 2.—THE SIMPLEX ELECTRIC ENGINE.

a veritable necessity to furnish him with some cheap piece of electrical apparatus which he can operate himself, and from which he can learn the principles of the larger forms of dynamos and motors. Recognizing this fact, and aware that there was no perfect toy motor in the market, Mr. L. H. Rogers, well known to the

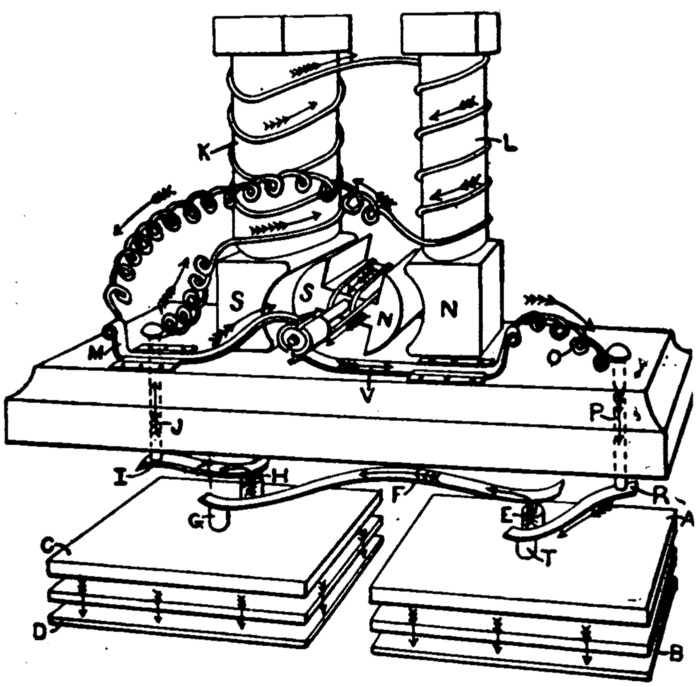


FIG. 3.—THE SIMPLEX ELECTRIC ENGINE.

electrical fraternity in the East, set himself to design a toy motor which would meet the requirements, be built on thoroughly sound electrical principles, be at the same time lasting, and yet be so cheap as to be within the reach of every boy in the land. After a long series of experiments Mr. Rogers at last designed the Simplex electric engine, which we illustrate herewith, and which is composed principally of two parts, the motor and the battery.

The engraving, Fig. 1, shows the general appearance of the engine, as furnished, driving a small mechanical toy, such as the "Wandering Minstrel." The motor itself is composed of two soft iron field magnets, with a simple Siemens armature, and the method of winding is well shown in Fig. 3, showing also the general direction of the current. The motor is fastened to a wooden frame, which is hinged to the wooden base forming the receptacle for the battery elements, as shown in Fig. 2.

The base is divided into two partitions, so that there are really two cells in series, the connections being made by the springs underneath the motor frame. The elements of the battery are arranged as follows: In the bottom of the receptacle is placed a piece of sheet copper, and at the top a piece of sheet zinc. Between the two is a little pad made of three sheets of blotting paper with powdered sulphate of copper between the lowest sheet and the upper two, and stitched at the edges. On top of the zinc a small stud is riveted in to form a contact for the spring, and a similar stud projects through an insulated ring in the zinc from the copper so as to give contact on the copper terminal. The battery is then moistened with a little water, and when the motor is hinged down it is ready for operation.

The motor runs at about 1,500 revolutions per minute for about six hours, and the battery can easily be replenished by keeping a supply of the battery pads.

The greatest attention has been paid to the most minute details and the motor and battery are complete in every way. The commutator is perfect, and the brushes can be shifted by a small attachment, just as in an ordinary commercial motor. Mr. Rogers has written a very complete and interesting pamphlet which goes with the engine, and which is a thoroughly scientific, but simple, explanation of the laws embodied in producing motion from an electric motor. The motor, its windings, and some of its details are all patented, and the sale has been something unprecedented, thirty weekly newspapers having offered it as a premium.

The Electro Novelty Company, of 9 Knapp street, Boston, are manufacturing these engines, and have a most complete machine shop, capable of manufacturing 1,000 a day. The engine and pamphlet complete with toy sells for $1.25, and we would cheerfully recommend one for every boy studying electricity, as a source of infinite amusement and considerable education.

THE EDISON MINING LOCOMOTIVE.

The Edison General Electric Co. have issued a very neat 18 page circular descriptive of their various styles of electric locomotives for mining and mill work, recently illustrated in THE ELECTRICAL ENGINEER. In addition to this, the circular contains an interesting little essay on "Underground Haulage by Electric Power."

CENTRAL ELECTRIC CO.

The Central Electric Company are receiving some very large orders for extra sizes of Okonite wire, and have recently taken several contracts for this wire, running as high as 600,000 circular mills in diameter. As the most of this is for underground and submarine work, it is evident the large purchasers are beginning to realize that the best is always the cheapest.

QUEEN'S NEW BUNSEN PHOTOMETER.

We are informed by Queen & Co., of Philadelphia, that a large standard photometer designed for the measurement of incandescent lamps has recently been made by them for the Standard Lamp Co., Appleton Wis. This photometer differs from the large ones previously made, in that it has special attachments for holding and testing the lamps, which enable the work to be done rapidly as well as accurately. The instrument may be briefly described as follows:—Two tables about four feet high (with drawers in them for accessories) support the standard bar, which is made of brass, 500 centimeters long and graduated in 1000 equal parts. The left-hand table carries a sensitive candle balance arranged for weighing the candle while in use. A standard Methvin burner is furnished in addition, which gives a uniform gas flame, which has been found much more reliable than the candle flame. On the right-hand table is a special-lamp holder, which can be rotated so as to present any part of the lamp to the sight box. This holder is extremely convenient, as it is only necessary to insert the lamp in the socket when a test is made, all connections being from below. A sight box on wheels moves along the bar and curtains are provided to shut out all light, except from the standard and the lamp under test.

A USEFUL COMBINATION TOOL.

The accompanying illustration represents a combination plier manufactured by the Cincinnati Tool Co., of Cincinnati, O. This little tool is exceptionally strong, and is a veritable case of *multum*

THE CINCINNATI TOOL CO.'S COMBINATION PLIERS.

in parvo, including, as it does, a large and a small screwdriver, one on either handle, a pipe wrench, and two wire cutters of different sizes, besides performing the function of the ordinary lineman's pliers. Its convenience and great strength are sure to recommend it to those engaged in construction work.

THE BALL & WOOD SHOPS.

The new machine shop for The Ball & Wood Co., at Elizabethport, N. J., is fast approaching completion. The building is made of brick and iron, designed and built by The Berlin Iron Bridge Co., of East Berlin. Conn., and will be used by The Ball & Wood Co. for a machine shop. The central portion is 40 ft. wide with a wing on each side 20 ft. wide, the entire central portion of the building being served by a traveling crane driven by electricity.

This promises to be one of the most complete machine shops in the Eastern States.

PARMLY, MITCHELL & CO.

We are pleased to announce the formation of the firm of Parmly, Mitchell & Co. This concern has recently embarked in the electrical supply business, with offices in the Telephone Building, No. 18 Cortlandt street, New York City. The members of the firm are all favorably known to the electrical fraternity.

Mr. C. F. Parmly graduated from the Edison Machine Works in 1885 and joined the Marr Construction Company soon after it began to install Edison central stations. In the service of the Marr Co. and its successor, the North American Construction Co., Mr. Parmly, as superintendent, installed many important arc and incandescent plants all over the United States, and in Cuba. He is, by education and experience, a practical electrician and construction expert.

Mr. P. W. Mitchell is well known in the West, where he traveled several years, and also in the vicinity of New York City. He acquired a practical knowledge of construction with the North American Construction Co.; of general supplies he has a most extensive and valuable knowledge. He was until quite recently connected with the Electrical Supply and Construction Co., of Pittsburgh, the customers of which concern will congratulate him and his partners on the arrangement he has just consummated.

Mr. C. D. Doubleday joined the Marr Construction Co. during the period of its employment as Edison constructors and afterwards had with the Marr Co. and its successor a valuable Westinghouse training. He is better known in the East as the New York district manager in charge of the interests of the Marr Construction Co. and its successor, the North American Construction Co. This position he filled for about three years, and during this time under his management was installed, we are informed, upwards of $400,000 worth of electric light and railway work in the Eastern and Middle States, in the West Indies and in South America.

It will be admitted that with the knowledge these gentlemen collectively possess of electrical matters—the result of exceptional advantages—and with their large acquaintance with the trade, both consumers and dealers, they are well equipped to make a successful record in their chosen business.

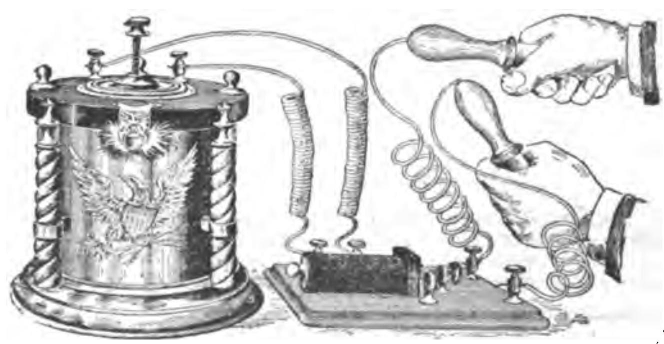
They have not as yet issued a catalogue, but when it appears it will advertise one particularly important feature. Parmly, Mitchell & Co. have secured the exclusive sales agency of the Columbia incandescent lamp, manufactured in St. Louis, Mo. The introduction of this electrical element in the East, where it has hitherto been but little known, could not have been put in better hands. They handle also a number of other specialties of value; sockets, cut-outs, switches, etc., the sale of which they control. It is a part of their plan to deal in all varieties of electrical supplies. We are well assured that, having had, as above stated, an exceptional education, they know where to go to get the best goods at the lowest figures, and it follows, therefore, that as general dealers they possess unusual advantages.

BELTS AND DRESSINGS.

Belts should be cleaned regularly, and, after cleaning, a good belt-dressing should be applied to keep the belt soft and elastic, and cause it to hug the pulley and transmit its greatest power. The use of a good belt-dressing is superior in economy to any other method for correcting a slipping or slightly loose belt. The custom of tightening a belt whenever it slips is not a good one. The belt is liable to be made too tight, which heats the bearings and strains the belt. Great care, however, should be taken in selecting a belt-dressing. A belt-dressing that is guaranteed to prevent slipping, and at the same time keep the leather soft and elastic, is certainly worthy of careful consideration. Such is Dixon's Belt-Dressing, made and sold by the Jos. Dixon Crucible Co., Jersey City, N. J. There is no trouble in applying it, and all who have used it commend it in the highest terms.

THE BARR ELECTRIC LIGHTER.

IN a recent number of THE ELECTRICAL ENGINEER appeared a description of the Barr cigar lighter, as it was then called, manufactured by the Barr Electric Manufacturing Co., of 17 and 19 Broadway, this city. Since the appearance of the article referred



THE BARR ELECTRIC LIGHTER.

to, however, the lighter has been applied to other uses, one of which is illustrated in the accompanying engraving. Instead of the medical coil attachment, a burglar alarm, call bell, or other device may be used, the lighter performing the office of an ordinary battery.

THE ELECTRIC CONSTRUCTION AND SUPPLY CO., of New York, has furnished installation for electric lights at the ferry house and docks of the Central Railroad of N. J., foot of Liberty street, New York. The specification called for, and there was used in the various buildings, upwards of 18 miles of Okonite wire and 2,000 feet No. 0000 Okonite cable underground. The installation consists of upwards of 300 incandescent, and 37 arc lights.

NEW YORK NOTES.

THE GOULDS MANUFACTURING Co., of Senaca Falls, N. Y., have been testing their large sizes of triplex pumps for electric motors, and the results thus far have been very satisfactory. This pump is especially designed for work in mines equipped with electricity.

THE ROCHESTER MACHINE TOOL WORKS, builders of the Acme Automatic Safety Engine, which burns kerosene oil or natural gas, report business as unusually brisk, and that a great many of their engines are being applied to electric light plants.

THE SYRACUSE TWIST DRILL Co., of Syracuse, who manufacture this well-known type of drill, which is extensively used in electric work, it being so designed that should the bit encounter a nail when boring through a partition, it will cause no damage to the drill, report business as very good, it being almost impossible to keep up with orders.

MR. W. VALKENBURGH, of Oneida, N. Y., sole manufacturer of the Crown Safety Water Column, recently received the following letter from the Smith Premier Typewriter Co., of Syracuse: "Some months ago we ordered of you one of your Crown Safety Water Columns, which you attached to our boilers at once. We wish to state that after using the same we have found that it meets every requirement imaginable, and all claims that you make for it are fully met with a practical test. It is an attachment that we would not want to do without in connection with our boiler."

MESSRS WALWORTH & GATLEY, two young men in the employ of the Rome Gas Light and Electric Co., have patented, and are placing on the market, a connection for arc lamps to eliminate the difficulties often encountered where the arc lamp is raised and lowered to be trimmed, as on mast-arms, etc. Their device consists of a hinge connection which relieves the wire of the pressure brought upon it when the lamp is lowered. This apparatus has been thoroughly tested and found to work entirely satisfactorily.

THE LITTLE HERCULES CHUCK.—The following letter has recently been received by the Oneida Mfg. Chuck Co., who make the Little Hercules Chuck:

"We have used several sizes of your Little Hercules Drill Chucks, and find them durable and efficient; in fact, they are all you claim them.

"Yours truly,
"THE GARVIN MACHINE CO.
"THOS. TOWNE."

THE PAGE BELTING Co. have assisted in the establishment of several mechanical and electric plants by means of furnishing their belting during the past month. The following are among the many parties whom they have supplied: Quincy Market Cold Storage Co., Boston; Mfg. Investment Co., of Madison, Me., including both link and flat belts, among the latter a three-ply large driving belt; Milton Electric Light Co., Milton, Mass.; Concord Street Railway Co., Concord, N. H.; E. W. Littlefield, East Boston, Mass.; Santley Lumber Co., Wilmington, Ohio, and a large establishment in Virginia. Among the various "Acme" link belts of their manufacture was a 12-inch belt for Carthage, N. Y., and one to Lynchburg, W. Va.

MR. J. D. WILKES, of Toledo, O., has become superintendent of the East Side Electric Railway Co., of Brockton, vice Reynolds, resigned.

PHILADELPHIA NOTES.

WRIGHT & STARR have transferred their car from the experiment station at Lehigh avenue to Chester, Pa., where they will introduce the Waddell-Entz system, making regular trips on the Potter street division of the Chester Street Railway Co.

MAJOR & MORRELL, 934 Ridge avenue, will act as Philadelphia agents for the Card Electric Motor & Dynamo Co., of Cincinnati, O., and have placed their first machine with a complete plant for Messrs. Bickle & Miller, 12 Vine street.

MR. WM. HAZELTON, 3D, of this city, has been appointed agent for Philadelphia and vicinity for The Short Electric Railway Co., of Cleveland, O. The wide experience which Mr. Hazelton has acquired will be no small means of bringing him the success which he doubtless will have with the Short gearless motor, of which he will make a specialty. Well-appointed offices will soon be fitted up in the new Penn Mutual Building, 925 Chestnut street. Room 601 is being used as temporary quarters.

WALKER & KEPLER have installed a plant for Messrs. N. W. Ayer & Son consisting of a 400-light Edison dynamo and a 7½ h. p. Edison motor. This plant will be so constructed that by turning a switch the plant can be run on either the 110 or the 220 volt circuit, from outside. This is the first plant of this kind ever installed in this vicinity. This firm have sold over $3,500 worth of ceiling fans and fan motors within the past ten days.

WESTERN TRADE NOTES.

THE HAY-HORN MANUFACTURING Co., of Chicago, have been appointed Western agents for the famous Mason primary batteries, which are manufactured by James H. Mason, of Brooklyn, New York.

MR. J. R. MARKLE, President of the Electrical Fibre Carbon Co., of Detroit, Mich., was in Chicago last week for a few days, and a caller at the Western office of THE ELECTRICAL ENGINEER.

MESSRS. SARGENT AND LUNDY, consulting mechanical and electrical engineers, report that business is good. They are now prepared to engaged in the construction work of electric street railway plants, and any work placed in their hands cannot fail to be carried out in the most thorough and perfect manner. Mr. Fred Sargent, who is well known in electrical circles, has had many years of experience in mechanical and electrical engineering with the E. P. Allis Co., of Milwaukee, Wis.; Robt. Wetherell & Co., of Chester, Pa., and later as assistant to the engineer-in-chief of the Edison General Electric Co. of New York. He is now the electrical engineer for the World's Fair. His assistant, Mr. Lundy, is one of the early workers in the street railway field and was the chief engineer of the Sprague Electric Equipment Co., and of the Southern district of the Edison General Electric Co. The firm are also the Western agents for the famous McIntosh & Seymour engines, of which they are installing large numbers in the West.

THE ELECTRIC MERCHANDISE Co., of Chicago, are furnishing a large number of street railways with the necessary line supplies, and business prospects are exceedingly bright. All the line equipment of the Sioux City electric street railway, Westinghouse system, which was recently started up, was supplied by this well-known company.

THE CHAS. MUNSON BELTING Co. are selling a large quantity of their Eagle and dynamo belting. They have recently been giving away a very handsome souvenir in the shape of a steel pocket rule, in a handsome leather case, which is exceedingly useful and handy.

THE ILLINOIS ELECTRIC MATERIAL Co. are meeting with quite a demand for the Russell arc lamps, which, it will be remembered, employ a circular carbon, thereby prolonging its life to almost any desired extent. Economic lamps, and Bishop and Canvas Jacket wires and cables are also selling well.

THE SPERRY ELECTRIC MINING MACHINERY Co. are very busy in their factory at 39th and Stewart avenue, building mining machinery, mining locomotives, street car motors, and other electrical apparatus, all of which show the very best workmanship and most excellent design.

THE GREAT WESTERN ELECTRIC SUPPLY Co., manufacturers, dealers, and importers, of electrical supplies of all kinds, are finding a ready sale for their goods, and their business is continually on the increase.

WILLIAM HOOD, the general agent for the Jewel incandescent lamps, is meeting with great success, and is receiving numerous orders for these lamps, which are giving first class results.

THE CLEVELAND WHEELBARROW AND MFG. Co.—The above-named company, manufacturers of the Cleveland wheelbarrows, trucks, pounders, mauls, hods, etc., have purchased the business of the Cleveland Wheelbarrow & Truck Co., and now have a largely increased capacity, which will insure the prompt execution of orders. Mr. J. W. Hornsey, who is known to many of our readers, becomes secretary and treasurer of the new concern.

THE EXCESSIVELY HOT WEATHER of the past week is what electrical people call "good fan weather," and the Central Electric Company report large sales of motor fans, and keep a variety of electric fans for customers to select from.

THE MORRIS TROLLEY-HANGERS are the only ones giving double insulation, and for this reason many railway plants insist on their use. George Cutter is making them in large lots, and hears only the most favorable comments on these hangers. They are all fitted with the strong and simple clamp ear, which experienced railway men favor so much.

J. E. HOCKETT was appointed general manager of the Card Electric Motor & Dynamo Co., of Cincinnati, O., June 15th, vice Mr. H. H. Walter, resigned. This company seems to be in a most flourishing condition on account of the largely increased demand for the Card motor. We understand the company contemplate increasing their facilities within the next sixty days.

☞ *Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Miscellaneous, etc., will be found in the advertising pages.*

THE
Electrical Engineer.

VOL. XII. JULY 8, 1891. No. 168.

ELEMENTARY GEOMETRICAL THEORY OF THE ALTERNATE-CURRENT TRANSFORMER.—VI.

BY

Chas. Steinmetz.

THESE circles, e_0, e, e_1, etc., Fig. 9, have still another interesting meaning, besides giving the instantaneous values of the electric quantities.

In alternate current engineering, the *effective* values of the electric quantities, that is, the *square-roots of the mean square*, are almost the only ones of any practical use; the "*mean*" or "*average*" values being almost useless.

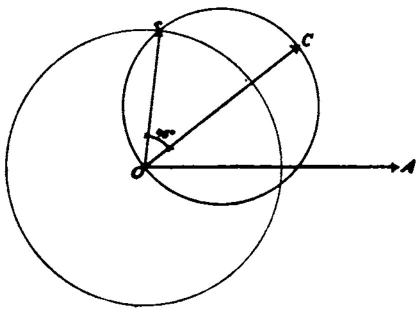


FIG. 10.

But in the usual representation by rectangular co-ordinates, this "effective" value nowhere appears, and the areas of the sine-waves give the "average," that is useless, values.

In the representation by polar co-ordinates, the area of those circles, which represent the sine-waves, are the *effective* values of the electric quantities, or rather, their *squares*.

This holds good not only for sine-waves, but for waves of any shape, which in the polar-diagram are represented by any curve whatever:

"*The radius of the concentric circle, the area of which equals the area of the wave of* E. M. F., *current, etc., in the polar diagram, is the effective value of the* E. M. F., *current etc.*"

This law holds for alternating, as well as pulsating, continuous, intermittent, or any kind of periodical currents, etc., of any desired shape.

The continuous current is represented in the polar diagram by a concentric circle, the alternating current of sine-shape, by the circle explained above, which is produced twice during each period, so that its area has to be counted twice.

"*All the electric currents, etc., which in the polar-diagram are represented by curves of equal area* (the area of those curves, which are produced twice during each period, counted twice), *have the same "effective" value, no matter whether they are alternating, continuous, pulsating, or any other kind of currents.*"

Hence, the effective value of an electric sine-wave is found in the polar-diagram in Fig. 10, by producing a line at an angle of 45° to the maximum value of the sine-wave, $\overline{o\,C}$. This line intersecting the circle, which represents the sine-wave, at c, $\overline{oc}$ represents the "effective" value of the sine-wave.

Proof:

If T is the period of a periodical current, which is given by the equation: $c = f(t)$; then its effective value is $\sqrt{\frac{1}{T}\int_0^T c^2\,d\,t}$; but the differential of the area of its polar-curve is $d\,A = \frac{c^2}{2}\,d\,\vartheta$, where $\vartheta = \frac{2\,\pi}{T}\,t$, and therefore, $d\,A = \frac{c^2\,\pi}{T}\,d\,t$.

The radius of the circle of the same area, A, being called R, gives, $R^2\,\pi = A = \frac{\pi}{T}\int_0^T c^2\,d\,t$; hence,

$$R = \sqrt{\frac{1}{T}\int_0^T c^2\,d\,t} = \text{effective value } c. \quad \text{Q. E. D.}$$

Therefore, for any shape of electric wave, the effective value can be derived graphically by producing the wave in polar co-ordinates and measuring its area.

V. *Magnetic Leakage in the Transformer.*

In the former construction, it was supposed that every line of magnetic force produced by, and surrounding, the primary coil, surrounds the secondary coil also, and inversely, so that no lines of magnetic force are "short-circuited," by surrounding only one of the coils.

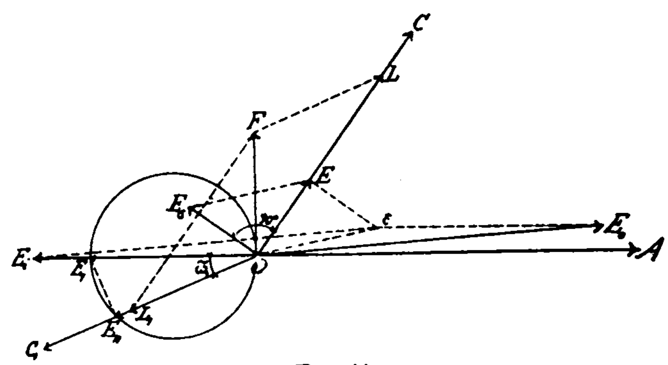

FIG. 11.

Very approximately this will be the case in all the better types of transformers, except where, for constant-current regulation, magnetic leakage is intentionally produced.

If, as in the instance of constant-current transformers, magnetic leakage has to be taken into consideration, this may be done in the following manner; Let σ_1 = the *magnetic resistance of the secondary magnetic leakage current*, that is, of those lines of magnetic force, which, produced by the secondary coil, do not intersect the primary coil, but only surround the secondary proper. Then the number of these lines of magnetic force will be, $M_1^\sigma = \frac{n_1 C_1}{\sigma_1} = \frac{n_1 E_1}{\sigma_1 R_1}$, hence the E. M. F. induced by them is,

$$E_1^\sigma = 2\pi n_1 N M_1^\sigma 10^{-8} = \frac{2\pi n_1^2 N E_1}{\sigma_1 R_1}$$

and the shifting of phase of the secondary current against the secondary E. M. F., caused thereby is,

$$\sin \omega_1 = \frac{E_1^\sigma}{E_1} = \frac{2\pi n_1^2 N}{\sigma_1 R_1}.$$

Hence the magnetic leakage acts upon the secondary like ordinary self-induction (as it really is), which shall be considered more particulary later, producing a shifting of phase by an angle ω_1.

Let, for instance, this angle $\omega_1 = 22.5$ degrees. Now, after producing in the diagram in Fig. 11 in the usual way, $\overline{OF} = 2400$ ampere turns $= .72$ inch, $\overline{OE_1} = 100$ volts $= 1.00$ inch, we now draw a half circle with diameter $\overline{OE_1}$ and make angle $E_1 O E_{11} = \omega_1 = 22.5°$, then $\overline{OE_{11}} = .923$ inch $= 92.3$ volts is the *resulting* E. M. F. *of the secondary circuit*, and produces the *current* $\overline{OC_1} = 46.15$ amperes $= 1.385$ inch.

The secondary M. M. F., $\overline{OL_1} = 2770$ ampere turns $= .83$ inch, which combines with the primary M. M. F., $\overline{OL}$ to the resulting M. M. F., $\overline{OF} = .72$ inch[1] by the parallelogram of sine-waves O L, F L, and thus gives the *primary* M. M. F., $\overline{OL} = 1.29$ inch $= 4300$ ampere turns.

The *primary current* $\overline{OC} = 53.8$ amperes $= 1.61$ inch and the *primary resulting or heating* E. M. F., $\overline{OE} = 53.8$ volts $= .538$ inch.

Now this primary current $\overline{OC}$ produces by its leakage magnetism a counter E. M. F., E^σ, which is found in the same way as E_1^σ, and lags behind C by one-quarter of a period, or 90°.

Let this *counter* E. M. F. *of primary self-induction* $E^\sigma = 50$ volts; then it is represented in the diagram Fig. 11, by the ray, $\overline{OE^\sigma} = .50$ inch.

The *induced primary* E. M. F., $\overline{OE_1} = 133$ volts $= 1.33$ inch combines with the impressed primary E. M. F., $\overline{OE_0}$, and the self-induction E. M. F., $\overline{OE^\sigma} = 50$ volts by the polygon of sine-waves V, or successively by parallelograms of sine-waves W, to the resulting primary E. M. F., $\overline{OE} = 53.8$ volts.

From this we get the *impressed primary* E. M. F., $\overline{OE_0} = 2.06$ inch $= 206$ volts.

Hence magnetic leakage in the transformer produces a shifting of phase in the secondary, as well as in the primary circuit, and thereby a decrease of the resulting secondary E. M. F., which decrease will increase with increasing secondary current, and thus show the tendency to keep the current more constant.

For the same reason, for constant-potential transformers, leakage should be carefully avoided, because it decreases the compounding of the converter.

1. We neglect again hysteresis and eddies, not to complicate the diagram unnecessarily.

TERRESTRIAL MAGNETISM.

One result of the magnetic researches of M. Moureaux and others is to render practically obsolete the old-fashioned magnetic charts with their mathematically regular curves. M. Moureaux is engaged in drawing up charts showing the "isanomal" lines, or curves, passing through the points of maximum abnormality.

M. Moreau, we learn, will shortly show at Brussels an electric voting machine. It has a series of electric buttons, above which are ranged the names of the various candidates. Pressing a button registers one vote on a numbered dial. This can be locked up until the voting is complete, rendering the tedious counting unnecessary.

THE EFFICIENCY OF QUARTZ FIBRES AS A MEANS OF SUSPENDING GALVANOMETER NEEDLES.

BY

Henry M. Fisher.

Anyone who has used short silk fibres for suspending galvanometer needles, knows how unreliable large deflections of the galvanometer needle may be, on account of the needle failing to return to its zero or starting point. Hence, several months ago, it was with a great deal of pleasure that the writer heard of the excellent qualities claimed for quartz fibres as a means of suspending galvanometer needles. Upon inquiry it was found that these fibres, in 15-inch lengths, could be imported for the sum of $8 apiece, but no definite information as to their strength or sensitiveness could be obtained. Hence the writer determined to make some, and give them a test with a view to using them in place of silk.

An ordinary arc lamp was placed on a convenient table, and in front of the lamp a large pane of smoked glass was arranged so that the arc could be clearly observed without injury to the eye.

Off to the right of the arc a long, light wooden arm was mounted on a pivot. At the extreme end of this a small spring clasp, such as could be used to grip firmly a piece of quartz, was fastened rigidly. A strong spring was arranged so that it would cause the arm to revolve instantly through half a revolution, and thus the piece of quartz could be made to go through a distance of seven or eight feet very rapidly. The quartz used was the kind that is so prevalent in the form of white pebbles. These were broken up into pieces of a convenient size.

In making these fibres the plan of procedure was as follows: A piece of quartz was held in the edge of the arc by means of a tongs, and then the piece attached to the movable arm was made to touch this until both pieces of quartz were fused at the point of contact. Then they were removed instantly out of the arc where the heat was not sufficient to fuse the fibre, the arm being liberated at the same time. A fibre was thus made whose size depended upon the amount of quartz that was fused, upon the distance traversed by the moving quartz, and upon the rate of its motion. The state of fluidity also was found to materially affect the size of the fibre. Many attempts were made before the very fine fibres, such as will be described later, were produced. Practice showed that better results could be obtained by regulating the rate and distance of the movement of the arm by means of the hand, as both of these depend upon the size of the globule of fused quartz, and upon its fluidity. Good results were obtained by melting a very small globule of quartz and then drawing it quickly through a distance of five or six feet. One of the most difficult parts of the operation was the securing of the fibres after they were made. This was especially true of the very delicate ones which were scarcely visible to the naked eye. These were preserved for future use by placing them on strips of hard rubber and fastening the ends with mucilage or liquid shellac. As soon as a portion of one of these was needed the desired length was measured and before cutting the fibre a little mucilage was placed on the rubber so that the remaining portion of fibre would not blow away, after the desired part was removed. Some of the fibres were so small that they were with difficulty discernible, even on the hard rubber. Hence it will be understood how much care is required to fasten one of these in place between the galvanometer needle and the rod from which the needle is suspended.

This operation can be accomplished with dispatch and certainty by the following method: Place the rod and galvanometer needle at the right distance apart in a suitable wooden frame. Then dip the point of a needle into a paste made of shellac dissolved in alcohol. By means of the shellac adhering to the needle, secure temporarily one end of the quartz fibre to the galvanometer needle; in a similar manner fasten the other end to the snspension rod. Then evaporate the alcohol by applying a hot iron to the pasty shellac, after which the rod and galvanometer needle are ready to be placed in their relative positions in the galvanometer.

Having thus briefly dwelt upon the method used in making quartz fibres, the writer will now speak of the tests to which they were subjected. Before entering upon this, however, it might be well to state that the data relative to silk fibres applies to the silk of the South American silk spider, several cocoons of which the writer gathered in the Argentine Republic. This silk was found to be very tough, and to answer admirably for experiments where very great accuracy is not desired. The measurements and tests of quartz fibres apply neither to the largest nor to the smallest that were made, but to a size that was found to be suitable for the purposes under consideration.

The dimensions of the fibres are as follows:

Diameter of quartz fibre = .0068 millimeter = .00027 inch,
" " silk " = .015 " = .0006 "
Length of suspension of quartz fibre = ¾ inch,
" " " " silk " = ¾ "
The quartz fibre stood a maximum tensile strain of 70 grains,
" silk " " " " " " " 63 grains.

Reducing to equivalent dimensions it appears that the quartz fibre is 5.4 times stronger than the silk fibre.

From the above measurements it follows that one square inch area of quartz fibre would stand a tensile strain of 172,000 lbs., and a square inch area of silk fibre would stand a tensile strain of 31,800 lbs. From this we see that quartz is over 1½ times stronger than ordinary steel.

In making tests to illustrate the sensitiveness of the quartz fibre, a Thomson reflecting galvanometer of the square pattern was used. It had an astatic needle, two coils actuating one set of magnets, and two lower coils actuating the other set. The resistance of the galvanometer was 10,000 B. A. ohms. The distance between the scale and the mirror was 39½ inches and 40 scale divisions = 1 inch.

By means of the controlling magnet the galvanometer needle was made very sensitive, and then 1 Leclanché cell, having an electromotive force of 1.49 volts, gave a deflection of 320 scale divisions through 100,000 ohms, the $\frac{1}{999}$ shunt plug being inserted.

This, of course, would mean a deflection of 320,000 scale divisions were all the current allowed to pass through the galvanometer, or a deflection of 32,000 scale divisions through one megohm.

From this it is apparent that with one cell an insulation resistance of 32,000 megohms could be detected, and when 100 cells are used, which is the custom in making insulation resistance tests, enormously high resistances can be measured. Surface leakage across such a good insulator as hard rubber can be detected. Under such sensitive conditions the galvanometer and battery should, of course, be very highly insulated, otherwise the measurements made cannot be relied upon. Any movement of iron in the neighborhood will also very materially affect the galvanometer needle.

The most remarkable part of this test was the fact that the needle invariably returned to its zero or starting point. This would not be strange were the experiment performed with a long suspension fibre, but when we consider that the fibre used was only ¾ inch long and that the needle was deflected in some of the tests through five or six hundred scale divisions, this return to zero must be considered quite remarkable.

A single silk fibre was next tested; the galvanometer needle being placed as nearly as possible under the same conditions of sensitiveness. A Leclanché cell having an electromotive force equal to 1.49 volts gave a deflection of 70 scale divisions through 100,000 ohms, the $\frac{1}{999}$ shunt plug being inserted. Under similar conditions the deflection with the quartz fibre in use was 320 scale divisions, therefore, in this particular case, the quartz fibre was about 4½ times more sensitive than the silk fibre. The needle, however, failed to return to its starting point when the silk fibre was used, and this feature became very marked under conditions of extreme sensitiveness. When seven cells were used a deflection of about 600 scale divisions was obtained, but upon breaking the battery circuit the needle failed immediately to return to its starting point to the amount of about 100 divisions. Hence it is evident how unreliable silk is for delicate work.

Remembering that it is possible to make very much smaller quartz fibres than those described in this article, the manifold uses to which these attenuated threads can be applied become at once apparent. For electrometer purposes they are unexcelled, and they will be received with enthusiasm by the ambitious physicist who would go over the experiments of Cavendish to demonstrate once more the laws of universal attraction by means of lead balls.

LIGHTNING PROTECTION.

BY

A. A. Knudson.

The recent paper by Mr. Hodges read before the Institute in April last, and also the article by Mr. C. J. Hubbell in The Electrical Engineer of 17th inst., have interested me away here in Canada, and induced me to say a few words on this interesting subject.

In regard to Mr. Hodges' theory, that of "*dissipating conductors*" being a protection to buildings, even should it be correct, there are, I think, obstacles in the way of its application which would render it impractical and interfere with its general use. For instance, the small copper ribbon which is to be placed on buildings is put there with a view to being "dissipated" or destroyed at the first discharge of lightning which strikes the building. After being destroyed (if the building is still there) the strips must be replaced again, and this might occur several times in one summer. In fact, cases have been known where buildings have been struck more than once during the same shower. After the first discharge, when the conductors had been destroyed, the building would then be left to the mercy of the second. Again, take the case of protecting tall chimneys and church steeples with "dissipating strips." After once being destroyed, how could they be replaced? In some cases this would be impossible, in others very difficult and expensive.

Again, in the light of experience, I think there are good reasons for believing that a building equipped with these strips would be in more danger of being damaged or destroyed by the effects of lightning than without them. Take, for instance, one that has gas and water pipes in its interior, also wires, iron posts, and other metals which form part of its construction. All these offer a more or less good outlet to ground. Should the copper strips be placed in proxmity to these interior metals, lightning in its descent would be likely to jump through the building to some of these metals in its efforts to find a more perfected ground conductor, thereby damaging, and possibly setting it on fire. A case in point occurred in Brooklyn a few years ago when the tall steeple of the Classon Avenue Presbyterian Church was struck by lightning. As this was a case near at home, I took occasion to investigate and see if there were any reason why the Franklin rod which ran from the top of the steeple to the ground was not able to carry off the discharge without damage to the building. I found what might be expected where rods in similar cases have failed to protect. *About ten feet of it was missing at the ground end.* The lightning followed the rod down the steeple until it came opposite some iron work inside, when it tore a hole through the steeple, scattering the slate, shingles, and woodwork in every direction, and finally passed off to the ground without further damage.

A similar condition of things would prevail, I think, with any strips of metal on a building that were not well grounded, as in the case of "dissipating" strips. Mr. Hodges states in one part of his paper that "there is no need of providing a good earth connection," and that "there is no need of the conductor following the shortest course to the ground."

Thus, with one sweep of the pen as it were, he attempts to upset the well-established laws of electrical action that have been accepted for the past one hundred years. But Mr. Hubbell ably defends the Franklin principle of lightning rods from his practical business standpoint, and his reference to experiments with models of oil tanks five years ago calls to mind my own experiments of nine years ago, when I conducted a series of very similar tests while illustrating a paper which was read before the New York Electrical Society. At that time I used one of the largest electrical machines to be had in New York to produce the lightning, and a copper cylinder suspended from the ceiling represented the charged thunder cloud. Under this were placed models of oil tanks equipped with various forms of lightning conductors, among them one that was freely advocated at that time and was similar in principle to the "dissipating" system. It, however, was made of larger metal than strips, and was placed upon insulators, but had no ground connection; the result of the test I well remember, and I pointed out at the time that, with each discharge to the tips of the conductors, sparks appeared at various places between the conductor and iron roof of the tank. These sparks were the very thing to be avoided in such a place, as the ignitable gas in and about an oil tank was the cause of many explosions and the destruction of much property every summer.

The system of protecting oil tanks from lightning, which I recommended and showed at that time, could not be made to produce a spark, although subjected to the most powerful discharges of which the machine was capable. This plan of protection was based on the Franklin principle with special means for making permanent well-grounded conductors, and was endorsed by letters from such men as Prof. Morton, Mr. Edison, Mr. Frank Pope, Prof. Elisha Gray, and others. I also had the same experience in my negotiations with the Standard Oil Co., as Mr. Hubbell, so far as their adopting the device is concerned, with the possible difference of mine being adopted in a modified form so as to evade the patent.

So far as the protection of buildings from lightning is concerned, I believe the old Franklin principle is the only true one, and very few doubters, I think, can be found among electrical men at the present day on this point. Where there have been failures, it is certainly due to improper construction, or a rod has been allowed to become inoperative on account of being damaged, such as the one on the church above referred to.

During the construction of the electric power station with which I am connected here in St. John, N. B., I had placed upon the chimney, which is of brick, and one hundred feet high, a good-sized copper wire stapled direct to the brickwork, the top terminating in the iron cap; a six-foot rod held by a tripod with points at the top completed the terminal. The lower end is firmly secured to the city water mains. I should consider it a piece of neglect if the designer of an electric light station omitted this point of lightning protection, for many a station manager knows to his cost what it is to have lightning jumping through dynamos.

Lightning arresters of special manufacture are now made for the purpose of being placed on wires where they pass out of a station, all based on the old and accepted Franklin principle. If lightning comes in over the wires or down the chimney a convenient and easy path to earth is offered, so that it will not injure or destroy instruments or dynamos.

Lightning conductors, however, should be made of sufficient size so that they will carry the heaviest discharge of lightning without becoming "dissipated." It would, indeed, be a sad state of affairs should one come to his station some morning and find that the lightning in the night had *chewed up*, as it were, his chimney conductor, and be confronted with the problem of how to replace it. In conclusion, I may say the only appropriate places for "dissipated' conductors I can think of are inebriate asylums and penitentiaries.

CENTRAL STATION MANAGEMENT AND FINANCE.—X

For bills to send to customers for service of light or power, Blank No. 25 is a convenient form for arc lights or motors, and monthly or contract incandescent lamps. Blank No. 26 is a bill designed for meter service and can be printed to accommodate stations running on watt-hours, or lamp-hours, or ampere-hours, as desired.

THE ELECTRIC RAILWAY AT SIOUX CITY, IOWA.

BY

THE formal opening of the Riverside Park Railway, at Sioux City, Iowa, occurred on the 19th of June, and the first cars passed over the line carrying a party of gentlemen, among them the owners of the road, and the representatives of the companies who furnished the equipment and of the daily and technical press.

In this particular case, the ideal of the electric railway has been realized, steam giving way to electricity. The results accomplished are very much in favor of the new method of propulsion, smoke, dust, dirt and noise being done away with, rendering a trip on the cars one of comfort and pleasure. It is also noteworthy that the operation is far less costly, easier and more reliable, and the electric car shows itself fully equal, and in many respects, superior, to the steam locomotive.

The line comprises some nine miles of road, commencing at the centre of Sioux City and running out as far as North Riverside, a new addition to Sioux City, where a large number of factories, employing many workmen, are situated. Besides taking care of the travel at North Riverside, the Suburban Electric Railway carries a very large number of people from Sioux City to Riverside Park, which is a noted pleasure resort in this part of the country, from its great natural beauty. It contains about 400 acres of land, situated on the bank of the Sioux river.

From the centre of the city the road starts out with double track as far as the bridge across Floyd Creek, where it becomes single track, equipped with single-pole bracket construction, on one side of the track; and notwithstanding that the line in all has about thirty-eight curves varying from four to twenty degrees, it was found unnecessary to employ curve brackets or appliances,

FIG. 1.—ELECTRIC RAILWAY, SIOUX CITY, IOWA.

the specially designed trolley hangers being capable of permitting the trolley wire to conform to the curves of the road.

Cuttings and fills form one of the features of the road, the former having from fifty thousand to one hundred yards of earth excavated in building the road, the earth being used for crossing the numerous valleys. Fig. 1 shows the old line descending to Riverside and also one of the depots; Fig. 2 is a very picturesque view of the car ascending from the valley. The trestle work, which forms quite a feature of the road is 634 feet long and having a 19 degree curve of 300 feet, with a rise of 4 per cent. The trestle crosses the Chicago, Milwaukee and St. Paul tracks at an elevation of 34 feet, and a most magnificent view is obtained while running over it, of the surrounding country.

The power plant is installed in a handsome brick building 62 x 95 feet, at Riverside. The steam plant comprises two 60 inch x 16 feet Worthington pumps, Krochell heater, Hancock inspirators and four sets of steam loops which are installed to insure the successful and economical operation of the engines. Westinghouse, Church, Kerr & Co. were the contractors for the complete steam plant. Two Westinghouse compound engines, each of 125 h. p., are employed, driving by direct belting two 100 h. p. generators, each run at 350 R. P. M. The current is conveyed to a very handsome switchboard, made of polished sycamore with marble face, on which all the switches and instruments are placed.

There are three circuits, the new Westinghouse circuit-breakers being used, and the engineers in charge of the plant express their approbation of the efficacy of this ingenious apparatus.

The car house, which is in close proximity to the power house, is 50 x 150 feet, and has four tracks the entire length of the building, with ample pit room. A complete outfit of track switches is

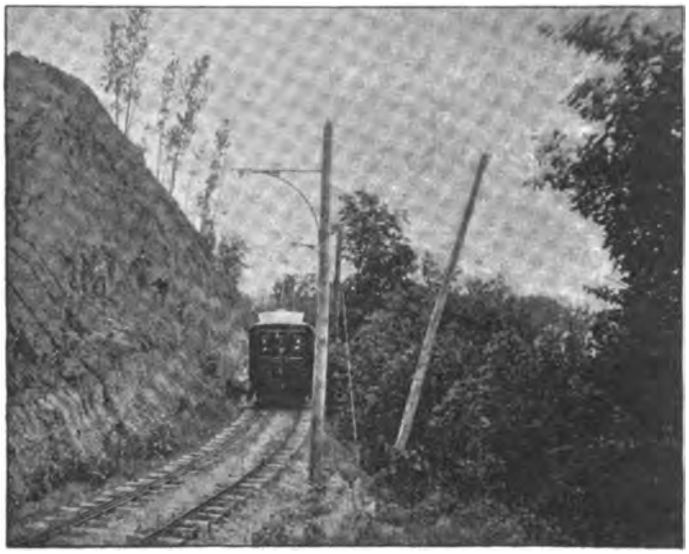

FIG. 2.—ELECTRIC RAILWAY, SIOUX CITY, IOWA.

laid in front of the car house, and switch signal lights are employed on the road, which is run in a manner exactly similar to a steam road.

Each motor car is equipped with two 30 h. p. motors, built by the Westinghouse Electric and Mfg. Co., and runs at a speed of 25 miles an hour easily, and as soon as certain improvements which are going on are made in the track even higher speeds than this will be reached. The six motor cars and six trailers now in use, were built by the Northern Car Co., of Minneapolis. The former are vestibuled, very beautifully finished and upholstered, their entire length being 36 feet. The trail cars are open, 36 feet long, and have seating capacity for 78. The trucks for all these cars were furnished by the McGuire Mfg. Co., of Chicago, and are of latest pattern Hubbard truck, and built specially for the high speed used on this road.

The electrical installation of the plant was in charge of Mr. B. F. Jones, the electrical engineer for the Westinghouse Electric and Mfg. Co., and great credit is due him for the very careful way the work has been carried out and especially the pole-and-bracket construction, which is one of the neatest and most symmetrical pieces of work ever done. The feed wires are No. 000 Roebling wires. All the overhead material, insulators, brackets, etc., was furnished by the Electric Mdse. Co., of Chicago, and much of the success of the road is due to the material furnished, the result of their long and practicable experience in building roads and manufacturing line material.

The necessities of the road, owing to the sharp and continual curves, grades, etc., were such that special devices were needed, and these were promptly designed by the Electric Mdse. Co., who have been complimented very highly for the successful manner in which they met and overcame the difficulties incident to the construction.

The equipment of the line compares favorably with anything built up to date and in many particulars surpasses anything yet attempted.

No expenses were spared to make the system perfect, and Mr. C. W. Hornick, president of the road, is justly gratified with his plant.

Mr. J. M. Atkinson, of the Westinghouse Co., was present and took charge of the lever to start the car, evincing as he did so, most complete satisfaction.

After the formal opening of the road Mr. J. Livingston Barclay and Mr. Atkinson, representing the Westinghouse Co., entertained the gentlemen interested in the road, the local press, and visitors, at the Hotel Garretson, and remarks of approbation at the splendid success achieved were heard on all sides.

VOL. XII. NEW YORK, JULY 8, 1891. No. 166.

It is not enough for a physical investigation that we have the simple idea, which may be embodied in a mathematical equation; we must see clearly in the mind's eye the operations in nature, and how the phenomena are produced in accordance with the well-known laws of force and motion.—Joseph Henry.

MR. TESLA'S LECTURE.

NOW that we have the full text of Mr. Tesla's paper before us, we are better able to judge of the character and scope of his work. The ground covered by Mr. Tesla is so vast that even in his somewhat extended paper he has, as he states, only been able to pay passing notice to many facts, each one of which might have been made the subject of a separate paper; and it is to be hoped that he may shortly find time to enter more into the detail of the various points brought out.

Although Mr. Tesla's work has relation to many matters of the highest importance and discloses some startling possibilities, yet its immediate bearing on the question of producing light economically is perhaps that which will appeal most strongly to the electrical engineer.

Taking up the course of reasoning followed by Mr. Tesla, it will be noted that he started out with the recognition of the fact, which he has now experimentally demonstrated, that for the production of light waves, primarily, electrostatic effects must be brought into play, and continued study has led him to the opinion that all electrical and magnetic effects may be referred to electrostatic molecular forces. This opinion finds a singular confirmation in one of the most striking experiments which he describes, namely, the production of a veritable flame by the agitation of electrostatically charged molecules. It is of the highest interest to observe that this result points out a way of obtaining a flame which consumes no material and in which no chemical action whatever takes place. It also throws a light on the nature of the ordinary flame, which Mr. Tesla believes to be due to electrostatic molecular actions, which, if true, would lead us directly to the idea that even chemical affinities might be electrostatic in their nature and that, as has already been suggested, molecular forces in general may be referable to one and the same cause. This singular phenomenon accounts in a plausible manner for the unexplained fact that buildings are frequently set on fire during thunder-storms without having been at all struck by lightning. It may also explain the total disappearance of ships at sea.

One of the striking proofs of the correctness of the ideas advanced by Mr. Tesla is the fact that, notwithstanding the employment of the most powerful electromagnetic inductive effects, but feeble luminosity is obtainable, and this only in close proximity to the source of disturbance; whereas, when the electrostatic effects are intensified, the same initial energy suffices to excite luminosity at considerable distances from the source. That there are only electrostatic effects active seems to be clearly proved by Mr. Tesla's experiments with an induction coil operated with alternating currents of very high frequency. He shows how tubes may be made to glow brilliantly at considerable distances from any object when placed in a powerful, rapidly alternating, electrostatic field, and he describes many interesting phenomena observed in such a field. His experiments open up the possibility of lighting an apartment by simply creating in it such an electrostatic field, and this, in a certain way, would appear to be the ideal method of lighting a room, as it would allow the illuminating device to be freely moved about. The power with which these exhausted tubes, devoid of any electrodes, light up is certainly remarkable.

That the principle propounded by Mr. Tesla is a broad one is evident from the many ways in which it may be practically applied. We need only refer to the variety of the devices shown or described, all of which are novel in character and will, without doubt, lead to further important results at the hands of Mr. Tesla and other investigators. The experiment, for instance, of lighting up a single filament or block of refractory material with a single wire, is in itself sufficient to give Mr. Tesla's work the stamp of originality, and the numerous other experiments and effects which may be varied at will are equally new and interesting. Thus, the incandescent filament spinning in an unexhausted globe, the well-known Crookes experiment on open circuit, and the many others suggested will not fail to interest the reader. Mr. Tesla has made an exhaustive study of the various forms of the discharge presented by an induction coil when operated with these rapidly alternating currents, starting from the thread-like discharge and passing through various stages to the true electric flame.

A point of great importance in the introduction of high tension alternating current which M. Tesla brings out is the necessity of carefully avoiding all gaseous matter in the high tension apparatus. He shows that, at least with very rapidly alternating currents of high potential, the discharge may work through almost any practicable thickness of the best insulators, if air is present. In such cases the air included within the apparatus is violently agitated and by molecular bombardment the parts may be so greatly heated as to cause a rupture of the insulation. The practical outcome of this is, that, whereas with steady currents, any kind of insulation may be used, with rapidly alternating currents oils will probably be the best to employ, a fact which has been observed, but not until now satisfactorily explained. The recognition of the above fact is of special importance in the construction of the costly commercial induction coils which are often rendered useless in an unaccountable manner. The truth of these views of Mr. Tesla is made evident by the interesting experiments illustrative of the behavior of the air between charged surfaces, the luminous streams formed by the charged molecules appearing even when great thicknesses of the best insulators are interposed between the charged surfaces. These luminous streams afford in themselves a very interesting study for the experimenter. With these rapidly alternating currents they become far more powerful and produce beautiful light effects when they issue from a wire, pinwheel or other object attached to a terminal of the coil; and it is interesting to note that they issue from a ball almost as freely as from a point, when the frequency is very high.

From these experiments we also obtain a better idea of the importance of taking into account the capacity and self-induction in the apparatus employed and the possibilities offered by the use of condensers in conjunction with alternate currents, the employment of currents of high frequency, among other things, making it possible to reduce the condenser to practicable dimensions. Another point of interest and practical bearing is the fact, proved by Mr. Tesla, that for alternate currents, especially those of high frequency, insulators are required possessing a small specific inductive capacity, which at the same time have a high insulating power.

Mr. Tesla also makes interesting and valuable suggestion in regard to the economical utilization of iron in machines and transformers. He shows how, by maintaining by continous magnetization a flow of lines through the iron, the latter may be kept near its maximum permeability and a higher output and economy may be secured in such apparatus. This principle may prove of considerable commercial importance in the development of alternating systems. Mr. Tesla's suggestion that the same result can be secured by heating the iron by the hysteresis and eddy currents, and increasing the permeability in this manner, while it may appear less practical, nevertheless opens another direction for investigation and improvement.

The demonstration of the fact that with alternating currents of high frequency sufficient energy may be transmitted under practicable conditions through the glass of an incandescent lamp by electrostatic or electromagnetic induction may lead to a departure in the construction of such devicces. Another important experimental result achieved is the operation of lamps, and even motors, with the discharges of condensers, this method affording a means of converting direct or alternating currents. In this connection Mr. Tesla advocates the perfecting of apparatus capable of generating electricity of high tension from heat energy, believing this to be a better way of obtaining electrical energy for practical purposes, particularly for the production of light.

While we were prepared to encounter curious phenomena of impedance in the use of a condenser discharged disruptively, the experiments shown were extremely interesting on account of their paradoxical character.

The burning of an incandescent lamp at any candle power when connected across a heavy metal bar, the existence of nodes on the bar and the possibility of exploring the bar by means of an ordinary Cardew voltmeter, are all curious developments, but perhaps the most interesting observation is the phenomenon of impedance observed in the lamp with a straight filament, which remains dark while the bulb glows.

Mr. Tesla's manner of operating an induction coil by means of the disruptive discharge, and thus obtaining enormous differences of potential from comparatively small and inexpensive coils, will be appreciated by experimenters and will find valuable application in laboratories. Indeed, his many suggestions and hints in regard to the construction and use of apparatus in these investigations will be highly valued and will aid materially in future research.

Looked at from the standpoint of scientific research we believe that Mr. Tesla's paper will be conceded to be one of the most remarkable productions of recent years, and worthy of a very high rank among the classical publications on electricity. In addition to its great scientific value, however, it opens up possibilities not only in the production of light, but of power, the contemplation of which, as Mr. Tesla eloquently puts it, "expands our minds, strengthens our hopes and fills our hearts with supreme delight."

THE SUPPLANTING OF STEAM AT SIOUX CITY.

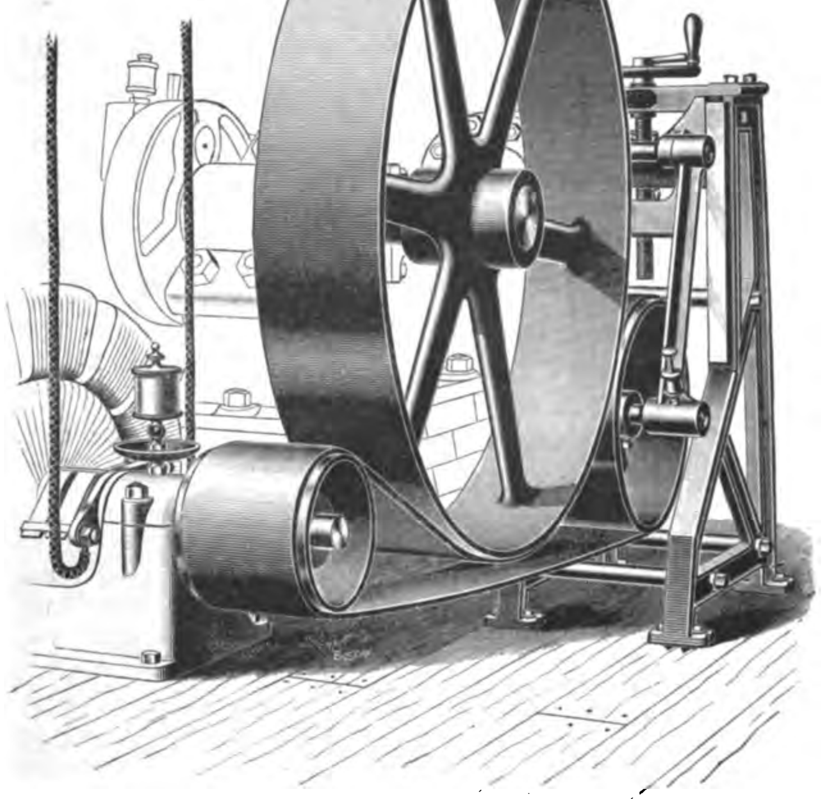
It is interesting to note that on another steam road out West the change to electricity has been made that has already been so significant and so successful in the service between St. Paul and Minneapolis. In the present case, the Riverside Road, running out of Sioux City for nine miles, the advantages of electricity have again demonstrated themselves so clearly, that we believe it is only a matter of a few months when a great many other short and "commuter" roads around the larger cities will adopt electricity as their motive power. This new Westinghouse road, about which Iowa is very enthusiastic, compares in every way with regular steam railways, for it was one. There is a standard railway track with deep cuts and fills, trestle-work 600 feet long, depots, and a speed of 25 miles an hour, which is to be soon improved upon. The people of the city and all that wide suburban region have every benefit that rapid transit can bestow, but they travel now without the accompaniments of smoke, soot and flying cinders, and without the possibility of setting fire to grass or trees. Steam locomotion has been an enormous boon to suburban residents, but electricity, as something far better, now claims the field. The fact that this extension of electric railway work has already begun, while yet the street railway work that it was to follow is in the early stages, must be most gratifying to all who take part in it, and shows once again how rapid electric development in this country is, when the apparatus has been proven equal to its work.

THE "L. P. & D." METHOD OF DRIVING DYNAMOS.

In an electric plant, for the production of either light or power, much space is necessarily taken up with the belting and countershafts, and engineers have for years been trying to find some method of applying the power from the engines more directly to the pulley of the dynamos. There are many so-called friction drives in use to-day, some of which have proved very successful, while some have had to be abandoned, owing either to their unreliability or to the cost of necessary repairs. We illustrate in the accompanying engraving the L. P. and D. system, which is entirely new, though it has been successfully tried in two or three electric light stations for the past year. The figure shows the general principle of the machine, in which a dynamo is being driven direct from a high-speed engine, though the system can be equally well applied to a pulley on a line of shafting. The dynamo is bolted firmly to the floor, and does not require any sliding base, and it will be at once seen that the belt has a contact on two-thirds of the dynamo pulley, thereby preventing liability to hot bearings, there being much less strain. A strong cast-iron frame is set up behind the driving pulley, with a swinging frame attached to it carrying an idler pulley, called the transmitter pulley, round which the driving belt has to pass. The engine pulley is revolving, as represented in the cut, so that the top of the pulley is approaching the observer. When not in use the belt hangs loose, and in starting all that is necessary to do is to screw up the hand wheel on top of the frame, which draws up the transmitter and tightens the belt against the engine pulley, and the dynamo is gently and evenly set in motion. There is not belt wrap enough on the driving pulley to carry a large load, but the belt is supported in such a manner by the transmitter pulley that it is gripped firmly between it and the driving pulley, and as the arrangment is such that the grip increases with the pull of the belt, it follows that the machine is automatic.

Belts that have been running one year on this system show no more wear than those used in the old way.

In stations using lines of shafting it is not uncommon to find six h. p. per dynamo needed to bring the empty machines up to speed, with the belts drawn up as tight as when carrying the load. This, of course, applies to stations where dynamos and shafting are on the same floor, for in those belting from shafting on one floor to dynamos above, the friction is not as much, for obvious reasons. In the "L. P. & D." system, however, the same results are secured as in the last method. The system is the invention of Mr. W. E. Laird of Montpelier, Vt., and the machines are being built and installed by Messrs. Perry and Demerritt, of the same city, who are selling them on approval. They guarantee them to transmit ten per cent. more power with less strain in the bearings, and with a belt of the same width, than any other method of driving now in use. The cost is said not to exceed that of any other system, where the dynamos can be operated independently of each other.



Laird System of Driving Dynamos.

THE HYER-SHEEHAN MOTOR.

We illustrate on this page a very good type of small motor, in the design that has just been put upon the market by the Hyer-Sheehan Electric Motor Co., of Newburgh, N. Y., whose agents for New England are the Redding Electric Co., of Boston. The motor is now being built in four sizes, namely, one-twelfth, one-eighth, one-sixth and one-half h. p.; and the general design is the same throughout the series. Taking the one-twelfth h. p. as an example, it may be stated that all the running parts, except the commutator, are enclosed by the iron frame and are thus protected from injury. The lower half of each bearing is integral with the bedplate, and solidity, strength and smooth running are thus ensured. The armature is a modification of the drum pattern, with projecting teeth, by means of which it is run with a lessened air gap and a consequent greater intensity of field of force. The teeth of the armature hold the coils rigidly in position. The discs of the armature core are stamped from the softest charcoal iron, and the winding is insulated by fibre, so as to prevent any "ground." The field consists of but one coil, wound in a mold and then bound with tape. It is very accessible. The commutator is made of tempered copper with mica insulation, held on a brass sleeve by nuts which press on the beveled ends of the bars. As a general thing the motors are fitted with carbon brushes, whose pressure is kept constant by a spring. The whole motor weighs 12 lbs. It runs at a speed of 2,200 revolutions. The half h. p., a very solid, massive-looking little machine, weighs 80 lbs. and runs at 1,800. All the four sizes are built for 110 and 220 volts constant potential circuits, and for 6½ or 10 ampere arc circuits.

Half Horse Power Hyer-Sheehan Motor.

Mr. W. A. Fitzgerald, superintendent and manager of the Detroit Electric Light & Power Co., is to superintend the electrical exhibit at the next Detroit Exposition.

EXPERIMENTS WITH ALTERNATE CURRENTS OF VERY HIGH FREQUENCY AND THEIR APPLICATION TO METHODS OF ARTIFICIAL ILLUMINATION.[1]

BY NIKOLA TESLA.

THERE is no subject more captivating, more worthy of study, than nature. To understand this great mechanism, to discover the forces which are active, and the laws which govern them, is the highest aim of the intellect of man.

Nature has stored up in the universe infinite energy. The eternal recipient and transmitter of this infinite energy is the ether. The recognition of the existence of ether, and of the functions it performs, is one of the most important results of modern scientific research. The mere abandoning of the idea of action at a distance, the assumption of a medium pervading all space and connecting all gross matter, has freed the minds of thinkers of an ever-present doubt, and, by opening a new horizon—new and unforeseen possibilities—has given fresh interest to phenomena with which we are familiar of old. It has been a great step towards the understanding of the forces of nature and their multifold manifestations to our senses. It has been for the enlightened student of physics what the understanding of the mechanism of the firearm or of the steam engine was for the barbarian. Phenomena upon which we used to look as wonders baffling explanation, we now see in a different light. The spark of an induction coil, the glow of an incandescent lamp, the manifestations of the mechanical forces of currents and magnets are no longer beyond our grasp; instead of the incomprehensible, as before, their observation suggests now in our minds a simple mechanism, and although as to its precise nature all is still conjecture, yet we know that the truth cannot be much longer hidden, and instinctively we feel that the understanding is dawning upon us. We still admire these beautiful phenomena, these strange forces, but we are helpless no longer; we can in a certain measure explain them, account for them, and we are hopeful of finally succeeding in unraveling the mystery which surrounds them.

In how far we can understand the world around us is the ultimate thought of every student of nature. The coarseness of our senses prevents us from recognizing the ulterior construction of matter, and astronomy, this grandest and most positive of natural sciences, can only teach us something that happens, as it were, in our immediate neighborhood: of the remoter portions of the boundless universe, with its numberless stars and suns, we know nothing. But far beyond the limit of perception of our senses the spirit still can guide us, and so we may hope, that even these unknown worlds—infinitely small and great—may in a measure become known to us. Still, even if this knowledge should reach us, the searching mind will find a barrier, perhaps forever unsurpassable, to the *true* recognition of that which *seems* to be, the mere *appearance* of which is the only and slender basis of all our philosophy.

Of all the forms of nature's immeasurable, all-pervading energy, which ever and ever changing and moving, like a soul animates the inert universe, those of electricity and magnetism are perhaps the most fascinating. The effects of gravitation, of heat and light we observe daily, and soon we get accustomed to them, and soon they lose for us the character of the marvelous and wonderful; but electricity and magnetism, with their singular relationship, with their seemingly dual character, unique among the forces in nature, with their phenomena of attractions, repulsions and rotations, strange manifestations of mysterious agents, stimulate and excite the mind to thought and research. What is electricity, and What is magnetism? These questions have been asked again and again. The most able intellects have ceaselessly wrestled with the problem; still the question has not as yet been fully answered. But while we cannot even to-day state what these singular forces are, yet we have made good headway towards the solution of the problem. We are now confident that electric and magnetic phenomena are attributable to ether, and we are perhaps justified in saying, that the effects of static electricity are effects of ether under strain, and those of dynamic electricity and electro-magnetism effects of ether in motion. But this still leaves the question, as to what electricity and magnetism are, unanswered.

First, we naturally inquire, What is electricity, and is there such a thing as electricity? In interpreting electric phenomena, we may speak of electricity or of an electric condition, state or effect. If we speak of electric effects, we must distinguish two such effects, opposite in character and neutralizing each other, as observation shows that two such opposite effects exist. This is unavoidable, for in a medium of the properties of ether, we cannot possibly exert a strain, or produce a displacement or motion of any kind, without causing in the surrounding medium an equivalent and opposite effect. But if we speak of electricity, meaning a *thing*, we must, I think, abandon the idea of two electricities, as the existence of two such things is highly improbable. For how can we imagine that there should be two things, equivalent in amount, alike in their properties, but of opposite character, both clinging to matter, both attracting and completely neutralizing each other? Such an assumption, though suggested by many phenomena, though most convenient for explaining them, has little to commend it. If there *is* such a thing as electricity, there can be only *one* such thing, and, excess and want of that one thing, possibly; but more probably its condition determines the positive and negative character. The old theory of Franklin, though falling short in some respects, is, from a certain point of view, after all, the most plausible one. Still, in spite of this, the theory of the two electricities is generally accepted, as it apparently explains electric phenomena in a more satisfactory manner. But a theory which better explains the facts is not necessarily true. Ingenious minds will invent theories to suit observation, and almost every independent thinker has his own views on the subject.

It is not with the object of advancing an opinion, but with the desire of acquainting you better with some of the results, which I will describe, to show you the reasoning I have followed, the departures I have made—that I venture to express, in a few words, the views and convictions which have led me to these results.

I adhere to the idea that there is a thing which we have been in the habit of calling electricity. The question is, What is that thing? or, What, of all things, the existence of which we know, have we the best reason to call electricity? We know that it acts like an incompressible fluid; that there must be a constant quantity of it in nature; that it can be neither produced nor destroyed; and, what is more important, the electro-magnetic theory of light and all facts observed teach us that electric and ether phenomena are identical. The idea at once suggests itself, therefore, that electricity might be called ether. In fact, this view has in a certain sense been advanced by Dr. Lodge. His interesting work has been read by everyone and many have been convinced by his arguments. His great ability and the interesting nature of the subject, keep the reader spellbound; but when the impressions fade, one realizes that he has to deal only with ingenious explanations. I must confess, that I cannot believe in two electricities, much less in a doubly-constituted ether. The puzzling behavior of the ether as a solid to waves of light and heat, and as a fluid to the motion of bodies through it, is certainly explained in the most natural and satisfactory manner by assuming it to be in motion, as Sir William Thomson has suggested; but regardless of this, there is nothing which would enable us to conclude with certainty that, while a fluid is not capable of transmitting transverse vibrations of a few hundred or thousand per second, it might not be capable of transmitting such vibrations when they range into hundreds of million millions per second. Nor can anyone prove that there are transverse ether waves emitted from an alternate current machine, giving a small number of alternations per second; to such slow disturbances, the ether, if at rest, may behave as a true fluid.

Returning to the subject, and bearing in mind that the existence of two electricities is, to say the least, highly improbable, we must remember, that we have no evidence of electricity, nor can we hope to get it, unless gross matter is present. Electricity, therefore, cannot be called ether in the broad sense of the term; but nothing would seem to stand in the way of calling electricity ether associated with matter, or bound ether; or, in other words, that the so-called static charge of the molecule is ether associated in some way with the molecule. Looking at it in that light, we would be justified in saying, that electricity is concerned in all molecular actions.

Now, precisely what the ether surrounding the molecules is, wherein it differs from ether in general, can only be conjectured. It cannot differ in density, ether being incompressible; it must, therefore, be under some strain or in motion, and the latter is the most probable. To understand its functions, it would be necessary to have an exact idea of the physical construction of matter, of which, of course, we can only form a mental picture.

But of all the views on nature, the one which assumes one matter and one force, and a perfect uniformity throughout, is the most scientific and most likely to be true. An infinitesimal world, with the molecules and their atoms spinning and moving in orbits, in much the same manner as celestial bodies, carrying with them and probably spinning with them ether, or in other words, carrying with them static charges, seems to my mind the most probable view, and one which, in a plausible manner, accounts for most of the phenomena observed. The spinning of the molecules and their ether sets up ether tensions or electrostatic strains; the equalization of ether tensions sets up ether motions or electric currents,

1. A lecture delivered before the American Institute of Electrical Engineers, at Columbia College, N. Y., May 20, 1891.

and the orbital movements produce the effects of electro and permanent magnetism.

About fifteen years ago, Prof. Rowland demonstrated a most interesting and important fact, namely, that a static charge carried around produces the effects of an electric current. Leaving out of consideration the precise nature of the mechanism, which produces the attraction and repulsion of currents, and conceiving the electrostatically charged molecules in motion, this experimental fact gives us a fair idea of magnetism. We can conceive lines or tubes of force which physically exist, being formed of rows of directed moving molecules; we can see that these lines must be closed; that they must tend to shorten and expand, etc. It likewise explains in a reasonable way, the most puzzling phenomenon of all, permanent magnetism, and, in general, has all the beauties of the Ampere theory without possessing the vital defect of the same, namely, the assumption of molecular currents. Without enlarging further upon the subject, I would say, that I look upon all electrostatic, current and magnetic phenomena as being due to electrostatic molecular forces.

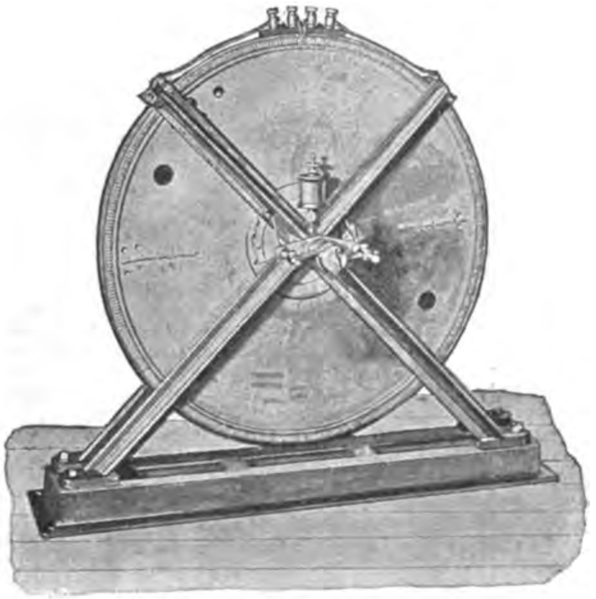


FIG. 1.—HIGH FREQUENCY ALTERNATOR WITH DRUM ARMATURE.

The preceding remarks I have deemed necessary to a full understanding of the subject as it presents itself to my mind.

Of all these phenomena the most important to study are the current phenomena, on account of the already extensive and ever-growing use of currents for industrial purposes. It is now a century since the first practical source of current has been produced, and, ever since, the phenomena which accompany the flow of currents have been diligently studied, and through the untiring efforts of scientific men the simple laws which govern them have been discovered. But these laws were found to hold good only when the currents are of a steady character When the currents are rapidly varying in strength, quite different phenomena, often unexpected, present themselves, and quite different laws hold good, which even now have not been determined as fully as is desirable, though through the work, principally of English scientists, enough knowledge has been gained on the subject to enable us to treat simple cases which now present themselves in daily practice.

The phenomena which are peculiar to the changing character of the currents are greatly exalted when the rate of change is increased, hence the study of these currents is considerably facilitated by the employment of properly constructed apparatus. It was with this and other objects in view that I constructed alternate current machines capable of giving more than two million reversals of current per minute, and to this circumstance it is principally due, that I am able to bring to your attention some of the results thus far reached, which I hope will prove to be a step in advance on account of their direct bearing upon one of the most important problems, namely, the production of a practical and efficient source of light.

The study of such rapidly alternating currents is very interesting. Nearly every experiment discloses something new. Many results may, of course, be predicted, but many more are unforeseen. The experimenter makes many interesting observations. For instance, we take a piece of iron and hold it against a magnet. Starting from low alternations and running up higher and higher we feel the impulses succeed each other faster and faster, get weaker and weaker, and finally disappear. We then observe a continuous pull; the pull, of course, is not continuous; it only appears so to us; our sense of touch is imperfect.

We may next establish an arc between the electrodes and observe as the alternations rise, that the note which accompanies alternating arcs gets shriller and shriller, gradually weakens, and finally ceases. The air vibrations, of course, continue, but they are too weak to be perceived; our sense of hearing fails us.

We observe the small physiological effects, the rapid heating of the iron cores and conductors, curious inductive effects, interesting condenser phenomena, and still more interesting light phenomena with a high tension induction coil. All these experiments and observations would be of the greatest interest to the student, but their description would lead me too far from the principal subject. Partly for this reason, and partly on account of the vastly greater importance, I will confine myself to the description of the light effects produced by these currents.

In the experiments to this end a high tension induction coil or equivalent apparatus for converting currents of comparatively low into currents of high tension is used.

If you will be sufficiently interested in the results I shall describe as to enter into an experimental study of this subject; if you will be convinced of the truth of the arguments I shall advance, your aim will be to produce high frequencies and high potentials; in other words, powerful electrostatic effects. You will then encounter many difficulties, which, if completely overcome, would allow us to produce truly wonderful results.

First will be met the difficulty of obtaining the required frequencies by means of mechanical apparatus, and, if they be obtained otherwise, obstacles of a different nature will present themselves. Next it will be found difficult to provide the requisite insulation without considerably increasing the size of the apparatus, for the potentials required are high, and, owing to the rapidity of the alternations, the insulation presents peculiar difficulties. So, for instance, when a gas is present, the discharge may work, by the molecular bombardment of the gas and consequent heating, through as much as an inch of the best solid insulating material, such as glass, hard rubber, porcelain, sealing wax, etc.; in fact, through any known insulating substance. The chief requisite in the insulation of the apparatus is, therefore, the exclusion of any gaseous matter.

In general my experience tends to show that bodies which possess the highest specific inductive capacity, such as glass, afford a rather inferior insulation to others, which, while they are good insulators, have a much smaller specific inductive capacity, such as oils, for instance, the dielectric losses being no doubt greater in the former. The difficulty of insulating, of course, only exists when the potentials are excessively high, for with potentials such as a few thousand volts there is no particular difficulty encountered in conveying currents from a machine giving, say, 20,000 alternations per second, to quite a distance. This number of alternations, however, is by far too small for many purposes, though quite sufficient for some practical applications. This difficulty of insulating is fortunately not a vital drawback; it affects mostly the size of the apparatus, for, when excessively high potentials would be used, the light-giving devices would be located not far from the apparatus, and often they would be quite close to it. As the air-bombardment of the insulated wire is

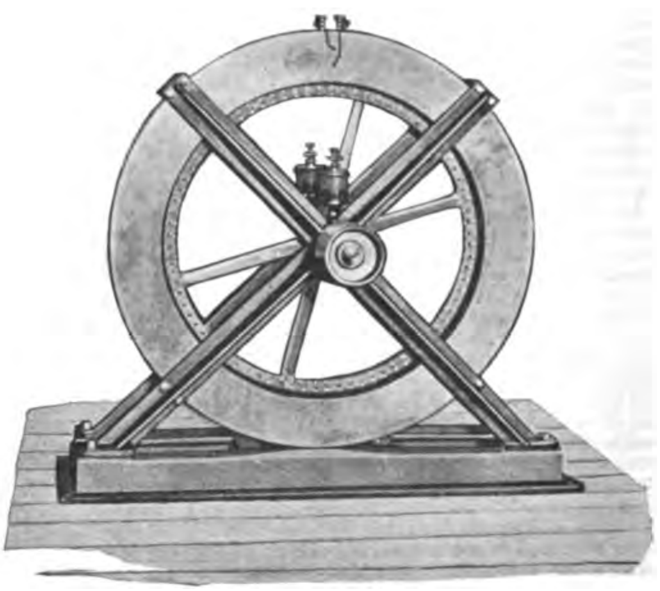

FIG. 2.—HIGH FREQUENCY ALTERNATOR WITH REVOLVING DISC ARMATURE.

dependent on condenser action, the loss may be reduced to a trifle by using excessively thin wires heavily insulated.

Another difficulty will be encountered in the capacity and self-induction necessarily possessed by the coil. If the coil be large, that is, if it contain a great length of wire, it will be generally unsuited for excessively high frequencies; if it be small, it may be well adapted for such frequencies, but the potential might then not be as high as desired. A good insulator, and preferably one possessing a small specific inductive capacity, would afford a two-fold advantage. First, it would enable us to construct a very small coil capable of withstanding enormous differences of potential; and secondly, such a small coil, by reason of its smaller capacity and self-induction, would be capable of a quicker and more vigorous vibration. The problem then of constructing a coil or induction apparatus of any kind possessing the requisite qualities I regard as one of no small importance, and it has occupied me for a considerable time.

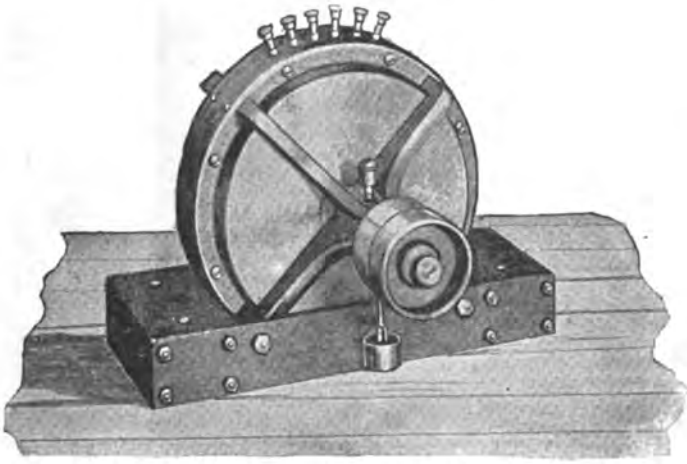

FIG. 3.—HIGH FREQUENCY ALTERNATOR WITH STATIONARY DISC ARMATURE AND STATIONARY EXCITING COIL.

The investigator who desires to repeat the experiments which I will describe, with an alternate current machine, capable of supplying currents of the desired frequency, and an induction coil, will do well to take the primary coil out and mount the secondary in such a manner as to be able to look through the tube upon which the secondary is wound. He will then be able to observe the streams which pass from the primary to the insulating tube, and from their intensity he will know how far he can strain the coil. Without this precaution he is sure to injure the insulation. This arrangement permits, however, an easy exchange of the primaries, which is desirable in these experiments.

The selection of the type of machine best suited for the purpose, must be left to the judgment of the experimenter. There are here illustrated three distinct types of machines, which, besides others, I have used in my experiments.

Fig. 1 represents the machine used in my experiments before this Institute. The field, magnet consists of a ring of wrought iron with 384 pole projections. The armature comprises a steel disc to which is fastened a thin, carefully welded rim of wrought iron. Upon the rim are wound several layers of fine, well annealed iron wire, which, when wound, is passed through shellac. The armature wires are wound around brass pins, wrapped with silk thread The diameter of the armature wire in this type of machine should not be more than ¼ of the thickness of the pole projections, else the local action will be considerable.

Fig. 2 represents a larger machine of a different type. The field-magnet of this machine consists of two like parts which either enclose an exciting coil, or else are independently wound. Each part has 480 pole projections, the projections of one facing those of the other. The armature consists of a wheel of hard bronze, carrying the conductors which revolve between the projections of the field magnet. To wind the armature conductors, I have found it most convenient to proceed in the following manner: I construct a ring of hard bronze of the required size. This ring and the rim of the wheel are provided with the proper number of pins, and both fastened upon a plate. The armature conductors being wound, the pins are cut off and the ends of the conductors fastened by two rings which screw to the bronze ring and the rim of the wheel respectively. The whole may then be taken off and forms a solid structure. The conductors in such a type of machine should consist of sheet copper, the thickness of which, of course, depends on the thickness of the pole projections; or else twisted thin wires should be employed.

Fig. 3 is a smaller machine, in many respects similar to the former, only here the armature conductors and the exciting coil are kept stationary, while only a block of wrought iron is revolved.

It would be uselessly lengthening this description were I to dwell more on the details of construction of these machines. Besides, they have been described somewhat more elaborately in THE ELECTRICAL ENGINEER, of March 18, 1891. I deem it well, however, to call the attention of the investigator to two things, the importance of which, though self evident, he is nevertheless apt to underestimate; namely, to the local action in the conductors which must be carefully avoided, and to the clearance which must be small. I may add, that since it is desirable to use very high peripheral speeds, the armature should be of very large diameter in order to avoid impracticable belt speeds. Of the several types of these machines which have been constructed by me, I have found that the type illustrated in Fig. 1 caused me the least trouble in construction, as well as in maintenance, and, on the whole, it has been a good experimental machine.

In operating an induction coil with very rapidly alternating currents, among the first luminous phenomena noticed are naturally those presented by the high-tension discharge. As the number of alternations per second is increased, or as—the number being high—the current through the primary is varied, the discharge gradually changes in appearance. It would be difficult to describe the minor changes which occur, and the conditions which bring them about, but one may note five distinct forms of the discharge.

First, one may observe a weak, sensitive discharge in the form of a thin, feeble-colored thread. (Fig. 4.) It always occurs when, the number of alternations per second being high, the current through the primary is very small. In spite of the excessively small current, the rate of change is great, and the difference of potential at the terminals of the secondary is therefore considerable, so that the arc is established at great distances; but the quantity of "electricity" set in motion is insignificant, barely sufficient to maintain a thin, threadlike arc. It is excessively sensitive and may be made so to such a degree that the mere act of breathing near the coil will affect it, and unless it is perfectly well protected from currents of air, it wriggles around constantly. Nevertheless, it is in this form excessively persistent, and when the terminals are approached to, say, one-third of the striking distance, it can be blown out only with difficulty. This exceptional persistency, when short, is largely due to the arc being excessively thin; presenting, therefore, a very small surface to the blast. Its great sensitiveness, when very long, is probably due to the motion of the particles of dust suspended in the air.

When the current through the primary is increased, the discharge gets broader and stronger, and the effect of the capacity of the coil becomes visible until, finally, under proper conditions, a white flaming arc, Fig. 5, often as thick as one's finger, and striking across the whole coil, is produced. It develops remarkable heat, and may be further characterized by the absence of the high note which accompanies the less powerful discharges. To take a shock from the coil under these conditions would not be advisable, although under different conditions, the potential being much higher, a shock from the coil may be taken with impunity To produce this kind of discharge the number of alternations per

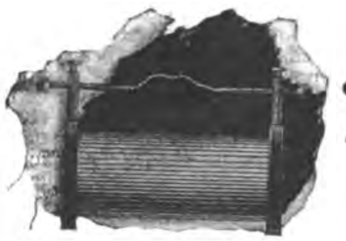

FIG. 4.—SENSITIVE THREAD DISCHARGE.

FIG. 5.—FLAMING DISCHARGE.

second must not be too great for the coil used; and, generally speaking, certain relations between capacity, self-induction and frequency must be observed.

The importance of these elements in an alternate current circuit is now well-known, and, under ordinary conditions, the general rules are applicable. But in an induction coil exceptional conditions prevail. First, the self-induction is of little importance before the arc is established, when it asserts itself, but perhaps never as prominently as in ordinary alternate current circuits, because capacity is distributed all along the coil, and by reason of the fact that the coil usually discharges through very great resistances; hence the currents are exceptionally small. Secondly, the capacity goes on increasing continually as the potential rises, in consequence of absorption which takes place to a considerable extent. Owing to this there exists no critical relationship between these quantities, and ordinary rules would not seem to be applicable. As the potential is increased either in consequence of the increased frequency or of the increased current through the primary, the amount of the energy stored becomes greater and greater, and the capacity gains more and more in importance. Up to a certain point the capacity is beneficial, but after that it begins to be an enormous drawback. It follows from this that each coil gives the best result with a given frequency and primary current. A very large coil, when operated with currents of very high frequency, may not give as much as ¼ inch spark. By adding capacity to the terminals, the condition may be improved, but what the coil really wants is a lower frequency.

When the flaming discharge occurs, the conditions are evidently such that the greatest current is made to flow through the circuit. These conditions may be attained by varying the frequency within wide limits, but the highest frequency at which the flaming arc can still be produced, determines, for a given primary current, the maximum striking distance of the coil. In the flaming discharge the *éclat* effect of the capacity is not perceptible; the rate at which the energy is being stored then just equals the rate at which it can be disposed of through the circuit. This kind of discharge is the severest test for a coil; the break, when it occurs, is of the nature of that in an overcharged Leyden jar. To give a rough approximation I would state that, with an ordinary coil of, say 10,000 ohms resistance, the most powerful arc would be produced with about 12,000 alternations per second.

When the frequency is increased beyond that rate, the potential, of course, rises, but the striking distance may, nevertheless, diminish, paradoxical as it may seem. As the potential rises the coil attains more and more the properties of a static machine until, finally, one may observe the beautiful phenomenon of the streaming discharge, Fig. 6, which may be produced across the whole length of the coil. At that stage streams begin to issue freely from all points and projections. These streams will also be seen to pass in abundance in the space between the primary and the insulating tube. When the potential is excessively high they will always appear, even if the frequency be low, and even if the primary be surrounded by as much as an inch of wax, hard rubber, glass, or any other insulating substance. This limits greatly the output of the coil, but I will later show how I have been able to overcome to a considerable extent this disadvantage in the ordinary coil.

Besides the potential, the intensity of the streams depends on the frequency; but if the coil be very large they show themselves, no matter how low the frequencies used. For instance, in a very large coil of a resistance of 67,000 ohms, constructed by mesome time ago, they appear with as low as 100 alternations per second and less, the insulation of the secondary being ¾ inch of ebonite. When very intense they produce a noise similar to that produced by the charging of a Holtz machine, but much more powerful, and they emit a strong smell of ozone. The lower the frequency, the more apt they are to suddenly injure the coil, With excessively high frequencies they may pass freely without producing any other effect than to heat the insulation slowly and uniformly.

The existence of these streams shows the importance of constructing an expensive coil so as to permit of one's seeing through the tube surrounding the primary, and the latter should be easily exchangeable; or else the space between the primary and secondary should be completely filled up with insulating material so as to exclude all air. The non-observance of this simple rule in the construction of the commercial coils is responsible for the destruction of many an expensive coil.

At the stage when the streaming discharge occurs, or with somewhat higher frequencies, one may, by approaching the terminals considerably and regulating properly the effect of capacity, produce a veritable spray of small silver-white sparks or a bunch of excessively thin silvery threads (Fig. 7) amidst a powerful brush—each spark or thread possibly corresponding to one alternation. This, when produced under proper conditions, is probably the most beautiful discharge, and when an air blast is directed against it, it presents a singular appearance. The spray of sparks, when received through the body, causes some inconvenience, whereas, when the discharge simply streams, nothing at all is likely to be felt if large conducting objects are held in the hands to protect them from receiving small burns.

If the frequency is still more increased, then the coil refuses to give any spark unless at comparatively small distances, and the fifth typical form of discharge may be observed (Fig. 8). The tendency to stream out and dissipate is then so great that when the brush is produced at one terminal no sparking occurs, even if, as I have repeatedly tried, the hand, or any conducting object, is held within the stream; and, what is more singular, the luminous stream is not at all easily deflected by the approach of a conducting body.

At this stage the streams seemingly pass with the greatest freedom through considerable thicknesses of insulators, and it is particularly interesting to study their behavior. For this purpose it is convenient to connect to the terminals of the coil two metallic spheres which may be placed at any desired distance, Fig. 9. Spheres are preferable to plates, as the discharge can be better observed. By inserting dielectric bodies between the spheres, beautiful discharge phenomena may be observed. If the spheres be quite close and a spark be playing between them, by interposing a thin plate of ebonite between the spheres the spark instantly ceases and the discharge spreads into an intensely luminous circle several inches in diameter, provided the spheres are sufficiently large. The passage of the streams heats, and, after a while, softens, the rubber so much that two plates may be made to stick together in this manner. If the spheres are so far apart that no spark occurs, even if they are far beyond the striking distance, by inserting a thick plate of glass the discharge is instantly induced to pass from the spheres to the glass in the form of luminous streams. It appears almost as though these streams pass *through* the dielectric. In reality this is not the case, as the streams are due to the molecules of the air which are violently agitated in the space between the oppositely charged surfaces of the spheres. When no dielectric other than air is present, the bombardment goes on, but is too weak to be visible; by inserting a dielectric the inductive effect is much increased, and besides, the projected air molecules find an obstacle and the bombardment becomes so intense that the streams become luminous. If by any mechanical means we could effect such a violent agitation of the molecules we could produce the same phenomenon. A jet of air escaping through a small hole under enormous pressure and striking against an insulating substance, such as glass, may be luminous in the dark, and it might be possible to produce phosphorescence of the glass or other insulators in this manner.

The greater the specific inductive capacity of the interposed dielectric, the more powerful the effect produced. Owing to this, the streams show themselves with excessively high potentials even if the glass be as much as one and one-half to two inches thick. But besides the heating due to bombardment, some heating goes on undoubtedly in the dielectric, being apparently greater in glass than in ebonite. I attribute this to the greater specific inductive capacity of the glass, in consequence of which, with the same same potential difference, a greater amount of energy is taken up in it than in rubber. It is like connecting to a battery a copper and a brass wire of the same dimensions. The copper wire, though a more perfect conductor, would heat more by reason of its taking more current. Thus what is otherwise considered a virtue of the glass is here a defect. Glass usually gives way much quicker than ebonite; when it is heated to a certain degree, the discharge suddenly breaks through at one point, assuming then the ordinary form of an arc.

The heating effect produced by molecular bombardment of the dielectric would, of course, diminish as the pressure of the air is increased, and at enormous pressures it would be negligible, unless the frequency would increase correspondingly.

It will be often observed in these experiments that when the spheres are beyond the striking distance, the approach of a glass plate, for instance, may induce the spark to jump between the spheres. This occurs when the capacity of the spheres is somewhat below the critical value which gives the greatest difference of potential at the terminals of the coil. By approaching a dielectric, the specific inductive capacity of the space between the spheres is increased, producing the same effect as if the capacity of the spheres were increased. The potential at the terminals may then rise so high that the air space is cracked. The experiment is best performed with dense glass or mica.

Fig. 6.—Streaming Discharge.

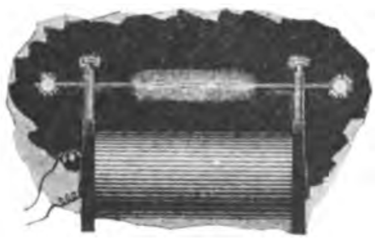

Fig. 7.—Brush and Spray Discharge.

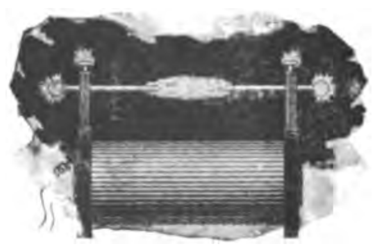

Fig. 8.—Fifth Typical Form of Discharge.

Another interesting observation is that a plate of insulating material, when the discharge is passing through it, is strongly attracted by either of the spheres, that is, by the nearer one, this being obviously due to the smaller mechanical effect of the bombardment on that side, and perhaps also to the greater electrification.

From the behavior of the dielectrics in these experiments we may conclude, that the best insulator for these rapidly alternating currents would be the one possessing the smallest specific inductive capacity and at the same time one capable of withstanding the greatest differences of potential; and thus two diametrically opposite ways of securing the required insulation are indicated, namely, to use either a perfect vacuum or a gas under great pressure; but the former would be preferable. Unfortunately neither of these two ways is easily carried out in practice.

It is especially interesting to note the behavior of an excessively high vacuum in these experiments. If a test tube, provided with external electrodes and exhausted to the highest possible degree, be connected to the terminals of the coil, Fig. 10, the electrodes of the tube are instantly brought to a high temperature and the glass at each end of the tube is rendered intensely phosphorescent, but the middle appears comparatively dark, and for a while remains cool.

When the frequency is so high that the discharge shown in Fig. 8 is observed, considerable dissipation no doubt occurs in the coil. Nevertheless the coil may be worked for a long time, as the heating is gradual.

In spite of the fact that the difference of potential may be enormous, little is felt when the discharge is passed through the body, provided the hands are armed. This is to some extent due to the higher frequency, but principally to the fact that less energy is available externally, when the difference of potential reaches an enormous value, owing to the circumstance that, with the rise of potential, the energy absorbed in the coil increases as the square of the potential. Up to a certain point the energy available externally increases with the rise of potential, then it begins to fall off rapidly. Thus, with the ordinary high tension induction coil, the curious paradox exists, that, while with a given current through the primary the shock might be fatal, with many times that current it might be perfectly harmless, even if the frequency be the same. With high frequencies and excessively high potentials when the terminals are not connected to bodies of some size, practically all the energy supplied to the primary is taken up by the coil. There is no breaking through, no local injury, but all the material, insulating and conducting, is uniformly heated.

To avoid misunderstanding in regard to the physiological effect of alternating currents of very high frequency, I think it

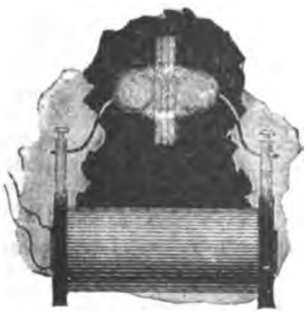

FIG. 9.—LUMINOUS DISCHARGE WITH INTERPOSED INSULATORS.

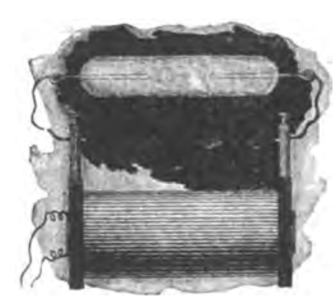

FIG. 10.—DISCHARGE THROUGH HIGHEST VACUUM.

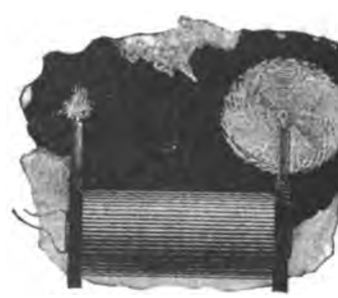

FIG. 11.—PINWHEEL DRIVEN BY A POWERFUL BRUSH.

necessary to state that, while it is an undeniable fact that they are incomparably less dangerous than currents of low frequencies, yet it should not be thought that they are altogether harmless. What has just been said refers only to currents from an ordinary high tension induction coil, which currents are necessarily very small; if received directly from a machine or from a secondary of low resistance, they produce more or less powerful effects, and may cause serious injury, especially when used in conjunction with condensers.

The streaming discharge of a high tension induction coil differs in many respects from that of a powerful static machine. In color it has neither the violet of the positive, nor the brightness of the negative, static discharge, but lies somewhere between, being, of course, alternatively positive and negative. But since the streaming is more powerful when the point or terminal is electrified positively, than when electrified negatively, it follows that the point of the brush is more like the positive, and the root more like the negative, static discharge. In the dark, when the brush is very powerful, the root may appear almost white. The wind produced by the escaping streams, though it may be very strong—often indeed to such a degree that it may be felt quite a distance from the coil—is, nevertheless, considering the quantity of the discharge, smaller than that produced by the positive brush of a static machine, and it affects the flame much less powerfully. From the nature of the phenomenon we can conclude that the higher the frequency, the smaller must, of course, be the wind produced by the streams, and with sufficiently high frequencies no wind at all would be produced at the ordinary atmospheric pressures. With frequencies obtainable by means of a machine, the mechanical effect is sufficiently great to revolve, with considerable speed, large pin-wheels, which in the dark present a beautiful appearance owing to the abundance of the streams (Fig. 11).

In general, most of the experiments usually performed with a static machine can be performed with an induction coil when operated with very rapidly alternating currents. The effects produced, however, are much more striking, being of incomparably greater power. When a small length of ordinary cotton covered wire, Fig. 12, is attached to one terminal of the coil, the streams issuing from all points of the wire may be so intense as to produce a considerable light effect. When the potentials and frequencies are very high, a wire insulated with gutta percha or rubber and attached to one of the terminals, appears to be covered with a luminous film. A very thin bare wire when attached to a terminal emits powerful streams and vibrates continually to and fro or spins in a circle, producing a singular effect (Fig. 13). Some of these experiments have been described by me in *The Electrical World*, of February 21, 1891.

Another peculiarity of the rapidly alternating discharge of the induction coil is its radically different behavior with respect to points and rounded surfaces.

If a thick wire, provided with a ball at one end and with a point at the other, be attached to the positive terminal of a static machine, practically all the charge will be lost through the point, on account of the enormously greater tension, dependent on the radius of curvature. But if such a wire is attached to one of the terminals of the induction coil, it will be observed that with very high frequencies streams issue from the ball almost as copiously as from the point (Fig. 14).

It is hardly conceivable that we could produce such a condition to an equal degree in a static machine, for the simple reason, that the tension increases as the square of the density, which in turn is proportional to the radius of curvature; hence, with a steady potential an enormous charge would be required to make streams issue from a polished ball while it is connected with a point. But with an induction coil the discharge of which alternates with great rapidity, it is different. Here we have to deal with two distinct tendencies. First, there is the tendency to escape which exists in a condition of rest, and which depends on the radius of curvature; second, there is the tendency to dissipate into the surrounding air by condenser action, which depends on the surface. When one of these tendencies is a maximum, the other is at a minimum. At the point the luminous stream is principally due to the air molecules coming bodily in contact with the point; they are attracted and repelled, charged and discharged, and, their atomic charges being thus disturbed, vibrate and emit light waves. At the ball, on the contrary, there is no doubt that the effect is to a great extent produced inductively, the air molecules not *necessarily* coming in contact with the ball, though they undoubtedly do so. To convince ourselves of this we only need to exalt the condenser action, for instance, by enveloping the ball, at some distance, by a better conductor than the surrounding medium, the conductor being, of course, insulated; or else by surrounding it with a better dielectric and approaching an insulated conductor; in both cases the streams will break forth more copiously. Also, the larger the ball with a given frequency, or the higher the frequency, the more will the ball have the advantage over the point. But, since a certain intensity of action is required to render the streams visible, it is obvious that in the experiment described the ball should not be taken too large.

In consequence of this two-fold tendency, it is possible to produce by means of points effects identical to those produced by capacity. Thus, for instance, by attaching to one terminal of the coil a small length of soiled wire, presenting many points and offering great facility to escape, the potential of the coil may be raised to the same value as by attaching to the terminal a polished ball of a surface many times greater than that of the wire.

An interesting experiment, showing the effect of the points, may be performed in the following manner: Attach to one of the terminals of the coil a cotton covered wire about two feet in length,

FIG. 12.—LUMINOUS STREAMS ESCAPING FROM A COTTON-COVERED WIRE.

and adjust the conditions so that streams issue from the wire. In this experiment the primary coil should be preferably placed so that it extends only about half way into the secondary coil. Now touch the free terminal of the secondary with a conducting object held in the hand, or else connect it to an insulated body of some size. In this manner the potential on the wire may be enormously

cule is able to get away, and this the more so, as for a given effect the potential required is smaller; and a frequency is conceivable —perhaps even obtainable—at which practically the same molecules would strike the terminal. Under such conditions the exchange of the molecules would be very slow, and the heat produced at, and very near, the terminal would be excessive. But if the frequency would go on increasing constantly, the heat produced would begin to diminish for obvious reasons. In the positive brush of a static machine the exchange of the molecules is very rapid, the stream is constantly of one direction, and there are fewer collisions; hence the heating effect must be very small. Anything that impairs the facility of exchange tends to increase the local heat produced. Thus, if a bulb be held over the terminal of the coil so as to enclose the brush, the air contained in the bulb is very quickly brought to a high temperature. If a glass tube be held over the brush so as to allow the draught to carry the brush upwards, scorching hot air escapes at the top of the tube. Anything held within the brush is, of course, rapidly heated, and the possibility of using such heating effects for some purpose or other suggests itself.

When contemplating this singular phenomenon of the hot brush, we cannot help being convinced that a similar process must take place in the ordinary flame, and it seems strange that after all these centuries past of familiarity with the flame, now, in this era of electric lighting and heating, we are finally led to recognize, that since time immemorial we have, after all, always had "electric light and heat" at our disposal. It is also of no little interest to contemplate, that we have a possible way of producing —by other than chemical means—a veritable flame, which would give light and heat without any material being consumed, without any chemical process taking place, and to accomplish this, we only need to perfect methods of producing enormous frequencies

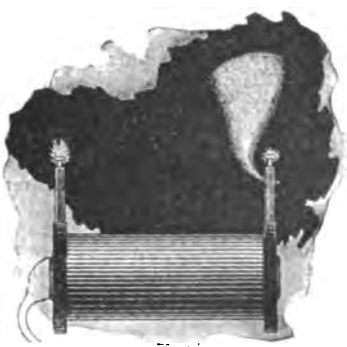

FIG. 13.—ASPECT PRESENTED BY A VERY THIN WIRE ATTACHED TO A TERMINAL OF THE COIL.

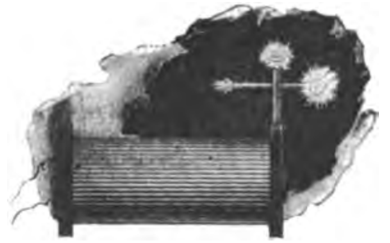

FIG. 14.—EFFECT OF BALL AND POINT.

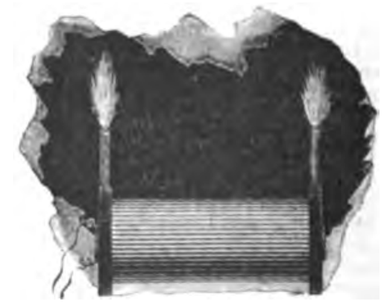

FIG. 15.—ASPECT OF COIL UNDER POWERFUL BRUSH DISCHARGE.

raised. The effect of this will be to either increase, or to diminish, the streams. If they increase, the wire is too short; if they diminish, it is too long. By adjusting the length of the wire, a point is found where the touching of the other terminal does not at all affect the streams. In this case the rise of potential is exactly counteracted by the drop through the coil. It will be observed that small lengths of wire produce considerable difference in the magnitude and luminosity of the streams. The primary coil is placed sidewise for two reasons: First, to increase the potential at the wire and, second, to increase the drop through the coil. The sensitiveness is thus augmented.

There is still another and far more striking peculiarity of the brush discharge produced by very rapidly alternating currents. To observe this it is best to replace the usual terminals of the coil by two metal columns insulated with a good thickness of ebonite. It is also well to close all fissures and cracks with wax so that the brushes cannot form anywhere except at the tops of the columns. If the conditions are carefully adjusted—which, of course, must be left to the skill of the experimenter—so that the potential rises to an enormous value, one may produce two powerful brushes several inches long, nearly white at their roots, which in the dark bear a striking resemblance to two flames of a gas escaping under pressure (Fig. 15). But they do not only *resemble*, they *are* veritable flames, for they are hot. Certainly they are not as hot as a gas burner, *but they would be so if the frequency and the potential would be sufficiently high.* Produced with, say, twenty thousand alternations per second, the heat is easily perceptible even if the potential is not excessively high. The heat developed is, of course, due to the impact of the air molecules against the terminals and against each other. As, at the ordinary pressures, the mean free path is excessively small, it is possible that in spite of the enormous initial speed imparted to each molecule upon coming in contact with the terminal, its progress—by collision with other molecules—is retarded to such an extent, that it does not get away far from the terminal, but may strike the same many times in succession. The higher the frequency, the less the mole-

and potentials. I have no doubt that if the potential could be made to alternate with sufficient rapidity and power, the brush formed at the end of a wire would lose its electrical characteristics and would become flamelike. The flame must be due to electrostatic molecular action.

This phenomenon now explains in a manner which can hardly

FIG. 16.—INCANDESCENT WIRE OR FILAMENT SPINNING IN AN UNEXHAUSTED GLOBE

be doubted the frequent accidents occurring in storms. It is well known that objects are often set on fire without the lightning striking them. We shall presently see how this can happen. On a nail in a roof, for instance, or on a projection of any kind, more or less conducting, or rendered so by dampness, a powerful brush may appear. If the lightning strikes somewhere in the neighborhood the enormous potential may be made to alternate or fluctuate perhaps many million times a second. The air molecules are violently attracted and repelled, and by their impact produce such a powerful heating effect that a fire is started. It is conceivable that a ship at sea may, in this manner, catch fire at many points at once. When we consider, that even with the comparatively low frequencies obtained from a dynamo machine, and with potentials of no more than one or two hundred thousand volts, the heating effects are considerable, we may imagine how much more powerful they must be with frequencies and potentials many times greater, and the above explanation seems, to say the least, very probable. Similar explanations may have been suggested, but I am not aware that, up to present, the heating effects of a brush produced by a rapidly alternating potential have been experimentally demonstrated, at least not to such a remarkable degree.

By preventing completely the exchange of the air molecules the local heating effect may be so exalted as to bring a body to incandescence. Thus, for instance, if a small button, or preferably a very thin wire or filament be enclosed in an unexhausted globe and connected with the terminal of the coil, it may be rendered incandescent. The phenomenon is made much more interesting by the rapid spinning round in a circle of the top of the filament, thus presenting the appearance of a luminous funnel, Fig. 16, which widens when the potential is increased. When the potential is small the end of the filament may perform irregular motions, suddenly changing from one to the other, or it may describe an ellipse; but when the potential is very high it always spins in a circle; and so does generally a thin straight wire attached freely to the terminal of the coil. These motions are, of course, due to the impact of the molecules, and the irregularity in the distribution of the potential, owing to the roughness and dissymmetry of the wire or filament. With a perfectly symmetrical and polished wire such motions would probably not occur. That the motion is not likely to be due to other causes is evident from the fact that it is not of a definite direction, and that in a very highly exhausted globe it ceases altogether. The possibility of

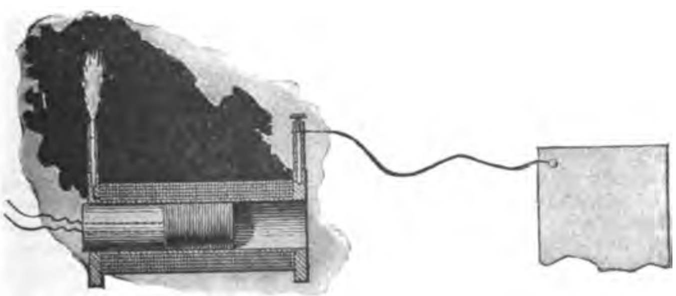

FIG. 17A.—COIL ARRANGED FOR POWERFUL BRUSH EFFECTS.

bringing a body to incandescence in an unexhausted globe, or even when not at all enclosed, would seem to afford a possible way of obtaining light effects, which, in perfecting methods of producing rapidly alternating potentials, might be rendered available for useful purposes.

In employing a commercial coil, the production of very powerful brush effects is attended with considerable difficulties, for when these high frequencies and enormous potentials are used, the best insulation is apt to give way. Usually the coil is insulated well enough to stand the strain from convolution to convolution, since two double silk covered paraffined wires will withstand a pressure of several thousand volts; the difficulty lies principally in preventing the breaking through from the secondary to the primary, which is greatly facilitated by the streams issuing from the latter. In the coil, of course, the strain is greatest from section to section, but usually in a larger coil there are so many sections that the danger of a sudden giving way is not very great. No difficulty will generally be encountered in that direction, and besides, the liability of injuring the coil internally is very much reduced by the fact that the effect most likely to be produced is simply a gradual heating, which, when far enough advanced, could not fail to be observed. The principal necessity is then to prevent the streams between the primary and the tube, not only on account of the heating and possible injury, but also because the streams may diminish very considerably the potential difference available at the terminals. A few hints as to how this may be accomplished will probably be found useful in most of these experiments with the ordinary induction coil.

One of the ways is to wind a short primary, Fig. 17 A, so that the difference of potential is not at that length great enough to cause the breaking forth of the streams through the insulating tube. The length of the primary should be determined by experiment. Both the ends of the coil should be brought out on one end through a plug of insulating material fitting in the tube as illustrated. In such a disposition one terminal of the secondary is attached to a body the surface of which is determined with the greatest care so as to produce the greatest rise in the potential. At the other terminal a powerful brush appears, which may be experimented upon.

The above plan necessitates the employment of a primary of comparatively small size, and it is apt to heat when powerful effects are desirable for a certain length of time. In such a case it is better to employ a larger coil, Fig. 17 B, and introduce it from one side of the tube, until the streams begin to appear. In this case the nearest terminal of the secondary may be connected to the primary or to the ground, which is practically the same

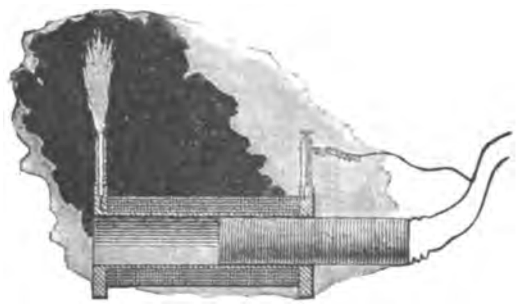

FIG. 17B.—COIL ARRANGED FOR POWERFUL BRUSH EFFECTS.—ST. ELMO'S HOT FIRE.

thing, if the primary is connected directly to the machine. In the case of ground connections it is well to determine experimentally the frequency which is best suited under the conditions of the test. Another way of obviating the streams, more or less, is to make the primary in sections and supply it from separate well insulated sources.

In many of these experiments, when powerful effects are wanted for a short time, it is advantageous to use iron cores with the primaries. In such case a very large primary coil may be wound and placed side by side with the secondary, and, the nearest terminal of the latter being connected to the primary, a laminated iron core is introduced through the primary into the secondary as far as the streams will permit. Under these conditions an excessively powerful brush, several inches long, which may be appropriately called "St. Elmo's hot fire," may be caused to appear at the other terminal of the secondary, producing striking effects. It is a most powerful ozonizer, so powerful indeed, that only a few minutes are sufficient to fill the whole room with the smell of ozone, and it undoubtedly possesses the quality of exciting chemical affinities.

For the production of ozone, alternating currents of very high frequency are eminently suited, not only on account of the advantages they offer in the way of conversion but also because of the fact, that the ozonizing action of a discharge is dependent on the frequency as well as on the potential, this being undoubtedly confirmed by observation.

In these experiments if an iron core is used it should be carefully watched, as it is apt to get excessively hot in an incredibly short time. To give an idea of the rapidity of the heating, I will state, that by passing a powerful

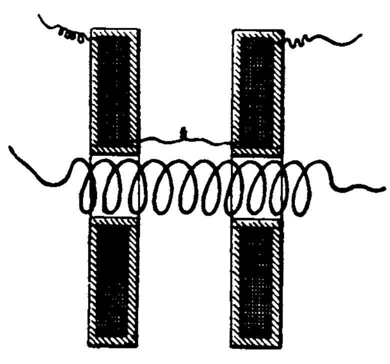

FIG. 18.—COIL FOR PRODUCING VERY HIGH DIFFERENCE OF POTENTIAL.

current through a coil with many turns, the inserting within the same of a thin iron wire for no more than one second's time is sufficient to heat the wire to something like 100° C.

But this rapid heating does not need to discourage us in the use of iron cores in connection with rapidly alternating currents. I have for a long time been convinced, that in the industrial distribution by means of transformers, some such plan as the following might be practicable. We may use a comparatively small iron core, subdivided, or perhaps not even subdivided. We may surround this core with a considerable thickness of material which is fire-proof and conducts the heat poorly, and on top of that we may place the primary and secondary windings. By using either higher frequencies or greater magnetizing forces, we may by hysteresis and eddy currents heat the iron core so far as to bring it nearly to its maximum permeability, which, as Hopkinson has shown, may be as much as sixteen times greater than that at ordinary temperatures. If the iron core were perfectly enclosed it would not be deteriorated by the heat, and, if the enclosure of fire-proof materi l would be sufficiently thick, only a limited amount of energy could be radiated in spite of the high temperature. Transformers have been constructed by me on that plan, but for lack of time, no thorough tests have as yet been made.

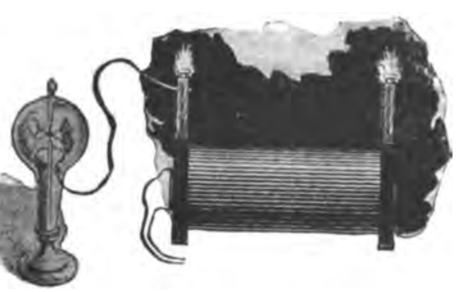

FIG. 19.—THE CROOKES EXPERIMENT ON OPEN CIRCUIT.

Another way of adapting the iron core to rapid alternations, or, generally speaking, reducing the frictional losses, is to produce by continuous magnetization a flow of something like seven thousand or eight thousand lines per square centimetre through the core, and then work with weak magnetizing forces and preferably high frequencies around the point of greatest permeability. A higher efficiency of conversion and greater output are obtainable in this manner. I have also employed this principle in connection with machines in which there is no reversal of polarity. In these types of machines, as long as there are only few pole projections, there is no great gain, as the maxima and minima of magnetization are far from the point of maximum permeabilty; but when the number of the pole projections is very great, the required rate of change may be obtained, without the magnetization varying so far as to depart greatly from the point of maximum permeability, and the gain is considerable.

The above described arrangements refer only to the use of commercial coils as ordinarily constructed. If it is desired to construct a coil for the express purpose of performing with it such experiments as I have described, or, generally, rendering it capable of withstanding the greatest possible difference of potential, then a construction as indicated in Fig. 18 will be found of advantage. The coil in this case is formed of two independent parts which are wound oppositely, the connection between both being made near the primary. The potential in the middle being zero, there is not much tendency to jump to the primary and not much insulation is required. In some cases, the middle point may, however, be connected to the primary or to the ground. In such a coil the places of greatest difference of potential are far apart and the coil is capable of withstanding an enormous strain. The two parts may be movable so as to allow a slight adjustment of the capacity effect.

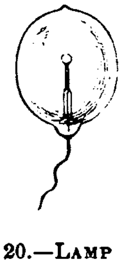

FIG. 20.—LAMP WITH SINGLE BLOCK OF REFRACTORY MATERIAL.

As to the manner of insulating the coil, it will be found convenient to proceed in the following way: First the wire should be boiled in paraffine, until all the air is out; then the coil is wound by running the wire through melted paraffine, merely for the purpose of fixing the wire. The coil is then taken off from the spool, immersed in a cylindrical vessel filled with pure melted wax and boiled for a long time until the bubbles cease to appear. The whole is then left to cool down thoroughly, and then the mass is taken out of the vessel and turned up in a lathe. A coil made in this manner and with care is capable of withstanding enormous potential differences.

It may be found convenient to immerse the coil in paraffine oil or some other kind of oil; it is a most effective way of insulating, principally on account of the perfect exclusion of air, but it may be found that, after all, a vessel filled with oil is not a very convenient thing to handle in a laboratory.

If an ordinary coil can be dismounted, the primary may be taken out of the tube and the latter plugged up on one end, filled with oil, and the primary reinserted. This affords an excellent insulation and prevents the formation of the streams.

Of all the experiments which may be performed with rapidly alternating currents the most interesting are those which concern the production of a practical illuminant. It cannot be denied, that the present methods, though they were billiant advances, are very wasteful. Some better methods must be invented, some more perfect apparatus devised. Modern research has opened new possibilities for the production of an efficient source of light, and the attention of all has been turned in the direction indicated by able pioneers. Many have been carried away by the enthusiasm and passion to discover, but in their zeal to reach results, many have been misled. Starting with the idea of producing electro-magnetic waves, they turned their attention, perhaps, too much to the study of electro-magnetic effects, and neglected the study of electrostatic phenomena. Naturally, nearly every investigator availed himself of an apparatus similar to that used in earlier experiments. But in those forms of apparatus, while the electro-magnetic inductive effects are enormous, the electrostatic effects are excessively small.

In the Hertz experiments, for instance, a high tension induction coil is short circuited by an arc, the resistance of which is very small, the smaller, the more capacity is attached to the terminals; and the difference of potential at these is enormously

FIG. 21.—LAMP WITH TWO FILAMENTS IN HIGHEST VACUUM WITH LEADING-IN WIRES.

diminished. On the other hand, when the discharge is not passing between the terminals, the static effects may be considerable, but only qualitatively so, not quantitatively, since their rise and fall is very sudden, and since their frequency is small. In neither case, therefore, are powerful electrostatic effects perceivable. Similar conditions exist when, as in some interesting experiments of Dr. Lodge, Leyden jars are discharged disruptively. It has been thought—and I believe asserted—that in such cases most of the energy is radiated into space. In the light of the experiments, which I have described above, it will now not be thought so I feel safe in asserting, that in such cases most of the energy is partly taken up and converted into heat in the arc of the discharge and in the conducting and insulating material of the jar, some energy being, of course, given off by electrification of the air; but the amount of the directly radiated energy is very small.

When a high tension induction coil, operated by currents alternating only 20,000 times a second, has its terminals closed through even a very small jar, practically all the energy passes through the dielectric of the jar, which is heated, and the electrostatic effects manifest themselves outwardly only to a very weak degree. Now the external circuit of a Leyden jar, that is, the arc and the connections of the coatings may be looked upon as a circuit generating alternating currents of excessively high frequency and fairly high potential, which is closed through the coatings and the dielectric between them, and from the above it is evident that the external electrostatic effects must be very small, even if a recoil circuit be used. These conditions make it appear, that with the apparatus usually at hand the observation of powerful electrostatic effects was impossible, and what experience has been gained in that direction is only due to the great ability of the investigators.

But powerful electrostatic effects are a *sine qua non* of light production on the lines indicated by theory. Electro-magnetic effects are primarily unavailable, for the reason that to produce the required effects we would have to pass current impulses through a conductor which, long before the required frequency of the impulses could be reached, would cease to transmit them. On the other hand, electro-magnetic waves many times longer than those of light, and producible by sudden discharges of a condenser, could not be utilized, it would seem, except we avail ourselves of their effect upon conductors as in the present methods, which are wasteful. We could not affect by means of such waves the static molecular or atomic charges of a gas, cause them to vibrate and to emit light. Long transverse waves cannot, apparently, produce such effects, since excessively small electro-magnetic disturbances may pass readily through miles of air. Such dark waves, unless they are of the length of true light waves, cannot, it would seem, excite luminous radiation in a Geissler tube, and the luminous effects, which are producible by induction in a tube devoid of electrodes, I am inclined to consider as being of an electrostatic nature.

FIG. 22.—LAMP WITH TWO REFRACTORY BLOCKS IN HIGHEST VACUUM.

To produce such luminous effects, straight electrostatic thrusts are required; these, whatever be their frequency, may disturb the molecular charges and produce light. Since current impulses of the required frequency cannot pass through a conductor of measurable dimensions, we must work with a gas, and then the production of powerful electrostatic effects becomes an imperative necessity.

It has occurred to me, however, that electrostatic effects are in many ways available for the production of light. For instance, we may place a body of some refractory material in a closed, and preferably more or less exhausted, globe, connect it to a source of high, rapidly alternating, potential, causing the molecules of the gas to strike it many times a second at enormous speeds, and in this manner, with trillions of invisible hammers, pound it until it gets incandescent; or, we may place a body in a very highly exhausted globe, in a non-striking vacuum, and, by employing very high frequencies and potentials, transfer sufficient energy from it to other bodies in the vicinity, or in general to the surroundings, to maintain it at any degree of incandescence; or, we may, by means of such rapidly alternating high potentials, disturb the ether carried by the molecules of a gas or their static charges, causing them to vibrate and to emit light.

But, electrostatic effects being dependent upon the potential and frequency, to produce the most powerful action it is desirable to increase both as far as practicable. It may be possible to obtain quite fair results by keeping either of these factors small, provided the other is sufficiently great; but we are limited in both directions. My experience demonstrates that we cannot go below a certain frequency, for, first, the potential then becomes so great that it is dangerous; and, secondly, the light production is less efficient.

I have found that, by using the ordinary low frequencies, the physiological effect of the current required to maintain at a certain degree of brightness a tube four feet long, provided at the ends with outside and inside condenser coatings, is so powerful that, I think, it might produce serious injury to those not accustomed to such shocks; whereas, with twenty thousand alternations per second, the tube may be maintained at the same degree of brightness without any effect being felt. This is due principally to the fact that a much smaller potential is required to produce the same light effect, and also to the higher efficiency in the light production. It is evident that the efficiency in such cases is the greater, the higher the frequency, for the quicker the process of charging and discharging the molecules, the less energy will be lost in the form of dark radiation. But, unfortunately, we cannot go beyond a certain frequency on account of the difficulty of producing and conveying the effects.

I have stated above, that a body enclosed in an unexhausted bulb may be intensely heated by simply connecting it with a source of rapidly alternating potential. The heating in such a case is, in all probability, due mostly to the bombardment of the molecules of the gas contained in the bulb. When the bulb is exhausted the heating of the body is much more rapid, and there is no difficulty whatever in bringing a wire or filament to any degree of incandescence by simply connecting it to one terminal of a coil of the proper dimensions. Thus, if the well-known apparatus of Prof. Crookes, consisting of a bent platinum wire with vanes mounted over it (Fig. 19), be connected to one terminal of the coil—either one or both ends of the platinum wire being connected—the wire is rendered almost instantly incandescent and the mica vanes are rotated as though a current from a battery were used. A thin carbon filament, or, preferably, a button of some refractory material (Fig. 20), even if it be a comparatively poor conductor, enclosed in an exhausted globe, may be rendered highly incandescent; and in this manner a simple lamp capable of giving any desired candle-power is provided.

The success of lamps of this kind would depend largely on the selection of the light-giving bodies contained within the bulb. Since, under the conditions described, refractory bodies—which are very poor conductors and capable of withstanding for a long time excessively high degrees of temperature—may be used, such illuminating devices may be rendered successful.

It might be thought at first that if the bulb, containing the filament or button of refractory material, be perfectly well exhausted—that is, as far as it can be done by the use of the best apparatus—the heating would be much less intense, and that in a perfect vacuum it could not occur at all. This is not confirmed by my experience; quite the contrary, the better the vacuum the more easily the bodies are brought to incandescence. This result is interesting for many reasons.

At the outset of this work the idea presented itself to me, whether two bodies of refractory material enclosed in a bulb exhausted to such a degree that the discharge of a large induction coil, operated in the usual manner, cannot pass through, could be rendered incandescent by mere condenser action. Obviously, to reach this result enormous potential differences and very high frequencies are required, as is evident from a simple calculation.

But such a lamp would possess a vast advantage over an ordinary incandescent lamp in regard to efficiency. It is well-known

FIG. 23.—LAMP WITH SINGLE STRAIGHT FILAMENT AND ONE LEADING-IN WIRE.

that the efficiency of a lamp is to some extent a function of the degree of incandescence, and that, could we but work a filament at many times higher degrees of incandescence, the efficiency would be much greater. In an ordinary lamp this is impracticable on account of the destruction of the filament, and it has been determined by experience how far it is advisable to push the incandescence. It is impossible to tell how much higher efficiency could be obtained if the filament could withstand indefinitely, as the investigation to this end obviously cannot be carried beyond a certain stage; but there are reasons for believing that it would be very considerably higher. An improvement might be made in the ordinary lamp by employing a short and thick carbon;

but then the leading-in wires would have to be thick, and, besides, there are many other considerations which render such a modification entirely impracticable. But in a lamp as above described, the leading-in wires may be very small, the incandescent refractory material may be in the shape of blocks offering a very small radiating surface, so that less energy would be required to keep them at the desired incandescence; and in addition to this, the refractory material need not be carbon, but may be manufactured from mixtures of oxides, for instance, with carbon or other material, or may be selected from bodies which are practically non-

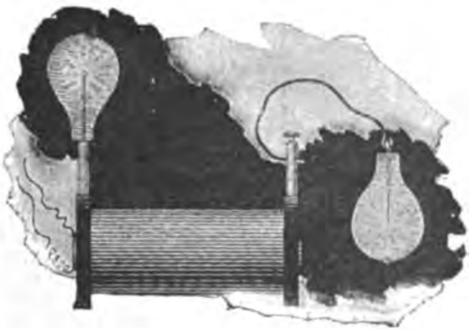

FIG. 24.—LAMPS WITH ONE LEADING-IN WIRE RENDERED INCANDESCENT.

conductors, and capable of withstanding enormous degrees of temperature.

All this would point to the possibility of obtaining a much higher efficiency with such a lamp than is obtainable in ordinary lamps. In my experience it has been demonstrated that the blocks are brought to high degrees of incandescence with much lower potentials than those determined by calculation, and the blocks may be set at greater distances from each other. We may freely assume, and it is probable, that the molecular bombardment is an important element in the heating, even if the globe be exhausted with the utmost care as I have done; for although the number of the molecules is, comparatively speaking, insignificant, yet on account of the mean free path being very great, there are fewer collisions, and the molecules may reach much higher speeds, so that the heating effect due to this cause may be considerable, as in the Crookes experiments with radiant matter.

But it is likewise possible that we have to deal here with an increased facility of losing the charge in very high vacuum, when the potential is rapidly alternating, in which case most of the heating would be directly due to the surging of the charges in the heated bodies. Or else the observed fact may be largely attributable to the effect of the points which I have mentioned above, in consequence of which the blocks or filaments contained in the vacuum are equivalent to condensers of many times greater surface than that calculated from their geometrical dimensions. Scientific men still differ in opinion as to whether a

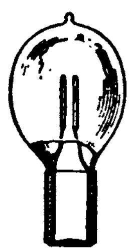

FIG. 25.—LAMP WITH TWO BLOCKS OR FILAMENTS AND A PAIR OF INDEPENDENT INSIDE AND OUTSIDE CONDENSER COATINGS.

charge should, or should not, be lost in a perfect vacuum, or in other words, whether ether is, or is not, a conductor. If the former were the case, then a thin filament enclosed in a perfectly exhausted globe, and connected to a source of enormous, steady potential, would be brought to incandescence.

Various forms of lamps on the above described principle, with the refractory bodies in the form of filaments, Fig. 21, or blocks, Fig. 22, have been constructed and operated by me, and investigations are being carried on in this line. There is no difficulty in reaching such high degrees of incandescence that ordinary carbon is to all appearance melted and volatilized. If the vacuum could be made absolutely perfect, such a lamp, although inoperative with apparatus ordinarily used, would, if operated with currents of the required character, afford an illuminant which would never be destroyed, and which would be far more efficient than an ordinary incandescent lamp. This perfection can, of course, never be reached, and a very slow destruction and gradual diminution of the size always occurs, as in incandescent lamps; but there is no possibility of a sudden and premature disabling which occurs in the latter by the breaking of the filament, especially when the incandescent bodies are in the shape of blocks.

With these rapidly alternating potentials there is, however, no necessity of enclosing two blocks in a globe, but a single block, as in Fig. 20, or filament, Fig. 23, may be used. The potential in this case must of course be higher, but it is easily obtainable, and besides it is not necessarily dangerous.

The facility with which the button or filament in such a lamp is brought to incandescence, other things being equal, depends on the size of the globe. If a perfect vacuum could be obtained, the size of the globe would not be of importance, for then the heating would be wholly due to the surging of the charges, and all the energy would be given off to the surroundings by radiation. But this can never occur in practice. There is always some gas left in the globe, and although the exhaustion may be carried to the highest degree, still the space inside of the bulb must be considered as conducting when such high potentials are used, and I assume that, in estimating the energy that may be given off from the filament to the surroundings, we may consider

FIG. 26A.

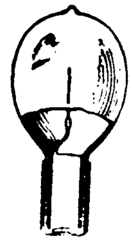

FIG. 26B.

LAMP WITH ONE FILAMENT, ONE INSIDE AND ONE OUTSIDE CONDENSER COATING.

the inside surface of the bulb as one coating of a condenser, the air and other objects surrounding the bulb forming the other coating. When the alternations are very low there is no doubt that a considerable portion of the energy is given off by the electrification of the surrounding air.

In order to study this subject better, I carried on some experiments with excessively high potentials and low frequencies. I then observed that when the hand is approached to the bulb,—the filament being connected with one terminal of the coil,—a powerful vibration is felt, being due to the attraction and repulsion of the molecules of the air which are electrified by induction through the glass. In some cases when the action is very intense I have been able to hear a sound, which must be due to the same cause.

When the alternations are low, one is apt to get an excessively powerful shock from the bulb. In general, when one attaches bulbs or objects of some size to the terminals of the coil, one should look out for the rise of potential, for it may happen that by merely connecting a bulb or plate to the terminal, the potential may rise to many times its original value. When lamps are attached to the terminals, as illustrated in Fig. 24, then the capacity of the bulbs should be such as to give the maximum rise of potential under the existing conditions. In this manner one may obtain the required potential with fewer turns of wire.

The life of such lamps as described above depends, of course, largely on the degree of exhaustion, but to some extent also on the shape of the block of refractory material. Theoretically it would seem that a small sphere of carbon enclosed in a sphere of glass would not suffer deterioration from molecular bombardment, for, the matter in the globe being radiant, the molecules would move in straight lines, and would seldom strike the sphere obliquely. An interesting thought in connection with such a lamp is, that in it "electricity" and electrical energy apparently must move in the same lines.

The use of alternating currents of very high frequency makes it possible to transfer, by electrostatic or electromagnetic induction through the glass of a lamp, sufficient energy to keep a filament at incandescence and so do away with the leading-in wires. Such lamps have been proposed, but for want of proper apparatus they have not been successfully operated. Many forms of lamps on this principle with continuous and broken filaments have been constructed by me and experimented upon. When using a secondary enclosed within the lamp, a condenser is advantageously combined with the scondary. When the transference is effected by electrostatic induction, the potentials used are, of course, very high with frequencies obtainable from a machine. For instance, with a condenser surface of forty centimetres square, which is not impracticably large, and with glass of good quality 1 mm. thick, using currents alternating twenty thousand times a second, the potential required is approximately 9,000 volts. This may seem large, but since each lamp may be included in the secondary of a transformer of very small dimensions, it would not be inconvenient, and, moreover, it would not produce fatal injury. The transformers would all be preferably in series. The regulation would offer no difficulties, as with currents of such frequencies it is very easy to maintain a constant current.

In the accompanying engravings some of the types of lamps of this kind are shown. Fig. 25 is such a lamp with a broken filament, and Fig. 26 A and 26 B one with a single outside and inside coating and a single filament. I have also made lamps with two outside and inside coatings and a continuous loop connecting the latter. Such lamps have been operated by me with current impulses of the enormous frequencies obtainable by the disruptive discharge of condensers.

The disruptive discharge of a condenser is especially suited for operating such lamps—with no outward electrical connections—by means of electromagnetic induction, the electromagnetic inductive effects being excessively high; and I have been able to produce the desired incandescence with only a few short turns of wire. Incandescence may also be produced in this manner in a simple closed filament.

Leaving now out of consideration the practicability of such lamps, I would only say that they possess a beautiful and desirable feature, namely, that they can be rendered, at will, more or less brilliant simply by altering the relative position of the outside and inside condenser coatings, or inducing and induced circuits.

FIG. 27.—LAMP WITH ONE FILAMENT AND LEADING-IN WIRE AND EXTERNAL CONDENSER COATING.

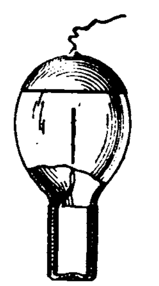

FIG. 28.—LAMP WITH ONE FILAMENT, ONE INSIDE AND ONE OUTSIDE CONDENSER COATING, AND AUXILIARY COATING.

When a lamp is lighted by connecting it to one terminal only of the source, this may be facilitated by providing the globe with an outside condenser coating, which serves at the same time as a reflector, and connecting this to an insulated body of some size. Lamps of this kind are illustrated in Fig. 27 and Fig. 28. Fig. 29 shows the plan of connections. The brilliancy of the lamp may, in this case, be regulated within wide limits by varying the size of the insulated metal plate to which the coating is connected.

It is likewise practicable to light with one leading wire lamps such as illustrated in Fig. 21 and Fig. 22, by connecting one terminal of the lamp to one terminal of the source, and the other to an insulated body of the required size. In all cases the insulated body serves to give off the energy into the surrounding space, and is equivalent to a return wire. Obviously, in the two last-named cases, instead of connecting the wires to an insulated body, connections may be made to the ground.

The experiments which will prove most suggestive and of most interest to the investigator are probably those performed with exhausted tubes. As might be anticipated, a source of such rapidly alternating potentials is capable of exciting the tubes at a considerable distance, and the light effects produced are remarkable.

During my investigations in this line I endeavored to excite tubes, devoid of any electrodes, by electromagnetic induction, making the tube the secondary of the induction device, and passing through the primary the discharges of a Leyden jar. These tubes were made of many shapes, and I was able to obtain luminous effects which I then thought were due wholly to electromagnetic induction. But on carefully investigating the phenomena I found that the effects produced were more of an electrostatic nature. It may be attributed to this circumstance that this mode of exciting tubes is very wasteful, namely, the primary circuit being closed, the potential, and consequently the electrostatic inductive effect, is much diminished.

FIG. 29.—INCREASING THE BRILLIANCY OF LAMP ON ONE WIRE.

When an induction coil, operated as above described, is used, there is no doubt that the tubes are excited by electrostatic induction, and that electromagnetic induction has little, if anything, to do with the phenomena.

This is evident from many experiments. For instance, if a tube be taken in one hand, the observer being near the coil, it is brilliantly lighted and remains so no matter in what position it is held relatively to the observer's body. Were the action electromagnetic, the tube could not be lighted when the observer's body is interposed between it and the coil, or at least its luminosity should be considerably diminished. When the tube is held exactly over the centre of the coil—the latter being wound in sections and the primary placed symmetrically to the secondary—it may remain completely dark, whereas it is rendered intensely luminous by moving it slightly to the right or left from the centre of the coil. It does not light because in the middle both halves of the coil neutralize each other, and the electric potential is zero. If the action were electromagnetic, the tube should light best in the plane through the centre of the coil, since the electromagnetic effect there should be a maximum. When an arc is established between the terminals, the tubes and lamps in the vicinity of the coil go out, but light up again when the arc is broken, on account of the rise of potential. Yet the electromagnetic effect should be practically the same in both cases.

By placing a tube at some distance from the coil, and nearer to one terminal—preferably at a point on the axis of the coil—one may light it by touching the remote terminal with an insulated body of some size or with the hand, thereby raising the potential at that terminal nearer to the tube. If the tube is shifted nearer to the coil so that it is lighted by the action of the nearer terminal, it may be made to go out by holding, on an insulated support, the end of a wire connected to the remote terminal, in the vicinity of the nearer terminal, by this means counteracting the action of the latter upon the tube. These effects are evidently electrostatic. Likewise, when a tube is placed at a considerable distance from the coil, the observer may, standing upon an insulated support, between coil and tube, light the latter by approaching the hand to it; or he may even render it luminous by simply stepping between it and the coil. This would be impossible with electromagnetic induction, for the body of the observer would act as a screen.

When the coil is energized by excessively weak currents, the experimenter may, by touching one terminal of the coil with the tube, extinguish the latter, and may again light it by bringing it out of contact with the terminal and allowing a small arc to form. This is clearly due to the respective lowering and raising of the potential at that terminal. In the above experiment, when the tube is lighted through a small arc, it may go out when the arc is broken, because the electrostatic inductive effect alone is too weak, though the potential may be much higher; but when the arc is established, the electrification of the end of the tube is much greater, and it consequently lights.

If a tube is lighted by holding it near to the coil, and in the hand which is remote, by grasping the tube anywhere with the other hand, the part between the hands is rendered dark, and the singular effect of wiping out the light of the tube may be produced by passing the hand quickly along the tube and at the same time withdrawing it gently from the coil, judging properly the distance so that the tube remains dark afterwards.

If the primary coil is placed sidewise, as in Fig. 17 B for instance, and an exhausted tube be introduced from the other side in the hollow space, the tube is lighted most intensely because of the increased condenser action, and in this position the striæ are most sharply defined. In all these experiments described, and in many others, the action is clearly electrostatic.

The effects of screening also indicate the electrostatic nature of the phenomena and show something of the nature of electrification through the air. For instance, if a tube be placed in the direction of the axis of the coil, and an insulated metal plate be interposed, the tube will generally increase in brilliancy, or if it be too far from the coil to light, it may even be rendered luminous by interposing an insulated metal plate. The magnitude of the effects depends to some extent on the size of the plate. But if the metal plate be connected by a wire to the ground, its interposition will always make the tube go out even if it be very near the coil. In general, the interposition of a body between the coil and tube, increases or diminishes the brilliancy of the tube, or its facility to light up, according to whether it increases or diminishes the electrification. When experimenting with an insulated plate, the plate should not be taken too large, else it will generally produce a weakening effect by reason of its great facility for giving off energy to the surroundings.

If a tube be lighted at some distance from the coil, and a plate of hard rubber or other insulating substance be interposed, the tube may be made to go out. The interposition of the dielectric in this case only slightly increases the inductive effect, but diminishes considerably the electrification through the air.

field. For this purpose I suspend a sheet of metal a distance from the ceiling on insulating cords and connect it to one terminal of the induction coil, the other terminal being preferably connected to the ground. Or else I suspend two sheets as illustrated in Fig. 30, each sheet being connected with one of the terminals of the coil, and their size being carefully determined. An exhausted tube may then be carried in the hand anywhere between the sheets or placed anywhere, even a certain distance beyond them; it remains always luminous.

In such an electrostatic field interesting phenomena may be observed, especially if the alternations are kept low and the potentials excessively high. In addition to the luminous phenomena mentioned, one may observe that any insulated conductor gives sparks when the hand or another object is approached to it, and the sparks may often be powerful. When a large conducting object is fastened on an insulating support, and the hand approached to it a vibration, due to the rythmical motion of the air molecules is felt, and luminous streams may be perceived when the hand is held near a pointed projection. When a telephone receiver is made to touch with one or both of its terminals an insulated conductor of some size, the telephone emits a loud sound; it also emits a sound when a length of wire is attached to one or both terminals, and with very powerful fields a sound may be perceived even without any wire.

How far this principle is capable of practical application, the future will tell. It might be thought that electrostatic effects are unsuited for such action at a distance. Electromagnetic inductive effects, if available for the production of light, might be thought better suited. It is true the electrostatic effects diminish nearly with the cube of the distance from the coil, whereas the electromagnetic inductive effects diminish simply with the distance. But when we establish an electrostatic field of force, the condition is very different, for then, instead of the differential effect of both the terminals, we get their conjoint effect. Besides, I would call attention to the fact, that in an alternating electrostatic field, a conductor, such as an exhausted tube, for instance, tends to take up most of the energy, whereas in an electromagnetic alternating field the conductor tends to take up the least energy, the waves being reflected with but little loss. This is one reason why it is difficult to excite an exhausted tube, at a distance, by electromagnetic induction. I have wound coils of very large diameter and of many turns of wire, and connected a Geissler tube to the ends of the coil with the object of exciting the tube at a distance; but even with the powerful inductive effects producible by Leyden jar discharges, the tube could not be excited unless at a very small distance, although some judgment was used as to the dimensions of the coil. I have also found that even the most powerful Leyden jar discharges are capable of exciting only feeble luminous effects in a closed exhausted tube, and even these effects upon thorough examination I have been forced to consider of an electrostatic nature.

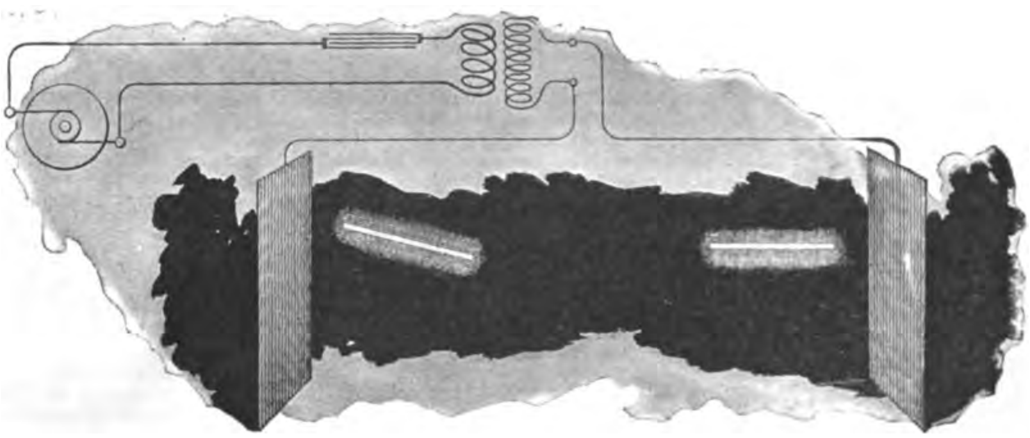

FIG. 30.—IDEAL METHOD OF LIGHTING A ROOM.—TUBES DEVOID OF ANY ELECTRODES RENDERED BRILLIANT IN AN ALTERNATING ELECTROSTATIC FIELD.

In all the cases, then, when we excite luminosity in exhausted tubes by means of such a coil, the effect is due to the rapidly alternating electrostatic potential; and, furthermore, it must be attributed to the harmonic alternation produced directly by the machine, and not to any superimposed vibration which might be thought to exist. Such superimposed vibrations are impossible when we work with an alternate current machine. If a spring be gradually tightened and released, it does not perform independent vibrations; for this a sudden release is necessary. So with the alternate currents from a dynamo machine; the medium is harmonically strained and released, this giving rise to only one kind of waves; a sudden contact or break, or a sudden giving way of the dielectric, as in the disruptive discharge of a Leyden jar, are essential for the production of superimposed waves.

In all the last described experiments, tubes devoid of any electrodes may be used, and there is no difficulty in producing by their means sufficient light to read by. The light effect is, however, considerably increased by the use of phosphorescent bodies such as yttria, uranium glass, etc. A difficulty will be found when the phosphorescent material is used, for with these powerful effects, it is carried gradually away, and it is preferable to use material in the form of a solid.

Instead of depending on induction at a distance to light the tube, the same may be provided with an external—and, if desired, also with an internal—condenser coating, and it may then be suspended anywhere in the room from a conductor connected to one terminal of the coil, and in this manner a soft illumination may be provided.

The ideal way of lighting a hall or room would, however, be to produce such a condition in it that an illuminating device could be moved and put anywhere, and that it is lighted, no matter where it is put and without being electrically connected to anything. I have been able to produce such a condition by creating in the room a powerful, rapidly alternating electrostatic

How then can we hope to produce the required effects at a distance by means of electromagnetic action, when even in the closest proximity to the source of disturbance, under the most advantageous conditions, we can excite but faint luminosity? It is true that when acting at a distance we have the resonance to help us out. We can connect an exhausted tube, or whatever the illuminating device may be, with an insulated system of the proper capacity, and so it may be possible to increase the effect qualitatively, and only qualitatively, for we would not get *more* energy through the device. So we may, by resonance effect, obtain the required electromotive force in an exhausted tube, and excite faint luminous effects, but we cannot get enough energy to render the light practically available, and a simple calculation, based on experimental results, shows that even if all the energy which a tube would receive at a certain distance from the source should be wholly converted into light, it would hardly satisfy the practical requirements. Hence the necessity of directing, by means of a conducting circuit, the energy to the place of transformation. But in so doing we cannot very sensibly depart from present methods, and all we could do would be to improve the apparatus.

From these considerations it would seem that if this ideal way of lighting is to be rendered practicable it will be only by the use of electrostatic effects. In such a case the most powerful electrostatic inductive effects are needed; the apparatus employed must, therefore, be capable of producing high electrostatic potentials changing in value with extreme rapidity. High frequencies are

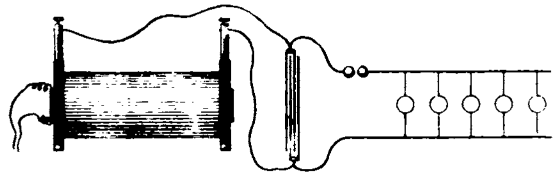

FIG. 31.—DIAGRAM OF CONNECTIONS FOR CONVERTING FROM HIGH TO LOW TENSION BY MEANS OF THE DISRUPTIVE DISCHARGE.

especially wanted, for practical considerations make it desirable to keep down the potential. By the employment of machines, or, generally speaking, of any mechanical apparatus, but low frequencies can be reached; recourse must, therefore, be had to some other means. The discharge of a condenser affords us a means of obtaining frequencies by far higher than are obtainable mechanically, and I have accordingly employed condensers in the experiments to the above end.

When the terminals of a high tension induction coil, Fig. 31, are connected to a Leyden jar, and the latter is discharging disruptively into a circuit, we may look upon the arc playing between the knobs as being a source of alternating, or generally speaking, undulating currents, and then we have to deal with the familiar system of a generator of such currents, a circuit connected to it, and a condenser bridging the circuit. The condenser in such case is a veritable transformer, and since the frequency is excessive, almost any ratio in the strength of the currents in both the branches may be obtained. In reality the analogy is not quite complete, for in the disruptive discharge we have most generally a fundamental instantaneous variation of comparatively low frequency, and a superimposed harmonic vibration, and the laws governing the flow of currents are not the same for both.

In converting in this manner, the ratio of conversion should not be too great, for the loss in the arc between the knobs increases with the square of the current, and if the jar be discharged through very thick and short conductors, with the view of obtaining a very rapid oscillation, a very considerable portion of the energy stored is lost. On the other hand, too small ratios are not practicable for many obvious reasons.

As the converted currents flow in a practically closed circuit, the electrostatic effects are necessarily small, and I therefore convert them into currents or effects of the required character. I have effected such conversions in several ways. The preferred plan of connections is illustrated in Fig. 32. The manner of operating renders it easy to obtain by means of a small and inexpensive apparatus enormous differences of potential which have been

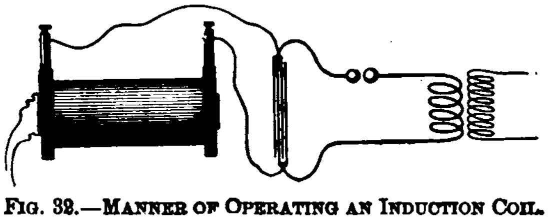

FIG. 32.—MANNER OF OPERATING AN INDUCTION COIL.

usually obtained by means of large and expensive coils. For this it is only necessary to take an ordinary small coil, adjust to it a condenser and discharging circuit, forming the primary of an auxiliary small coil, and convert upward. As the inductive effect of the primary currents is excessively great, the second coil need have comparatively but very few turns. By properly adjusting the elements, remarkable results may be secured.

In endeavoring to obtain the required electrostatic effects in this manner, I have, as might be expected, encountered many difficulties which I have been gradually overcoming, but I am not as yet prepared to dwell upon my experiences in this direction.

I believe that the disruptive discharge of a condenser will play an important part in the future, for it offers vast possibilities, not only in the way of producing light in a more efficient manner and in the line indicated by theory, but also in many other respects.

For years the efforts of inventors have been directed towards obtaining electrical energy from heat by means of the thermopile. It might seem invidious to remark that but few know what is the real trouble with the thermopile. It is not the inefficiency or small output—though these are great drawbacks—but the fact that the thermopile has its phylloxera, that is, that by constant use it is deteriorated, which has thus far prevented its introduction on an industrial scale. Now that all modern research seems to point with certainty to the use of electricity of excessively high tension, the question must present itself to many whether it is not possible to obtain in a practicable manner this form of energy from heat. We have been used to look upon an electrostatic machine as a plaything, and somehow we couple with it the idea of the inefficient and impractical. But now we must think differently, for now we know that everywhere we have to deal with the same forces, and that it is a mere question of inventing proper methods or apparatus for rendering them available.

In the present systems of electrical distribution, the employment of the iron with its wonderful magnetic properties allows us to reduce considerably the size of the apparatus; but, in spite of this, it is still very cumbersome. The more we progress in the study of electric and magnetic phenomena, the more we become convinced that the present methods will be short-lived. For the production of light, at least, such heavy machinery would seem

FIG. 33.—LAMP KEPT AT INCANDESCENCE ACROSS A THICK COPPER BAR—SHOWING NODES.

to be unnecessary. The energy required is very small, and if light can be obtained as efficiently as, theoretically, it appears possible, the apparatus need have but a very small output. There being a strong probability that the illuminating methods of the future will involve the use of very high potentials, it seems very desirable to perfect a contrivance capable of converting the energy of heat into energy of the requisite form. Nothing to speak of has been done towards this end, for the thought that electricity of some 50,000 or 100,000 volts pressure or more, even if obtained, would be unavailable for practical purposes, has deterred inventors from working in this direction.

In Fig. 31 a plan of connections is shown for converting currents of high, into currents of low, tension by means of the disruptive discharge of a condenser. This plan has been used by me frequently for operating a few incandescent lamps required in the laboratory. Some difficulties have been encountered in the arc of the discharge which I have been able to overcome to a great extent; besides this, and the adjustment necessary for the proper working, no other difficulties have been met with, and it was easy to operate ordinary lamps, and even motors, in this manner. The line being connected to the ground, all the wires could be handled with perfect impunity, no matter how high the potential at the terminals of the condenser. In these experiments a high tension induction coil, operated from a battery or from an alternate current machine, was employed to charge the condenser; but the induction coil might be replaced by an apparatus of a different kind, capable of giving electricity of such high tension. In this manner, direct or alternating currents may be converted, and in both cases the current-impulses may be of any desired frequency. When the currents charging the condenser are of the same direction, and it is desired that the converted currents should also be of one direction, the resistance of the discharging circuit should, of course, be so chosen that there are no oscillations.

In operating devices on the above plan I have observed curious phenomena of impedance which are of interest. For instance if a thick copper bar be bent, as indicated in Fig. 33, and shunted by ordinary incandescent lamps, then, by passing the discharge between the knobs, the lamps may be brought to incandescence although they are short-circuited. When a large induction coil is employed it is easy to obtain nodes on the bar, which are rendered evident by the different degree of brilliancy of the lamps, as shown roughly in Fig. 33. The nodes are never clearly defined, but there are simply maxima and minima of potentials along the bar. This is probably due to the irregularity of the arc between the knobs. In general when the above described plan of conversion from high to low tension is used, the behavior of the disruptive discharge may be closely studied. The nodes may also be investigated by means of an ordinary Cardew voltmeter which should be well insulated. Geissler-tubes may also be lighted accross the points of the bent bar; in this case, of course, it is better to employ smaller capacities. I have found it practicable to light up in this manner a lamp, and even a Geissler tube, shunted by a short heavy block of metal, and this result seems at first very curious. In fact, the thicker the copper bar in Fig. 33, the better it is for the success of the experiments, as they appear more striking. When lamps with long slender filaments are used it will be often noted that the filaments are from time to time violently vibrated, the vibration being smallest at the nodal points. This vibration seems to be due to an electrostatic action between the filament and the glass of the bulb.

In some of the above experiments it is preferable to use special lamps having a straight filament as shown in Fig. 34. When such

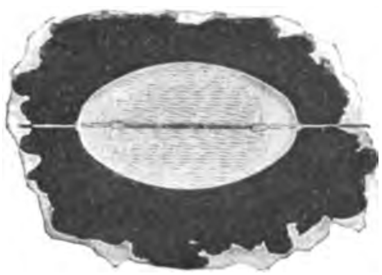

FIG. 34.—PHENOMENON OF IMPEDANCE IN AN INCANDESCENT LAMP.

a lamp is used a still more curious phenomenon than those described may be observed. The lamp may be placed across the copper bar and lighted, and by using somewhat larger capacities, or, in other words, smaller frequencies, or smaller impulsive impedances, the filament may be brought to any desired degree of incandescence. But when the impedance is increased, a point is reached when comparatively little current passes through the carbon, and most of it through the rarefied gas; or perhaps it may be more correct to state that the current divides nearly evenly through both, in spite of the enormous difference in the resistance, and this would be true unless the gas and the filament behave differently. It is then noted that the whole bulb is brilliantly illuminated, and the ends of the leading-in wires become incandescent and often throw off sparks in consequence of the violent bombardment, but the carbon filament remains dark. This is illustrated in Fig. 34. Instead of the filament a single wire extending through the whole bulb may be used, and in this case the phenomenon would seem to be still more interesting.

From the above experiment it will be evident, that when ordinary lamps are operated by the converted currents, those should be preferably taken in which the platinum wires are far apart, and the frequencies used should not be too great, else the discharge will occur at the ends of the filament or in the base of the lamp between the leading-in wires, and the lamp might then be damaged.

In presenting to you these results of my investigation on the subject under consideration, I have paid only a passing notice to facts upon which I could have dwelt at length, and among many observations I have selected only those which I thought most likely to interest you. The field is wide and completely unexplored, and at every step a new truth is gleaned, a novel fact observed.

How far the results here borne out are capable of practical applications will be decided in the future. As regards the production of light, some results already reached are encouraging and make me confident in asserting that the practical solution of the problem lies in the direction I have endeavored to indicate. Still, whatever may be the immediate outcome of these experiments I am hopeful that they will only prove a step to further development towards the ideal and final perfection. The possibilities which are opened by modern research are so vast that even the most reserved must feel sanguine of the future. Eminent scientists consider the problem of utilizing one kind of radiation without the others a rational one. In an apparatus designed for the production of light by conversion from any form of energy into that of light, such a result can never be reached, for no matter what the process of producing the required vibrations, be it electrical, chemical or any other, it will not be possible to obtain the higher light vibrations without going through the lower heat vibrations. It is the problem of imparting to a body a certain velocity without passing through all lower velocities. But there is a possibility of obtaining energy not only in the form of light, but motive power, and energy of any other form, in some more direct way from the medium. The time will be when this will be accomplished, and the time has come when one may utter such words before an enlightened audience without being considered a visionary. We are whirling through endless space with an inconceivable speed, all around us everything is spinning, everything is moving, everywhere is energy. There *must* be some way of availing ourselves of this energy more directly. Then, with the light obtained from the medium, with the power derived from it, with every form of energy obtained without effort, from the store forever inexhaustible, humanity will advance with giant strides. The mere contemplation of these magnificent possibilities expands our minds, strengthens our hopes and fills our hearts with supreme delight.

LONDON.

Communication with Lighthouses.—Law Cases.—Making of Phosphorus by Electricity.

YESTERDAY Sir M. Hicks-Beach received at the Board of Trade a deputation from the Associated Chambers of Commerce which asked that a system of telegraphic or telephonic communication might be established between coast-guard and life-boat stations, lighthouses and light-ships, and the general telegraphic system of the country. The memorial which was presented set forth the need for this communication, instancing the wreck of the Schiller, when 331 lives were lost close to the Bishop Lighthouse. The coroner's jury found that had the lighthouse-keepers been able to communicate with the shore, the whole of these 331 lives would have been saved. It was a matter of national importance that means of communicating with the shore should be provided, and it was estimated that this could be done for £100,000. In time of war the information that could be given of the movement of ships would be most valuable to the naval and military authorities. Other countries, such as France, Denmark, Norway, Holland, Sweden, Canada, and the Cape, had their lighthouses connected by telegraph and telephone with the general telegraphic systems of those countries. Sir Michael Hicks-Beach in reply said the movement had his sympathy, but he would recommend them to see the Chancellor of the Exchequer.

Two cases of interest will be brought before the courts at an early date. In one Messrs. Crompton are engaged in an action with Phillips Brothers, the dispute having arisen as to certain wire supplied. The other is the Lane-Fox claims, which will be either finally quashed or upheld.

The Electrical Construction Corporation have begun to make phosphorus by electricity. H. S.

LONDON, June 8, 1891.

City Electric Railway.—The Earth and Electric Railway.—Electric Lighting Orders.

The City Railway Co. yesterday held an extraordinary general meeting for the purpose of raising some additional capital to carry out further extensions.

The chairman, in the course of his remarks, said he considered the working had been satisfactory, seeing that they had had to educate the staff in the new power with which they worked their line. The electrical engines, however, had not been equal to the growing service, and they had ordered new locomotives by which they hoped to improve their service and run the trains more frequently. During the time the line had been opened they had carried 3,000,000 passengers in perfect safety. They were earning an income at the present time at the rate of £40,000 a year, and after meeting all expenses, they estimated that this amount left a profit of £12,000, which, though a small sum, was sufficient to cover their debenture interest and to leave a surplus of £3,000 or £4,000. It was decidedly a cheerful tone adopted by the chairman, and convinced the shareholders that things were in a good condition, but there were one or two rather ominous suggestions for the future dividends of ordinary shareholders. If, as the chairman said, they were able to increase their traffic to the extent of £20,000 a year they could pay a dividend of 3½ per cent. It is difficult to see how this is to be done, for, to increase their income they must extend their line further, and to meet the expense of such an extension it would be necessary to get further capital which would, of course, swallow up any small dividends.

Work in connection with the electric lighting of Dublin has been commenced in real earnest. The building of the central station is going on rapidly, and not many months will elapse before something substantial is the result.

For some months past the Greenwich observations on the earth's magnetic currents have been interfered with in a mysterious manner. This disturbance consists in a continuous vibration of the registering needles, commencing just before seven o'clock in the morning, going all through the day, and terminating shortly after eleven o'clock at night. This went on for a long time on week days only; but on Sunday, the 5th of April, and on every succeeding Sunday up to the present time, the interference has been experienced, from about one o'clock in the afternoon till about 10 P. M. or a little later. It has now been determined that these disturbances are due to the electric railway between Stockwell and the city, corresponding as they do, exactly with the working hours on that line, the Sunday disturbances not beginning until trains were run on that day. The curious part about this phenomena is that the distance between the railway and Greenwich Observatory is about 4 miles. Ferranti's Deptford station is within a few hundred yards.

Some five or more years ago, Mr. Ellis notes, a similar disturbance was registered in the circuit on the south bank of the Thames. The cause was not traced at the time, although it has been conjectured to be in some way connected with the electric "installations" in progress at the time. H. S.

LONDON, June 17, 1891.

Letters to the Editor.

THE PRINCIPLE OF THE WINKLER DYNAMO.

In your issue of June 24th, we notice a cut and description of a new "Universal" dynamo, viz., the Winkler. From the description given, the claim for newness is based upon the fact of the armature having a commutator at each end and wound with two independent windings. We also notice that the inventor claims for the machine that by this means he does away with all sparking, and also dispenses with the use of a rheostat. It is useless, however, to dilate upon the many advantages claimed for the machine, as it is not that question that we wish to discuss—it is the newness of the idea or invention. In the year 1882, Mr. F. A. La Roche, of Philadelphia, constructed several machines of the same general principle, and operated them successfully, doing even more than the Winkler machine will do by running both arc and incandescent lights from the one machine or two separate and distinct circuits; and at times I used the one circuit for charging fields alone. We have now one of our old machines on hand that was built about seven years ago by our firm.

F. A. LA ROCHE.

PHILADELPHIA, PA.

Society and Club Notes.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

At the regular monthly meeting of the Council of the American Institute of Electrical Engineers, the following delegates were appointed to attend the Frankfort Electrical Conference, in accordance with a resolution adopted at the general meeting, May 21st: Carl Hering, chairman; Prof. R. O. Heinrich, Nikola Tesla, Dr. E. L. Nichols. Prof. Heinrich is already in Europe, and Mr. Hering sailed July 2d on the Normannia.

The following associate members were elected:

Barnard, John H.; general manager, Asheville Street Railway Co., and Asheville Light and Power Co., Asheville, N. C.
Cram, Henry B.; treasurer, Bernstein Electric Co., 175 Prospect street, Cambridgeport, Mass.
Dame, Frank L.; superintendent, Vancouver Electric Railway and Light Co., Vancouver, B. C.
Emery, Charles Edward; consulting engineer, 22 Cortlandt street, New York.
Fay, Thomas J.; Maine Electric Improvement Co., 136 Liberty street, New York.
Fisk, Walter C.; manager, Bernstein Electric Co., 620 Atlantic avenue, Boston, Mass.
Gans, John L.; superintendent and electrician, The Electric Company, Connellsville, Penn.
Hadley, Warren B.; superintendent wiring department, Edison Electric Illuminating Co., 431 Fifth avenue, New York.
Healy, Louis W.; The Wightman Electric Co., 1,205 Marion street, Scranton, Pa.
Kellogg, James W.; assistant to district engineer, Edison General Electric Co., 140 E. 27th street, New York.
Luquee, Thatcher T. P.; assistant in surveying and practical mining, and student in electrical engineering, Columbia College, N. Y. and Bedford, N. Y.
Rosebrugh, Thomas Reeve; lecturer in electrical engineering, School of Practical Science, Toronto, Ont.
Taintor, Giles; assistant electrician, N. E. Telephone and Telegraph Co., 7 Walnut street, Boston, Mass.
Wirt, Herbert C.; electrician, marine department, Thomson-Houston Electric Co., 12 Millmont street, Roxbury, Mass.
Woodward, Francke L., student in electricity, 49 Grand street, Albany, N. Y.

Mr. Jesse M. Smith, was transferred from associate to full membership.

No further meetings of the Institute will be held until September.

ASSOCIATION OF EDISON ILLUMINATING COMPANIES.

The annual meeting of this association has now been definitely arranged to be held in this city on August 11, and preparations have been begun by Secretary Jenks. It is expected that the convention will be one of the largest ever held by the association. The Edison General Electric Co. will extend hospitalities to the members by arranging for special trips to the Schenectady and other Edison factories.

Reports of Companies.

AMERICAN BELL TELEPHONE CO.

The Bell Telephone Company has declared a regular quarterly dividend of 3 per cent. and an extra one of 6 per cent. It will take $1,350,000 to pay this dividend. The business of the American Bell Telephone Co. is steadily on the increase. On June 20, 1891, there were 502,953 instruments in licensees' hands under rental, against 483,790 on December 20, 1890, a gain of 19,163; and 465,334 on June 20, 1890, a gain of 36,619, or 8 per cent.

THE EMPIRE CITY ELECTRIC COMPANY.—A VOLUNTARY DISSOLUTION.

On Monday, June 29, the Empire City Electric Company, of New York, applied to the Supreme Court for the appointment of a receiver to liquidate its business, the directors of the company having decided to make a voluntary dissolution. Judge Beach granted the application, and appointed as receiver Charles S. Beardsley, of Yonkers, N. Y. It is stated, in behalf of the company that its business has been conducted at a loss during the past six months. The officers and principal shareholders are unwilling to invest further, and deem a voluntary liquidation the most expedient course to pursue in justice to their creditors and themselves. It is reported that the condition of the company's affairs is such as to indicate that creditors will be paid in full. No statement of assets and liabilities has yet been published. The receiver, Mr. Beardsley, is now in possession.

Appointments, Etc.

MR. A. H. HARDY TROTT, late of the Thomson-Houston Electric Co. has been appointed electrical engineer of the Georgetown, Demerara, Electric Lighting Co., now about to extend its plant.

MR. HARRY W. TRUE, of Natick, will be the new manager of the Woburn, Mass. Electric Light Co.

MR. HOMER CORSE has been elected superintendent of the Groveton Electric Co., of Groveton, N. H.

MR. W. S. REED, of Kankakee, Ill., has been appointed vice-president and general manager of the Harvey Water, Electric Light & Street Railway Co.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

Convince the public that you have a right to its attention, and it will always listen to you.

THE CLIMAX NOISELESS GEAR.

The accompanying illustration represents a novel form of gear wheel recently designed by the Climax Mfg. Co., of Buffalo, N. Y. It is especially adapted to mill work, electric motors, and other machinery where high duty and speed is required.

The points of excellence claimed for this gear are simplicity of construction and durability. It is made of two pieces firmly riveted together, making it impossible for the parts to work loose or for the wheel to get out of true. The teeth are machine cut, are perfect in shape and pitch, and are made in two sections, with a circumferential space between each set, and placed in such a way that each tooth of one part registers exactly with the space of the other, making the pitch practically one-half that for which

CLIMAX NOISELESS GEAR.

it is cut, and at the same time preserving the strength. This peculiar arrangement of the teeth enables the gear to engage with the pinion closely and accurately twice the usual number of teeth, thus preventing any vibration or "backlash," and, with the addition of a chamber in the web of the gear filled with non-sonorous material, the wheels when at work are practically noiseless. The space between the two sets of teeth prevents injurious contact between the teeth of the two wheels should a slight lateral displacement occur. These wheels are made of iron, and the pinions of steel, and, aside from their noiselessness, are recommended on account of their long life and durability.

C. & C. FAN OUTFITS.

The "partial list" of users of the C. & C. fan outfits has now become a fat little pamphlet of 24 pages. Even this does not disclose the full extent of the business. In New York, for example, there are nearly 250 users of these fan outfits, but many of them have ten or a dozen; and it would not be safe to say how many more have been put in during the recent hot spell. These outfits are also widely scattered all over the country, and are to be found in Japan, Canada, and other countries. The C. & C. Co. has also made a great success of its Blackman ventilating fan combination and of its blower combination for ships. The latter is now in use on board seven U. S. men-of-war.

PITTSFIELD, MASS., ELECTRIC CO.

A most interesting and valuable little brochure has been issued by the above company for the instruction and benefit of its customers, and we really must congratulate Mr. W. A. Whittlesey on so neat and masterly a piece of work. It is a model of the kind of literature that should be addressed to the actual and probable customers of a local company, and will beyond question do lots of good.

HEISLER ELECTRIC LIGHT CO.

The Heisler Electric Light Co. of Philadelphia, through their agents, the Belton Electric Co., of Belton, Tex., have just sold a complete plant at Hallettsville, Tex.

NEW YORK CITY NOTES.

THE ELECTRIC RAILWAY SPECIALTY Co. have removed their offices from 50 Broadway to the Columbia Building, 29 Broadway. This company are general agents for R. D. Nuttall & Co., and deal in railway specialties of all kinds.

MESSRS. TRUEX & VAIL, of the Electrical Exchange Building received this letter relating to the efficiency of their Swinging Ball Lightning Arrester:

ELIZABETH, N. J., June 18, 1891.

To MESSRS. TRUEX & VAIL.

Gentlemen:—In reply to your inquiry in reference to the damage done in the recent storm to our plant, would say that the account in the New York *World* newspaper of to-day is entirely wrong. The facts in the case are: We have just started an Edison power circuit in this city and had not provided it with lightning arresters, except two of the old style, which were placed in the station in the usual manner. These carried off the small inductive discharges for the early period of the storm until the very heavy and direct stroke came, when it passed the arrester and made a report like a cannon and burned out several sections of the generator armature. We had a spare armature and put the machine in operation that night. We have the Swinging Ball Arresters on our incandescent circuits, and on those circuits there was not a light out. We desire you to send us as many arresters of the Swinging Ball pattern as are necessary to thoroughly protect our power circuit, the voltage of which is 220. We may mention that we saw the Swinging Ball Arresters on the incandescent circuits, which are in the station board at work snapping off the discharges. The storm was unusually severe and struck buildings in town.

Respectfully yours,

ELIZABETH-SCHUYLER ELECTRIC CO.,

per F. H. TIDMAN, *General Manager.*

J. G. WHITE & Co. have removed their offices from 50 Broadway to the Columbia Building, where they will be glad to welcome their many friends.

MESSRS. TAYLOR & SON, of 39 Dey street, have made an improvemement in the connection of the carbon pole of their well-known primary battery. Some of the batteries which have been shipped have not worked satisfactorily owing to the carbon pole having been affected by the acid and eaten off. As this new improvement eliminates the difficulty entirely, and as Mr. Taylor desires to keep up the standard of his battery, he places this new improvement on any batteries which have been affected by the drawback cited above.

ENGINEERING EQUIPMENT CO.

WHEN it was announced last February that a number of men of good record and excellent experience in the practical affairs of the electrical equipment business were to associate themselves under the name of the Engineering Equipment Company, with headquarters in New York City, an early success and a bright future for the enterprise was predicted. This prediction has already been fulfilled in large measure, although but about four months have elapsed since the company received its first order. Among those interested in promoting the success of this company are: C. J. Field, M. E.; Albert C. Hale, Ph. D.; F. L. Perine; A. L. Tinker; F. A. Magee, M. E.; W. F. D. Crane, M. E.; C. S. Merrill, C. H. Sewall and R. B. Cone.

The company is engaged solely in the business of furnishing steam and electric equipment materials. No construction work is attempted, although facilities are at command which enable them to secure the "inside track" on figures for construction of steam power plants and electric railways. The company handles certain specialties of recognized value in the trade, and controls, in large measure or wholly, the selling of these goods in this country, in Canada, and in South America. No attempt is made to secure orders on miscellaneous steam or electrical supplies. Customers are catered to for large orders on the most important equipment materials, and, with the single exception of belting, no small orders are filled, unless as a matter of accomodation.

The Engineering Equipment Company have their chief offices in the Central Building, 143 Liberty street, New York; their stock and repair rooms at 75 Cortlandt street, New York, and their Eastern offices and salesrooms at 126 Pearl street, Boston, Mass. This company is the sole Eastern selling agency for cotton leather belting and belting specialties, manufactured only by the Underwood Mfg. Co., and for the Boston trolley and line materials, made solely by Albert & J. M. Anderson. It is also the United States and Canadian selling agency for the indurated fibre pipe, produced only at Mechanicville, New York; the Kellogg steel centre and side poles, made by the Kellogg Iron Works, of Buffalo, New York; Eastern selling agents for Habirshaw wire, cables and cores; and general agents for the machine tools manufactured by Edward Harrington Son & Co.

In addition to the foregoing lines of equipment materials, the Engineering Equipment Company deal in boilers and engines, wooden poles and cross-arms, cars, trucks, iron roofs, cranes, etc.

Those who need standard equipment materials at close figures for large quantities will do well to correspond with this enterprising and reliable company, by which large orders are being filled to the full satisfaction of customers.

MR. J. BRONILET has been appointed electrician of the Berkeley, Cal. Rapid Transit Road.

IMPROVED "STANDARD" BATTERY GAUGE.

THE Standard Electric Time Co., of New Haven, Conn., have just put their improved pocket battery gauge on the market.

This is similar in appearance to the one formerly advertised in this paper, but the mechanical parts have been changed considerably, thereby making it much stronger and less liable to damage in use or transportation.

THE TAYLOR FAN OUTFIT.

Seeing that for an initial outlay of $5 and an expense for maintenance of about half a cent an hour at the most, one can enjoy cooling breezes from an electric fan, it follows that the demand for such fans must be enormous as they become known. Taylor & Son, 39 Dey street, are making a great hit with their little fan outfit, which just answers these conditions. The motor is well built and has a 4-bladed fan, the whole thing standing 6½ inches high. Their No. 2 cell runs the motor for 12 hours on a charge which costs 6 cents, and if the solution powder is bought in larger quantities the cost is proportionally reduced.

NEW HEISLER CONTRACTS.

After a very close competition, the Heisler Electric Light Co., of Philadelphia, carried off the prize and secured the contract for an incandescent electric light plant at West Toronto Junction, Can. This company has also just sold a plant for Morrilton, Ark. They have also closed contract for an electrical installation for the Corporation of Halletsville, Texas. This contract was secured by the general agents of the Heisler Electric Light Co. for the State of Texas, M. V. Smith & Son, of Belton, Tex.

THE WORLD'S FAIR.

Mr. E. E. Keller, one of Chicago's prominent electrical engineer's and a man well known in electrical circles from his long association with the business as manager of the North American Construction Co. until the recent withdrawal from business of the company, ha saccepted an appointment from the World's Columbian Exposition as assistant electrical engineer to Prof. J. P. Barrett, Chief of the Electrical Dept., to develop and carry out the Professor's ideas and the general technical electrical work of the department. It is a position for which Mr. Keller is eminently suited, having had a wide practical and technical experience in electrical matters and especially in the arrangement, construction and erection of electrical and power machinery, and Prof. Barrett is to be heartily congratulated on his selection of so wide-awake, well-posted and energetic an assistant.

NOVELTY ELECTRIC CO.

The above company, of 50, 52 and 54 North Fourth street, Philadelphia, have published a large and very handsome catalogue of their wares and specialties. It is known as No. 15, and is 14 by 10½ inches, with 51 pages. As a frontispiece it has four fine views of the company's offices, salesroom, factory and engine room, showing a most convenient and commodious establishment. In the arrangement of the catalogue a very original method has been adopted. All the various cuts are grouped together successively, each with a simple explanatory caption. Then at the end of the book each page is taken in its turn, and very full details are given of the apparatus. In this way one gets a bird's-eye view, so to speak. of all the various apparatus in any one line, and is not bothered to keep on turning over 20 or 30 pages. After this section come several pages devoted to insulated wires, cords, cables, etc., and a variety of minor appliances. The catalogue is beautifully printed and has a stiff bronze cover and cloth back.

RAW HIDE PINIONS ON STREET CARS.

The New Process Raw Hide Co. have received the following from the Syracuse, N. Y., Consolidated Street Railway Co., under date of June 12:—" After several months' use of your pinions upon our electric cars, we are so well satisfied that we have concluded to use them on all our cars now building, and recommend them to all companies who desire to study economy, durability and comfort."

THE A. U. ALCOCK ELECTRIC LIGHT CO.

Our last Australian mail brought the third half-yearly report of the above company, of Melbourne, Victoria. It appears that the company finds a very ready appreciation of the electric light, and is preparing to build a new and very large central station at Richmond to supply Melbourne and its suburbs. Of 15,000 shares issued for the purpose, 7,000 have already been taken up by the stockholders and the remainder will be offered to the public. The Richmond station will soon be ready, and the company will sell by meter. Mr. A. U. Alcock, M. I. E. E., is the managing director and electrical engineer.

A BIG ACCUMULATOR ORDER.

Mr. Wm. Hood, the Western agent of the Accumulator Co., has recently booked one of the largest orders for storage batteries for an isolated plant ever placed. It comprises 600 15 L type, 300 ampere hour cells, which are to be used for a private lighting plant in the residence of Mr. James J. Hill, the owner of the Great Northern Railway, at St. Paul, Minn. There will be ten series of 60 cells each, giving a storage capacity for 650 16-candle power incandescent lamps for a ten-hour run. The batteries alone will require two or three freight cars to haul them to St. Paul. The landing of such a stupendous order reflects great credit on Mr. Hood, who has secured some of the largest orders for the Accumulator Company that they have ever received. Among others will be remembered the storage battery equipment for the Dubuque Street Railway Co., of Dubuque, Iowa.

NEW "WESTERN ELECTRIC" BOX BELL.

WE illustrate on this page a new box bell introduced by the Western Electric Co. It is called their "Chicago iron box bell." As will be seen, it is simple and compact. It gives a maximum power with a minimum of battery, on account of the shape and

THE "WESTERN ELECTRIC" BOX BELL.

disposition of the magnets. With one cell of battery the bell will ring over a length of 600 to 800 feet of No. 18 wire, so that for any ordinary call a single cell of battery will suffice. The hammer and armature are made from a single punching, which is copper-plated to prevent rusting. Each bell is thoroughly tested and adjusted before shipment and is guaranteed in every respect.

A BOOK FOR ADVERTISERS.

Geo. P. Rowell & Co., the well-known advertising agents, of 10 Spruce street, have just issued a "Book of Advertisers," of 368 pages, in paper cover for $1 and in cloth for $2. It contains lists of the best American newspapers and of all the trade journals, with circulation ratings, information about advertising rates, and hints as to the best means of placing newspaper advertising. Such a manual proves of the utmost value to advertisers, who always and naturally want the greatest possible return for their outlay.

THE "W. B. G." PROTECTOR FOR TELEPHONE CIRCUITS.

On this page we illustrate the "W. B. G." Protector. The inventors of this device are practical telegraph and telephone men, and understand fully the necessity nowadays of a thoroughly reliable protector for telephone and telegraph stations and instruments. Of course, any device that would be efficient in these two lines of electrical business, would be equally so in others, where apparatus is exposed to damage from heavy or abnormal currents. The protectors are mounted, 1, 2, and 3 on a base, (which is of vulcanized fibre) and in sections of 50, handsomely finished.

The single, double, and triple protectors are intended for use at telephone subscribers' stations and are mounted to accommodate "single," "metallic," and "law system," wiring. The sections of 50 are intended for use at central offices, or any place where a large number of wires enter. They are also mounted to order.

The main feature of the invention is the manner in which the fuse is melted by the generation of heat in the small coil of comparatively high resistance wire, which is wound upon one end of

The "W. B. G." Protector for Telephone Circuits.

the fuse, and which is part of the circuit. The coil is formed of German silver wire of size and length necessary to produce heat enough to melt the fuse upon the passage of any current that it may be deemed desirable to have the line "open" at. For ordinary use at subscribers' stations, they are wound to open the line at about 4-10 ampere, and for use at other places, such as central offices, where more delicate apparatus may need protection, they are wound accordingly.

The principle upon which they operate is well known and very simple, and it is evident that the device is an excellent protection against the "sneak" current, so destructive to electrical apparatus, containing electromagnets and coils of fine wire, as well as against heavy or abnormal currents.

It is also used in cable boxes, and, by a very simple arrangement, forms good protection agains lightning, as well as strong currents. These devices are already manufactured and on sale by the supply house of the E. S. Greeley & Company, of New York, who are headquarters for the goods.

The Triumph Compound Engine Co., Cincinnati, O., are doing a phenomenal business with their engines, which are giving remarkable and satisfactory results on account of their small fuel consumption and excellent service.

"THE UNITED ELECTRIC CO."

There has been a good deal of talk in the newspapers during the past week as to an electrical supply combination, and some very wild statements have been made. The rumors may, perhaps, have been due to the fact that a movement was set on foot out West about a month ago by leading men in the business for the formation of the Electrical Supply Dealers' Association, for the whole country, but the work of that body is only intended to be protective in a general way. Anyhow, the actual truth, so far as it can now be got at, is that under the name of the United Electric Co., which is now forming under the laws of Maine, the three well-known Eastern supply houses of Pettingell-Andrews Co., of Boston; Alexander, Barney & Chapin, of New York; and the Southern Electric Co., of Baltimore, have effected a consolidation, with a capital stock of $1,000,000. One or two other affiliations are spoken of, and it is said that the new concern will control the output of nine factories. Prices will not be raised, but will tend lower, owing to the economy of management, and the saving on large purchases. It is reported that the new concern will begin business under its own name August 1.

WESTERN TRADE NOTES.

Mr. F. H. Burger, the representative of the "Universal" arc lamp, 42-44 Broad street, New York, was in Chicago last week, and states that this famous arc lamp for incandescent circuits is meeting with great success in the West, and orders are rapidly coming in.

Mr. R. Humffreys-Roberts, secretary and manager of the Fontaine Crossing Co., spent a few days in Chicago last week on business in connection with the new slow-speed dynamos which are meeting with such success in ship-lighting plants. Mr. Roberts dropped in at the Western office of The Electrical Engineer.

Mr. W. F. D. Crane, M.E., the engineer of the Engineering Equipment Co., 143 Liberty street, New York, was a welcome caller at the Western office of The Electrical Engineer last week. Mr. Crane is making a short stay in Chicago looking up matters mechanical and electrical.

Mr. Clift Wise, the chief engineer of the Interior Conduit & Insulation Co., has just returned from Minneaopolis, where he conducted a very complete test of their underground feeder conduits, which showed the isulation to be perfect in every particular, the tests showing on the conduit feeders as high as 87 megohms. It will be remembered that bare conductors are used in this conduit, and the results showed the soundness of Mr. Wise's judgment in carrying out the work in this daring manner.

The Central Electric Co. are prepared to furnish the Bryant all-porcelain key and keyless sockets for Sawyer, Thomson-Houston, Brush-Swan, and Edison bases.

The Central Electric Co. report having secured more orders during the last month for special Okonite cables than ever before, and trade in general electrical supplies of all kinds is exceedingly large.

The Central Electric Co. are placing a new lead-covered cable on the market, which is known as the "Acme." It is composed of the Okonite insulation specially treated, and is designed for use under water with high voltage currents. They have recently sold one of these Okonite lead-covered cables for use in water, and have guaranteed it to withstand 5,000 volts, to which enormous pressure it will be subjected in regular service. The Central Electric Co.'s Packard lamp is rapidly coming into general favor, and they report more than 10,000 sold last month, and the new tied filament lamp of any candle power for street car use is meeting with universal approval.

Mr. George Cutter is enlarging the capacity of his shop so as to keep up with the growing demand for his pulleys and street-hoods. On his recent Eastern trip he disposed of the inventions which have been developed in his shop, and found that there is plenty of room for such specialties as he is making.

The Cicero & Proviso Electric Street Railway line is proving exceedingly popular and an immense success. It runs on West Madison street from West 48d to Harlem avenue, and returns on West Lake to West 48th and thence to Madison and back to starting point. The week-day traffic is considerable, and is steadily growing, and the Sunday line carries a very large complement of passengers. Real estate values have also been considerably enhanced by the new road.

THE
Electrical Engineer.

VOL. XII. JULY 15, 1891. No. 169.

THE FRANKFORT INTERNATIONAL ELECTRICAL EXHIBITION—I.

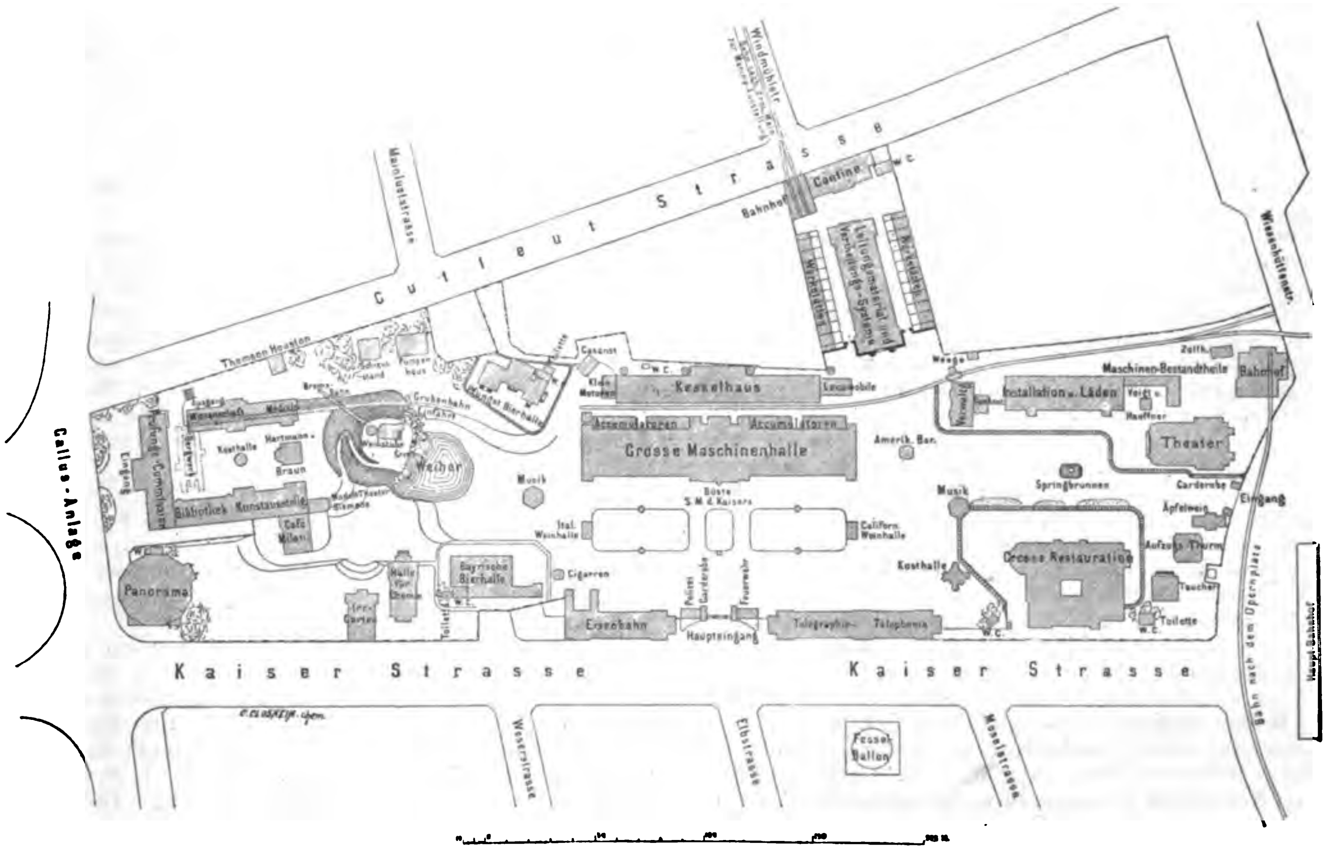
BY

Richard O. Heinrich.

NOW that nearly everything is in running order, the "Internationale Electrotechnische Ausstellung zu Frankfurt-am-Main" must be voted a great success. Most gratifying to the eye is the thoroughly artistic execution of everything on the spot, from the imposing "Machinery Hall" down to the American Bar and the drop-a-nickel-in-the-slot devices. The wiring and installation work in its extreme neatness will be a revelation to the American. The arc lamps make an excellent impression with their steady, noiseless burning.

It may be well to give intending visitors from abroad a superficial idea of what is to be seen in the exhibition. Directly opposite the main entrance is the very ornamental and imposing Machinery Hall with the boiler-house in the rear. Twenty boilers of different makes furnish steam for the engines in Machinery Hall, which aggregate about 3,000 h. p. Nearly 1,000 more are furnished by gas, petroleum and benzine motors. This boiler-house will furnish many very interesting points to the central station manager. Scarcely anything is missing of the modern devices which insure thorough economy and a complete utilization of fuel and water.

The exhibits in Machinery Hall are magnificent, and some highly interesting novelties may be seen and studied there. Between 60 and 70 engines of different makes furnish power to the dynamos exhibited. A pronounced tendency is apparent of coupling directly very large dynamos to tremendous compound engines with vertical cylinders. The majority of the engines are those intended for central station work, but quite a number of smaller gas and petroleum motors, amongst them some highly perfected types as regards regulation, illustrate the application of that class of machinery to isolated electric illumination.



PLAN OF THE FRANKFORT ELECTRICAL EXHIBITION.

One of the most interesting features and one necessitating a scrutinizing study is the "Drehstrom" motor and dynamo. Some objections have been raised against this newly coined word "Drehstrom" (rotary current), for which an English word has yet to be invented. Indeed it does not seem to cover in its signification the nature of the three-phase alternating current employed. Three different firms exhibit this new system of transmission of electrical energy for light and motor purposes. Lahmeyer

& Co., of Frankfort-on-the-Main, make a very complete exhibit of their system which also includes, besides the "Drehstrom" motors and dynamos, a system of transmission by direct current transformation by the employment of a combined motor-dynamo, that is, an electric motor which has an extra winding on the armature for the purpose of having a current generated in it for the various purposes of lighting, power transmission and charging of storage batteries. I hope to be able to give you very full information on these novelties very shortly.

The alternating current machines are, of course, fully represented, the machines of Siemens and those of "Helios," the agents for Ganz & Co., of Budapest, are the most noteworthy ones. Of long-distance power transmission we find one from the "Palmengarten," 4 kilometres distant; from Offenbach, 14 km. distant; and the one great feature to which the electrical fraternity all over the world looks with so much interest, namely, the transmission of 300 h. p. from Lauffen to the exhibition, which is to be finished, according to contract, by the middle of August.

For this transmission the Portland cement works of Lauffen furnish the turbines to utilize 300 h. p. of the Lauffen Falls. The Oerlikon works have built the necessary "Drehstrom" dynamos, which are to furnish 4,000 amperes at 50 volts. A step-up transformer will send this energy at 25,000 volts pressure from its secondary over 3 wires of 4 mm. diameter each. These wires, furnished for the purpose by Hesse & Söhne, Heddenheim, are stretched on oil insulators for a distance of 175 kilometres to the exhibition, where a step-down transformer will furnish what is left of the 300 h. p. for lighting purposes and for the running of the "Drehstrom" motors of the Allgemeine Elektricitäts-Gesellschaft.

A separate building to the southeast of Machinery Hall contains electrical appliances for central station work, overhead and underground cables and underground conduits. Felten & Guilleaume make a splendid exhibit of their famous cables. Some very beautiful metal spinning and drawing is exhibited in this building. To either side of this are workshops in which the application of the electric motor to workshop machinery is shown to advantage. This part of the exhibition, although by no means a very complete one, gives a fair idea to the non-technical public of the great flexibility, convenience and safety of the electric transmission of power. Our beloved American fan motor seems to have found no demand; there is none to be seen, but some large ventilators, driven by electric motors of course, provide the buildings with fresh air where needed.

The part of the exhibition showing the application of electric light to domestic purposes is a revelation in more than one sense. The artistic value, especially of the light fixtures, is not to be underestimated. If it has not so much direct interest for the electrical engineer, it certainly will call forth the admiration of the artist and of the manufacturer. Bronze castings and wrought-iron fixtures exquisitely delicate and of fine workmanship are the predominating materials for incandescent light fixtures. Combination gas and electric light fixtures are rarely encountered, such is the confidence of our confrères in their installation work, which is indeed remarkable even under these temporary conditions, where everything had to be done in a hurry. The sentiment on this point was very well expressed by Herr Director Lahmeyer on the occasion of the meeting of the "Gas and Water Experts," when he said that gas was good enough as long as electric light was not known, and the gas motor quite satisfactory before the time of the electric motor of to-day. I shall touch upon this meeting more fully, since some very interesting points were brought out in regard to the use of gas engines in combination with storage batteries for central station work, as practiced in Dessau and Düsseldorf.

The employment of the electric motor for traction purposes does not come up to the standard to which we are accustomed in America. Only a very small part of the electric railway as proposed is in operation at the time of this writing. It is the connecting railway between the main exhibition and the Marine Exhibition, a distance of about 1,000 feet. The motor operates smoothly, but the regulating and braking devices lack the necessary precision and the trolley seems to give occasional trouble. A later occasion will enable me to give a fuller description of the model of the single rail system of Ganz & Co. A marine railway is exhibited by Siemens and Halske, who also are to operate two cars on the street railway with storage batteries.

Some very interesting novelties are to be seen in the building for electro-metallurgy and electrolysis. Herr Fr. Goppelsroeder exhibits a process of fixing aniline colors by means of electrolysis. Electroplating is exemplified in very fine specimens, especially a process for electrobronzing palm leaves and plaster of paris castings for decorative purposes.

Quite a number of interesting and new things can also be found in the Hall for Science and Electromedicine. The exhibition of Hartmann & Braun of instruments of precision for electrical purposes is very remarkable. In this department is one of the few genuine American exhibits, that of the Weston Electrical Instrument Company, of Newark, N. J. This exhibit on account of its completeness and the remarkable properties of the well-known instruments has made quite a stir in electrical circles here. It is the intention of the Committee of Judges to use these instruments as official standard testing instruments. If America should gain a point in this new enterprise it may well be proud of it. Up to a very short time ago Germany was one of the principal exporters of testing instruments to America, but a vigorous effort of a few years only seems sufficient to turn the tide in the opposite direction.

The Maritime Exhibition is small but contains some objects of great interest, such as Schuckert's large parabolic glass mirrors, one of them having a diameter of 1,100 mm., for searchlights, while Siemens Brothers' exhibit of a torpedo station for harbor defense is very complete. The lighthouse with one of Schuckert's immense searchlights on top makes a great impression on the public. The sharply defined brilliant beams of light emanating from the searchlight proves the superiority of the patent glass mirrors made by Schuckert & Co.

It is scarcely necessary to mention that there is no lack of opportunity for the intellectual and bodily recreation of the visitor. The restaurants, cafés, kiosks, etc., speak well for the designers in their tasteful and appropriate exterior and just as well for mine host in the quality of restoratives given to the weary visitor.

The participation in the exhibition of foreign countries is fair. The United States is represented by the Thomson-Houston Co., with their dynamos and motors and with a special exhibit of electrical appliances for mining purposes. The Edison Co. is represented through the Allgemeine Elektricitäts-Gesellschaft. McIntosh, Seymour & Co. exhibit with the Thomson-Houston Co. The American Otis Elevator Co. have their electrical elevators on exhibition, and the Edison Phonograph Co., Emile Berliner's gramophone, the Westinghouse high-speed engines, and Babcock & Wilcox boilers are well represented, while American inventions can be found by the score under the names of their English and German representatives. Among the English exhibitors are Woodhouse & Rawson, the Brush Electric Co. (partly represented through Kremenezky, Mayer & Co., of Vienna,); the Swan United Electric Co., the Eastern Telegraph Co., Siemens Brothers and Johnson & Phillips, with their large coil insulators, and Ferranti with his cables. Switzerland, and especially Austria-Hungary, are very well represented. The exhibit of Ganz & Co., under the name of their agents "Helios," of Cologne, is one of the remarkable features of the exhibition and occupies the entire centre of Machinery Hall. The

German Government makes a remarkable and highly interesting exhibit, historical and otherwise. It gives a complete idea of the progress and present state of railroad signaling, automatic electric safety devices, telegraphy and telephony. A comparison with our American practice will be valuable and interesting to the visitor from abroad.

Every day, of course, brings new additions. The hall for technical drawings of central stations and isolated plants was opened a few days ago; it will furnish interesting material for a detailed description, illustrating the adopted systems of distribution of electrical energy as practiced in Germany.

As a whole it may be strongly emphasized that a visit to the exhibition will be highly profitable to the electrical engineer as well as to the non-technical public. The untiring efforts of the committee, with Herr L. Sonnemann as president, and Herr O. von Miller as vice-president, cannot be praised too highly. The visitor from the States, and especially the journalist, is always sure of a hearty welcome and of special attention and courtesy, which will enable him to study points of interest to great advantage.

ELEMENTARY GEOMETRICAL THEORY OF THE ALTERNATE-CURRENT TRANSFORMER.—VII.

(PART SECOND.)

BY

Chas. Steinmetz.

VI. Dependence of the Electric Quantities upon Variations of the Constants of the Transformer.

In the polar diagram, we are enabled now to follow the dependence of the electric quantities in the transformer upon its constants, r_1, r, g, l, N, ρ, F, n, n_1, etc.

A. Dependence upon r_1 the Secondary Resistance.

Let, in the diagram, Fig. 12, the values, $E_0{}^1$, E^1, E_1, F_1, C^1, $C_1{}^1$, L^1, $L_1{}^1$, F, K, Λ, correspond to the transformer, when working under full load, that is, with a secondary resistance of $r_1 = 2\ \Omega$, as given before in diagram Fig. 8.

The secondary E. M. F., E_1 may be supposed to remain constant. Then the primary induced E. M. F., E_1, and thus the resulting M. M. F., F, the impressed M. M. F., K, and the M. M. F. of magnetic work, Λ also remain constant.

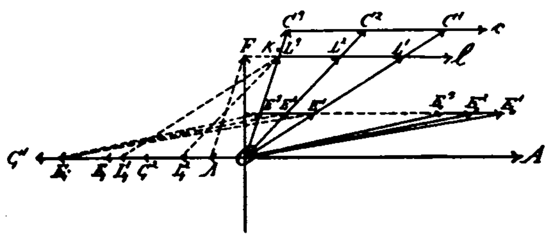


FIG. 12.

But, an increase of the secondary resistance from $r_1 = 2$ ohms, for full load, up to $r_1 = \infty$, for no load, or open circuit, produces a decrease of the secondary current, C_1 from its maximum value, $C_1{}^1$, down to zero.

Hence, with increasing secondary resistance, r_1, the point c_1, Fig. 12, moves on the ray $\overline{O\,C_1}$ from $c_1{}^1$ to O

Therefore the secondary M. M. F., L_1 proportionally decreases from $L_1{}^1$ to O, point L_1 moving from $L_1{}^1$ at full load to O, along $\overline{O\,L_1}$.

In consequence of this, ray $\overline{K\,L_1}$ shifts around the centre K from $\overline{K\,L_1{}^1}$ for full load, to $\overline{K\,O}$ for open secondary, and because of the parallelogram, O L_1 K L, ray $\overline{O\,L}$ shifts around O from $\overline{O\,L^1}$ to $\overline{O\,K} = \overline{O\,L^3}$, point L, the primary M. M. F., traveling on a horizontal line, l, from L^1 to $L^3 = K$.

Hence the primary current, C, moves along a horizontal line, c, also, from c^1 to c^3, and the resulting, or heating, primary E. M. F., E, on a horizontal line from E^1 to E^3, both E and C being proportional to L by the equations:

$$C = \frac{L}{n}, \text{and } E = \frac{C}{r} = \frac{L}{n\,r}.$$

Hence for increasing secondary resistance, that is, for decreasing load, the phase of the primary current increases

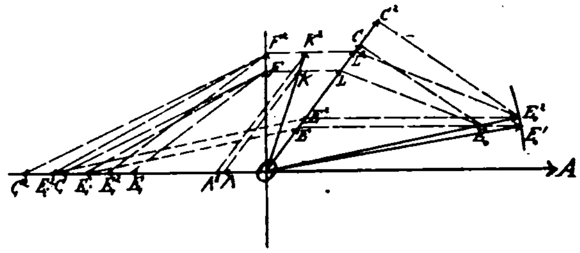

FIG. 13.

from $\varphi^1 = $ A O $c^1 = 32°$ to $\varphi^3 = $ A O $c^3 = 71°$, and the primary current decreases from:

$C^1 = \overline{O\,C^1} = 56.6$ amperes to $C^3 = \overline{O\,C^3} = 32.0$ amperes.

From this we derive the following result:

"To get a small primary current C for open secondary circuit (the so-called 'leakage current') $\overline{O\,C^3}$ must be small, that is, $\overline{O\,F}$, or rather $\overline{O\,K}$ small, with a given number of turns; that is, the magnetic resistance of the transformer must be as small as possible."

The primary impressed E. M. F., $\overline{O\,E_0}$, is derived from the parallelogram of primary E. M. F.'s, O E_1 E E_0; therefore, when for increasing secondary resistance, r_1, E travels from E^1 to E^3, E_0 travels on a horizontal line from $E_0{}^1$ to $E_0{}^3$.

"For increasing secondary resistance, r_1, if the secondary E. M. F., E_1 shall remain constant, the primary E. M. F., E_0 must decrease from $E_0{}^1 = \overline{O\,E_0{}^1} = 183$ volts, to $E_0{}^3 = \overline{O\,E_0{}^3} = 143$ volts, its phase increasing slightly from angle $\psi^1 = $ A O $E_0{}^1 = 10°$ to angle $\psi^3 = $ A O $E_0{}^3 = 13°$.

Hence the difference of phase between primary current and primary impressed E. M. F. increases with decreasing load from angle $\omega^1 = \varphi^1 - \psi^1 = 22°$ to angle $\omega^3 = \varphi^3 - \psi^3 = 58°$, and the effective power consumed by the transformer, that is, expended by the primary circuit, decreases from

$$\frac{C^1\,E_0{}^1 \cos\omega^1}{2} = 4840 \text{ watts to } \frac{C^3\,E_0{}^3 \cos\omega^3}{2} = 1830 \text{ watts.}$$

In actual practice, certainly for open circuit, all the quantities are esssentially smaller than assumed here, as remarked before.

Fig. 12 gives the diagrams for the secondary resistances:

1. $r_1{}^1 = 2$ ohms: full load.
2. $r_1{}^2 = 4$ " : half load.
3. $r_1{}^3 = \infty$: no load.

Therefore, if for increasing secondary resistance, that is, decreasing load, the secondary E. M. F. shall remain constant, the dynamo has to be regulated so that the impressed primary E. M. F. decreases from $\overline{O\,E_0{}^1}$ to $\overline{O\,E_0{}^3}$.

On the other hand, if the primary E. M. F. E_0 is kept constant, as usually, the secondary E. M. F., E_1, will not remain constant, but will increase for increasing resistance r_1, that is, for decreasing load.

The amount of this decrease we get in the following way:

After having produced, in Fig. 13, the transformer diagram for full load, and for any other load, for instance half load, under the assumption of constancy of secondary E. M. F., E_1, we increase, in this latter diagram, all the lines proportionally, so that the primary impressed E. M. F., E_0, has again the same value as for full load.

Graphically we do this by drawing parallel lines.

Let, for instance, in Fig. 13, E_0^1, E^1, E_1, E_1, C^1, C_1^1, L^1, L_1^1, F, K, $\varDelta$ be the diagram for full load, E_0, E, E_1, E_1, C, C_1, L, L_1, F, K, $\varDelta$, the diagram for half load, or any other load.

Then we draw a circle with radius $\overline{O E_0^1}$ and produce $\overline{O E_0}$ until it intersects this circle in E_0^2, produce $\overline{E_0^2 E^2} \parallel \overline{E_0 E}$, $\overline{E_0^2 L^2} \parallel \overline{E_0 L}$, $\overline{F^2 L^2} \parallel \overline{F L}$, $\overline{E_1^2 F^2} \parallel \overline{E_1 F}$, $\overline{E_1^2 F^2} \parallel \overline{E_1 F}$, $\overline{C_1^2 F^2} \parallel \overline{C_1 F}$, etc.

then E_0^2, E^2, E_1^2, E_1^2, C^2, C_1^2, L^2, L_1^2, F^2, K^2, $\varDelta^2$ is the transformer diagram for half load, and the same impressed E. M. F., E_0.

CENTRAL STATION MANAGEMENT AND FINANCE.—XI.

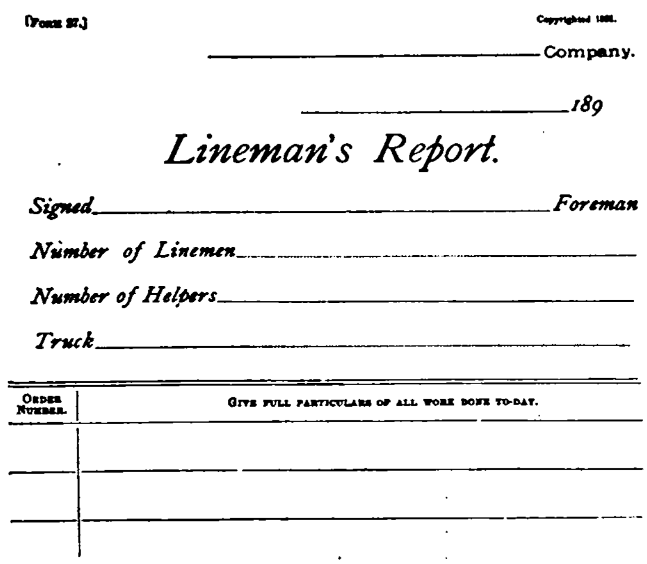
BY

Horatio A. Foster

Miscellaneous Forms.

The foregoing finish up the blanks used in the department of accounts and leave us only one more of the regular order. That form is No. 27, Lineman's Report, on which is recorded all work of any nature done by line gangs. It must be filled out in detail by all foremen or any man who has a job all alone; this blank will be all that is necessary outside of the regular order blank No. 1.

When electrical apparatus or wires are placed inside of buildings it is necessary to notify the Board of Fire Underwriters immediately of such fact, so that the customer's

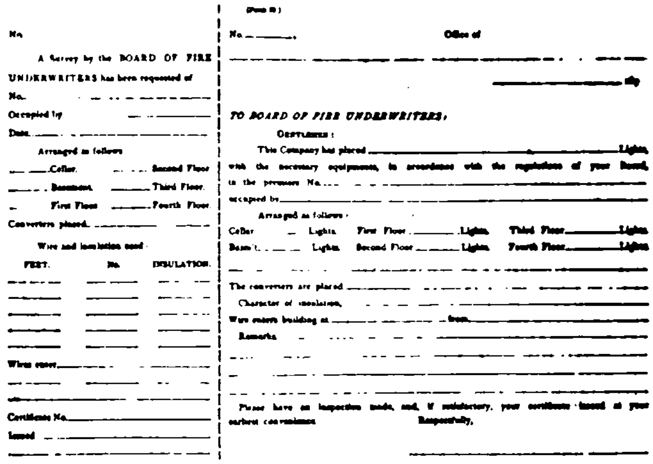


BLANK NO. 27.—LINEMAN'S REPORT.

insurance may not be made invalid. For such notification the form issued or suggested by the New York Board has been found very convenient, and when a stub is added and it is made into books of about 200 pages leaves little to be desired. No. 29 shows this form. I use it here with the kind permission of the Board of Fire Underwriters, through Mr. A. E. Van Gieson.

This furnishes the line of regular reports, and it is hoped that they have been found to cover the ground more or less fully. Many stations will require special blanks, and I shall be glad to render assistance on application, with proper blanks gotten out to meet the service.

In closing, I will say that the foregoing system of blanks, while not being advanced as absolutely perfect, has been well tried and found to answer the writer's purpose in his own central station work with considerable satisfaction. It is hoped others may find some assistance in



BLANK NO. 29.—APPLICATION FOR FIRE UNDERWRITER'S SURVEY.

them, and that they may lead to a more intelligent knowledge of the costs of maintaining and operating electric lighting and power stations.

SCIENTIFIC NOTE MAKING.

BY

J. Stanford Brown.

MOST of us, especially in the great field of electricity, have to keep abreast of the times by diligent perusal of periodical literature in one or several languages, and everything that can assist the task of memory is a blessing of no small import.

The student must, weekly at least, glance through such a pile of papers that he shrinks from the task. No one can hope to retain much or accurately from a single reading, and consequently the only safe way is to put down the titles of articles and the facts to which it may be necessary to refer for further study or direct application in the engineering problem in hand.

Note books belong to the methods of the past, for at the end of a few months all available time would be consumed in making indices to the indices of the volumes filled.

Our resource, then, must be a scientific system such as that offered by the Library Bureau, so admirably worked out first for use in cataloguing collections of books.

The plan is simple. Cards of two sizes are provided. When the titles only of books or articles are required, a narrow card is used, while more extensive notes are made on those of ordinary postal size (3″ x 5″). If both kinds of memorandums are to be made, it is best to use only the larger size.

These cards are filed in tin boxes, or in wood cases of any desired dimensions and finish, holding from 3,000 to 50,000 cards. For many reasons, a number of boxes of some medium size will be found preferable in case of change of residence, or when a part of the cards are taken to one's office, or on a journey, when spare time is put in studying or writing up. The cards stand on edge and can be consulted in situ or removed, as preferred. As soon as subject-matter is out of date, or of no further value, for any reason, out it goes, without defacing anything, and leaving room for new facts and figures.

One great advantage in this system of records is that for any particular work the whole collection can be rearranged at any time, on any new classification seeming to offer peculiar advantage.

The classification of notes forms in itself an interesting study. The top line of each note card should be left for the title and subdivision heading. The arrangement of cards in the cabinet can be made to suit individual fancy by subject groups and alphabetically within each group, or all under one general alphabet with subdivisions. Zinc didivisions, with the tops turned over for labels, and cards with projecting tops, of various shapes, can be had, as well as alphabets in cardboard of several colors.

The headings to cards are the most difficult stumbling-block for the beginners. It is wise for them even to omit these for the first few months, until by practice and thought a system of classification has been elaborated to suit individual ideas or necessity. In any event, titles should be put down according to the rules universally adopted for cataloguing, which rules should be strictly adhered to.

It would be of immense help if all writers of articles and the editors of our technical journals would unite to make titles as simple as possible. Were this thought kept in view, then, in taking notes or cataloguing, few or but small changes would be needed. Too many titles to articles fail to strike the keynote. For instance, in the current electrical journals we find "A German Current Transformer." Those interested want to know who designed it, and if it had been termed "Lahmeyer Continuous Current Converter, Type '91," no one would have had to go further, unless in search of detailed information.

Do not forget to put down the source of the memorandum. Without this it frequently loses half, if not all, its value. The information may be used, and some one may challenge its accuracy; a slip may have been made in copying it; not quite enough may have been taken for clearness, or track of the context have been lost, when occasion requires further reference to it.

Not infrequently it is very important to put down the author of the article when a simple fact or statement is extracted. Such memoranda may be useful either for the purpose of knowing the views of some authority or his peculiar use of terms where the same technical term is used by different men in various senses.

How often one runs across the title "A New Dynamo" which is new for that copy of the paper only in which the account is given. Take the file of almost any electrical journal, and such entries will be found half a dozen times in a single volume. A little different wording, and we could pass along without delving into the text.

"On a possible method of making physical measurements with the aid of a modified form of——————'s galvanometer," might better have been "Blank's Tangent Galvanometer." The last was from our German friend, and yet some of the titles to articles read before the English learned societies require considerable study to decide under which of several heads they properly fall.

To make the title describe the article concisely and briefly is not always an easy matter, but a little thought will improve matters wonderfully, and let us give thanks to our editors who appreciate these points.

Double entries are many times necessary, but take time —too much time—to be used freely.

Abbreviations for works recurring regularly will, of course, facilitate note making, and the advantages of uniformity are self-evident. Impressed with its importance, in Nov., '84, Mr. Haspitalier brought the subject before the International Society of Electricians at Paris, who appointed a committee to investigate and report on a standard list of terms and abbreviations. For full details see *L'Electricien*, 15 D., '84.

On 14th May, '85, Andrew Jamieson read a paper before the S. of T. E. and E. on "Electrical Definitions, Nomenclature and Notation," which gives very fully suggestive abbreviations, as well as the many meanings of the same terms as used at that date. Those desiring to look up this matter will find it in E. E., IV., 338 (No. 45, Sept. '85), or in E. W., V., 18, or L. E., XV., 30. Useful letters bearing on the correct use of terms may also be found in L. E., XV., 60, and 311.

In the matter of the names of electrical journals the writer is accustomed to use, among others, the following initials:

E. E.	For the N. Y. *Electrical Engineer;*
E. R.	" " " " *Review;*
E. A.	" " " " *Age;*
E. W.	" " N. Y. *Electrical World;*
E. P.	" " *Electric Power;*
W. E.	" " *Western Electrician;*
E. R.	" " London *Electrical Review;*
L. E.	" " " *Electrician;*
E. E.	" " " *Electrical Engineer.*

&c., using square letters for the English, and round caps for the American periodicals. Probably no shorter ones will suggest themselves.

Some might think it wise to use stenography. The chief objection to this is the one common to all short hand work. Before long too much of it will probably be "Greek" even to the writer, and so be consigned to the waste basket; the notes are meaningless to any one else who might profit by them, and you cannot ask your brother or sister or office boy or any one to find a reference for you while you are busy at something else.

To the scientist and engineer the taking of notes must be an art, and one of sufficient importance some think to warrant consideration in our schools and colleges. No doubt in our most advanced institutions this matter does receive the deserved attention. If not, and these suggestions serve to call the matter before professor or student, to the benefit of either, they will have accomplished a useful purpose.

THOMSON'S INDUCTION PREVENTER FOR TELEPHONE CIRCUITS.

In the operation of telephone lines much annoyance has been caused by the induction from neighboring electric light or railway wires. This defect may be overcome, it is true, by the use of metallic circuits, but the great cost of this remedy has proved a drawback to its general use, and the all-metallic circuit has in this country been principally confined to long-distance telephony.

In order to prevent these injurious inductive effects on single circuits with earth return, Prof. Elihu Thomson has recently devised an arrangement, the object of which is to obtain a compensation for the induction from one line to several others in a simple and effective manner, without, in so doing, causing one of the affected lines to induce currents upon another affected line or lines. Thus, in the case of two telephone-circuits affected by an electric light wire, the induction of the electric-light wire upon both telephone wires is eliminated without causing induction from one telephone wire to another.

This result is accomplished by setting up a counteracting field of induction, which operates upon both telephone circuits, each of which is arranged in a different portion of the field of counter-induction, but in position not to induce upon the other.

The method will be understood by reference to the diagram. Fig. 1 represents diagrammatically an ordinary telephone line, which lies parallel to a line L L L either along a part or the whole of its course. The line in the electric-lighting circuit is one in which fluctuations or alternations occur in the current supplied from a generator D. Looped into the electric-light line at any convenient point is the coil P of a comparatively small number of turns, according to the strength of the current and the induction which it is expected to balance. Placed near it, either parallel to it, or at an angle with its axis, is a coil S, generally of much finer wire, and including with it the telephone-circuit T as a loop. By adjusting the relative angular positions of the coils S and P with respect to each other while listening at a telephone in the telephone line, a counter-induction may be set up equal to that which is

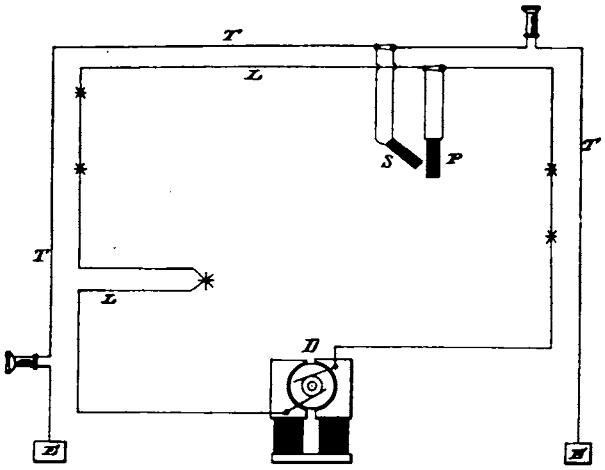


FIG. 1.—THOMSON'S METHOD OF PREVENTING INDUCTION IN TELEPHONE LINES.

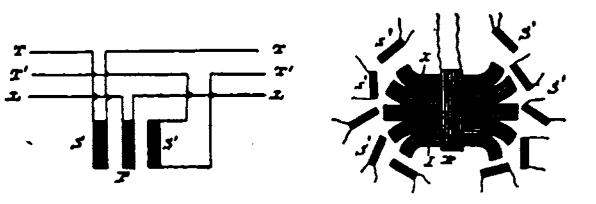
produced on the main line, thus producing silence in the telephonic circuit.

This compensating effect may, of course, be produced in a variety of ways. It is necessary, of course, that the connections be so made that an impulse inductively set up shall be met by a reverse or opposite impulse also inductively set up. One of these impulses, however, is that which is due to the long lines in parallelism on poles or in conduits, and the other is that due to the adjustment of the inducing-coils one to the other.

The arrangement preferred by Prof. Thomson is shown in Fig. 2, where T T and T′ T′ indicate two lines parallel with, or adjacent to, the electric-light line L L, with alternating or fluctuating currents flowing in it. The coil P in the electric-light line has on one side of it adjustably placed a coil S in the circuit of the line T T, and in the other side a similar coil S′ in the circuit of line T′, so that the coil P may act inductively on both circuits T T and T′ T′. The coils S S′ are kept sufficiently far apart not to allow cross-talk by induction from one of the telephone coils to the other.

Fig. 3 illustrates a modified way of permitting a single coil P of moderate size in an electric-light line to affect in-



FIGS. 2 AND 3.—THOMSON'S METHOD OF PREVENTING INDUCTION IN TELEPHONE LINES.

ductively a number of coils variably placed as to the power of induction, and each inserted in a particular telephone circuit, without permitting the approach of the small telephonic-circuit coils to allow cross-induction, or cross-talk. The small coils are adjusted both as to the position and angle, &c., and arranged around the coil P, which may be without a core of any kind, or which may have a core I, of iron wire bundles, threaded through it and run in different directions, as indicated, to separately-influenced coils S′, &c., which are connected in individual telephone-circuits.

TESLA'S METHOD OF OPERATING ALTERNATING CURRENT MOTORS WITH CONDENSERS.

If the terminals or plates of a condenser be connected with two points of a circuit, the potentials of which are made to rise and fall in rapid succession, the condenser allows the passage, or, more strictly speaking, the transference of a current, although its plates or armatures may be so carefully insulated as to prevent almost completely the passage of a current of unvarying strength or direction and of moderate electromotive force; again, if a circuit, the terminals of which are connected with the plates of the condenser, possess a certain self-induction, the condenser will overcome or counteract to a greater or less degree, dependent upon well-understood conditions, the effects of such self-induction; third, if two points of a closed or complete circuit through which a rapidly rising and falling current flows, be shunted or bridged by a condenser, a variation in the strength of the currents in the branches, and also a difference of phase of the currents therein, is produced.

These effects Mr. Tesla has utilized and applied in a variety of ways in the construction and operation of his well-known alternating motors, as, by producing a difference in phase in the two energizing circuits of an alternating-current motor by connecting the two circuits in derivation, and connecting up a condenser in series in one of the circuits.

In an alternating-current motor of the type which has an armature coil or circuit closed upon itself, however, the latter represents not only an inductive resistance, but one which is periodically varying in value, both of which facts

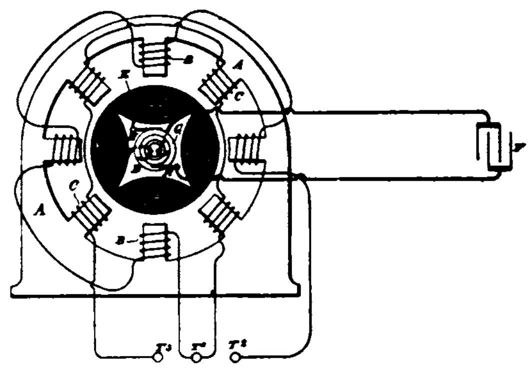


FIG. 1.—TESLA'S NEW ALTERNATING MOTOR WITH CONDENSER.

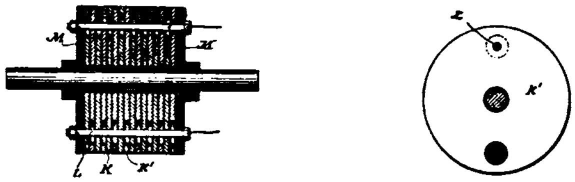
complicate, and render difficult, the attainment of the conditions best suited to the most efficient working of the motors. The most efficient working conditions, in other words, require, first, that for a given inductive effect upon the armature there should be the greatest possible current through the armature or induced coils, and, second, that there should always exist between the currents in the energizing and the induced circuits a given relation of phase. Hence whatever tends to decrease the self-induction and increase the current in the induced circuits will, other things being equal, increase the output and efficiency of the motor, and the same will be true of causes that operate to maintain the mutual attractive effect between the field-magnets and armature at its maximum. He secures these results by connecting with the induced circuit a condenser, and also by constructing the motor in a special manner.

The general plan of operation adopted by Mr. Tesla is illustrated in Fig. 1. A A in this figure represent the frame and field-magnets of an alternating-current motor, the poles or projections of which are wound with coils B and C, so that the alternating currents flowing through the circuits, respectively, will have a difference of phase. Within the influence of this field is an armature-core D, wound with coils E. In Mr. Tesla's motors of this description, heretofore these coils have been closed upon themselves, or connected in a closed series; but in the present case each coil or the connected series of coils terminates in the opposite plates of a condenser F. For this purpose the ends of the series of coils are brought out through the shaft to collecting-rings G, which are connected to the condenser by contact brushes H, the condenser being independent of the machine. The armature-coils are wound or connected in such a manner that adjacent coils produce opposite poles.

The action of this motor and the effect of the plan followed in its construction are as follows: The motor being started in operation and the coils of the field-magnets being



FIGS. 3 AND 4.—COMBINED ARMATURE AND CONDENSER.

traversed by alternating currents, currents are induced in the armature coils by one set of field coils, as B, and the poles thus established are acted upon by the other set, C. The armature coils, however, have necessarily a high self-induction, which opposes the flow of the currents thus set up. The condenser F not only permits the passage or transferrence of these currents, but also counteracts the effects of self-induction, and by a proper adjustment of the capacity of the condenser, the self-induction of the coils, and the periods of the currents, the condenser may be made to overcome entirely the effect of the self-induction.

It is preferable on account of the undesirability of using sliding contacts of all kinds to combine the condenser with the armature directly, or make it a part of the armature. In some cases, as shown in Fig. 2, Mr. Tesla builds up the armature of annular plates K K, held by bolts L between heads M, which are secured to the driving shaft, and in the hollow space thus formed is placed a condenser F, generally by winding the two insulated plates spirally around the shaft. In other cases he utilizes the plates of the core itself as the plates of the condenser, as shown in Figs. 3 and 4.

In motors in which the armature coils are closed upon themselves—as, for example, in any form of alternating-current motor in which one armature coil or set of coils is in the position of maximum induction with respect to the field coils or poles, while the other is in the position of

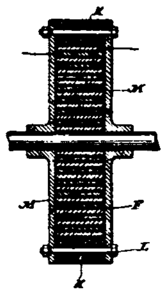


FIG. 2.

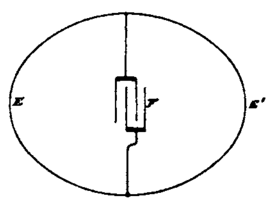

FIG. 5.

minimum induction—the coils are connected in one series, and two points of the circuit thus formed are bridged by a condenser. This is illustrated in Fig. 5, in which E represents one set of armature coils and E′ the other. Their points of union are joined through a condenser F. It will be observed that in this disposition the self-induction of the two branches E and E′ varies with their position relatively to the field-magnet, and that each branch is alternately the predominating source of the induced current. Hence the effect of the condenser F is twofold. First, it increases the current in each of the branches alternately, and, secondly, it alters the phase of the currents in the branches, this being the well-known effect which results from such a disposition of a condenser with a circuit, as above described. This effect is favorable to the proper working of the motor, because it increases the flow of current in the armature circuits due to a given inductive effect, and also because it brings more nearly into coincidence the maximum magnetic effects of the coacting field and armature poles. This method of operation is more particularly adapted to systems in which a very high rate of alternation or change is maintained.

THE DIELECTRIC PROPERTIES OF MICA AT HIGH TEMPERATURES.

IN a paper recently read before the Académie des Sciences, M. E. Bouty described some investigations carried out by him with regard to the dielectric properties of mica at high temperatures. The result of M. Bouty's researches is to demonstrate the almost complete invariability of the dielectric constant of mica, which, between 0° and 300°C., certainly does not alter by one-fiftieth of its original value. Above 300°C. experimental complications occur, and tend to obscure the result. M. Bouty made use of silvered sheets of mica, and when the temperature was carried beyond 300°C., the silver was attacked if in contact with the air, and the mica was soon covered by a transparent electrolytic film. This defect may be minimized by covering the silver with a fairly thick layer of copper. Above 300°C. the charge furnished by the battery is no longer entirely recoverable, which is doubtless due to the formation of the conducting film, since the conductivity at the same temperature rapidly increases if the application of the heat is prolonged, and the conductivity is maintained on cooling until the superficial hygrometric layer has been washed away in alcohol. It is possible that between 300° and 400°C. mica may possess some slight specific conductivity. However that may be, says M. Bouty, the resultant conductivity between 300° and 400°C. is negligible for charges of brief duration.

A SENSITIVE ELECTRICAL ALARM.

AT the last meeting of the Académie des Sciences, MM. G. and L. Richard described an electrical alarm devised by them for the purpose of responding to variations in the pressure of a current of air or gas. The alarm is extremely sensitive, and will act for variations of a few hundredths of a millimetre of water. The apparatus consists of a metallic box communicating with the flue, through which the gas is flowing, by a small tube. This tube is closed inside the box by a light metal valve, the movements of which open and close an electric alarm circuit. By altering the position of the box with regard to the vertical, the sensitiveness of the apparatus is more or less modified, and beyond a certain point the apparatus may be made to indicate an increase of pressure. MM. Richard propose to fix this device to ventilating tubes or to flues. In some cases it may be necessary to have an additional automatic device to prevent purely momentary depressions from affecting the instrument. Where required the alarm circuit could be made to include an electro-magnet which should attract a bar of soft iron actuating a train of clock wheels, which, when a certain definite time had elapsed, should allow the alarm to ring.

MAGNETIZATION OF NICKEL.

ONE of the most interesting of the exhibits at the recent Royal Society *conversazione* was Mr. Shelford Bidwell's nickel pendulum, arranged to show that nickel, which at ordinary temperatures is magnetizable, loses its power of being magnetized when heated to 300 deg. C.

THE NEW CROCKER-WHEELER ARC MOTORS.

The problem of designing a successful automatic speed regulator for constant current or arc motors has been grappled with as often as almost any problem in electrical engineering. A method which has been frequently tried consists in shifting the brushes in correspondence with variations in the load on the motor. This attempt has never been sufficiently successful to warrant the commercial use of the method, owing to excessive sparking at the brushes, and bad design and construction of the device.

In the new constant current motor of the Crocker-Wheeler Co., designed by Dr. S. S. Wheeler, this method of regulating by shifting the brushes has been very successfully accomplished, and the difficulties of sparking and faulty mechanical operation have been entirely overcome. The details of the construction of the regulator are shown in the engravings, Figs. 1, 2 and 3. The means for adjusting the governor are very complete, the tension of the spring being regulated by a nut on the shaft at E, so that the governor can be set to run at any desired speed. The stroke of the governor is also limited by two set-screws controling the extent of the motion of the bell-crank lever connecting the centrifugal governor and the rocker-arm carrying the brushes. A dash-pot is also connected with this lever to prevent too sudden action of the governor. The rocker-arm is carried on the end of the bearing by three friction rollers, shown at *c* in Fig. 3. These contribute greatly to the prompt and easy action of the governor. The workmanship of the whole device is of the most perfect character, and its operation is correspondingly effective. The centrifugal governor on the end of the shaft is surrounded by a guard ring as indicated in Fig. 4, which shows the complete motor in perspective.

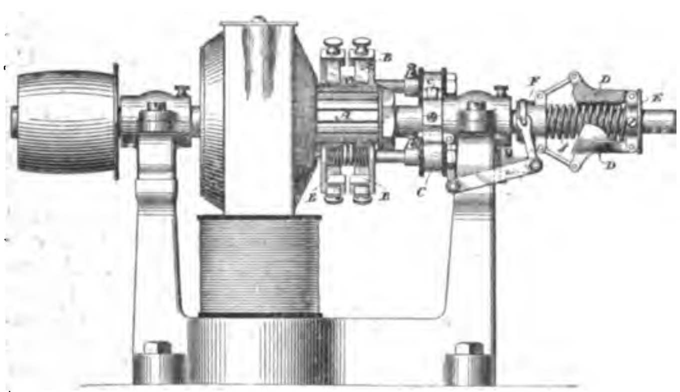

Fig. 1.—New Crocker-Wheeler Automatic Constant Current Motor.

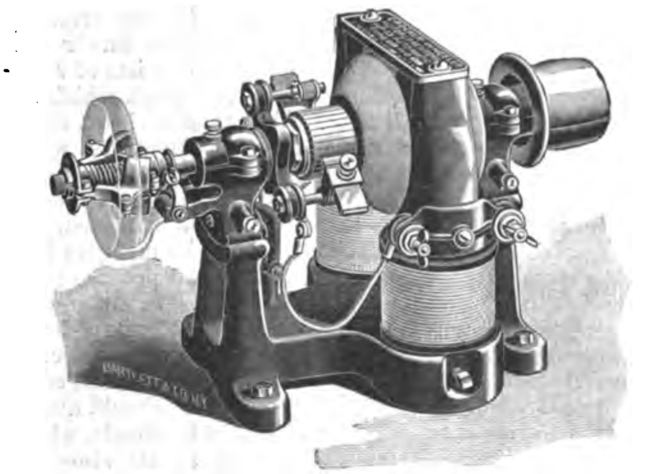

Fig. 4.—Crocker-Wheeler Automatic Arc Motor.

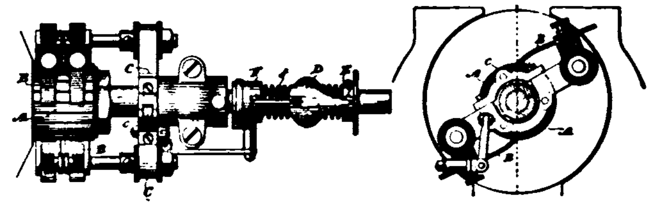
It is obvious that this method of regulation is prompt, because the instant the position of the brushes is shifted, the torque of the motor is correspondingly reduced, and even when the belt is thrown off with full load, the action of the governor, and its effect in controling the speed of the motor is practically instantaneous.



Figs. 2 and 3.—Crocker-Wheeler Arc Regulator.

The automatic form of regulator is employed on all the larger sizes of motors, but the sizes which are too small to make it practicable to apply the centrifugal governor and connecting mechanism are provided with a hand regulator. This form is shown in Fig. 5. The rocker-arm shifts the brushes from the position of maximum effect to minimum effect in proportion to the load, as in the larger motors, the motion being effected by a lever and string, which may be worked by hand or treadle. When the lever is released the brushes are thrown back to the position of least effect by the spring shown in the engraving.

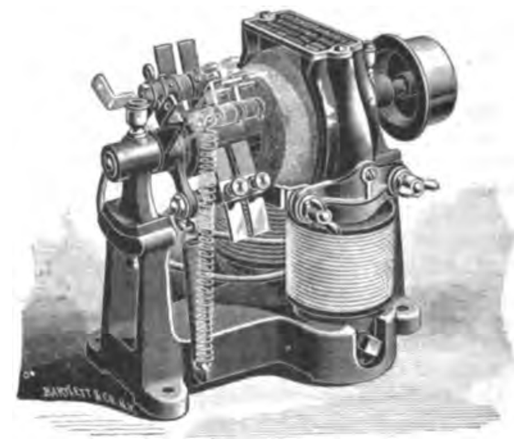


Fig. 5.—Small Crocker-Wheeler Arc Motor.

A DEFINITION OF "DEVELOPMENT" WANTED.

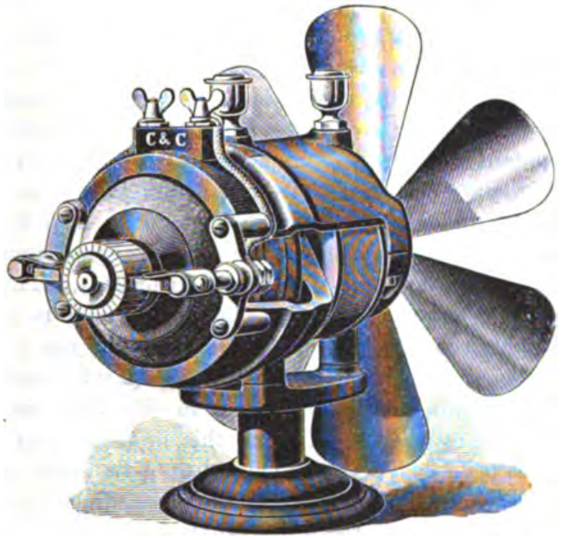
Referring to the serious fire last week in this city in the Sixth Avenue horse car stables, and commenting on the fact that the road still sticks to horses, the New York *Times* says:—"The delay may very probably be due to the fact that the managers of the lines are waiting for the development of electric traction, *which cannot as yet be said to have been developed*, and object in the meantime to going to the expense of a plant for a system of cables which may, after all, be provisional." The italics are ours, for we would like to be informed as to what is understood by the word "developed." There are now over 325 electric roads in the world, and 90 per cent. of them in this country. Those roads figure up about 4,000 cars, 7,000 motors, 2,600 miles of track, a daily run of 400,000 miles and a traffic of 750,000,000 passengers yearly, and not a single death attributable to contact with the circuit or the electric apparatus. If this be not development, and of a very high form, too, we would very much like to know what is.

THE "C. & C." 500-VOLT FAN OUTFIT.

The great increase in street railway and other power circuits of a pressure of 500 volts has recently led to a demand for small motors and fan outfits adapted to this voltage.

The problem of designing a 1/6 or 1/4 h. p. motor for so high a voltage has many factors that do not occur in building larger machines, while some of the main objects to be attained in large machines assume a very different aspect in these pygmies. For example, in the matter of economy of copper these small motors cannot be laid out for the least weight as larger ones, owing to the great increase in cost of the smaller sizes of wire, so that the least cost may be far from the least weight.

Again, one is limited by the mechanical strength of the wire, as the finer sizes are apt to be drawn out or broken in the rapid handling necessary in manufacturing on a large scale.



"C. & C." 500-Volt Fan Outfit.

Another difficulty in designing is the limitation in size, especially in fan outfits which must be small enough to move from place to place, while at the same time the area of the pole pieces must be large enough to reduce the armature turns to a reasonable number. Finally the cost of construction must be reduced to a minimum, as the wire alone on a high-volt machine may cost as much as a whole motor of low voltage.

With these points in view the motor herewith illustrated has been designed by Mr. F. V. Henshaw, of the "C. & C." Electric Motor Co.

The field magnet is semi-ironclad, being formed of two castings joined at one end and held by a single bolt, while the opposite projecting ends form the poles. The lower casting has a cylindrical core over which the single field coil is slipped. This core is cast hollow and the shaft passes through it, having bearings at each end. As will be seen, this arrangement allows a relatively large diameter of armature without increasing the size of the machine greatly. The armature is of the ring type supported on the shaft by three arms. The whole front of the armature is covered by a rubber disc against which the commutator is fastened. This disc serves to keep the frail connecting wires in place and also as a protection to the armature. The brush-holders carry two or more round carbons of standard size, which can be replaced by simply turning the holder around, putting in new pieces and turning back. Both field and armature coils are wound separately on a lathe. With duplicate sets of armatures and field bobbins of the proper winding it is but the work of a few minutes to change these machines from one voltage to another, which is sometimes convenient.

The 1/6 h. p. motors are finished with bearings requiring very little oil, while the larger motors have self-oiling bearings.

The "C. & C." Electric Motor Co. are turning out large numbers of those machines, the demand for which is constantly increasing.

APPRECIATION OF "THE ELECTRICAL ENGINEER."

A letter received last week from a reader of The Electrical Engineer in Southbridge, Mass., says: "I am a subscriber to your paper; have been for some time; like it better than any other. May your shadow never grow less." Another kind reader in Kewannee, Ill., writes: "I do not want to miss one number if I can help it. I have read several electrical papers, but the The Electrical Engineer is *the* paper for anyone who wants to learn the news in that line. I would not give it for two of the other papers."

THE IMPROVED WURTS-WINSOR LIGHTNING ARRESTER.

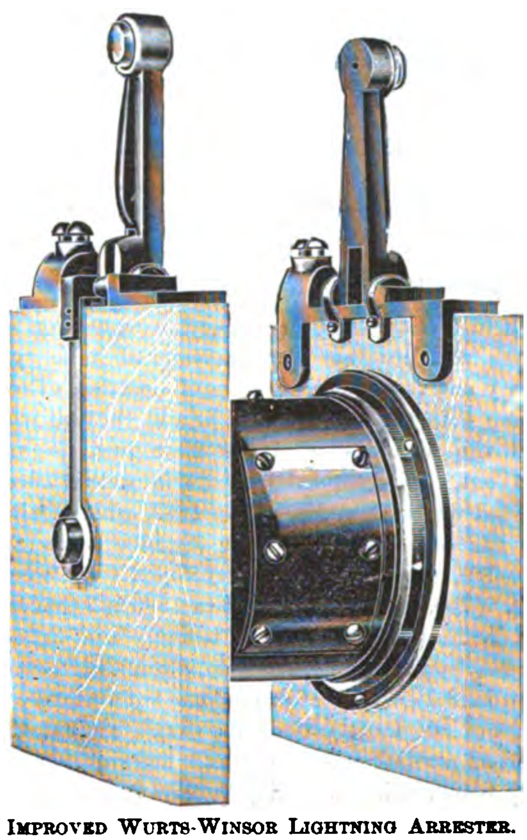
Since the Wurts-Winsor lightning arrester was brought out by the Westinghouse Electric & Manufacturing Company the demand for these appliances has greatly increased, and to-day lightning arresters are considered to be an essential feature in all electric light and power stations.

Mr. Wurts has lately made many improvements in the construction of this apparatus, and while it was unnecessary to modify the principle embodied in the very first one, the changes made add much to its simplicity.

The accompanying illustration represents the new style of the arrester for incandescent circuits. Its distinctive features are that it is constructed of incombustible material, it operates without any electromagnetic device, and its arc is self-destructive.

The engraving represents the lightning arrester in its normal position ready for a discharge. The apparatus is compact and consists of very few parts. It has a cylindrical air chamber of brass, each end of which is covered with a marble plate. Two discharge points on opposite sides of the air chamber, consisting of brass tubes tipped with carbon, are attached to brass lever arms in such a manner as to swing freely through circular openings in the marble plates. Within the air chamber is a carbon ball held stationary in the centre, and the two discharge points approach this ball to within one-sixteenth of an inch. The carbon ball is grounded and the lever arms connected to the respective poles of the generator.

The operation of a discharge is as simple as it is effective. Supposing a lightning discharge to come in from the line, the discharge will take place from two discharge points to the carbon ball and from thence to the ground, forming a double arc in the air chamber. The dynamo current will then follow, causing a short circuit on the generator, and the heat produced by these arcs will expand the air in the chamber and drive the two discharge points out, thus extinguishing the arcs and rupturing the short



Improved Wurts-Winsor Lightning Arrester.

circuit. The next moment the discharge points swing back to their former position within the chamber, and the apparatus is at once ready for another discharge. The entire apparatus is automatic, and when the lightning arrester is once placed in position it requires no further attention.

In testing one of these arresters the binding posts were connected to the poles of a 1000 volt 1,500 light alternator, and the two air-spaces were bridged over with a small strip of tin foil. Then by the throw of a switch the generator was short-circuited through the arrester, the tin foil was fused, the air expanded, the discharge points were forced out of the air chamber against the bumpers, the arcs were blown out with a report like a pistol shot, and the discharge points returned to their normal positions ready for a fresh discharge; all in an inconceivably short space of time,

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers*

VOL. XII. NEW YORK, JULY 15, 1891. No. 167.

The first requisite of an observer is that his mind should be actively awakened to the phenomena of nature with which he is surrounded.—Joseph Henry.

THE FRANKFORT ELECTRICAL EXHIBITION.

ONE of the most significant facts in connection with the rise and progress of the electrical industry is the popularity and frequent recurrence of electrical exhibitions. Beginning with the one held in Paris in 1881, at which the arc and the incandescent lamp were first prominently brought out, there followed others in annual succession. The second was that at Munich in 1882, where Deprez first showed the possibilities of long-distance electric power transmission, which have now developed into tremendous realities. The Vienna exhibition in 1883 and that at Philadelphia in 1884 served only to increase the demand for such shows, so that no general exhibition since that period has been held in which electricity has not formed a prominent, if not the most prominent, part. That the interest in electrical matters is not only not flagging, but on the contrary is increasing from day to day, is evidenced by the exhibition just opened in Frankfort, which, from the account given of it by our special correspondent, Prof. R. O. Heinrich, evidently contains much that has never been publicly shown before, and hence offers a most valuable opportunity for study and the comparison of present methods and apparatus. Prof. Heinrich's subsequent communications will deal in detail with the Frankfort exhibits, and our readers will therefore be placed in a favorable position to judge of the progress made and to have a permanent record of it. Although American progress in the industrial applications of electricity would long since have warranted the holding of another electrical exhibition in this country, there is little doubt that the Chicago World's Fair will, in due time, afford adequate opportunity for a fitting exhibition of our advance and achievements.

THE ARGUMENTS IN THE INCANDESCENT LAMP CASE.

IT is by no means an easy task to undertake to present to the readers of a technical journal, under the limitations of space which circumstances render unavoidable, an intelligible synopsis of more than 210,000 words of argument, emanating from half a dozen of the foremost legal minds of the day; but the vast importance of the interests which will be affected by the results of the litigation which has been in progress for the past six years over the incandescent lamp patent of Mr. Edison, has seemed to justify us in making the attempt. We are well aware that it is quite impossible, under such conditions, to make an adequate presentation of the legal points so forcibly urged upon the attention of the court by the learned disputants. The eloquent closing argument of Mr. Lowrey, which is begun in abstract elsewhere, especially suffers under the process of severe condensation to which it has been subjected, and to which it lends itself perhaps less readily than those of some of his colleagues. But as this is the only attempt which has been made by any journal to give even an approximately complete report of the proceedings in one of the most important trials in the annals of patent litigation, we trust that the results of our labor may prove to be not wholly without value.

CONDENSERS IN ALTERNATING CURRENT WORK.

ONE of the most noteworthy developments in the domain of alternate current working is the prominence which has been given within a comparatively short time to the condenser and its action in relation to circuits possessing high self-induction. Heretofore regarded seriously as a working device only by the telegraph and telephone engineer, the condenser has suddenly risen to occupy a place such that it would be difficult to predict to what uses it may hereafter be put. As another illustration of its present wide application we note this week its use by Mr. Tesla in his well-known alternating motor. In alternating motors of this type the induced circuit in the armature represents an inductive resistance which has a considerable value and which is constantly changing with the varying position of the coil with respect to the field magnets. Such a motor is virtually a transformer, and anything that tends to increase its output will, other things being equal, improve it. Evidently one of the chief requisites in a motor in which currents are induced in the armature is to pass through the armature circuit the greatest possible current which can be produced by a given impressed E. M. F., or, in other words, by a given inductive effect of the field. Mr. Tesla accomplishes this by placing a condenser in the armature circuit, thereby counteracting the self-induction and hence permitting a larger volume of current to pass through the induced circuit. In order to permit of the rotation of the condenser Mr. Tesla places it in the armature, or very ingeniously connects the armature plates so as to form a condenser. Mr. Tesla, we may add, also uses a like connection in other forms of induction apparatus, such as converters.

OUTLOOK.

The suspension of the Empire City Electric Company and its proceedings for a voluntary dissolution and liquidation of its business led a New York daily newspaper to print, some days ago, a sensational article, in which an imaginative writer set forth " whispered " rumors and suspicions in "Wall Street" of an early collapse of other electrical companies on the ground that electrical manufacturing and trading was overdone and therefore unprofitable. The article contained a further tale of the attempted formation of a trust by a considerable number of more or less prominent electrical supply houses. The trust was to control prices in some measure and to restrict production, or, at least, to limit the accumulation of stocks by the several members of the combination.

The officers and directors of the Empire City Company admit the unprofitableness of their business for some time past, and deliberately prefer to liquidate rather than to invest more capital and continue under existing conditions. They estimate their resources as sufficient to pay creditors nearly if not quite in full. Their course in dissolving voluntarily would seem to be a commendable one. Meantime rumors and reports of various sorts are current touching attempts to form some kind of an agreement among a number of large supply houses, East and West, looking to community of action in purchasing and in keeping selling prices up to paying rates.

Several companies of less prominence have failed during the last few months and have gone out of business or are now liquidating. Among the large electric manufacturing companies the Westinghouse Company which has been in serious difficulty for some eight months, seems now likely to emerge in good position to hold its own and to augment its large business. It is now understood that shareholders, to more than the amount required, have assented to the reorganization scheme promulgated some months ago. The consummation of the plan, which has heretofore been set forth in this journal, may fairly be expected to enable the company, under conservative and judicious management, to go forward upon an improved and sounder financial basis in the work it has so energetically undertaken of supplying alternating current apparatus and electric railway machinery. A final collapse of the Westinghouse electric interests, while temporarily eliminating a formidable competitor, would, no doubt, react unfavorably upon other prominent manufacturing companies through its tendency to induce distrust of electrical industry generally on the part of the public and of investors. Their rehabilitation, now apparently assured, should enhance general confidence in the merit of electrical business as a legitimate and reasonably profitable field for the employment of capital and of administrative ability.

Touching the opinion that electrical manufacturing and trading are overdone, it may be remarked that it would be much nearer the truth to say that they have too often, from the start, been *badly* done. We refer less to the quality of products than to the organization and business methods employed in marketing them. We have not yet, perhaps, wholly left behind the period for conjuring with the word " electrical," for pretending to believe and trying to make others believe, that there is some magic in electricity that will ensure the success of any scheme to employ its seeming marvels as a foundation for business. Patents for electrical inventions, sometimes of value sufficient to justify the investment of a few thousand dollars and the setting up of a modest business, have become at the hands of too enterprising or too sanguine promoters the principal assets of companies capitalized at $500,000 or $1,000,000 and decorated with a president, board of directors, and an executive staff. The inventor gets some shares of stock, probably a good many, perhaps not so many as the promoters ; the skillful use of the word "electrical," in the company's name, evokes from the pockets of a few outsiders some hundreds or thousands of dollars for " working capital," and all starts merrily off. The end in a year or so is not so merry. There have been no profits, the " working capital " has been expended and no more is forthcoming; then " this company regrets to inform its creditors, etc., etc." If the promoter have been sagacious enough he will have sold his shares some time ago ; the inventor will very likely have treasured his, and have done his best to make things go. Creditors take what they can get ; shareholders get nothing ; officers, staff, and employees are out of a job, and meritorious electrical concerns have to share in some measure the discredit thrown upon the trade in general. Happily it is becoming more and more difficult to float electrical enterprises that will not bear expert examination, both technical and financial. Good business principles and sound financiering are seen to be quite as indispensable to continued success in the electrical field as in any other department of industry and commerce.

ANTI-INDUCTION TELEPHONE DEVICES.

The almost unbroken series of decisions sustaining the rights of electric railway companies to operate their wires in the streets of cities, notwithstanding the prior occupation of such public highways by telephone lines and the interference caused by induction, has probably by this time brought the telephone companies to a realization of the fact that their remedy does not lie so much in the direction of the courts as in their own hands by the application of well-known methods. The metalic circuit, while all-sufficient for practical purposes, necessarily involves an expense which the telephone companies desire, if possible, to avoid, and many have been the " anti-induction " devices proposed and tried on single lines with earth return. But none of these so far as we are aware has yet proved successful enough to warrant its general adoption, so that the field in this direction is still open to all. Bent evidently upon removing even this smallest objection to the electric railway, Prof. Elihu Thomson has recently worked upon a method, described on another page, in which, by introducing a suitable counter E. M. F. device influenced by the same disturbing cause, the disturbing currents on the main line are neutralized.

ON ELECTRICAL EVAPORATION.[1]

BY WILLIAM CROOKES, F. R. S.

It is well known that when a vacuum tube is furnished with internal platinum electrodes, the adjacent glass, especially near the negative pole, speedily becomes blackened, owing to the deposition of metallic platinum. Whilst a solid body like platinum requires an intense heat to enable its upper stratum of molecules to pass beyond the sphere of attraction of the neighboring molecules, experiment shows that a very moderate amount of negative electrification superadds sufficient energy to enable the upper stratum of metallic molecules to fly beyond the attractive power of the rest of the metal. I have recently made some experiments upon the evaporation of different substances under the electric stress.

Evaporation of Water.—A delicate balance was taken, and two very shallow porcelain dishes were filled with acidulated water and balanced on the pans. Dipping into each dish—touching the liquid, but not the dish—was a platinum wire, one connected with the induction coil and the other insulated.

It was found that *negatively* electrified water lost in 1¼ hours $\frac{1}{1000}$ part of its weight more than did insulated water. This experiment shows that the disturbing influence which assists evaporation is peculiar to the negative pole, even at atmospheric pressures.

The metal cadmium was next experimented upon.

Evaporation of Cadmium.—If the flying-off of the metal of the negative pole is similar to evaporation or volatilization the operation should be accelerated by heat.

A tube was made as shown in Fig. 1. A and B are the platinum poles sealed through the glass. C and D are two blocks of metallic cadmium of the same size and weight. The piece C is in contact with the pole B, which in the experiment was always kept negative, the pole A being positive. When the exhaustion was such that the passage of the current gave green phosphorescence over the glass, heat was applied simultaneously to both ends of the U-shaped tube by means of a gas-burner and air-bath, so that one piece of cadmium was at the same temperature as the other. The current was then applied and was kept on for about an hour, and it was remarkable that no metal was deposited in the neighborhood of the positive pole, the surrounding portion of the tube being quite clean, while the corresponding part of the other limb of the tube having no electrodes, was thickly coated, the appearance being shown in the drawing.

As the temperature was high, metal had distilled off from both lumps; hence there was no visible difference in the amount of the deposit in the two sides. It is evident that, to render the electrical action most visible, the temperature should be kept short of the normal volatilizing point.

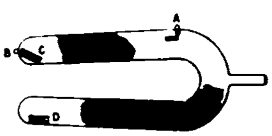

FIG. 1.

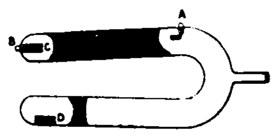

FIG. 2.

In the next experiment an exactly similar tube was used; the vacuum was such that the green phosphorescence of the glass was well seen, the temperature was kept just below the melting point of cadmium, and the current was kept on for an hour. On examining the tube at the end of this time, the appearance was as seen in Fig. 2. A considerable deposit had taken place on the end of the tube near the negative pole, the space round the positive pole was clear, while in the limb of the tube where no electricity had been passing only a very little deposit of metal was seen, as shown in the figure.

Another tube was made as shown in Fig. 3. The poles A, B, C, D, were platinum wires sealed through the glass, A and D having aluminum poles covering the platinum wire. In the ends of the tube, and touching the poles B and C, were two pieces of cadmium of the same size and shape. The tube was exhausted to the phosphorescent point, and the current was turned on, C being made negative and D positive. No heat was applied. The current was kept on for about half an hour, until a good deposit of metal had been deposited on the glass, the appearance being as shown in Fig. 4, the glass near the pole C being coated with metal, while the glass round the pole D was clean. The outer boundary of the dark space during the experiment is shown by the dotted line *e f*.

The pole B was now made positive, and pole A negative, the current being kept on for another half hour, At the end of the time the only additional effect was a slight darkening round the lump of cadmium, in the same place as, but very much fainter than, the deposit shown in Fig. 5. This is probably due to a little leakage of negative discharge from the positive pole. The experiment shows that positive electrification does not cause the metal sensibly to volatilize.

In these experiments no estimation was made of the weight of metal removed. To render the experiment quantitative, and at the same time to remove any disturbing effect that might be caused by heating at the point of indifferent contact, the following experiments were made:

A U-shaped tube, Fig. 6, had a platinum pole sealed in each end. Six grains of pure cadmium were put into each limb and fused round the platinum wire. The ends of the tube were then put into an air-bath, and kept at a temperature of 200°C. during the continuance of the experiment. The exhaustion remained at 0.00076mm., or 1 M. The induction current was kept going for 35 minutes. At the end of this time it was seen that most of the cadmium had disappeared from the negative pole, leaving the platinum wire clean, no metal being deposited near it, and the

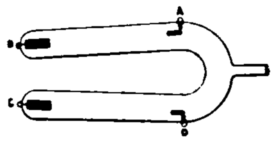

FIG. 3.

FIGS. 4 AND 5.

molecules appearing to have been shot off to a distance of about ¾in. The appearance of the postive pole was very different; scarcely any of the cadmium had been volatilized, and the condensed metal came almost close to the pole. The tube was opened, and the remaining wires and metal were weighed. The cadmium was then dissolved off the poles in dilute acid; the residue was washed, dried, and weighed.

	Positive pole.	Negative pole.
Original weight of cadmium......	6.00 grs.	6.00 grs.
Cadmium remaining on the pole...	3.65 "	0.25 "
Cadmium volatilized in 35 mins....	2.35 "	5.75 "

The difference between the amount of cadmium driven from the two poles having proved to be so decided, another experiment was tried in a tube so arranged that the metal could be more easily weighed before and after the experiment. The apparatus is shown in Fig. 7. A tube is blown U-shaped, having a bulb in each limb. The platinum poles were, as before, at the extremities of each limb, and in each bulb was suspended from a small platinum hook a small lump of cadmium, the metal having been cast onto the wire. The wires were each weighed with and without the cadmium. The tube was exhausted, and the lower half of the tube was enclosed in a metal pot containing paraffine wax, the temperature being kept at 230° C. during the continuance of the experiment. A deposit around the negative pole took place almost immediately, and in five minutes the bulb surrounding it was opaque with deposited metal. The positive pole with its surrounding luminosity could be easily seen the whole time. In 30 minutes the experiment was stopped, and after all was cold the tnbe was opened and the wires weighed again. The results were as follows:—

	Positive pole.	Negative Pole.
Original weight of cadmium........	9.34 grs.	9.38 grs.
Weight after experiment	9.25 "	1.86 "
Cadmium volatilized in 30 mins. ..	0.09 "	7.52 "

Finding that cadmium volatilized so readily under the action of the induction current, about 350 grains of the pure metal was sealed in a tube, and the end was heated to a little above the melting point.[2] The whole volatilized and collected at the opposite (positive) end, without touching the pole.

Volatilization of Silver.—Silver was the next metal experimented upon. Small lumps of pure silver were cast on the ends of platinum wires, and suspended to the inner ends of platinum terminals passing through the glass bulb. The platinum wires were protected by glass, so that only the silver balls were exposed. The whole apparatus was enclosed in a metal box lined with mica, and the temperature was kept as high as the glass would allow without softening. The apparatus was exhausted to a dark space of 3mm., and the current was kept on for 1¼ hours. The weights of silver, before and after the experiment, were as follows:—

	Positive pole.	Negative pole.
Original weight of silver............	18.14 grs	24.63 grs.
Weight after the experiment.......	18.13 "	24.44 "
Silver volatilized in 1¼ hours.......	0.01 "	0.19 "

It having been found that silver volatilized readily from the negative pole in a good vacuum, experiments were instituted to

1. Abstract of a paper read before the Royal Society, June 11, 1891.

2. Cadmium melts at 320° and boils at 860°.

ascertain whether the molecules of metal shot off from the pole were instrumental in producing phosphorescence. A glass apparatus was made as shown in Fig. 8. A pear-shaped bulb of German glass has near the small end, an inner concave negative pole, A, of pure silver, so mounted that its inverted image is thrown upon the opposite end of the tube. In front of the pole is a screen of mica, having a small hole in the centre, so that only a narrow pencil of rays from the silver pole can pass through, forming a bright spot of phosphorescence, D, at the far end of the bulb. The exhaustion was pushed to a high point, 0.00068mm., or 0.9 M. The current from an induction coil was allowed to pass continuously for some hours, the silver pole being kept negative, so as to drive off a certain portion of the silver electrode. On subsequent examination it was found that the silver had all been deposited in the immediate neighborhood of the pole, whilst at the far end of the tube the spot D, that had been continuously glowing with phosphorescent light, was practically free from silver.

A tube was next made as shown in Fig. 9. It had two negative poles connected together, A, A′, so placed as to project two luminous spots on the phosphorescent glass of the tube. One of the electrodes, A′, was of silver, a volatile metal; the other, A, was of aluminum, practically non-volatile. On connecting the two-negative poles, A, A′, with one terminal of the coil, and the positive pole, B, with the other terminal, it was seen in the course of half an hour that a considerable quantity of metal had been projected from the silver negative pole, blackening the tube in its neighborhood, while no projection of metallic particles took place from the aluminum positive pole. During the whole time of the experiment, however, the two patches of phosphorescent light, C and C′, had been glowing with exactly the same intensity, showing that the active agent in effecting phosphorescence was not the molecules of the solid projected from the poles, but the residual gaseous particles, or "radiant matter."

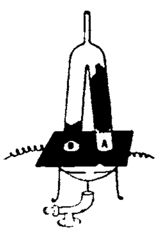

FIG. 6.

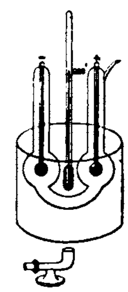

FIG. 7.

In the tubes hitherto made containing silver, it had not been easy to observe the spectrum of the negative pole, owing to the rapid manner in which the deposit obscured the glass. A special tube, Fig. 10, was therefore devised of the following character. The silver pole A was attached to the platinum pole at one end of the tube, and the aluminum positive pole, B, was at the side. The end of the tube opposite the silver pole was rounded, and the spectroscope was arranged to observe the light of the volatilizing silver "end on," as shown in the figure. In this way the deposit of silver offered no obstruction to the light, as none was deposited except on the sides of the tube surrounding the silver. At a vacuum giving a dark space of about 3 mm. from the silver, a greenish-white glow was seen to surround the metal. This glow gave a very brilliant spectrum. The spark from the silver poles in air was brought into the same field of view as the vacuum glow, by means of a right-angled prism attached to the spectroscope, and the two spectra were compared. The two strong green lines of silver were visible in each spectrum; the measurements taken of their wave-lengths were 3,344 and 3,675, numbers which are so close to Thalén's numbers as to leave no doubt that they are the silver lines. At a pressure giving a dark space of 2 mm. the spectrum was very bright, and consisted chiefly of the two green lines and the red and green hydrogen lines.

If, for the negative electrode, instead of a pure metal such as cadmium or silver, an alloy was used, the different components might be shot off to different distances, and in this way make an electrical separation—a sort of fractional distillation. A negative terminal was formed of clean brass, and submitted to the electrical discharge *in vacuo;* the deposit obtained was of the color of brass throughout, and on treating the deposit chemically I could detect no separation of its component metals, copper and zinc.

If we take several liquids of different boiling points, put them under the same pressure, and apply the same amount of heat to each, the quantity passing from the liquid to the gaseous state will differ widely in each case. It was interesting to try a parallel experiment with metals, to find their comparative volatility under the same conditions of temperature, pressure, and electrical influence. It was necessary to fix upon one metal as a standard of comparison, and for this purpose I selected gold, its electrical volatility being great, and it being easy to prepare in a pure state.

An apparatus was made with four negative poles at one end and one positive pole at the other, shown in Fig. 11. By a revolving commutator I was able to make electrical connection with each of the four negative poles in succession for exactly the same length of time (about six seconds); by this means the variations in the strength of the current, the experiment lasting some hours, affected each metal alike. The exposed surface of the various metals used as negative poles was kept uniform by taking them in the form of wires that had all been drawn through the same standard hole in the drawplate, and cutting them by gauge to a uniform length; the actual size used was 0.8 mm. in diameter, and 20 mm. long. The comparison metal, gold, had to be used in each experiment; the apparatus thus enabled me to compare three different metals each time. The length of time that the current was kept on the revolving commutator in each experiment was eight hours, making two hours of electrification for each of the four negative electrodes; the pressure was such as to give a dark space of 6 mm.

The following table of the comparative volatilities was in this way obtained, taking gold as = 100:

Palladium	108.00	Platinum	44.00
Gold	100.00	Copper	40.24
Silver	82.68	Cadmium	31.99
Lead	75.04	Nickel	10.99
Tin	56.96	Iridium	10.49
Brass	51.58	Iron	5.50

In this experiment equal surfaces of each metal were exposed to the current. By dividing the numbers so obtained by the specific gravity of the metal, the following order is found:

Palladium	9.00	Cadmium	3.72
Silver	7.88	Copper	2.52
Tin	7.76	Platinum	2.02
Lead	6.61	Nickel	1.29
Gold	5.18	Iron	0.71
Iridium	0.47		

Aluminum and magnesium appear to be practically non-volatile under these circumstances. The order of metals in the table shows at once that the electrical volatility in the solid state does not correspond with the order of melting points, of atomic weights, or of any other well-known constant.

It is seen in the above table that the electrical volatility of silver is high, while that of cadmium is low. In the two earlier experiments, where cadmium and silver were taken, the cadmium negative electrode in 30 minutes lost 7.52 grs., whilst the silver negative electrode in 1¼ hours only lost 0.19 gr. This apparent discrepancy is easily explained by the fact (already noted in the case of cadmium) that the maximum evaporation effect, due to electrical disturbance, takes place when the metal is at or near

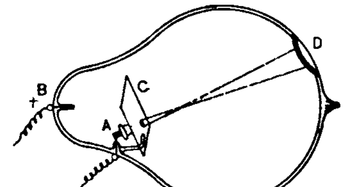

FIG. 8.

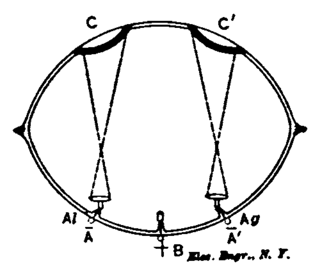

FIG. 9.

the point of liquefaction. If it were possible to form a negative pole *in vacuo* of molten silver, then the quantity volatilized in a given time would be probably much more than that of cadmium.

Gold having proved to be readily volatile under the electric current, an experiment was tried with a view to producing a larger quantity of the volatilized metal. A tube was made having at one end a negative pole composed of a weighed brush of fine wires of pure gold, and an aluminum pole at the other end. The tube was exhausted and the current from the induction coil put on, making the gold brush negative; the resistance of the tube was found to increase considerably as the walls became coated with metal, so much so that, to enable the current to pass through, air had to be let in after a while, depressing the gauge ½mm. The weight of the brush before experiment was 35.4949 grs. The induction current was kept on the tube for 14½ hours; at the end of this time the tube was opened and the brush removed. It now weighed 32.5613, showing a loss of 2.9327 grs. When heated below redness the deposited film of gold was easily removed from the walls of the tube in the form of very brilliant foil. After having been subjected to electrical volatilization, the appearance of the residual piece of gold under the microscope, using a ¼ in. object glass, was very like that of electrolytically deposited metal, pitted all over with minute hollows.

This experiment on the volatilization of gold having produced good coherent films of that metal, a similar experiment was tried, using a brush of platinum as a negative electrode. On referring to the table it will be seen that the electrical volatility of platinum is much lower than that of gold, but it was thought that, by taking longer time, a sufficient quantity might be volatilized to enable it to be removed from the tube. The vacuum tube was exhausted to such a point as to give a dark space of 6mm., and it was found, as in the case of gold, that as a coating of metal was deposited upon the glass the resistance rapidly increased, but in a much more marked degree, the residual gas in the tube apparently becoming absorbed as the deposition proceeded. It was necessary to let a little air into the tube about every 30 minutes, to reduce the vacuum. This appears to show that the platinum was being deposited in a porous, spongy form, with great power of occluding the residual gas. Heating the tube when it had become in this way non-conducting, liberated sufficient gas to depress the gauge of the pump 1mm., and to reduce the vacuum so as to give a dark space of about 3mm. This gas was not re-absorbed on cooling, but on passing the current for 10 minutes the tube again refused to conduct, owing to absorption. The tube was again

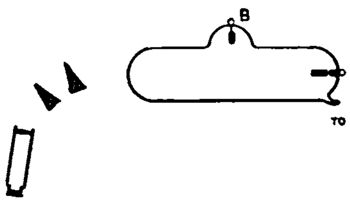

FIG. 10.

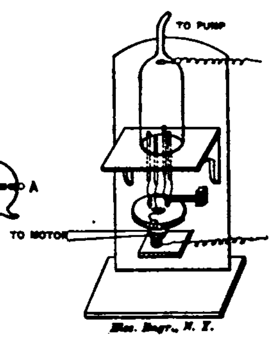

FIG. 11.

heated, with another liberation of gas, but much less than before, and this time the whole was re-absorbed on cooling. The current was kept on this tube for 25 hours; it was then opened, but I could not remove the deposited metal except in small pieces, as it was brittle and porous. Weighing the brush that had formed the negative pole gave the following results:

	Grains.
Weight of platinum before experiment..........	10.1940
" " after experiment..........	8.1570
Loss by volatilization in 25 hours...............	2.0370

Another experiment was made similar to that with gold and platinum, but using silver as the negative pole, the pure metal being formed into a brush of fine wires. Less gas was occluded during the progress of this experiment than in the case of platinum. The silver behaved the same as gold, the metal deposited freely, and the vacuum was easily kept at a dark space of 6mm. by the very occasional admission of a trace of air. In 20 hours nearly 3 grs. of silver were volatilized. The deposit of silver was detached without difficulty from the glass in the form of brilliant foil.

ELECTRIC NIGHT SIGHT FOR ORDNANCE.

The British Navy Department are using illuminated night sights on many of the guns of their war ships The sights are so constructed that they can be put on or removed in short time. The front sight consists of a metal socket inclosing a very small cone of pale-green glass, point up, and with only the rear half showing. A small incandescent light is placed under this cone, the light from which shines up through the base of the cone and is then reflected to the rear. The rear sight is similar except that instead of the cone there is a metal cross-bar with a V notch in the middle and a polished under surface, from which the light, which first passes through a ruby-colored glass, is reflected. In sighting, the point of pale-green light is brought to the bottom of the V notch and the line of ruby-colored light brought into coincidence with it. The electric current used is local for each gun, and is supplied by a battery of two elements contained in a water-tight box, so arranged that when turned upside down the battery is out of action and can be kept so until the sights are needed for use. The light can be brightened or dimmed.

Legal Notes.

EDISON INCANDESCENT LAMP LITIGATION—V.

CLOSING ARGUMENT OF GROSVENOR P. LOWREY, ESQ., FOR THE EDISON CO.

UPON the opening of court on June 3d, the closing argument for the complainants' was commenced by Grosvenor P. Lowrey, Esq. Mr. Lowrey commenced by saying that he regarded this contest as the most dignified and the most important one in which he had ever taken part; that he never expected to be engaged in another one comparable with it in dignity and importance. It was a great cause; whether they regarded the subject, which was great and complex, or the vast pecuniary interests, or the personal fame and noble ambitions of inventors and men of science which it involved. The truth of history was in issue, and future generations had a right to know it. It was a controversy prosecuted in the presence of a great tribunal, holding its commission to decide with all the sanction which the highest civilization, exerting itself through the most perfect system of laws, could give. The investigation which it was his Honor's duty to conduct must be cold and impartial, the judgment must be pronounced without reference to the extent of interests involved, without reference to consequences, however vast or however complex, for it was after all only a question of law. Certain elements had affected the case which could not be fully revealed to his Honor in the record, and yet could not be concealed. They were here dealing with interests in which personal feeling had become involved, and which had given to all in the case a certain color. They were not only dealing with the question of who had actually made the incandescent lamp and had obtained the patent in suit, but with the fact that there had been a resolute and persistent denial from the beginning, by a rapidly decreasing number of persons, of the just title and fame of Mr. Edison. He (Mr. Lowrey) represented a man who most of the world considered a great inventor and benefactor. The few remaining who still persisted in the contrary belief were nearly all present in that room, or in the record as witnesses for the defence. It was fair that an inventor should be weighed in a balance fitted to weigh the fine spiritual work of genius. Genius never intimated nor judged; it perceived. Lord Bacon had said:

> "The introduction of great inventions appears one of the most distinguished of human actions, and the ancients so considered it; for they assigned their divine honors to the office of invention, but only heroic honors to those who displayed civil merit; such as the founders of cities and empires, legislators, the deliverers of their country from lasting misfortunes; the quellers of tyrants and the like. And if any one rightly compare them, he will find the judgment of antiquity to be correct; for the benefits derived from inventions may extend to mankind in general, but civil benefits to particular lands alone; the latter, moreover, last but for a time, the former forever. Civil reformation seldom is carried on without violence and confusion, while inventions are a blessing and a benefit, without injuring or afflicting any."

There was now presented to his Honor the question, whether a man whom Lord Bacon's description clothed with striking aptness, after years of struggle and endeavor, and in full view of the great benefits conferred by him on mankind, could by a petty parsing and spelling of things; a subtle analysis of words and sentences composed in a patent solicitor's office; and especially words devised touching a subsequent application, lose the invention he had given to the world. Mr. Edison was a character quite unique and unprecedented in the history of the art. No wonder he had startled the idiots of the schools, and excited the animosities of men who teach to unresisting boys the knowledge, as well as the errors, found in books.

Endowed by nature with rarest faculties of observation; capable of realizing beforehand all that was to take place in any hitherto hidden physical action; with highest courage and enthusiasm; indomitable energy; capacity of concentration equal to that of the microscope; and notwithstanding the reprehensible suggestion of his friend Gen. Duncan,—a man whose modesty and intellectual honesty were as monumental as his constructive genius; a man most unjustly and insultingly derided by those who were as incapable of understanding him as they were of doing him justice. Edison had been an inventor by nature and from the beginning. His first thought had been a question; his constant tendency to remedy that which was deficient. He was not to be spoken of as an electrical engineer; nor yet as a philosophical discoverer; he was a commercial and industrial inventor, whose sole object it was to make things useful to mankind, taking his fair reward, as every laborer took his hire. To him, an abstract principle incapable of being applied to ameliorate some condition of human life, was as valueless as a cup of water thrown into a lake. Why go after that water? Mr. Edison runs quickly to the overflow, catches it there and uses it to turn a mill.

Bear in mind that he was not a reader of books, in the ordinary sense, neither was he an absorber nor derider of other men's ideas, not that he despised books, but his impulse was if the books said a thing could not be done to say: Don't stop with that, but try to do it. And one result of not stopping, but of trying to do things declared to be impossible, has been this electric light, and many other inventions given to the world by him. Mr. Edison had perhaps the most valuable private scientific library in the world, but he was no slave to books. He (Mr. Lowrey) had heard him say "It is a poor nature that has not got this thing in it; and if it has, give us time and don't bother us with books, and we will find it." That was the kind of man towards whom the scientific experts of the other side had been particularly contemptuous from the beginning; that was the kind of man who had given to mankind what he should sometimes call the "light of the patent" and sometimes the "Edison light"—in his construction absolutely synonymous terms. That was the man who stood for the moment, with the chance of losing his invention after he had made it, and gone away to other works, by some trifling pen-and-ink business in the shop routine of a patent solicitor's office.

His brother, Wetmore, with an art and judgment which it had not needed this case to give him a reputation for, had reserved until the last his most effective word. The effect produced upon him (Mr. Lowrey) had been like one of those sudden attacks of illness which when taken at once was easily controlled, but, otherwise was liable to result in constitutional difficulties which might take a great deal of skill to remove. He hoped to be able to disperse whatever ill influence that argument might have had, and although it was to the utter disordering of all his plans, he should devote himself first to the divisional application of 1880, and afterwards to his brother Betts and his eccentric understanding of the English decisions.

The question immediately under consideration was whether, as the defendants had asserted, when Mr. Edison had talked about a burner and a lamp, he had meant only a lamp in which the burner was made in a coil; or whether, as complainants contended, he had meant a lamp in which the burner was in whatever form was useful, as falling within the general and sufficient language of the art. His brother, Wetmore, was like that serpent which carried its sting in its tail; he had given them the last thrust, and it was a sharp one. He had proposed to read from a paper for which Mr. Edison was, as he thought, in his conscience and personally responsible, words which he (Mr. Lowrey), had never heard of before, and it seemed to him at first hearing to put Mr. Edison in an inconsistent position, and as displaying a motive which would justly rob him in a degree of his honor's esteem. His brother, Wetmore, had said: "In their sworn specification, in which they state that claim now pending before the Patent Office, and referring to this patent, they say:

'In my patent No. 223,898 is described and shown a lamp which meets all the conditions of commercial manufacture and use but has the disadvantage of being provided with a closely coiled filament, parts of which do not radiate available light but serve to heat other parts of the filament resulting in an intensely concentrated light which is disagreeable to the sight. The loop or horseshoe filament of my present lamp is more convenient and economical in manufacture and radiating available light throughout the length of its incandescent portion, a lamp which is better adapted for general use.'

Mr. Wetmore's statement that this language was contained in the sworn specification of Mr. Edison was true in a false sense; it was true that such words were in the specification; they had been actually inserted by amendment seven years after the specification had been sworn to, and entirely without Mr. Edison's knowledge. They had been inserted by his attorney, Mr. Dyer. One Mr. Serrell, a very respectable practitioner, had drawn the specification for the patent in suit; then Mr. Z. F. Wilber, now dead, had become the solicitor of Mr. Edison. He could conceive that Mr. Wilber's first work had been to look around and see how he could magnify his own merit by finding things by his predecessor left undone and to be done. He had found on file in the Patent Office an application for a patent on paper carbon. It had then contained nothing inconsistent with the patent in suit. In December, 1880, Mr. Wilber, as he (Mr. Lowrey) might fancy, having found his opportunity to show how great a man he was, had added the claims now thought to be inconsistent with the idea Mr. Edison had, when he took out the patent in suit. Even if it should be found that there were differences between the pending application so called (in fact it was not pending, it had long been dead) and the claims of the patent in suit, he supposed it was not forbidden to an active-minded man like Mr. Edison to change his mind with respect to the invention.

His Honor remarked that he did not think it important as bearing upon the construction of the patent in suit whether the application referred to was dead or not.

Resuming, Mr. Lowrey said that the application had proceeded to a consideration three times by the Commissioner of Patents. In its last decision the Office had held the invention to be identical with that shown, described and *claimed* in the patent in suit; so there had been a judicial construction, and a decision that had ended the controversy, to the effect that the patent in suit was like the application on which Mr. Wilber had sought to obtain for Mr. Edison a patent. They had, therefore, only to deal with a mixed, moral and equitable question: whether Mr. Edison, through Mr. Wilber, thought differently at different times, as to what was the legal construction of a paper, was, after all his great labors, to lose the fruits of them, for such a reason as that.

He would compare the divisional application with the patent in suit, and by a critical analysis endeavor to satisfy his Honor that there was nothing in the question which had been made thereon, and never had been anything in it than color and pretense.

Mr. Lowrey then entered at considerable length into a comparison of the pending divisional application with the patent in suit, and commenting thereupon, contended that Mr. Edison's act in making his application of December, 1880, could not in any way aid the Court in construing the claims of the patent in suit. He said that the complainant might safely admit, for the sake of argument, that the first claim of the application of December, 1880, was identical with complainant's construction of the first claim of the patent, and that the fifth claim of the application was identical with the second claim of the patent; and still maintain that Mr. Edison's act in making that application had not proved that he had not intended to make the first two claims of the patent in suit bear the construction for which the complainants were now asking, and for which they had always contended. They were to inquire what Mr. Edison had intended at that time; not what he had thought after he had changed his mind. The facts would, at most, show that thirteen months after making the claims for the patent in suit, Edison had come to fear that they might be construed more narrowly than he had originally intended to make them, and to fear that the utmost subtlety might be employed to attack his claims, and that he ought to protect his invention by a subordinate patent. It is conceivable that such a fear, if Mr. Edison had entertained it in December, 1880, might have arisen entirely out of rumors which might have come to his ears, of arguments in favor of unduly narrowing the construction of those claims; such arguments, perhaps, as those which had here been presented by defendant's counsel.

There was nothing of value in the present discussion, except to find out what Mr. Edison had meant; and certainly no intention could be inferred from facts which, as he says, had been unknown to him. Therefore, when they came to what he had said when Gen. Duncan examined him; when he had remarked, with a good deal of emphasis, that he did not understand Ohm's law; it was the answer of a scholar and of a philosopher. His brother Duncan had spoken of it to his Honor in a tone of contempt. Mr. Edison was not merely not an "expert," but he was not one of that class to whom he (Mr. Lowrey) was going to give a fitting name. There had been some experts in this case who were entitled to be distinguished above the rest of their class; they were "expert experts;" Mr. Edison had encountered one of those, and could not answer his questions. Mr. Lowrey then read a long extract from the testimony of Mr. Edison, having reference to his personal knowledge of the contents of the amended divisional application, and proceeded to argue that it was evident that the opinions of Mr. Wilber, the attorney, could not have been based upon any information received from Mr. Edison, but had been formed entirely upon his own estimate of the significance of the words of the first claim of the patent in suit. While Mr. Wilber had been Mr. Edison's attorney for the purpose of making and altering applications for patent, he could have had no authority and no function for furnishing evidence out of his own mind as to the state of Mr. Edison's mind in the previous year. He thought that this whole business arising out of expressions in that divisional application had disappeared, but the pertinent question would be asked: If there was nothing in it, why had we fought so to keep it out of the evidence? His brother Seward, who had read the papers, had said there was nothing in them of legal significance; his brother Dyer had been indisposed to resist it; it had been an entire surprise to him (Mr. Lowrey) to find in the specification those words which did seem to involve a certain moral indirection; it had startled and alarmed him, for he desired his client to stand well in the appreciation of the Court, but he took all the blame upon himself; he had read an affidavit by Mr. Curtis who stated that he had learned from persons formerly employed in the Patent Office that there was a pending application on file, which, if it could be seen, he believed would be found to contain things useful to the defendants, and that they had asked to have those papers. Now, amiability of an extreme sort, like his own, might be presumed on too far, and that was really too much. An application had been made to his Honor for help to get at those papers, and subsequently, equally without success, to other courts, and finally they had subpœnaed complainants and they had brought those papers into court in a sealed box. He did not know what was in the box, but he did know that a man, whom he regarded as a vagrant and a foot-pad, was demanding to open the box to see, in the language of the affidavit, if there was not something there which they might, if they saw fit, put in evidence. If it was asked why they had resisted, it was in defense of personal rights; he trusted his Honor would not be prejudiced that they stood up for a legal right in the face of an outrageous and insulting demand. He implied no criticism upon the final judgment, it was right, because the Court had said it was right, but at the Court of Appeals he should speak again on that subject and with emphasis.

Mr. Lowrey said he would next give some attention to his brother Betts. Complainants were in possession of authority of such influence that he did not wonder defendants had deputed the most adept sapper and miner he knew of, to get under the

English decisions, and if his way of getting under had been a straight way, what he had said would have been very effective, but his brother Betts had undertaken to criticise the English decisions upon the general ground that while they were good enough decisions for the facts they had, they would not serve for the facts here. He said the English courts did not know that complainants had elsewhere patented the principle of high resistance and small radiating surface; that they did not know about the platinum patent, and that the German court did, and that made all the difference in the world; and that his Honor would have to put aside those English decisions as having been pronounced without sufficient knowledge of the facts. His brother Betts had not examined all the English cases. With what difficulty did we see things we were not looking for, and sometimes we did not see for a long time what we were looking for; an observation which had a good deal of point in reference to the slow development of electric light people who were so busy looking for certain particular things that they did not see certain other particular things.

Mr. Lowrey then read extracts from the decision of Mr. Justice Kay, and the record in the Holland (English) case, and concluded his comments thereupon, by observing that Mr. Betts had supported the corner-stone of his criticism upon the erroneous assumption that the English courts had not heard of the platinum patent, but that it must now be carted away and tumbled into the dock.

Mr. Edison's invention, said Mr. Lowrey, was divisible into parts which together constituted a history. In 1878 he had come from Ansonia, where he had seen for the first time an arc light of 4,000 c. p. He had thought about that lamp and had said to himself: "That is not illumination in the great and important sense. Ninety-five per cent. of the illumination is inside of houses; why does not somebody make a small lamp?" The answer which the state of the art had given him was: "You cannot make any small lamps; if you divide the light, the loss is so great there is no use of talking about it; it is not worth trying." He (Mr. Lowrey) wished to impress upon his Honor that the platinum, the carbon, and other lamps, were not interchangeable inventions; they were rather like grapes growing from one vine, each by its separate stem but all having a common root; a root first indicated in an article published in the New York *Sun*. The reporter tells us that Edison, after returning from Ansonia, experimented with electric lights. On Friday, Octobr 4th, 1878, his efforts were crowned with success, and the project that had filled the minds of scientific men for years was developed. "I have it now"—he said—"and singularly enough I have obtained it through an entirely different process than that from which scientific men have always sought to secure it." He had used the word "process." "With the process I have just discovered, I can produce 1,000—aye 10,000—from one machine; indeed, the number may be said to be infinite."

Probably he had not even got to the point of thinking what kind of a lamp he should make; but he had intellectually evolved the *process*. "The great loss of energy," said this practical and sane man, "is no loss, because there is no loss in not using a thing you do not want; what I want"—he said—"is ten lamps of ten c. p. each in place of a thousand c. p. lamp." The art had told him if he divided it he could not get ten lamps, for there would be no light in any of them. He reflected upon it, and because he was Edison, he saw at once the whole which happened afterwards, by way of trying lamps of platinum; of this thing and of that thing; which, although they each constituted a separate invention were one and all an exemplification of the discovery of the subdivision of the electric light. Mr. Edison had seen that to insure the independence of his separate lamps he must use the multiple-arc distribution; but the multiple arc was not claimed to be an invention of Mr. Edison. The laws of nature, as he might say in speaking of his friend Duncan's ingenious argument, had not been made by Mr. Edison; the credit for those laws still rested with God.

But then he had found a new trouble; when more lights were put on, more current must be supplied. Prof. Farmer had read a paper in 1879, and had said there was no trouble about the subdivision of the light if there was "enough conductivity;" that would do if one had enough copper, or enough money to get the copper, but nobody had enough.

Then had been evolved the Edison principle of applying resistance in the lamps, for the purpose of economizing copper, and at the same time of making each lamp independent.

That was the outcome of the visit to Ansonia; that was the process, which Mr. Edison had said was so simple that when the scientific world heard of it, they would wonder that they had not thought of it before. Of course the lamp was not then made; it was in the man's brain, but he saw it as clearly from that hour, as he had since seen it burning. They now knew, by various things that Edison did immediately afterwards in pursuance of it, that that process was nothing in the world but making a burner commensurate in radiating surface and in resistance, and any radiating surface whether highest or not, or any resistance, whether highest or not, which was adjusted to the purpose of achieving that economy, was a theft from Mr. Edison and an infringement of his patent. It was well known that the human mind was a very slow-acting machine; it did not usually see the things which lay just before it. Everyone acted under the sway of prejudgments about everything. We did not do many of the best things because we were under the sway of prejudice. Mr. Lowrey illustrated this point in a striking manner by reading an extract from the introductory remarks of Grove in his work on the "Correlation of Forces," in which, the author, speaking of the tendency of the human mind, when a new phenomenon was for the first time observed, to refer it to something previously known, observed that a theory is often put forth which shortly comes, for want of a better, to be admitted as an established truth; it is handed from father to son and gradually takes its place in education, but is nevertheless often prejudicial to the advance of science, inasmuch as theories the most immature, frequently become the most permanent.

There was a class of men, continued Mr. Lowrey, who, upon seeing a thing done, were able to believe that it ought always to have been done. Mr. Edison had been asked, referring to the leakage of the lamp chamber: "When you saw all that; the leakage, and the cause or defect; was it not obvious to cure it by fusing the parts together?" and he had replied: "Obvious! I don't know what you mean by 'obvious'; things are never 'obvious' to me until I see them." It was only to counsel and to expert experts that things are assumed to have been "obvious" before they could have been seen. His friends Dr. Cross and Dr. Morton had constructed for his Honor's benefit a lamp out of the laws of nature; his Honor would not be able to read anything by it, or to find anything in his room by it, but it was a good enough lamp for purposes of litigation. They had built it up from what one man knew about resistance, and another man knew about sealing glass globes; and they say now that it is entirely obvious that anybody could have made such a lamp if they had really had a call to do it.

It seemed there had been an error about the calling. The potential lamp makers had never been called, and the world has been without that light on account of the fault of that careless man, who had been charged with the responsibility, and who had overslept himself until Edison, not waiting for other call than the stirring of his own genius, had come. It had been the fashion to speak of this great man, Thomas A. Edison, as a charlatan, an ignorant man, a braggart. His Honor would find that to be the tone pervading the talk of many, who now seeing what has been done, wish that they had spoken more prudently in declaring what could not be done. Now, excepting Mr. Edison's answers to questions, excepting the letter he was about to read, and perhaps his paper before the scientific society, he did not know that all these seven volumes had given a glimpse of the real Edison, speaking for and by himself. Professor Morton had written to him, what he (Mr. Lowrey) thought was not an ingenuous letter. He had perhaps hoped to get Edison boasting on paper, so that he might sustain the notion of him derived from the absurd *Sun* article. In his answer you will see Thomas A. Edison; a modest, clean-cut, perfectly sincere man, a thousand fathoms deep all over, and yet thought by many people to be shallow. He says:

"Dear sir: Your favor of the 9th has just been received. The *Sun* article was somewhat exaggerated; but it is safe to say that I have some new ideas with regard to the electric light, more especially relating to the infinite subdivision of the same. I expect to put in at least six months' solid work perfecting it. Am just ordering a 50 h. p. engine for this line of experiment.

That was a block of Edison; a real specimen of the real man.

He would return for a short time to his brother Betts, who, by way of showing that plaintiffs had misrepresented the state of the art, had said that the whole subject of arranging lamps in multiple arc and series, and the making of an incandescent lamp of 10 ohms resistance, was in the Sawyer and Man patent of 1878. That statement was based upon a total misapprehension of the patent. It was principally a patent for a switch, and it stated that the resistance of the carbon when hot was ten ohms, and when cold, nil. He would pause to advise his brother Betts that he could not take his views with safety within the Sawyer and Man range; there was utter rottenness and ignorance throughout the whole. The thing which Professor Cross had told Mr. Betts when advising him upon the patent in suit, had been that carbon, when hot, has much less resistance than when cold. The statement that the carbon would acquire resistance when heated was entirely erroneous. Half-considered guesses were put on paper and filed in the Patent Office, and afterwards produced in court as a part of the state of the art. It was not impossible that a man might be hung on that kind of testimony if nobody looked into it. Professor Cross in his report on the state of the art which he had made to Mr. Betts on behalf of the Edison Company, had said that he was inclined to think that the number 10 ohms "had been stated at a venture." Of course it had been stated at a venture. Sawyer must have been in one of the conditions described by his associate on the stand, as "not lying," but probably in his other condition of "reckless drunkenness."

Mr. Sawyer was not so very much to blame, however, for being ignorant, for Prof. Farmer as late as 1879 had not struck upon the specific differences between hot and cold carbon in respect of resistance. Therefore, when you come to find Edison saying in his testimony that he found the resistance of a certain lamp to be about 100 ohms, and the matter being brought to his attention—whether he measured it cold or hot, he really does not know—it becomes clear that with none of the electricians had the point been as yet sharply focussed, and the matter of difference between cold and hot in resistance been definitely ascertained.

Starting out with Edison in 1878 upon that memorable search which resulted in the finding of the incandescent lamp, you will see that the first words from him indicate that he had an idea. He has got a process, and he believes it will take him six months to work it out. They would see him disappear underground, like a miner after a jewel, and while he was gone, they would take a little advice as to his prospects of success from the other people who were making search for the same jewel, and who were saving what a fool Edison was to go at all in that way. They would find that Morton, Preece and others had adopted the figures of Fontaine, and all the others, without a dissentient, except Sir William Thomson and Dr. Tyndall, were committed, after Edison was underground, to a statement posted above ground, that he had gone on a fool's errand. They had written across the path "no thoroughfare," and had signed it "Mathematicus." Mr. Lowrey then read several extracts, which have already become familiar in electrical literature, in confirmation of his statements. These great authorities in electricity and mathematics—said Mr. Lowrey—do not seem to be able to get outside of their figures and their equations. Professor Cross and Professor Morton had professed to be able to see what was not invention in a machine, although there was not in this case, nor probably elsewhere in the world, evidence which would convict either of those gentlemen of the possession of inventive capacity enough to hang a tin dipper on a pump.

Yet they had been called up with their pencils and their little pads to figure out that an invention like this, for which the whole world had been waiting, was after all no invention at all. It was difficult to select, there was so much of it, but Professor Silvanus Thompson was a striking example of how "away off," as the phrase was, all these people had been, about what was needed to make this light, and how Edison was going to do it. Mr. Lowrey then read from a letter of Professor Thompson the following extract:

> Much vagueness appears to exist in the minds of men upon the possibility of dividing the electric light indefinitely, and much has recently been said and written upon the question, which if tested by sober reasoning and by the application of elementary dynamical principles, will be found to be sheer nonsense. . . . . The reporter of the *New York Sun*, in his enthusiasm, puts into Mr. Edison's mouth statements which exhibit the most airy ignorance of the fundamental principles both of electricity and of dynamics.

There had been the first man to call Edison a fool. His Honor would see just how much one of the really instructed men knew or foresaw at that date. It was not ignorance; he knew all there was to be known. What was not known in the scientific world had been then developing in the brain of that ingenious man at Menlo Park. His Honor would see proofs of the influences arising out of preconceived opinions, driving everybody away from the course which Edison had taken. When Professor Thompson had said: "I cannot tell you what Mr. Edison's particular method of distributing the current of the spirals may be," he understood him to have expressed a difficulty that Mr. Edison or anybody else would have met in getting the current to the lamps; the principle of high resistance and small radiating surface having not yet reached the ears of these gentlemen. Professor Preece, too, had published another demonstration that it could not be done, because he did not know what it had been proposed to do. Preece had pointed out that with the machines then known, five or six lamps in series appeared to be about the limit of subdivision. "It is this partial success in multiplying the light"—says Preece—"that has led so many sanguine experimenters to anticipate the ultimate possibility of its extensive subdivision—a possibility which this demonstration shows to be hopeless and which experiment has proved to be fallacious." His friends on the other side had said that Preece was talking about series. Of course he was; there was nothing at that time to be talked about but series; the art had not yet conceived of multiple-arc distribution in connection with a practical light. Now Professor Morton, who was not at all limited in talking of his knowledge at any given date, provided he was speaking later than that date, after reciting previous failures, says:

> Familiar as is the fact that history repeats itself, we cannot but be struck with the many points of resemblance between the above, and what we read in the newspapers of to-day concerning the wonderful doings at Menlo Park, and must hope that Mr. Edison's invention will escape that permanent obscuration which seems to have finally shrouded M. de Changy's. . . . It is, as I understand, just here that Mr. Edison has made his much announced but carefully concealed invention. He has devised some simple and ingenious invention by which the solid conductor can be brought up to the highest point of incandescence without risk of fusion.

Now it was not uncommon for these experts, when attention was called to their incautious writings, to explain that of course they had not been talking about this or that, or else they would have said something different. Dr. Morton had thought that what Edison had done had been to invent a lamp that would not melt, and he showed very clearly that that had often been tried before, and omitted a little of his delicate sarcasm on the man who was fooling away his time trying to make a lamp that wouldn't melt, when there was that great question in mathematics, still unsolved. All these men had been "away off" from any true conception of the real difficulty, and from the real remedy, and would have stayed away off, forever. There had been absolutely no progress made in the right direction; what defendants had said about the state of the art was most admirable because it told of the absolute nothingness from which this man had started in the right direction. His direction was high resistance; and how did he achieve it? By a filament. What was a filament? A very thin long thing. Well, there had been King in 1845 who had a thin long ribbon of carbon; one could read through it. Well, one might read through a ribbon of carbon for a thousand years, and not get a filamentary structure for an electric light. The idea which had been pursued by Edison was economical and scientific. He sought high resistance accompanied by a relatively adjusted radiating surface, and having put those things together, he could cancel the orders on the copper merchant for so large a part of what had otherwise been necessary, that he could get money in Wall street with which to do business; something the mathematicians and the scientists had never thought of.

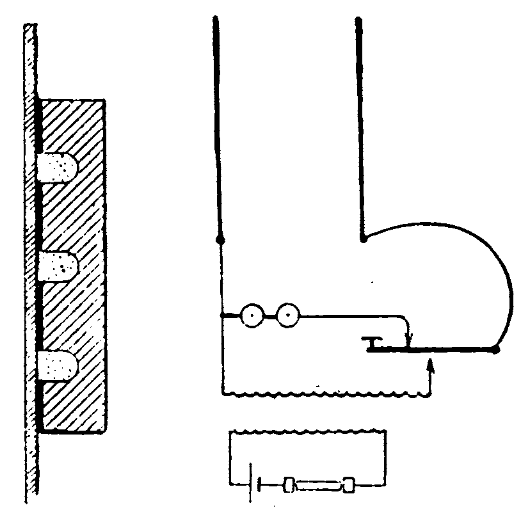
The defendants had labored quite uselessly to convince his Honor of what complainants would have conceded at any moment; that the platinum patent revealed all that was in the carbon patent, except that one crucial and all-resolving discovery, which notwithstanding the excellence of the platinum patent, was necessary to give the world electric lighting. His Honor had perhaps thought from the argument on the other side, that complainants were asking for a patent on those principles. They were supposing perhaps, that complainants were shut down to the mere discovery of the stability of carbon under certain conditions, so that if that did not involve patentable invention or discovery they had got nothing in the patent in suit. It would not be impossible to stampede the whole race of inventors, once the doctrine of interpretation which had insisted upon here should receive countenance by the Court.

(*To be concluded.*)

NOTE ON A MODIFICATION OF THE METHOD OF CONNECTING UP TELEPHONIC APPARATUS.[1]

BY E. MASSIN.

THE London-Paris telephone line was completed on Saturday, March 14th, by the laying of the submarine cable from Sangatte to St. Margaret's Bay. The following Tuesday the first experiment showed that success had crowned the enterprise, and that communication could be easily effected between the central offices.



FIGS. 1 AND 2.—MASSIN'S METHOD OF TELEPHONE CONNECTION.

All the instruments adopted in France for subterranean lines enabled conversation to be carried on more or less favorably. With the Gower-Bell, the Post Office instrument, communications were also exchanged without difficulty. Amongst the apparatus tried, the one which seemed to me to be the best, from the point of view of volume and clearness of sound, was the Roulez instrument.

In the Roulez instrument, the vibrating diaphragm is a carbon plate 10cms. in diameter. On this diaphragm is screwed a block of carbon 7cms. long, its face of contact being covered with a sheet of Bristol-board (Fig. 1), which acts as an insulator. The plate and block, insulated from one another by the Bristol-board, constitute the two poles of the microphone. The current gets from one pole to the other across fragments of incandescent lamp filaments arranged in three holes hollowed out of the carbon block and insulating sheet.

[1] *Annales Télégraphiques*, Vol. XVIII. Third Series.

I have stated that conversation was easy between the General Post Office and the Paris central office; but as soon as we added to the main line the high resistance gutta-percha covered cables which connect the central to the secondary offices, the state of affairs was altered, the voice was muffled, and while conversation was still practicable between two persons accustomed to converse by telephone, it was not, generally speaking, possible. If we took the most complex case, and tried to speak from a London subscriber's house to one at Paris, the voice was clear enough, but the volume of sound was insufficient for telephonic working.

With the existing urban lines only one apparatus was able to give the desired quantity and volume of sound, namely, the Roulez microphone, arranged in Fig. 2, where the receivers and the secondary of the induction coil are placed in parallel across the line. A special key closes the telephonic circuit, either of the receivers or of the secondary, but does not allow the two to be simultaneously to line. Instead of this arrangement, which was carried out in the apparatus employed at the Paris Observatory and the Treasury, one can keep both receivers and secondary in series and constantly in circuit, as is usually done, and content oneself by neutralizing one or the other of the two parts by short-circuiting them.

The theoretical advantages of the above modification of the usual arrangement are as follows: (1) The receivers do not spoil the transmission and the presence of the transmitter does not weaken the sound received; (2) the operator in the case of long lines does not have his ears deafened from the beginning by the currents generated by his own transmitter and traversing his receivers; (3) it is possible to increase the currents in the primary without fear of having currents in the microphone at the far end to cause troublesome crackling in the receivers at that end.

In the experiments between the Paris Observatory and the Treasury a battery of 10 Lalande cells arranged in series was used. With a *non-modified* Roulez this battery produced deafening cracklings in the receivers, and conversation was imperfect. But with the modified instrument conversation was perfect, the sound derived loud and clear, and one could even keep the receivers at some little distance from the ears and still perfectly understand what was being said.

This modification, therefore, possesses undeniable practical advantages. Applied to the Roulez instrument it increased the intensity of the sounds received at the Observatory and at the Treasury by 4 to 1, thus rendering conversation possible between a London Branch office and a Paris subscriber, to the exclusion of all other instruments tested. But the arrangement possesses two drawbacks, which are—firstly, the manipulation of the key; and, secondly, the impossibility of interrupting one's correspondent, who cannot be made to hear, so long as he is transmitting. The key is fitted in the handle of one of the receivers, and is manipulated with the thumb of the right hand; the button is pressed when transmitting, and freed when listening. This very simple manœuvre is easily learnt, and after two or three minutes' conversation the button is automatically moved without thinking. The impossibility of cutting into the conversation seems to me the only real disadvantage of the arrangement described, and we may ask whether this defect is not greatly compensated for by the increased range given to the telephone, and by the possibility of establishing communication between a Paris subscriber and a London branch office.

Letters to the Editor.

THE WINKLER DYNAMO.

In your issue of July 8th, Mr. F. A. La Roche, of Philadelphia, states that he fails to see the novelty of my dynamo as described in your issue of June 24th.

Mr. La Roche would be justified in denying any novelty if the claim were, as he seems to think, merely for a division of an ordinary armature winding between two commutators, as such a device is very old, antedating Mr. La Roche's experiment some years, and the disadvantages of which are well recognized.

My invention consists in utilizing part of the iron in the core of a Siemens drum to form a Gramme ring, or *vice versa*, the field taking its current from the latter, which, forming part of the magnetic circuit, thus answers a double purpose.

By so doing, valuable wire surface is gained, the air-gap is considerably reduced, the resistance of the copper-winding of the armature made a minimum, and the resultant resistance of the machine also decreased, while the action between the circuits is not detrimental, as in the old form of double-winding. Owing to the smaller quantity of copper wire required, the number of crossings on the heads is reduced.

In practice, the brushes of the exterior circuit may be kept in a constant position, and the field brushes moved through almost ninety degrees in regulating, with no spark at either commutator; or both brushes may be kept constant under a variable load, regulation with the field brushes being only necessary with variable, speed as in water-power installations.

These are all claims that cannot be fulfilled with the old form of machine with double copper-windings.

Some of my dynamos have been in use more than two years, and the results have been so remarkable that I have no intention of abandoning my invention, while, had it been the same as that of Mr. La Roche, I would probably have followed his example in that respect before this.

C. F. WINKLER.

TROY, N. Y., July 9, 1891.

Reports of Companies.

THE WESTINGHOUSE SITUATION.

Before the close of business on July 7, 131,096 shares of Westinghouse Electric stock had been deposited under the reorganization plan. This left only 4904 shares outstanding. The books closed that day, and the reorganizers have reserved the option of refusing further tenders of stock.

NORTH AMERICAN PHONOGRAPH CO.

The schedules of Jesse H. Lippincott, president of the North American Phonograph Company and sole licensee of the American Graphophone Company, have been filed in the Court of Common Pleas. They show liabilities of $1,191,050.47, nominal assets of $3,471,938.58, and actual assets of $168,950.92.

THE EDISON GENERAL ELECTRIC CO. has declared its seventh quarterly dividend of 2 per cent., payable August 1.

Society and Club Notes.

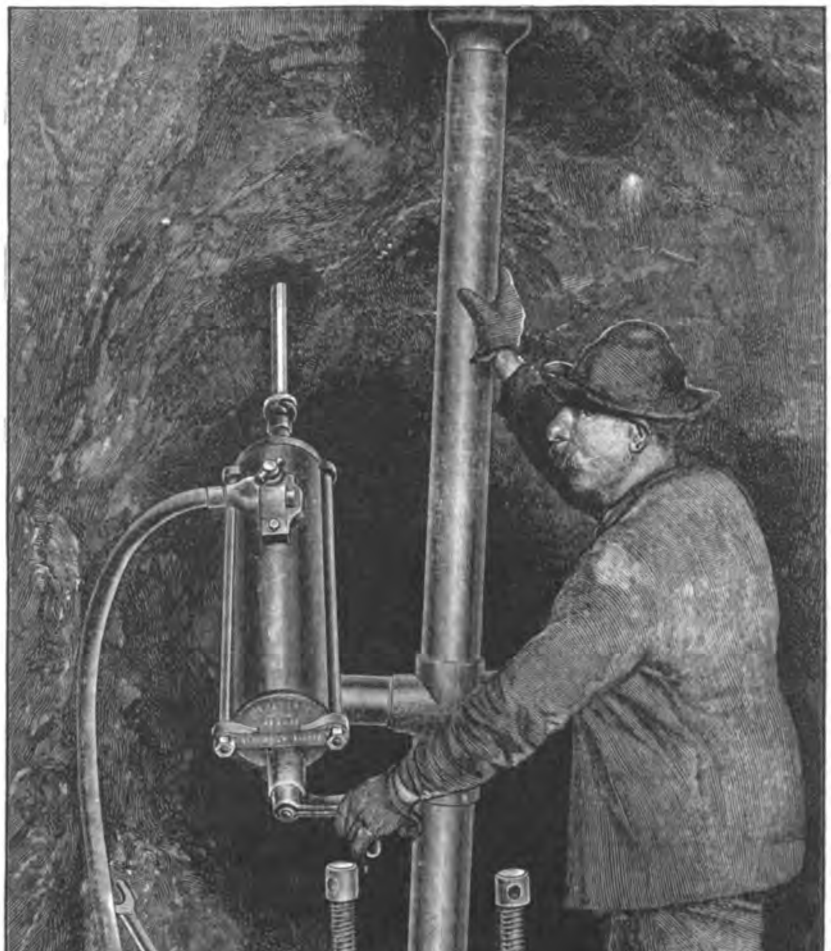
NEW YORK ELECTRICAL SOCIETY.

By invitation of the Palisades Amusement Co., extended through its consulting electrical engineer, Mr. W. J. Hammer, the New York Electrical Society was enabled last Friday to hold its annual meeting at the beautiful new resort "El Dorado," on the Hudson River heights of Weehawken. The business meeting was held at 8.15 p. m., when Treasurer Sinclair and Secretary Guy made highly satisfactory reports, showing the society to have a handsome balance and a total of 264 members. Prof. F. B. Crocker, who was in the chair, was re-elected president, Mr. H. A. Sinclair, who has so long been treasurer was re-elected, and the same honor, as secretary, fell to Mr. G. H. Guy, whose very intelligent work was acknowledged by a special vote of thanks. With these gentlemen were associated in the management for 1891-2 Messrs. E. L. Bradley, Chas. Steinmetz, T. C. Martin, W. J. Hammer, F. J. Sprague and G. H. Stockbridge. After a little other routine business the members and their friends to the number of about 200 adjourned to the amphitheatre to witness the great spectacle of the building and overthrow of Solomon's Temple. This done, they went under the escort of Mr. Hammer and Messrs. Radford and Martin, of the Thomson-Houston Co., to inspect the very neat and efficient electric light plant that has been installed. This plant, which stands apart in a building of its own, consists of three Thomson-Houston arc dynamos of 58 lights each of 1,500 c. p. and one Thomson-Houston direct incandescent dynamo of 700 lights capacity of 16 c. p. These machines are run by two McIntosh-Seymour engines of corresponding horse power, with Underwood cotton leather belting. There are two 80 h. p. boilers, single return tubular, and a 65 foot smokestack. The whole steam equipment was installed by Pearce & Thomas. There are 150 arcs scattered about the grounds on three circuits. There are 628 of the incandescents in the grand stand, castle, restaurant, offices, orchestra, dressing-rooms under the stage, and other places. It is proposed to change the lamps to 10 c. p. There are some 50,000 gas jets about the grounds. These, proving very uncertain at such a breezy altitude, cause one to hope that the electric plant will soon be extended. The plant was put in for the Thomson-Houston Co. by Mr. F. A. Bowman, and the whole work was done under Mr. Hammer's supervision and consultation.

After inspecting the plant, seeing the fireworks, and listening to an admirable concert, the Society returned to New York, with its mind fully made up that El Dorado is a place for every New Yorker to visit at once and often.

ELECTRIC DRILLING IN THE "LAST CHANCE" MINE.

THE illustration on this page affords a good idea of the ease with which electricity is introduced into mines. It shows one of the Edison drills at work in the "Last Chance" mine, at Wardner, Idaho. Speaking of the operation of the plant, which supplants a pneumatic outfit, the engineer in charge of the mine says: "Operating two air drills for twenty-four hours required five cords of wood, while for running four electric percussion drills for the same length of time, each drill doing more work than the air drills, it requires only one and one-half cords of wood. The electric percussion drills have been found to do more work than the air drills, and in consequence the air drills have been replaced by electric drills. The air plant was situated 1,000 feet higher up the mountain than was required with the electric drill, and the fuel had to be carried to the air plant this increased distance over that necessary for the electric percussion drill." Testimony of this kind is hard to gainsay, and is more than substantiated by the reports from other electric mining plants.



EDISON ELECTRIC DRILL IN THE "LAST CHANCE" MINE.

ELECTRICITY AND MINE VENTILATION.

In a communication appearing in the last issue of the *Coal Trade Journal* Mr. P. P. Quackenboss advances a novel theory to account for explosions in coal mines, which is of special interest, as the investigation was undertaken to controvert the opinion expressed by some mining engineers that the employment of electricity in coal mines was attended with danger on account of the liability to explosion due to a possible spark.

Mr. Quackenboss' investigations had led him to the conclusion that the forcing of hundreds of thousands of cubic feet of air into an air shaft to eliminate a few hundred feet of gas was a waste of power. Then, again, it was being constantly polluted by mephitic gases during its journey through a mine from the natural exudation of "blowers" and "blasting." Then carbureted hydrogen as it makes its first appearance in a mine is a *dry* gas and is expansive and inflammable, but if it finds an excess of hydrogen present it becomes a *saturated* gas and explosive. Thus, we have density and humidity and hydrogen in a finely subdivided state, and it only needs a little agitation of the air and gas to prepare a big or little pyrotechnic display.

The ordinary condition of a mine did not seem to present the excess of hydrogen spoken of above, so Mr. Quackenboss sought for it in the air forced into the mine by the fan at the mouth; he then saw at once that barometric change would produce the result if other conditions were right, and so taking a list of mine explosions to Sergeant Dunn, the Signal Service officer at New York, and explaining his theory, they took the record of temperature issued by the War Department, and selecting four cases, as follows, were surprised at the record.

January 23rd, 1889, at Wilkes Barre, explosion of mine gas. At that time the record shows a high pressure just passing off and a low pressure just approaching from the W. S. W.; barometer 30.10. April 15th, 1889, at Wilkes Barre, explosion and *precisely* the same conditions. January 18th, 1890, at Avondale, exactly the same conditions and result. June, 1890, the Hill Farm explosion at Dunbar, exactly the same conditions and result. They then started again with a list commencing with an explosion at Rich Hill, Missouri, March 23, 1888, and again the high pressure was receding and low pressure approaching; barometer 30.10 to 30.20. In all the cases from then down to January 1st, 1891, the conditions were identical, and in each case the humidity was increasing so as to be marked plus.

As a result of these investigations Mr. Quackenboss concludes that the mine ventilation of the future must be done by exhausting the foul air from the mines instead of the method now in vogue, in which the air is forced in from the outside. This will remove the final objection raised by some to the use of electricity in coal mines.

ELECTRICAL UTILIZATION OF WATER-POWER IN EUROPE.

It is expected, writes our London correspondent, that a feasible scheme will be promulgated for utilizing the countless tons of falling water in the Alpine district. A continental paper says that there are twelve towns in Switzerland erecting installations, and this activity is seen elsewhere, for in Austria an engineer proposes driving a train line electrically, as well as supplying electric light to six villages. In the Harz a syndicate is about to build an embankment across the Bodethal, and thus alleviate the inundations, at the same time utilizing the water-power for lighting the adjacent towns, Thale, Quedlinburg, and Blankenburg. The cost is estimated at 2,000,000 marks. At Lagenthal, in Switzerland, 3,000 h. p. are being obtained from the Aar for a light and power installation.

A very curious electric company has been formed at the village Faide, on the Gotthard railway, a place numbering 1,000 inhabitants. It obtains from the torrent Pinmogna a small supply of water (35 litres per second) by means of an iron pipe, which drives below a small high-pressure turbine, which, with a pressure of water of 145 metres, evolves 45 h. p. The turbine drives a dynamo which supplies the little village with 360 glow lamps. The whole cost 40,000 francs. In this manner, in addition to the streets and the railway station, the peasants and workingmen have their houses supplied very cheaply with the electric light, which is elsewhere regarded as a luxury.

FOUR murderers and one horse were executed by electricity at Sing Sing last week. The thing was done in secret, in accordance with the law which established electrical execution in New York, but the current appears to have been turned on each prisoner more than once. The crime of the horse is not stated.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED JUNE 30, 1891

Alarms and Signals:—

Hotel Indicator, F. B. Wood, 454,924. Filed Aug. 2, 1890.
A recording or indicating system; including means for signaling from the office of a hotel, or from a main station, to rooms or sub-stations, to indicate fire or for other purposes.

Electric Signaling Apparatus, M. Martin, 454,973. Filed Nov. 5, 1888.
Especially applicable to fire-alarm service, but applicable for other purposes. May be operated automatically or by hand.

Circuit for Electric Signaling, M. Martin, 454,974. Filed Nov. 5, 1888.
Particularly applicable to fire-alarms.

Circuit Closer for Burglar Alarms, D. A. Palmer, 455,005. Filed May 26, 1890.

Electrical Annunciator, W. F. Harte and C. A. Gerold, 455,016. Filed Mar. 28, 1891.
Especially adapted for hotel use and provides means for calling guests at previously designated times.

Push-Button, G. W. Wright, 455,086. Filed Apr. 10, 1891.

Electric Signal for Steam Vessels, D. D. Wass, 455,138. Filed Jan. 5, 1891.
For communication between the pilots and the engineers of steamers; provides means for indicating by sight as well as by sound.

Clocks:—

Electric Clock for use in Electric-Lighting and other Systems, F. von Hefner-Alteneck, 455,041. Filed Feb. 25, 1891.
Relates to the regulation of time-pieces which are inserted in electric lighting circuits or other systems of distribution. Shown as adapted to parallel distribution.

Electric Time-Denoting Device, W. Ramsay, 455,055. Filed Jan. 15, 1891.
Relates to operating and controlling a series of time-pieces from a main clock by electrical means.

Conductors, Conduits and Insulators:—

Method of Laying Electric Conduits, A. C. Chenoweth, 454,988. Filed June 30, 1887.
Forms a continuous conduit by preparing a centering, of the required shape and size, by spirally-winding a core with strips of the material of which the centering is made, withdrawing the core, and surrounding the centering with the material of the conduit in a plastic condition, and withdrawing the spiral centering after the plastic material has hardened.

Means for Constructing Electric Conduits, A. C. Chenoweth, 454,989. Filed Mar. 7, 1891.
Similar to the next above.

Dynamos and Motors:—

Electro-Dynamic Machine, G. J. Scott, 454,882. Filed Jan. 2, 1891.
Adapted to be used either as a motor or as a generator for either continuous or alternating currents.

Motor Generator or Transformer, G. J. Scott, 454,883. Filed Jan. 14, 1891.
An electric generator adapted to serve also as a motor, or, a primary and secondary circuit being provided, to serve as a transformer.

Electro-Magnetic Motor, N. Tesla, 455,067. Filed Jan. 27, 1891.
An improvement primarily designed for application to alternating-current motors of the type invented by Mr. Tesla. Employs a condenser or condensers in the armature to neutralize its self-induction. Provides an armature core, the plates or laminations of which serve as opposite plates or armatures of a condenser.

Electric Motor, F. L. McGahan, 455,109. Filed Feb. 11, 1891.
Composed of a series of coils connected by commutators and brushes to wires of a main circuit, so mounted upon a shaft that the ends of the cores of the magnet coils may be successively brought into frictional contact with the inner periphery of the wheel to be driven.

Electric Motor, F. L. McGahan, 455,110. Filed Feb. 16, 1891.
Similar to the next above. The inner periphery of the wheel to be driven has a corrugated surface which is engaged by corresponding projections upon the ends of the revolving magnet core.

Automatic Regulator for Electric motors or Dynamo-Electric Machines, S. S. Wheeler, 455,267. Filed Nov. 8, 1890.
Employs the method of shifting the position of the commutator brushes, but reduces the sparking effects generally encountered in that mode of automatic regulation by greatly increasing the magnetizing effect of the armature coils relatively to that of the field coils—making the armature magnetism and that of the field magnets nearly equal, instead of making the latter so strong as nearly to overpower the former.

Lamps and Appurtenances:—

Carbon for Electric-Arc Lamps, W. H. Lawrence, 454,873. Field April 9, 1887.
The carbon rod has a compressed seamless spheroidal end. Designed to form better points.

Electric Incandescent Lamp, N. Tesla, 455,069. Filed May 14, 1891.
Two conducting bodies, mounted in a very highly exhausted receiver, are rendered incandescent when connected directly or inductively to the terminals of a source of current of very high potential and very great frequency.

Clutch for Arc Lamps, F. H. Thompson, 455,071. Filed Oct. 18, 1890.

Electric Arc Lamp, C. R. Arnold, 455,087. Filed May 23, 1890.
Relates particularly to an adjustable arrangement of the support for the lower carbon; designed to permit the use of carbons of irregular lengths.

Filament for Incandescent Electric Lamps, G. Erlwein, 455,187. Filed Feb. 18, 1891.
Consists in providing filaments with a solid coating which will not melt at incandescent temperature, protecting the core from atomization. Employs a coating of nitrides of boron.

Socket for Incandescent Electric Lamps, B. B. Keyes, 455,297. Filed Oct. 6, 1890.

Measurement:—

Electric Meter, H. M. Pilkington and R. S. White, 454,949. Filed Sept. 26, 1890.
Relates to the class of meters in which the registering apparatus is driven by a separate source of motion and controlled by the variations of the current passing.

Electrical Meter, N. Tesla, 455,068. Filed March 27, 1891.
Maintains, by the current to be measured, a potential difference between two conductors in an electrolytic solution, uniform throughout the length of conductors exposed to the solution, and computes the energy expended in a given time by measuring the variation of the resistance of one or both conductors due to the gain or loss of metal by electrolysis.

Metal Working:—

Electric Soldering Iron, A. E. Appleyard, 455,010. Filed Oct. 1, 1890.
Has a conducting loop of platinum wire or other like material placed within the soldering head.

Miscellaneous:—

Apparatus for Removing Inductive Effects from Electric Lines, E. Thomson, 454,890. Filed April 8, 1889.
Especially applicable to neutralizing the effect on telephone lines of induction from parallel electric lighting lines. Consists, essentially, in setting up a counter-acting field of induction, operating upon two or more telephone lines, each of which latter is arranged in a different portion of the field of counter induction, so as not to induce upon each other.

Time-Lock, G. W. Adams, 454,897. Filed Feb. 9, 1891.

Aerial Cut-Out, J. R. Fletcher, 454,904. Filed Sept. 30, 1890.
A fuse cut-out for aerial conductors.

Protector for Use in Electric Circuits, W. H. Clausen, 454,926. Filed Dec. 22, 1890.
A device for diverting dangerously strong currents from telephonic, telegraphic and other apparatus by automatic means.

Phonograph Recorder or Reproducer, T. A. Edison, 454,941. Filed May 24, 1890.
Diaphragm is made thickest at its centre and thinnest at its periphery.

Phonograph, T. A. Edison, 454,942. Filed July 30, 1890.

Reproducer for Phonographs, W. McMahon, 454,947. Filed Nov. 19, 1890.
Employs a resonant box having an attached stylus.

Electric Current Regulator or Rheostat, C. D. Sigsbee, T. S. Hayward and F. S. Anderson, 454,969. Filed March 10, 1891.
Especially adapted to regulation of incandescent lamps, but may be used for other purposes requiring adjustable resistances. The resistances are composed of relatively long elastic fibres coated with a conducting substance.

Electric Heater, C. W. Drew and E. R. Francis, 454,979. Filed Feb. 20, 1890.
Employs an electric heating resistance arranged within a casing which also contains an adjustable rheostat; a switch is provided for cutting in or out the rheostat coils.

Electric Temperature Controller, E. H. Parker, 454,985. Filed Dec. 24, 1890.

Electric Switch, J. Des Brisay, 454,995. Filed Dec. 10, 1890.
A two-pole switch adapted especially for use on lighting circuits.

Apparatus for Boring Wells, F. Gardner, 455,037. Filed Sept. 1, 1890.
Employs an electric motor for operating the boring tool; the motor being of a diameter adapted to enter the bore of the well and to follow up the tool.

Automatic Electric Switch, C. O. C. Billberg and P. A. N. Winand, 455,099. Filed Nov. 11, 1890.
A time-switch, to be operated by hand or by means independent of the circuit to be controlled; applicable to the gradual throwing on or off of current serving an electric motor.

Appliance for Playing Games of Chance, A. Harris, 455,100. Filed Feb. 19, 1890.
Includes an electro-mechanical indicator.

Electric Post-Office Box, W. A. M. and R. T. F. Smith, 455,126. Filed March 4, 1891.
Employs an electro-magnetic door-releasing device.

Apparatus for Automatically Regulating the Firing of Ordnance on Ships, M. J. Cuadros, 455,176. Filed Aug. 27, 1890.
A contact device, depending upon the action of a pendulum, is employed to discharge a gun automatically when the ship, which may be rolling or otherwise moving, reaches the normal position.

Lightning Arrester, F. Mansfield and C. W. Mason, 455,223. Filed July 22, 1890.
Employs a series of safety-strips upon which a gravity lever makes contact successively.

Telethermometer, F. W. Wiesebrock, 455,268. Filed Aug. 9, 1890.

Railways and Appliances:—

Overhead Electric-Conductor System, G. J. Scott, 454,881. Filed Dec. 10, 1890.
A contact device intended to supersede the ordinary trolley and pole. Employs a long multiple-contact device adapted to hang from the top of the wire and to travel upon it, being drawn along after the car in any suitable manner.

Electric Car-Motor Jacket, J. Stephenson, 454,888. Filed Dec. 12, 1890.
A housing to protect the motor from mud and dust.

Method for Connecting Trolley and Feed Wires, J. R. Fletcher, 454,908. Filed Sept. 30, 1890.

Circuit-Connection for Electric Car Motors, A. A. Ingraham, 455,019. Filed Nov. 18, 1889.
Arrangement of circuits and switching apparatus adapted for storage-battery cars.

Insulator, J. F. Munsie, 455,107. Filed Mar. 28, 1890.
For electric railway conductors. Special provision made for excluding moisture.

Electric Railway, J. F. Munsie, 455,233. Filed May 8, 1891.
Employs an underground feeding conductor, a series of branch conductors therefrom separated by intervening spaces, overhead contacts normally out of connection with the branch conductors, and a bar mounted upon the car and in the motor circuit, the bar adapted to bring the overhead contacts successively into connection with the branch conductors.

Electric Railway, J. F. Munsie, 455,234. Filed May 8, 1891.
In connection with a feeding conductor employs a trolley track consisting of a series of sections suspended in an upright position and adapted to swing downwardly.

Electric Railway Signal, W. Stevens and H. J. Hovey, 455,296. Filed Nov. 11, 1890.
Automatic apparatus in which moving trains act upon circuit-controlling devices to alter the position of the signals to block and clear successive sections of the track.

Telegraphs:—

Electrical Transmission of Telegraphic and Time Indications, H. J. Haight, 454,867. Filed Mar. 27, 1889.
Amplification of the invention shown in the same inventor's patent of Dec. 16, 1890, No. 442,880; adds means for transmitting telegraph signals, time signals and meteorological indications.

Printing Telegraph Instrument, F. Sedgwick, 454,884. Filed June 1, 1886.
A printing telegraph machine or electric typewriter, operated by a rotary motor and the usual key-board; may be used singly as a typewriter or connected with one or more similar machines, all of which may be operated synchronously by the manipulation of any one of them or by that of a machine common to all.

Printing Telegraph, H. Van Hoevenbergh, 455,075. Filed Feb. 24, 1891.
Relates to the class of printing telegraphs in which the type-wheel is controlled by a segment contact wheel.

Printing Telegraph, D. H. Bates and H. Van Hoevenbergh, 455,291. Filed Mar. 4, 1891.
Employs two similar type-wheels on the same machine, serving to print messages in duplicate.

ALERNATING CURRENT LITIGATION.

A suit was commenced on July 2, in the U. S. Circuit Court of the district of Vermont, by the Westinghouse Electric and Manufacturing Co. against the Marble City Electric Light Company of Rutland, Vt., alleging an infringement of the patent of Rankin Kennedy, reissue No. 11,031 of September 4, 1889, for a system of electrical distribution. The real defendant in the case is the National Electric Manufacturing Co. of Eau Clair, Wis., which was the constructor of the Rutland plant. The system of distribution covered by this patent is that of operating transformers in multiple arc by alternating currents, in order to effect automatic regulation, and is an essential feature of all the alternating systems now in use. The Kennedy patent was purchased by the Westinghouse Company some years since, and is claimed to cover the fundamental invention embodying this principle.

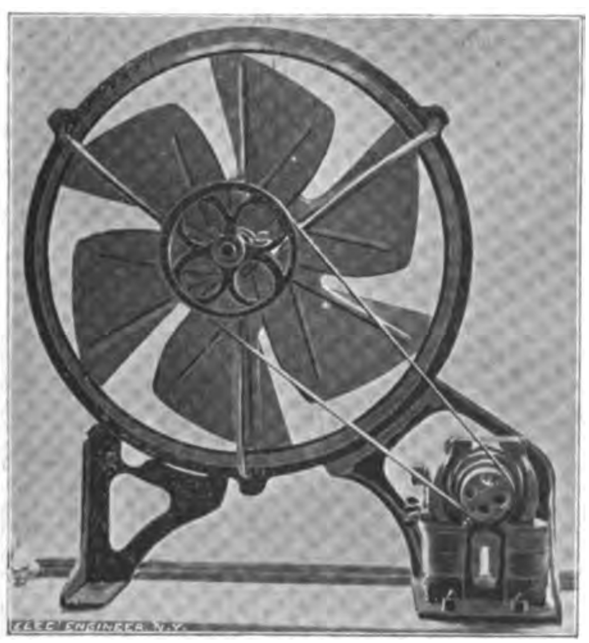
TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

An "ad" can be effective without being either saucy, or loud, or vulgar.

THE LA RUE ELECTRIC FAN OUTFIT.

THE accompanying illustration represents an electric fan combination manufactured by the Crocker-Wheeler Motor Co., of this city, for the ventilation of large rooms, halls, etc. The distinguishing feature of this combination is the relative position of the motor in regard to the fan. It has been found that, when the motor is placed at the centre of the fan, a very appreciable



LA RUE ELECTRIC FAN OUTFIT.

amount of breeze is cut off, and just so much power wasted, whereas this arrangement leaves the current of air practically uninterrupted.

The engraving shows a $\frac{1}{4}$ h. p. Crocker-Wheeler motor and 24 inch fan on one base, and known as the "La Rue Combination." Both fan and motor have self-oiling bearings, and the speed can be instantly changed from fast to slow, or vice versa, by means of a switch. The maximum speed of the fan is 600 revolutions per minute and the pulley is double flanged to prevent slipping of the belt. This combination is a very serviceable one, and has called forth many commendations.

GAYNOR ELECTRIC CO.

The Gaynor Electric Co., of Louisville, Ky., report that they are doing a large business in fire-alarm and police signal apparatus. They have just finished two large contracts for the installation of the central office fire-alarm system, one at San Antonio, Tex., and the other at Lincoln, Neb. Within the last week or ten days they have been awarded contracts for their fire-alarm system in Clinton, Ia., Rome, Ga., and Danville, Ill. Their new factory is now completed and they are moving into it. It will be the largest factory in the South for the manufacture of electrical apparatus. They will occupy the entire three floors of the building, 120 feet long and 60 feet wide. This factory is situated on the Belt line railroad, giving them excellent receiving and shipping facilities. They also have yard room of about one acre. Mr. J. H. Sutcliffe is president of the company; J. J. Barrett, vice-president, and T. F. Gaynor, superintendent.

MR. THOMAS G. SMITH, JR., M. E.

Mr. Thomas G. Smith, Jr., M. E., late member of the firm of C. R Vincent & Co., this city, has opened an office at No. 11 Hammond Building, Cincinnati, O., where he will continue the business of consulting and contracting engineer for the complete installation of steam plants for electrical and other purposes. Mr. Smith will represent the interests of the Ball & Wood Co., and will be the sole agent in that section for the sale of the Improved Ball Automatic Engine, which has acquired such an excellent reputation in electric lighting and railway work.

Mr. Smith has had an extended experience in the installation of all the best modern types of engines and will be prepared to furnish plans and specifications with special reference to the attainment of the highest economy in steam consumption.

JENNEY ELECTRIC MOTOR CO.

The catalogue recently issued by the Jenney Electric Motor Co., of 218 to 224 South Illinois street, Indianapolis, Ind., is an excellent piece of trade and technical literature. It is tastefully prepared, and everything is said to the point and with a purpose. Some of the quotations as to the value of electric power are very pertinent, especially that in which the Indianapolis *News* tells of the satisfactory work done by the 20 h. p. Jenney motor in its press room. The pamphlet, besides its general discussion of the subject, contains a full and interesting description of the motor and the various attachments, and shows sizes up to 50 h. p. A view is also given of a motor and pump outfit for hydraulic passenger elevator service, such as is now used in the Indianapolis Board of Trade Building. Following this come a number of pithy testimonials, and a short section devoted to data for power-users.

QUEEN & CO.'S TACHOMETERS.

Queen & Co., Philadelphia, are just now making a specialty of tachometers for indicating the speed of engines, dynamos, and motors. These instruments are quite as essential to the economical operation of a plant as ammeters and voltmeters, an appreciation of which fact is being demonstrated by the greatly increasing demand for them. By means of a tachometer it is possible to tell at a glance the exact rate of speed at which an engine or dynamo is running. For portable work a special instrument is made, which takes up but little space and can easily be carried about. This tachometer is as accurate in its readings as the larger type, mounted on a strong base and designed for permanent attachment in the engine or dynamo room.

BURTON ELECTRIC HEATER.

Mr. W. R. B. Willcox, who has charge of the electric heating department of the Electric Merchandise Co., of Chicago, has recently been in the East looking over the field and conferring with Mr. S. Dana Greene, the electrician of the Burton Electric Heater Co. This trip was rendered necessary by the large number of inquiries received not only from electric street railroads but also from a number of the leading steam roads that are using electricity for lighting purposes on some of their trains and are anxious to adopt the heater in place of other means of warming their electric-lighted cars.

WIRT INSULATING JOINT.

The Electrical Supply Co., of Chicago, have recently brought out the Wirt insulating joint. It is very simple, and has no loose parts or screws. It is guaranteed to be strong and absolutely gas and "electricity tight." It is only $\frac{3}{8}$ in. by $\frac{3}{8}$ in. and is listed at a low price.

THE SIOUX CITY ENGINE WORKS.

The Sioux City Engine Works report business as improving very greatly the past few weeks. They have steadily had work since January 1st, on the popular selling sizes of their standard Corliss and Giddings' automatic, and have a large number of engines finished and ready for prompt delivery. The prospects for the season's business were never before better at this time of the year. The applications for estimates and prices are largely for the largest size engines and steam plants They are now completing some special machinery which will greatly increase their facilities for both quantity and quality of work, and are also running and expect to run for the next six months a large night and day force in order to keep up with the demands of the trade.

Among the recent orders taken are two 22x36 compound condensing engines sold to W. J. Hobson for his electric lighting and railway plant now being built at Waco, Texas; one 14x36 to Morton, Lawshe, Savannah, Mo.; one 9x14 to the Sioux Refrigerator Co., of Sioux City, Ia., for electric lighting and to drive the elevators; a 9x14 to James F. Toy, of Sioux City for electric lighting; a 16x36 to M. P. Bewley, of Fort Worth, Texas; two 18x42 and one 12x36 Standard Corliss to the Moline Plow Co., Moline, Ill., and a 100 h. p. Corliss to the Illinois Chair Manufacturing Co., of Rockford, Ill. Negotiations are now pending for several other large plants, contracts for which will be closed within a few days.

Among the recent shipments was a 14x36 to the Fremont Milling Co., Fremont, Neb.; a 16x42 to the Crane Manufacturing Co., Chicago, and an 18x36 to the Northwestern Sewer Pipe & Tile Co., of Sioux City, including boilers and complete steam plant; one 11x24 Corliss to James Thorndyke & Son, Randolph, Neb.; 12x24 Corliss to the Menno Milling Co., Menno, S. D.; and one 14x36 Corliss to Fletcher & Case, of Sioux City, for their planing mill.

It is evident that these engines are rapidly winning their way into public favor; this has been done on the merits of the sample plants put in during the past two years. Reports from electric railway contractors indicate that they have found no better and closer regulating engines than the Sioux City Corliss.

THE BAXTER ELECTRIC MOTOR CO.'S QUICK WORK.

On the 8th of June the Baxter Electric Motor Co., of Baltimore, shipped three trucks with motors attached to Beatrice, Neb., and on the 12th they sent a generator of 80 h. p. At the same time an expert electrician was despatched from the works to put the road in operation, including the erection of the power house. The following telegram has since been received by the company: "Second car started June 27th, 11:30 P. M., 2,500 passengers Sunday, without a hitch of any kind."

The company have a large number of orders for cars and motors throughout the South and West, and are shipping the goods just as fast as they are finished. The company's electric motor cars are now running in Richmond on the Richmond and Manchester Street Railway; Dayton and Cleveland, O.; Chicago, Ills.; Washington, D. C., and many other places.

NEW EDITION OF THE OSTRANDER CATALOGUE.

W. R. Ostrander & Co., of 195–197 Fulton street, New York, and 1461–1463 DeKalb avenue, Brooklyn, have just issued the eighth edition of their Revised Catalogue. It now runs considerably over 100 pages, and includes a greater variety of appliances and apparatus than ever. All the familiar Ostrander specialties are shown, with many new applications and improvements. The catalogue ranges through tubes, push-buttons, bells, batteries, annunciators, gongs, letter boxes, whistles, etc., and shows an excellent choice of goods in every branch.

"NEVER FOUND ANY FAULT." "RELIABLE."

A. H. Baird, M. D.; writes from Jackson, Mich., April 7th, 1891, as follows: "Messrs.—Some twelve years ago I purchased one of the Jerome Kidder Electric Medical apparatus. Have never found any fault with the Battery, and always considered it a good one. The zincs are considerably worn but the rest, case and all, are practically as good as new."

E. C. Pence, M. D., writes from St. Louis, Mo., March 6, 1891: "Jerome Kidder Manufacturing Co., 820 Broadway, New York, Dear Sirs: We have been practicing with your electrical machines over twenty-five years, and when we want anything reliable always send to you. Enclosed please find Post Office order for—"

The Sun Arc Lamp Company, leased by the Great Western Electric Supply Company, Chicago, report unusually fine business for the past month. This company is manufacturing a lamp, which for simplicity, durability and excellence of construction is not excelled, it is claimed, by any other lamp in the market. We might add that it is sold for less money than any other arc lamp, good, bad or indifferent.

MOSHER ARC LAMPS FOR INCANDESCENT CIRCUITS.

The Mosher Arc Lamp Co. are in receipt of a number of testimonials as to the merits of their lamp. One of the most recent of these letters is subjoined:

BENICIA ELECTRIC LIGHT AND MOTOR CO.,
BENICIA CAL., June 26, 1891.

MOSHER ARC LAMP CO., CHICAGO.

Gentlemen:—Yours of 11th inst. received. In reply we have to say the lamp gives satisfaction, and we are well pleased with it. Our superintendent says he has tried two or three other lamps of different makes; this one is the best of them all. He wants you to send another just like it to the Dixon Light and Water Co., Dixon, Cal., of which he is superintendent. Enclosed please find check $26.75, to balance account. Yours truly,

S. C. GRAY, *Pres't.*

EDISON GENERAL ELECTRIC CO.

The Edison General Electric Co. has just issued a new pamphlet on their small Edison slow-speed motors, which are now being introduced in large numbers on incandescent circuits. The motor, which was recently illustrated and described in these columns, is of excellent design and finish, taking but little current and answering admirably for a great variety of uses.

THE PERKINS LAMP.

Messrs. Claflin & Kimball, 105 Summer street, Boston, the agents for New England of the Perkins incandescent lamp, write us that they have recently received two lamps from one of their customers, that had run over 12,000 hours and were still good. The remark that came with the lamps was that lamps lasting as long as that must be a curiosity. The average life of lamps on that plant was also high, reaching 2,500 hours, an evidence of what can be accomplished with good lamps in careful hands.

NEW YORK NOTES.

TRUEX AND VAIL, Electrical Exchange Building, report that the following railroad companies and electric light stations have adopted their swinging ball lightning arrester since they have been handling it: The Ball Electric Light Co., of New New York; The Hamilton and Lindenwald Electric Railroad, Hamilton, O.; The Federal Street and Pleasant Valley Railroad, Allegheny, Pa.; The Edison Company, Paterson, N. J.; The Danville Gas, Electric Light, and Street Railway Company, Danville, Ill.; The Cincinnati Electric Light Company, Cincinnati, O.; Porter Rawlings, Helena, Ark., electric light station; The Canton Electric Light and Power Company, Canton, O.; The City of Ottawa, Ill., on their local plant; The Jenkintown Electric Light Company, Jenkintown, Pa.; Utica and Mohawk Railroad, Utica, N. Y.: The Lindell Railroad Co., St. Louis, Mo.; and the Edison Electric Light Company, at New Brunswick, N. J.

PHILADELPHIA NOTES.

THE GLADSTONE APARTMENT HOUSE, owned by W. G. Warden, has had a fine plant designed, put in and started by Mr. A. J. Martin, the superintendent of the West End Electric Co. The plant comprises two Thomson-Houston 400-lighters and one 800-lighter, run by a double Greene engine of 200 h. p., high pressure. The building is wired for 3,000 lights, and has the Interior Conduit system throughout, with 34 feeders and risers. There are special switches arranged to connect the machines and circuits and also to charge storage batteries, and there is also a very fine black-slate switchboard.

THE HEISLER ELECTRIC LIGHT CO. have consummated arrangements with the Interstate Complete Electric Construction Co., 809 S. Seventh St., St. Louis, Mo., as their general agents for the sale of their apparatus in the State of Missouri and adjacent territory. They have also made similar arrangements with Messrs. M. V. Smith & Son (The Belton Electric Co.), of Belton, Tex., for the exclusive sale of their apparatus for the State of Texas and portions of Mexico.

MR. CHARLES G. BLANDY, formerly of the Columbia Electric Co., St. Paul, has become associated with Mr. M. S. Shapleigh, also well known in electrical circles in this vicinity. They have opened an office and factory at 244 Arch street, where they will continue to act as agents for the Electrical Supply Co., of Ansonia, Conn., and will also manufacture some electrical novelties of their own invention.

MR. J. W. PARKER has just closed a second contract with the Allentown & Bethlehem Rapid Transit Co. for a 150 h. p. Ball railway engine. He has also sold a 150 h. p. compound condensing Ball engine to the Lebanon (Pa.) & Annville Street Railway Co., and a 40 h. p. Ball engine to the Luxury Tobacco Works, of this city.

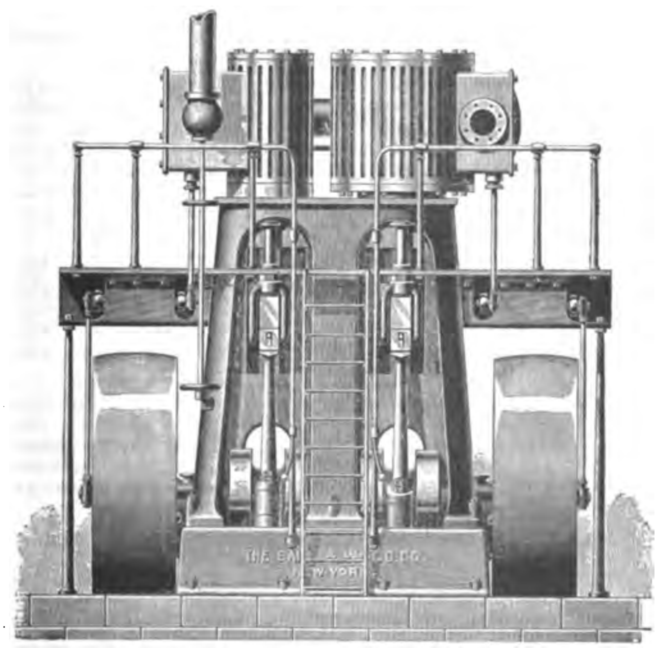
MR. M. S. SHAPLEIGH, dealer in electrical supplies, has removed from 112 So. 4th St., to more commodious quarters at 244 Arch street.

MR. H. L. LUFKIN of the C. & C. Electric Motor Co., has just returned from a trip to Colorado and Montana. His journey was so successful that he has brought orders for C. & C. motors for use in mining work, aggregating 200 h. p. or more. The motors ranging from 10 to 65 h. p., covering three separate installations.

BALL & WOOD HIGH-SPEED VERTICAL COMPOUND ENGINE.

A GLANCE at the comparative history of electricity and steam shows the interesting fact that, while the best form of slow-speed engine, the Corliss, was practically a perfected machine when the dynamo first came into commercial use, the high-speed engine may be said to have been developed simultaneously with the electrical industry.

The earlier dynamos were almost invariably driven by high-speed engines, not only because of the better regulation thus obtained, but because Corliss engines of small power were very expensive and cumbersome. Fuel economy in the small stations then in use was of less importance than compactness of plant and uniformity of speed.



BALL & WOOD HIGH-SPEED VERTICAL COMPOUND ENGINE.

As the business grew it was found that the relative economy of fuel between the two types of engines was about as twenty-seven is to thirty in favor of the Corliss engine, which figures represent the water consumption ordinarily obtained from each, per horse-power per hour. This advantage in economy was offset by the smaller cost of the high-speed engine, its less floor space, and the small cost of a reserved unit for emergencies, together with the better regulation obtained. To meet the popular demand for more efficient engines, compound cylinders were applied to high-speed engines with the most gratifying results.

It was found that compounding was specially adapted to this class of engines, and therefore a wider field for high-speed engines was opened. The scepticism at first expressed as to the desirability of non-condensing compounds was quickly answered by practical results.

The usual form for high-speed compounds is the horizontal, whether of the tandem or cross-compound type. In Europe the vertical form is extensively used, and it is believed by many that large high-speed, vertical compound engines will come into very general use here, particularly where floor space is valuable. The accompanying illustration shows a 500 h. p. engine of this class. The floor space required, including wheels, is about 8 ft. x 12 ft., thus giving over five h. p. per square foot of floor. The vertical height of this engine is about twelve feet above floor. This engine is built by the Ball & Wood Co. at their Elizabethport, N. J., shops, and has in its governor, valve, etc., all the characteristic features of the Ball engines.

For convenience of access, the front legs of the frame are arranged to be detached just below the gallery floor and removed entirely, thus allowing the shaft to be rolled out at the front of the engine. The rest of the frame is cast in one piece, except the guides, which are placed on finished seats in the frame. Both valves are driven from crank pins, instead of eccentrics, one being part of the automatic cut-off governor and the other set in a plate arranged for an adjustable cut-off.

The rock shafts are carried in adjustable boxes placed in a bracket, one end of which is attached to the frame and the other end supported by a pillar set on the foundation. This bracket is placed under the gallery floor and forms one of its supports at each side of the engine. A movable section of floor permits ready access to the rock shafts for inspection or oiling.

NEW APPLICATIONS OF THE CROWDUS CONSTANT PRIMARY BATTERY.

BY recent important and novel improvements made by Mr. Walter A. Crowdus the output of the primary battery has been so increased that quite a powerful and constant battery is made to occupy a very small space. An idea of this power is best obtained by a comparison with the well-known bluestone gravity cell. The Crowdus type of battery, 6 inches square, will, it is stated, develop a current equal to that of 200 bluestone cells, each 6 x 8 inches. Of course the total life of the 200 bluestone batteries would exceed considerably that of the Crowdus type; but the attention and handling demanded by the 200 batteries would be far in excess of the small one, doing the same work, hence the comparison has many points in favor of the new type. The Crowdus batteries are all made up in hard rubber cases, practically sealed, as far as handling is concerned, and are portable, there being no glass or loose porous cups in them. We have had occasion to illustrate these small batteries as they are now made up in hand and vase lamps. In this shape they are no larger than a coal oil lamp, and give greater light.

We illustrate this week another design and application of this battery. The engraving shows a small, square table with a 7-inch square battery placed upon the shelf beneath, with wire leading up to a portable or drop light placed upon the table. This outfit will give a 16 c. p. light for one evening, on one charge, at a cost of 1½ c. to 2c. an hour.

One very practical feature of this battery is that no electrical connections have to be studied out or attended to, and the only metal parts exposed are the two terminal knobs, which serve the

CROWDUS BATTERY WITH LAMP.

double purpose of handles for transporting the battery and electrical terminals.

The fan outfits are finding ready sale, even in offices located in the centre of electric power districts.

The Crowdus Chemical-Electric Co., Memphis, Tenn., owners of, and manufacturers under, Mr. Crowdus' patents, are also adapting these batteries to train lighting, and have a passenger train running regularly fully equipped with electric light, including head-light, supplied from their battery, the light being much brighter than was obtained from the oil lamps. Concerning this, however, we shall have more to say, as it is a departure of much importance.

WESTERN TRADE NOTES.

THE POND ENGINEERING CO. has recently received a large order for the well-known Armington & Sims engine, for which they are the general Western agents. This order is from the Chicago Edison Co., and the engines, of 400 h. p. each, will go in the central lighting station on Adams street. The first engines in this plant were made by the Armington & Sims Co., but the management thought best to make a trial of other makes. After careful tests they have ordered as above. They were anxious, it is stated, to place their entire order for their new equipment with the Armington & Sims Co., but the latter, owing to other large orders, were unable to promise delivery as required. The Edison Co., therefore, gave them orders for as many engines as they could furnish, and placed the contract for the rest of the equipment elsewhere.

POINTS ON LIGHTING.—At a recent meeting of the Illinois Chapter of the American Institute of Architecture, Mr. Thos. G. Grier read an excellent paper on incandescent electric lighting. After a clear statement of the elementary principles of electrical science employed in lighting, an interesting description was given of the various systems used in ordinary interior wiring. Mr. Grier also called attention to the importance of the assistance of the thoroughly trained electrical engineer to the architect, and urged the necessity of such expenditure in electrical work as would secure competent supervision and the use of good material.

THE CENTRAL ELECTRIC COMPANY are showing some very handsome samples of lead-encased Okonite cable. The demand for this class of cable has increased so lately that the Okonite Company have decided to go into its manufacture on a large scale, and are selling their product in the West through the above company, who are their general Western agents. They have already received some flattering contracts and will soon be in the field as active competitors for this class of work. They are also prepared to lay the cable, and deliver it connected up, ready for current, having especially good facilities for performing these contracts.

THE GREAT WESTERN ELECTRIC SUPPLY CO., Chicago, have leased spacious rooms at Nos. 193, 195, 197, and 199 South Canal street, where they contemplate moving about August 1st. In these greatly enlarged quarters they propose extending their manufacturing facilities, and we wish them the success which they well merit. This house carries one of the largest line of supplies in the United States and is progressive, energetic, and above all straightforward in its treatment of its many customers, scattered throughout every section of the country.

ELECTRICAL SUPPLY CO.—Upon calling on the Electrical Supply Co. at their new quarters, 102 and 104 Michigan avenue, one is confronted by tons and tons of articles electrical piled in chaotic masses—but behind it all beam the cheerful faces of Mr. Terry and his several managers. They don't seem "flustered" by the dismal disorder—but are all hustling things into place and shape. They will have one of the most complete establishments in existence when finished.

THE ELECTRIC MERCHANDISE CO., of Chicago, has received the entire order for the overhead electrical equipment of the electric street railway at Memphis, Tenn., as well as the rail bonds and poles. As it was necessary for all such material to have the approval of the company supplying the electrical plant, the Electric Merchandise Co. looks upon this very naturally as the strongest kind of endorsement of the line material of their manufacture.

THE NORTHWESTERN ELECTRICAL SPECIALTY CO. are meeting with great success in the sale of the Economic incandescent lamps, which they handle in the West. Mr. Kirkham, manager of the company, reports his sales as increasing rapidly, and says that the lamps are giving good satisfaction in the many places in which they have already been used.

MR. E. R. GILMAN, president of the Great Western Supply Co., sailed, July 8th, on the "City of New York," for a trip to Europe. He will make a tour through Scotland, Ireland, France and Germany, and will probably be gone a couple of months. Mr. Gilman, before sailing, closed contracts aggregating $100,000.

THE ILLINOIS ELECTRICAL MATERIAL CO. are doing quite a large business in electric street railway supplies, all kinds of which they handle, and also in the exclusive specialties for this work, which they control. They have recently closed contracts for the equipment and line material of several new railway plants.

MR. J. H. COOKE, secretary and treasurer of the Sunbeam Incandescent Lamp Co., of Chicago, has returned from a recent trip to New York, Boston and Philadelphia, from all of which cities he brought away valuable souvenirs in the shape of voluminous orders for Sunbeams.

MR. LEM. S. BOGGS, graduate of the mechanical department and also of the electrical department of Purdue University, Lafayette, Indiana, is in Chicago, where he proposes to locate and will probably enter the field of electrical mining.

CUTTER'S MINE SWITCHES.—Mr. George Cutter has developed some waterproof switches and cut-outs for use in mines and tunnels, and a number of these are already doing good service. The presence of excessive dampness and in some cases of running water renders the ordinary devices useless, and the good features of Cutter's mine switches and cut-outs will probably do much towards the extensive use of electricity in mines. Mr. Cutter is also working out some novel switchboard fittings and has just completed a slate-base theatre switchboard, which is as neat as it is serviceable.

MR. C. T. PAGE, manager of the Englewood Electric Light Company, sailed for Europe on the 11th inst. The Englewood Electric Light Co. have made Kohler Bros. & Grier, of 341 Rookery Building, their authorized agent and contractors for all inside wiring in their territory. Mr. Thomas G. Grier will have general supervision of the work. Mr. J. H. Stahley, formerly a construction superintendent for the North American Construction Co., will be in direct charge for Kohler Bros. & Grier.

THE GREAT WESTERN ELECTRIC SUPPLY CO. were awarded the contract for supplying the steel poles to be used on the extensions of the Citizens' Street Railway Co., of Indianapolis, Ind. The demand for their new steel pole for electric railways is very brisk, and numerous inquiries are received daily from all parts of the country. The pole is very remarkable for its strength and beauty. They have just issued a tastefully illustrated circular regarding its merits.

THE LINCOLN, ILL., ELECTRIC RAILWAY, of Lincoln, Ill., have contracted with the U. S. Railway Equipment and Construction Company, for a complete Westinghouse street railway plant, comprising one 80 h. p. generator, three motor car equipments having two 20 h. p. motors on each car. Four and a half miles of road will be immediately constructed.

MR. GEORGE CUTTER, the "Electrical Specialist," of the West, is doing a good business in his many valuable specialties for electric light, street railway and power plants. His new magnetic cut-out, which was recently illustrated in one of these columns, is finding a ready sale, on account of its excessive usefulness, simplicity and low cost.

MR. G. E. FISH has accepted an appointment as superintendent of electric lighting at Little Rock, Ark. He is a well-known electrician, having been for a long time superintendent of the Chicago Arc Light & Power Co., and well known to the electrical fraternity here, who will note with pleasure his new connection.

J. LANG & CO., who make the well and favorably known Andrews & Lang switches, are now, in addition to their direct-current switches, making a very fine line of alternate-current switches, which show the same excellent finish and workmanship for which their goods are noted.

MR. FREDERICK L. MERRILL, the recently appointed Chicago agent of the Jenney Electric Motor Co., has just installed a 1 h. p. machine for operating a 36-inch Andrews & Johnson exhaust fan, and reports the outlook for business with this excellent line of motors as very flattering.

MR. JEAN A. WETMORE, of the International Okonite Co., New York, was a Chicago visitor last week and a caller at the Western office of THE ELECTRICAL ENGINEER. Mr. Wetmore is talking Okonite as picturesquely and pertinently as ever.

MR. GEORGE H. MEEKER, the popular manager of the Chicago branch house of the New York Insulated Wire Co., 76, 80, 82 Franklin street, is shipping large quantities of the famous Grimshaw wires and cables to all parts of the West.

THE SUNBEAM INCANDESCENT LAMP CO., of Chicago, who recently shut down their factory for a time, making boiler and other necessary repairs, started again in full blast last week, and are once more turning out Sunbeams by the million.

THE JEWEL INCANDESCENT LAMP, in the hands of Mr. Wm. Hood, is selling very rapidly. Tests of the lamp have shown it to be very efficient and long lived, and they are giving satisfaction in all the plants where they are being used.

MR. CHARLES A. BROWN, the widely-known manager of the Western Electric Co., who has resigned that position to take up the practice of law, will be succeeded by Mr. C. D. Crandell, who will take hold immediately.

ANDREWS & JOHNSON, manufacturers of large fans for ventilating purposes, report business as prosperous, and they are turning out all the work they can handle.

MR. W. J. FLOYD, of the Sperry Electric Co., has gone East for a short trip.

EXTRA—The Edison Lamp Decision.

THE

Electrical Engineer.

A WEEKLY REVIEW OF THEORETICAL AND APPLIED ELECTRICITY.

Vol. XII. Extra No. NEW YORK, TUESDAY, JULY 14, 1891. Price 10 Cents.

DECISION UPHOLDING THE EDISON LAMP PATENT.

WE give below the full and exact text of the decision handed down by Judge Wallace this Tuesday morning, upholding the Edison lamp patent so recently argued before him. In sustaining the patent, the court has ordered a decree for an injunction and an accounting.

THE ELECTRICAL ENGINEER is the only paper that has published a report of the arguments of counsel in this great and important suit, in which millions of dollars and the future of a leading electrical industry have been at stake. It also printed in full in its issue of June 10 the patent No. 223,898, of January 27, 1880, granted to Mr. Edison, upon which the litigation was based.

THE EDISON ELECTRIC LIGHT COMPANY vs. THE UNITED STATES ELECTRIC LIGHTING COMPANY.	*Circuit Court of the U. S. for the Southern District of New York.*

WALLACE, Circuit Judge :

Two claims of Letters Patent No. 223,898, granted Thos. A. Edison, January 27th, 1880, for an improvement in electric lamps, are in controversy in this suit. These are claims 1 and 2. It is not asserted for plaintiff that the defendant infringes the other claims of the patent, consequently they will require no attention further than to see whether their terms may assist in defining the meaning of the claims in litigation.

The plaintiff contends that these claims are for fundamental inventions of great merit, and are entitled to a construction by which every incandescent lamp for electric lighting, consisting essentially of a filamentary carbon burner, hermetically sealed in a glass vacuum chamber, is within their terms. The defendant contends that unless the claims are limited to narrow inventions, not employed by the defendant, they are invalid for want of patentable novelty. The questions of the validity and scope of the patent have been adjudicated in the Courts of England and Germany with a diversity of opinion by the Judges who have considered them. The specification is a perplexing one The difficulty lies in its shadowy demarkation of the line between the essential and non-essential features of the invention described. It catalogues a number of discoveries which Mr. Edison has made; it sets forth some of the essential features of the lamp, and then it leaves to be found by inference from generalities what the elements are of the combinations included in the extremely elastic terms of the two important claims. Nevertheless, when a sufficient knowledge of the prior state of the art to which it relates has been acquired, the new departures from old devices which it describes, and which, presumably, the inventor proposed to incorporate into the claims of his patent, are reasonably apparent. The specification states that the object of the invention is "to produce electric lamps giving light by incandescence, which lamps shall have high resistance so as to allow of the practical subdivision of the electric light." The subdivision of the electric light is the concrete term for the division of the electric current into numerous small units and their conversion into luminous centres. By practical subdivision is meant a distribution and division of the current and its conversion into lights comparable with those of ordinary gas jets, on a scale and under conditions of convenience and economy adequate to a system of illumination for domestic purposes, in villages and cities, analogous to that of gas. Prior to 1879 there was no method known by which this could be done practically. The problem involved the perfection of devices for the proper distribution and regulation of the current as well as those for translating it into light. No reference to the pre-existing devices for generating electricity, conducting it to the translating devices, or regulating its pressure and quantity, is necessary except to state that the principles governing the relation of the resistance of translating devices to the character of the circuit in which they are arranged, whether in series or in multiple arc, were well known to electricians and had been applied in various forms of electrical apparatus. There were two well-known devices for converting the current into light—the arc lamp and the incandescent lamp. In the former the current is forced to leap an air gap separating two conductors, usually of carbon, and in overcoming the resistance of the air space heats the adjacent surfaces of the conductors and produces a light of great intensity. In the latter light is produced by the incandescence of an electrical conductor, a conducting strip or burner placed in a continuous circuit through which the current passes and which develops heat by its resistance to the flow. The arc lamp was suitable for use in streets, open spaces and large halls, but its light was too concentrated and powerful for the illumination of dwellings or rooms of small dimensions. It was the generally accepted opinion of electricians that the hope of progress in the subdivision of the electric light was to be found in modifying the features of the arc lamp The reasons for this conclusion need not be mentioned ; it suffices to say that Mr. Lane-Fox in England, and Mr. Edison in this country seem to have been the only notable dissidents, and each of them had expressed the conclusion that subdivision might be accomplished by the incandescent lamp when provided with a conductor of high resistance and small radiating surface arranged in a system of multiple arc. Lane-Fox had set forth the advantages of such a lamp in three patents granted to him in England, two in October, 1878, and one in March, 1879, and in a letter to the London *Times* published in December, 1878 ; and Mr. Edison had done so in a patent granted to him in France, May 28th, 1879, for improvements in electric lighting.

By arrangement in multiple arc no greater electromotive force is required for a large number of translating devices than for a single one, and the amount of current can be graduated to the number employed ; consequently a lamp with a conductor of high resistance can be utilized as efficiently as one with a conductor of low resistance. Higher resistance in the conductor permits the use of a weaker current, and consequently, of smaller and less expensive main conductors. With a small surface of conductor less energy is required to produce a candle-power, and the small incandescent mass will radiate a moderate light, like the domestic lamp. Electricians knew how to make conductors of high resistance, and how to make them with a small radiating surface. They knew that with material of the same specific resistance the total resistance of the conductor could be varied by varying its length or cross-section, high resistance being imparted by length and small section. They knew what materials were preferable, and what processes of treatment, to make conductors of high or low resistance. If they had only known how to construct a lamp in which the conductor would have adequate mechanical strength and durability for practical commercial use, while having the small radiating surface and high resistance desirable, there would have been nothing wanting, and electric lighting by incandescence would soon have been an accomplished fact. Although Lane-Fox and Edison had contributed to the state of the art the recognition of the principle that the conductor must have high resistance and small radiating surface, and each of them had embodied the principle in lamps for which they had severally obtained patents, neither of them had invented a lamp which satisfactorily met all the conditions of success, because a burner of the necessary materials, form and complementary adjuncts was yet to be devised. As to materials, experiments had been tried with platinum, iridium and alloys of these metals, and with carbon of various kinds. It was known that platinum, being a poor conductor, could be readily brought to incandescence by the electric current, but to do so it was necessary to raise it to a temperature very near the fusing point, and a minute increase would melt it. On the other hand, carbon was known to possess at an equal temperature much greater power of radiation than platinum, but the difficulty was that it would combine with oxygen at high temperature and rapidly disintegrate. It could only be used, therefore, in a vacuum from which the oxygen had been excluded, and a perfect vacuum was practically unattainable. From the earliest lamp (disregarding the Geissler tube, because it has no burner in the true sense), patented in England by King in 1845 to the latest examples, like those of Lane-Fox or Edison's platinum lamp, patented in 1878-9, the history of the art shows a variety of experiments to perfect a lamp in which a carbon burner or a platinum burner would have sufficiently long life for practical requirements. The result of these experiments may be succinctly shown by quoting two well-known electricians. Mr. Schwendler, in an article published in 1879, in the *Telegraphic Journal*, said: "Unless we shall be fortunate enough to discover a conductor of electricity with a much higher melting point than platinum, and the specific weight and the specific heat of which conductor is also much lower than for platinum, and which at the same time does not combine at high temperatures with oxygen, we can scarcely expect that the principle of incandescence will be made use of for practical illumination." Mr. Sawyer, in a patent to Sawyer and Man, granted in June, 1878, said: "At the present day it is not new to produce a light by causing the electric current to heat a carbon conductor to incandescence in a vacuum, or in nitrogen, or in other gas; but no lamp has yet been devised which would be practically operative, and for these reasons: First, the methods which have been adopted for charging the lamp with the artificial atmosphere, such as a displacement of mercury, water or air by the gas or the combustion of phosphorus in the lamp, are imperfect. A perfect vacuum is unattainable. Some oxygen, or other element or compound, remains in the lamp, and slow consumption or disintegration takes place, for the remaining gas or vapor other than hydrogen or nitrogen attacks the carbon, which in turn is decomposed, with a result of depositing the carbon upon the globe and setting free the oxygen to attack fresh carbon. Second, it has been found practically impossible under the varying degrees of heat and pressure to maintain perfect joints, and the result is that expansion of the artificial atmosphere by the heat from the luminous conductor expels a portion of the same, and the contraction of the atmosphere upon cooling causes a portion of the external air to penetrate the globe, thus supplying oxygen, which at the next lighting feeds upon the carbon. Third, the unequal expansion of the carbon and its holders has resulted in fractures of the former, so that, however perfect the atmosphere in the globe, the lamp has never been permanent."

The most advanced type of carbon burner lamps in 1875 were the lamps of Lodyguine or of Konn, and until the spring of 1879 lamps like those of the Sawyer and Man patent or the patent of Mr. Farmer. It was thought to be the merit of Lodyguine's lamp that it obviated the difficulty of the short life of the burner by using two burners, rods of diminished section at the luminous focus in a glass receiver, hermetically sealed and filled with nitrogen, electrically arranged so that the current could be passed to the second carbon when the first had been consumed. Mr. Konn provided his lamp with five carbon burners in the form of rods or pencils and devices for bringing them successively into circuit. In the lamp of Sawyer and Man the carbon burner was a rod or pencil maintained in a globe charged with nitrogen gas, and the globe and its stopper (both of glass) were held together by a clamping device. In the lamp of the patent granted to Mr. Farmer in March, 1879, the burner was a carbon rod or pencil enclosed in a globe filled with nitrogen or other analogous gas, and the globe was closed by a rubber stopper. In none of the lamps, except the one described in Mr. Edison's prior French and English Patents of 1879, had any attempt been made to make the vacuum chamber wholly of glass with the parts sealed together by fusion, or to seal the conducting wires leading to the burner through the glass by fusion of the glass. The impracticability of maintaining a carbon burner under such conditions that it would be sufficiently durable had apparently so impressed those who were studying lighting by incandescence, that we find as late in the early part of 1879 both Lane-Fox and Edison were trying to perfect a burner of other material. Edison's burner, in his French Patent of May 28th, 1879, and his English Patent of June 17th, 1879, was of platinum wire coiled upon a bobbin composed of an infusible oxide; and Lane-Fox's burner, in his patent of May 14th, 1879, was of platinum-iridium alloy, or of spiral strips of metal surrounding a tube of glass, fire clay, steatite or lime, with the surface of the metal strips covered with asbestos or some vitreous material.

This cursory view of the prior state of the art is sufficient for an intelligent reading of the specification. The specification describes the general nature of the invention as follows:

"The invention consists in a light-giving body of carbon wire or sheets coiled or arranged in such a manner as to offer great resistance to the passage of the electric current, and at the same time present but a slight surface from which radiation can take place.

"The invention further consists in placing such burner of great resistance in a nearly perfect vacuum to prevent oxidation and injury to the conductor by the atmosphere. The current is conducted into the vacuum bulb through platina wires sealed into the glass.

"The invention further consists in the method of manufacturing carbon conductors of high resistance, so as to be suitable for giving light by incandescence, and in the manner of securing perfect contact between the metallic conductors or leading wires and the carbon conductor."

The specification then recites that previously light by incandescence had been obtained from rods of carbon of one to four ohms of resistance, placed in closed vessels in which the atmospheric air had been replaced by gases that did not combine chemically with the carbon; that the vessels holding the burner had been composed of glass cemented to a metal base; that the connections between the leading wires and the carbon has been obtained by clamping the carbon with the metal; that the leading wires had always been large, so that their resistance should be many times less than the burner, and generally the attempts of previous persons had been to reduce the resistance of a carbon rod. It then points out the disadvantages of such a lamp, stating that it could not be worked in great numbers in multiple arc without the employment of main conductors of enormous dimension; that, owing to the low resistance the leading wires have to be of large dimensions and good conductors, and a glass globe cannot be kept tight at the place where the wires pass in and are cemented, and consequently the carbon is consumed, because there must be almost a perfect vacuum to render it stable, especially when it is small in mass and high in electrical resistance; and that the use of gas in the receiver at the atmospheric pressure serves to destroy the carbon by attrition.

The specification then states in substance that the patentee proposes a new departure; and that he has discovered that even a cotton thread properly carbonized and placed in a sealed glass bulb exhausted to one-millionth of an atmosphere, offers from one hundred to five hundred ohms resistance to the passage of the current, and that it is absolutely stable at very high temperature; that if the thread be coiled as a spiral and carbonized, or if any fibrous vegetable substance which will leave a carbon residue after heating in a closed chamber be so coiled, as much as two thousand ohms resistance may be obtained without presenting a radiating surface greater than three-sixteenths of an inch; that if such fibrous material be rubbed with a plastic composed of lamp-black and tar its resistance may be made high or low, according to the amount of lamp-black placed upon it; that carbon filaments may be made by a combination of tar and lamp-black, the latter being previously ignited in a closed crucible for several hours, and afterwards moistened and kneaded until it assumes the consistency of thick putty; that small pieces of this material may be rolled out in the form of wire as small as seven one-thousandths of an inch in diameter and over a foot in length; and the same may be coated with a non-conducting, non-carbonizing substance and wound on a bobbin, or as a spiral, and the tar carbonized in a closed chamber by subjecting it to high heat, the spiral after carbonization retaining its form; that he has carbonized and used cotton and linen thread, wood splints, papers coiled in various ways, also lamp-black, plumbago and carbon in various forms mixed with tar and kneaded so that the same may be rolled out into wires of various lengths and diameter; that each wire should be uniform in size throughout; that all these forms are fragile and cannot be clamped to the leading wires with sufficient force to ensure good contact and prevent heating; that if platinum wires are used and plastic lamp-black and tar material be moulded around it in the act of carbonization, there is an intimate union by combination and by pressure between the carbon and platinum, and nearly perfect contact is obtained without the necessity of clamps; that the burner and leading wires should be connected to the carbon ready to be placed in the vacuum bulb, and when fibrous material is used the plastic lamp-black and tar should be used to secure it to the platina before carbonizing.

The specification proceeds as follows:

"By using the carbon wire of such high resistance I am enabled to use fine platinum wires for leading wires, as they will have a small resistance compared to the burner, and hence will not heat and crack the sealed vacuum bulb. Platina can only be used as its expansion is nearly the same as that of glass.

"By using a considerable length of carbon wire and coiling it, the exterior, which is only a small portion of its entire surface, will form the principal radiating surface; hence I am able to raise the specific heat of the whole of the carbon and thus prevent the rapid reception and disappearance of the light, which on a plain wire is prejudicial, as it shows the least unsteadiness of the current by the flickering of the light, but if the current is steady the defect does not show."

The specification then gives directions for carbonizing the carbon thread in a manner to prevent its distortion, for blowing a glass bulb over it after it is formed, for exhausting the glass bulb, and for hermetically sealing the bulb when a high vacuum has been reached.

The claims are as follows:

"1. An electric lamp for giving light by incandescence, consisting of a filament of carbon of high resistance made as described, and secured to metallic wires, as set forth.

"2. The combination of carbon filaments with a receiver made entirely of glass and conductors passing through the glass and from which receiver the air is exhausted, for the purposes set forth.

"3. A carbon filament or strip coiled and connected electric conductors so that only a portion of the surface of such carbon conductors shall be exposed for radiating light, as set forth.

"4. The method herein described of securing the platina contact wires to the carbon filament, and carbonizing of the whole in a closed chamber, substantially as set forth."

The specification is addressed to those who were skilled in the art to which it relates; who appreciated the advantages of arranging incandescent lamps in a system of multiple arc, and of providing the lamp with a burner of high resistance and small radiating surface; who knew how high resistance, both specific and total, is imparted to a conductor; who knew that the rods, pencils, or other forms of carbon burners previously used, had not been designed to embody the principle of high resistance; who knew how desirable it was to maintain the burner in a perfect vacuum, or in gases that would exclude the oxygen; who knew what had been attempted and had proved impracticable in that behalf; who knew that such materials as are mentioned in the specification (even the tar-putty compound seems to have been used in Gauduin's process) would compose a carbon of high resistance when subjected to a proper process of carbonization; and who knew how to practice proper processes for the carbonization of such materials.

Read by those having this knowledge, the radically new discovery disclosed by the specification is that a carbon filament as attenuated before carbonization as a linen or cotton thread, or a wire seven one-thousandths of an inch in diameter, and still more attenuated after carbonization, can be made which will have extremely high resistance and be absolutely stable when maintained in a practically perfect vacuum. It informs them of everything necessary to utilize this discovery and incorporate it into a practical lamp. It describes, with the assistance of the recital in the second claim, as the vacuum in which the burner is to be maintained, a bulb made wholly of glass exhausted of air, sealed at all points by the fusion of the gas, and in which platinum leading wires are sealed by the fusion of the glass. It describes the materials of which the burner is to be made and instructs them that the materials are to be shaped into their ultimate form before carbonization. It describes the use of platinum for the leading wires, and a method of securing the leading wires and filaments, intending to dispense with clamping, which consists in molding tar putty about the joints, and carbonizing the whole in a closed chamber. Besides stating that the resistance of the burner will be greatly increased and the radiating surface still be kept within moderate limits by coiling it in the form of a spiral, the specification states that by increasing the length of the filament coiled, the exterior only will be the principal radiating surface, and greater steadiness of illumination will be promoted.

The first claim must be read with several limitations. The filament is to be made of carbon of high resistance; that is, as the experts agree, of high specific resistance. The filament is to be made as described; that is, the materials are to be of some of the kinds described, and are to be shaped in filamentary form and then carbonized. The filament is to be secured to metallic wires according to the method of the patent, because the claim implies the elements of a globe and metallic conductor arranged in circuit with the burner, otherwise the combination would not be operative and it would have been needless to specify the securing of the metallic wires to the filament, unless it was intended to import into the claim the specific method of doing so emphasized in the specification.

The defendant does not infringe this claim, if for no other reason, because the leading wires in its lamps are not secured to the filament according to the method of the patent; that is, by cement carbonized *in situ*, but by clamps such as the specification condemns.

The second claim is broad enough in its phraseology to secure the real invention described in the specification, and can be read consistently with its language so as to import into it every essential limitation.

It was a remarkable discovery that an attenuated thread of carbon would possess all the long-sought qualities of a practical burner when maintained in a perfect vacuum. The extreme fragility of such a structure was calculated to discourage experimentation with it, and it does not detract in the least from the originality of the conception that previous patents had suggested that thin plates or pencils or small bridges could be used. The futility of hoping to maintain a burner in vacuo with any permanency had discouraged prior inventors, and Mr. Edison is entitled to the credit of obviating the mechanical difficulties which disheartened them, but what he did in this respect was a matter of only secondary merit and was no longer new in the art, because he had already disclosed it in his French and English Patents. What he actually accomplished was to unite the characteristics of high resistance, small radiating surface and durability in a carbon conductor by making it in a form of extreme tenuity, out of any such materials as are mentioned in the specification, carbonizing it, and arranging it as he had previously arranged his platinum burner in an exhausted bulb made wholly of glass and sealed at all points, including those where the leading wires entered, by the fusion of the glass. He was the first to make a carbon of materials and by a process which was especially designed to impart high specific resistance to it—the first to make a carbon in the special form for the special purpose of imparting to it high total resistance, and the first to combine such a burner with the necessary adjuncts of lamp construction to prevent its disintegration and give it sufficiently long life. By doing these things he made a lamp which was practically operative and successful, the embryo of the best lamps now in commercial use, and but for which the subdivision of the electric light by incandescence would still be nothing but the *ignis fatuus*, which it was proclaimed to be in 1879 by some of the learned experts who are now witnesses to belittle his achievement and show that it did not rise to the dignity of an invention.

The coiled form of the burner is only an alternative feature, and is not a constituent of the second claim. It is the subject of the third claim. Nor is the bent form or any form other than the filamentary. It may be that in the haste which has always seemed to characterize Mr. Edison's efforts to patent every improvement, real or imaginary, which he has made or hoped to make, he had not stopped to reflect when he framed his application for the patent that the filamentary burner would do its work just as well uncoiled as coiled, provided the same length and cross-section were used. It is true that it is said in the general statement of the nature of the invention that the burner is so "coiled or arranged" as to offer high resistance and present a small radiating surface; but this description is satisfied by any arrangement, whether by coiling a considerable length in a small globe or using the same length uncoiled in a larger globe, by which sufficient total resistance is obtained from a filament of small diameter. It certainly would not involve invention to omit the coiling and elongate the globe; hence, it is manifest that the invention described is the same thing essentially whether the coiled form is used or not. The language is satisfied, if the burner is filamentary and so arranged as to offer great resistance and slight radiation, without importing into it anything which is not of the essence of the invention. No precise limitation upon the maximum diameter of the filament can be defined from the specification or is required as an element of the claim. The specification mentions by way of illustration the threads of linen or cotton which become more attenuated after carbonization, and the carbon wire which after carbonization would be from four to five one-thousandths of an inch in diameter; while the smallest rods of carbon previously known were about a millimeter in diameter, thus having a cross-section fifty times as great as the carbon wire. It is to be implied from the suggestions in the specification that it is to have sufficiently high total resistance for efficient use when the lamps are arranged in multiple arc, and to be used with leading wires of fine platinum. The claim is not limited to a carbon filament made of non-fibrous material. The conductors of the claim are the platinum wires mentioned in the specification. The receiver is the vacuum described in the specification. The peculiar method of securing the conductors to the filament, made a constituent of the first claim, is not imported into the second claim. A more exact interpretation of the meaning of the claim than has thus been indicated is not necessary in the present case, because each of the three lamps representing the kinds used by the defendant embodies the invention of the claim as thus interpreted.

It is of little import what Mr. Edison, or his patent solicitor, may have thought about the meaning of the claim during the pendency of the application for a subsequent patent, or that Mr. Edison may have supposed a resistance as high as one hundred ohms in the burner would be required for use with the means of distribution which he expected to employ with his system of lighting. There are many adjudicated cases in which it appears that the inventor builded better than he knew; where a patent has been sustained for an invention the full significance of which was not appreciated by the inventor when it was made. In the case of the Bell Telephone patent there was great room for doubt whether the speaking telephone had been thought of by Mr. Bell when he filed his application for a patent, but the Court said: "It describes apparatus which was an articulating telephone, whether Bell knew it or not" (22 Blatch., 532).

The nearest approach in the prior art to the invention of the second claim is undoubtedly the lamp of Edison's French and

English Patents with a platinum burner. It seems almost preposterous to argue that the substitution of the carbon filament for the platinum burner of that lamp was an obvious thing to electricians. It would have been probably if there had been such a thing as a filamentary carbon in the prior art. But the nearest approximations to it were the ribbon-shaped carbon burner of low resistance of Mr. Farmer (which was not a part of the prior art but an isolated example known only to a select few) and the low resistance carbon rod burners of the patent of Sawyer and Man.

Undoubtedly the improvements that have been made in the art, such for instance as the method of electrical carbonization of the filament, since Mr. Edison's invention, have been of great value, and the perfected commercial lamp of to-day is far superior to the one which could be made by applying to the description of the patent all the knowledge and skill then possessed by those to whom it was more particularly addressed. But as was said by Bowen, L. J., in the Court of Appeal in England, "the evidence shows that lamps made solely on the patent will and do succeed, although subsequent improvements have been engrafted on the original design." It is impossible to resist the conclusion that the invention of the slender thread of carbon as a substitute for the burners previously employed opened the path to the practical subdivision of the electric light.

The questions which have seemed the most meritorious of those argued at the bar have now been considered. Others, to which no reference has been made, have not been overlooked, and may be dismissed without discussion and with the single remark that nothing which has been presented by the voluminous proofs and the exceedingly able and elaborate arguments of counsel seems to supply any valid reason for refusing to decree for the plaintiff.

The usual decree for an injunction and accounting is accordingly ordered.

THE

Electrical Engineer.

VOL. XII. JULY 22, 1891. No. 168.

THE FRANKFORT INTERNATIONAL ELECTRICAL EXHIBITION—II.

BY

Richard O. Heinrich.

The Electric Grotto.

IN my previous communication, I referred to the artistic arrangement of the buildings and grounds of the Exhibition, but a far better idea may be obtained from the accompanying photograph of the Machinery Hall. The view is the work of Messrs. Wiesbaden & Co., of Frankfort.

The front of Machinery Hall, it will be noted, has a model railroad line with electric signals, demonstrating the operation of these very important adjuncts to railway work. One of the most picturesque spots in the Exhibition is the grotto and waterfall, which are electrically illuminated, and an idea of which will be obtained from the vignette engraving.

As I write, there is just going out the call for the International Electrical Congress, to be held from the 7th to the 12th of September, at Frankfort. It is proposed to organize into sections, as was the case with former Congresses, and to discuss the prominent electric topics of the day. Among the papers already promised I may mention the following, together with their authors:

CARHART: 1. The Substitution of Dynamo Machines for Voltaic Batteries in Telegraphy. 2. Current Regulators for Dynamo Machine.

DOLBEAR: Electrical Terminology.

VON DOLIVO DOBROWOLSKY: Electrical Transmission of Power by Alternating Currents.

EPSTEIN: Applicability of Electro Magnetic Measuring Instruments, that is, those containing iron, for Alternating Currents.

FEUSSNER: Material and Construction for Measuring Instruments.

FRÖLICH: 1. Objective Demonstration of Harmonic Curves, and Electro-Acoustic Experiments. 2. Generation and Application of Ozone.

HOLBORN: On the Magnetic Action of different Iron Alloys.

HUMMEL: Direct determination of the work of Magnetization and the Currents in an Iron Ring.

KAHLE: The Permissible Limits of Error in Measuring Instruments, in Relation to Heat, Remanent Magnetism, etc.

KAREIS: 1. Prevention of Cross-Talk in Telephone Wires Strung on the Same Pole. 2. Prevention of Disturbances in Telephone Circuits by Induction from Wires Carrying Heavy Currents. 3. Improvements in the Conductivity of Telegraph Lines.

KOHLRAUSCH: What is the Best Course of Study for the Education of the Electrical Engineer.

LÖWENHERZ: Introduction of Uniform Screws in Electrical Work and Instrument Making.

MAY: Regulations for Electrical Conductors from the Standpoint of the Fire Insurance Companies.

MEISSNER: Application of Lippmann's Capillary Electrometer to Cable Telegraphy.

MULLER: Arrangement of Storage Batteries for Light and for Heavy Work.

PEUKERT: On Electric Meters.

ROTHEN: Important Questions in the Domain of Telephony.

Papers have also been promised by Dubois, Ferraris, Grawinkel, Quincke, Alioth, Arnold, Görges, Slaby, and others.

Besides the purely electrical character of the Congress, its social side has by no means been forgotten. The evening of the first day will be occupied by a general reunion and reception of the delegates. On the second day there will be a gala performance in the Exhibition Theatre, followed by a banquet in the hall of the large restaurant in the Exhibition ground. On the third day the delegates are invited to attend a banquet in the great hall at the Palmengarten, which will be followed by promenade double concert. On the fourth day there will be an entertainment given at the Marine Exhibition, including a

MACHINERY HALL, FRANKFORT ELECTRICAL EXHIBITION.

vocal concert and the illumination of the banks of the river. On the fifth day there will be a gala performance at the Frankfort Opera House. On Saturday, September 12th, the last general meeting of the delegates takes place, and at 7 o'clock in the evening, there will be a grand ball in the hall of the Zoölogical Gardens.

Not satisfied with all these entertainments, the Committee has arranged for the following day, Sunday, September 13th, an excursion with special trains to Wiesbaden. Delegates will spend the day there and in the evening will be entertained at a large garden party in the great Kur-Park, accompanied by fireworks.

Those who propose to take part in the Congress will have to be provided with a ticket, which can be procured for the very moderate sum of 16 marks ($4), Ladies' tickets are 10 marks ($2.50). Application for tickets must be made to the *Vorstand der Electrotechnischen-Gesellschaft* *zu Frankfort a. M.* I may add that Dr. von Stephan, Secretary of State for Postal Telegraphs, has been asked to accept the Honorary Presidency of the Congress by the issuers of the call, and Dr. Werner v. Siemens will occupy the chair at the opening session of the Congress.

THE DYNAMICS OF A DYNE AS A UNIT OF FORCE.

BY

John A. Grier

PROFESSOR SILVANUS THOMPSON makes an apt quotation when he says: "Science is measurement."

Electrical units are the foundation of electrical measurements, and hence of the scientific study of electricity. Is it not a fact that, generally, there is not a very earnest attempt to grasp the true meaning of the units most commonly used? I admit that they are difficult to comprehend.

I will not touch on the more practical units, the volt, the ampere, the ohm, or any other except the dyne. As these others are all derived from the dyne, and are measured by it, let us glance at this unit with closer attention. A dyne is defined as "that force which, acting for one second on a mass of one gramme, gives to it a velocity of one centimetre per second."

A gramme is a weight with which many of us are not familiar—while a United States dime is handled by all of us daily. The legal weight of a dime is two and a half grammes, thus four-tenths of a dime will weigh one gramme. We also know that a centimetre is nearly four-tenths of an inch in length, as .3937 of an inch is almost .4. Thus, we may roundly define a dyne in language that will be more likely to stick to the memory and be more easily grasped by some if we slightly paraphrase the definition and say it is that force which, acting for one second on a mass of matter equal in weight to four-tenths of a dime, gives to it a velocity of almost four-tenths of an inch per second.

Now let us see what will be the total effect of expending one dyne in raising one gramme from rest in a vertical direction. The velocity to be produced is one centimetre per second. As the body is at rest at the commencement of the action and reaches a final velocity of one centimetre per second, then the space passed over, or the distance the body will be raised, is only a half centimetre. Then the force is all expended on the gramme, but the gramme will continue in motion after the expiration of the second until gravity overcomes this momentum. By the well-known laws which govern bodies moving in opposition to gravity alone, we find that the gramme will move on in a vertical direction during a little more than the one-thousandth of a second, and will ascend about two ten-thousandths of an inch higher. Thus, a dyne will lift our gramme one-half a centimetre during the second, and then it will ascend about two ten-thousandths of an inch farther. This is the total measure of one dyne as far as space is concerned.

Let S = space it would pass through after the end of the second when it had acquired a velocity (V) of .3937 inch per second.

By the formula, $S = \dfrac{V^2}{2\,g}$;

let g represent the acceleration or retardation of a body left free to the action of gravity. Gravity will produce or retard a motion of about 386 inches per second when left free to act on a body in certain places on the earth's surface having a fixed relation to the earth's centre and distance from the equator. Then we have

$$S = \frac{.3937^2}{2 \times 386} = .0002+.$$

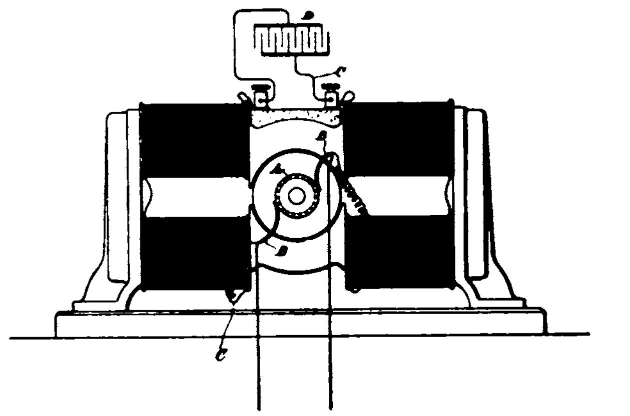
As we have slightly overrated the length of the centimetre, we find on a nicer calculation that the space moved over by the gramme is a trifle less than two ten-thousandths of an inch. In either case the motion could scarcely be measured as it would only be a slight tremor.

It should be observed that gravity will produce about 960 times as much motion on a gramme when left free to act on it, as a dyne will in acting in opposition to gravity.

The minuteness of all electrical units is a troublesome feature in comprehending their meaning, and the dyne partakes of this feature. *A clear conception of a dyne is the bed-rock of electrical science.*

THE STANLEY AND KELLY ALTERNATING CURRENT MOTOR.

IF a shunt-wound, continuous current motor be operated by an alternating current, a loss is occasioned by the high self-induction of the field-circuit, which retards the phase of the current-imparting magnetism to the field-magnets, and, as a consequence, the maximum magnetic effects of armature and field are not coincident, a condition which impairs the efficiency of the motor. In order to counteract this, and to bring the maximum magnetic conditions of the two elements, armature and field, more nearly into coincidence, Messrs. William Stanley, Jr., and John F. Kelly have devised a method of introducing into the field-circuit a condenser, which has the effect of bringing the phase nearer to that of the impressed electromotive force of the source of current. The efficiency and economy of this disposition will, of course, depend upon the electromotive force, rate of change of the current, and other well-understood conditions.



STANLEY AND KELLY ALTERNATING CURRENT MOTOR.

The device is clearly shown in the accompanying illustration, which represents an ordinary shunt-wound motor with a condenser included in the field-circuit.

THE HAYES-HIBBARD BATTERY TERMINAL.

IN battery circuits it is, of course, advantageous to eliminate all unnecessary resistance, and that caused by the corrosion of terminal contacts has always been a source of annoyance and loss. Messrs. H. V. Hayes and A. S. Hibbard, of the Long Distance Telephone Co., have perfected a method of making contacts intended to obviate this difficulty and keep the resistance at the lowest possible point. To accomplish this the connections are made by means of a soldered joint, the solder being carried upon one or both of the wires to be connected, so that it is only necessary to twist them together and apply a moderate heat, such as that of a candle or spirit lamp. Perfect connections are thus made with the greatest facility, and the joint can be readily broken in a like manner.

THE WIGHTMAN SINGLE-REDUCTION RAILWAY MOTOR.

Among the very first to recognize the desirability of as well as the possibility of eliminating one set of transmission gears in electric street railway cars was Mr. Merle J. Wightman, who, as electrician of the Wightman Electric Manufacturing Co., of Scranton, Pa., over a year ago commenced experiments towards the development of a slow-speed single reduction motor. The results of this work are embodied in the motor shown in the accompanying engraving, Fig. 1, from which it will be seen that the "Kennedy" type of field-magnet is employed. This form of field-magnet has the advantage of almost completely covering the field coils and producing an "iron-clad" motor. It gives a very strong and efficient field and all four poles are excited by two field windings.

The armature is of the Gramme type, and the commutator is cross-connected so that but two brushes are used, placed at an angle of 90 degrees and on top of the commutator.

The cross-connecting of the commutator is accomplished in a remarkably simple way. All the crossing cables are formed symmetrically into a flat disc which is firmly bolted to the head of the commutator and becomes an integral part of it. In this way all possibility of vibration and risk of breakage is overcome. The commutator lead-wires are all of flexible cable, after the Wightman Company's well-known method of armature winding. These lead-wires are fastened to the commutator without screws and in such a way that they can be detached in a few minutes, when it becomes necessary to remove a commutator. The armature is mounted within a strong, continuous frame forming part of the field-magnets. The bearings are self-oiling and dust-proof and are designed to be used with grease, oil, or both.

Either field winding is removable without disturbing the other or the armature, each winding being made up of separate coils, one of which is shown in Fig. 2. The removal of two bolts at one end makes it possible to lift out one of the fields, after which the armature can be taken out. The top field pole is hinged at one end for convenience in removing the fields or armature.

The ratio of the reduction of the gearing is 4.4 to 1, the armature pinion having fifteen teeth and a diameter of five inches. This ratio gives about 480 revolutions of the armature at a car-speed of 10 miles an hour.

The aim of the designer of the Wightman motor has been to attain as great an efficiency as possible with the wide variation of speed and load met with in street railway practice. This has been obtained by means of large field magnets of a great number of turns of wire. In fact, speed regulation is obtained without the use of any external resistance above three or four miles an hour. On a level, cars equipped with two 20 h. p. Wightman motors have frequently attained a speed above twenty-five miles an hour.

Mr. Wightman's experience has led him to the belief that there is no economy in operating motors of small capacity. Many roads are operated in such a way that cars are barely maintained on schedule time by dangerous and reckless running on down grades. A little calculation will show that by the expenditure of a little more power grades may be climbed rapidly, and as a result, much more service can be gotten from a given expenditure in wages for conductors and motor-men and interest on plant; and the cost of the extra coal will be comparatively insignificant. It is much safer to climb grades rapidly rather than to descend them at a high rate of speed, not to mention the greater satisfaction of patrons. When climbing a grade a stoppage of power and application of brakes will bring a car to a standstill within surprisingly short distance. Since the wear and tear of ample-sized motors is obviously less than those overworked, all considerations of economy and safety would therefore point to the use of the former.

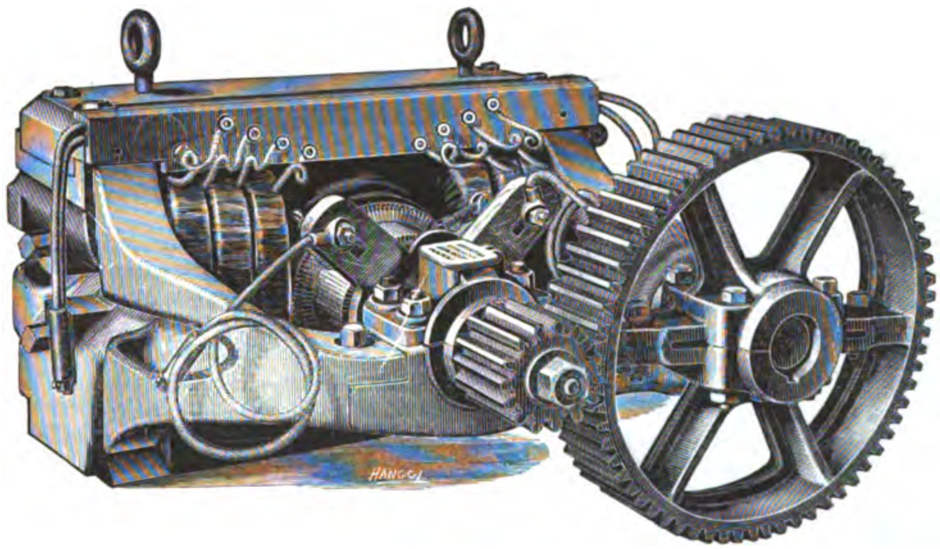


Fig. 1.—Wightman Single Reduction Railway Motor.

While in the Wightman motor electrical perfection has not been sought for at the expense of simplicity and durability, a very high efficiency is obtained. The armature resistance of the 20 h. p. motor is .75 ohm, and that of the main field coils .15 ohm, with a load of 40 amperes, or over 26 electrical horse power; this would give a loss of potential in the motor of 36 volts, or an electrical efficiency of 92.8. Even with this excessive load the commercial efficiency has been found to be as high as 87 per cent. The large field, referred to above, makes possible a high efficiency at low speed and light loads. These qualities are synonymous with powerful torque or starting force. A loaded car equipped with Wightman motors requires not more than from 15 to 20 amperes to start on a level.

Not the least interesting improvement in car equipment is the new controlling device employed by the Wightman Co., shown in perspective in Fig. 3. Here, again, simplicity and durability have been the aim of the designer. Corresponding points in each controller are connected at each end of the car, and all mechanical contrivances beneath the car, such as reversing switches, rheostat cables, etc., are done away with. There are five speed contacts on each side of the middle stop. A movement of the controller handle to the left causes the car to go forward, while an opposite movement reverses the direction of motion. The gradation of resistance on the reversing side of the controller is such that a car can be brought either slowly or suddenly to a standstill without the use of brakes or undue strain on the motors. The control is as absolute and flexible as in the case of a steam locomotive, yet very much more convenient in operation. The top of the controller is provided with notches in which a catch on the operating handle engages. This arrangement enables the motor-man to confine his attention to the track ahead, and yet be aware of the position of the controlling lever.

Another valuable feature of the controller is the device for extinguishing the arc formed on breaking contact. This consists of a small magnet let in from the back of the slate base and the poles of which come directly opposite

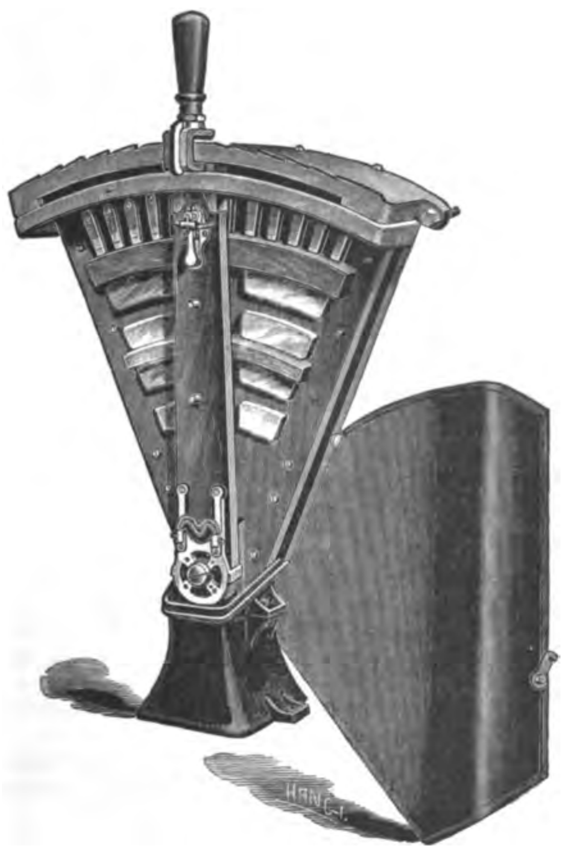

FIG. 3.—CONTROLLING DEVICE OF WIGHTMAN SINGLE REDUCTION RAILWAY MOTOR.

the spaces between the contacts; the well-known action of the magnet serves to blow out the arc and thus preserves the contacts. The latter in addition are all arranged to be readily removable for renewal, in case of necessity, and for this purpose all connections are in sight and can be gotten at merely by removing the cover.

Another interesting feature is the rheostat employed; this consists of very thin sheet-iron rings, slit and lapping over each other slightly, making a continuous spiral; the convolutions are insulated from each other by mica and liquid glass, and when the whole is screwed up tight it makes a perfectly fire-proof rheostat 3 inches in diameter and only 18 inches long. It has a resistance of 12 ohms and is divided into two sections.

The motor suspension adopted by the Wightman Co. consists of a regular carriage spring, which makes it very flexible and easy riding. The motor is thoroughly protected from dust and the gear case is built up in halves, which are hinged at the centre, so that one slides within the other; to open this case requires the loosening of but a single thumb-screw. The weight of the motor complete

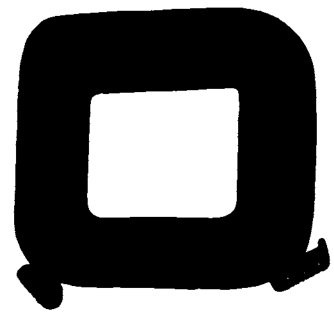

FIG. 2.—FIELD WINDING OF WIGHTMAN SINGLE REDUCTION RAILWAY MOTOR.

is 2,200 lbs. We may add that the Wightman motors are now in successful operation in Auburn, N. Y., Scranton and Easton, Pa.

ELEMENTARY GEOMETRICAL THEORY OF THE ALTERNATE-CURRENT TRANSFORMER.—VIII.

BY

Chas. Steinmetz.

In Fig. 14 the diagram for constant primary impressed E. M. F. is drawn for the secondary resistances.

1. $r_1^{\,1} = 2$ ohms: full load.
2. $r_1^{\,2} = 4$ ohms: half load.
3. $r_1^{\,3} = \infty$: no load.

Thus, if the primary impressed E. M. F., E_0, is kept constant, and the secondary resistance varies from 2 ohms, for full load, to ∞, for no load, the maximum primary impressed E. M. F. moves from $E_0^{\,1}$ to $E_0^{\,3}$, on the arc e_0, which, because of its shortness, can be replaced by a straight line.

Primary resulting E. M. F., E, primary M. M. F., L, and primary current, C, travel on the lines e, l, c, decreasing for decreasing load, while the difference of phase between primary current and impressed E. M. F. increases with decreasing load.

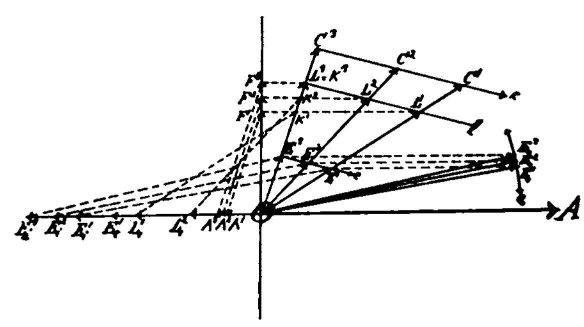

FIG. 14.

The resulting and the impressed M. M. F. increase with decreasing load, from F^1 and K^1, respectively, to F^3 and K^3, and hence the induced E. M. F.'s decrease with increasing load, from $E_1^{\,3} = E_1^{\,3}$ to $E_1^{\,1} = E_1^{\,1}$, etc.

The secondary terminal pressure, E_1, decreases still more with increasing load, because of the drop of potential caused by the internal resistance of the secondary coil, $E_1 = E_1^{\,3}$ for open secondary circuit, and decreases to $E_1^{\,1}$ for full load.

This construction of the diagram for constant primary impressed E. M. F. is not absolutely exact, because we supposed the angle of magnetic lag $\alpha = \text{K O F}$, to be constant; while it slightly decreases with increasing magnetization, but the increase of the magnetization from full load to no load, *i. e.*, from $\overline{\text{O F}^2}$ to $\overline{\text{O F}^1}$, is so small in good constant potential transformers, that we can allow this approximation. Where, for instance, as in constant-current transformers, the change of the magnetization is large enough to cause a perceptible change in the angle of magnetic lag, we have to replace the ray $\overline{\text{O K}}$ by that curve, which gives the dependence of the magnetic lag upon the magnetization. Chapter VIII. on "Constant Current Transformers," will contain more on this subject.

In the same way as we did here, by producing the diagrams for constant secondary E. M. F., E_1 and then increasing or decreasing all the quantities proportionally, we can produce the diagram of the transformer, which gives constant potential at the secondary terminals, and therefrom determine the changes of primary impressed E. M. F., necessary to be produced by the dynamo alternator, to give constant voltage at the secondary terminals.

Thus, in Fig. 15, is shown the diagram of the transformer for full load, E_0^1, E^1, E_1^1, C^1, etc., and for open secondary circuit, under the condition that the secondary terminal pressure at full load, E_1, is equal to the secondary E. M. F. at open circuit. E_0, E, L, C, then move along the lines e_0, e, l, c, and the dynamo alternator has for increasing load to increase its E. M. F. from $\overline{\text{O E}_0}$ on open secondary circuit up to $\overline{\text{O E}_0^1}$, for full load, to keep the pressure at the secondary terminals constant. At the same time we see, that : *If different transformers are fed by the same dynamo alternator, and the load on the transformers is different, it is not possible to regulate the* E. M. F. *of the dynamo so that the secondary terminal pressure of all the transformers is constant.*

Hence it is of the utmost importance to design parallel transformers so, that for constant primary impressed E. M. F. the pressure at the secondary terminals is as constant as possible, for varying load, and either to keep the E. M. F. of the dynamo alternator constant, or, better, to regulate it so as to keep constant pressure at the centre of distribution.

Means to accomplish this good compounding of the con-

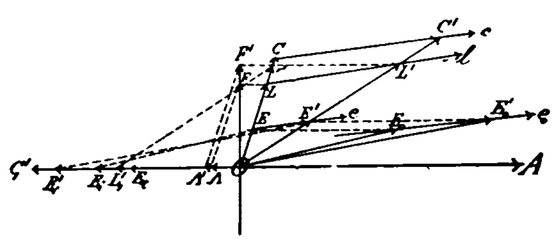

FIG. 15.

verters we derived from the foregoing, and shall consider them still more in the following.

Good compounding generally means low internal resistance of transformer and line ; low self-induction, that is, low magnetic leakage ; low magnetic resistance, P; high frequency, N; large number of turns, n and n_1; low magnetization, F; low hysteresis and eddies, A, etc.

B. Dependence upon the Primary Resistance, r.

The letter r is understood to represent the electric resistance between those two points of the primary conductor between which E_0 was the maximum E. M. F. Thus r is the internal resistance of the primary coil, if E_0 is the potential difference at the primary terminals of the converter. If r is the whole electric resistance of the primary circuit, E_0 is the E. M. F. of the dynamo alternator, etc.

Let r change from r_0^2, the internal resistance of the primary coil, to r^1, the whole resistance of the primary circuit, that is, let us go along the primary line from the converter to the dynamo.

Then, in Fig. 16, $C, L, F, K = \text{L}^\infty$, etc., remain constant, but E increases from E^2, consumed in the primary coil proper, to E^1, consumed in the whole primary circuit, and E therefor travels on the ray $\overline{\text{O E}}$ from E^2 to E^1, for full load. Similarly, for open secondary circuit, E^∞ changes from $\text{E}^{\infty\,2}$ to $\text{E}^{\infty\,1}$, on the ray $\overline{\text{O E}^\infty}$. Hence, because of the parallelogram of primary E. M. F.'s, E_0 (full load) and E_0^∞ (open circuit) travel on the lines e_0 that is, e_0^∞, from E_0^2 at the primary terminals, up to E_0^1 in the dynamo ; that is, from $\text{E}_0^{\infty\,2}$ to $\text{E}_0^{\infty\,1}$.

At the same time, when r increases, that is, when we go farther away from the transformer terminals, on the

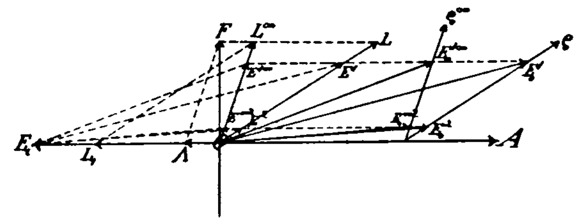

FIG. 16.

primary line, the difference of phase between primary current and primary E. M. F.,

angle $\omega = \text{L O E}_0$ for full load, that is,
angle $\omega^\infty = \text{L}^\infty \text{O E}_0^\infty$ for open secondary circuit,

decreases, especially for open secondary circuit, but much less for full load.

Hence the difference of phase between current and E. M. F. in alternating transformer circuits, and in all inductive circuits, is not a constant, but varies from point to point on the line, increasing with the increasing distance from the dynamo.

Thus, in inductive circuits, we have not only a drop of potential in the line, but also an increase of the shifting of phase by approaching the inductive part of the circuit, except in the case where the inductance is distributed over the whole circuit proportional to its resistance; but then the loss of potential in the line is considerably less than the line resistance accounts for.

For instance, in the transformer, Fig. 16, for open secondary circuit, the potential difference at the primary terminals of the transformer is :

$\overline{\text{O E}_0^{\infty\,2}} = 136$ volts, and at the dynamo, $\overline{\text{O E}_0^{\infty\,1}} = 162$ volts. Hence a loss in the line, of $\overline{\text{O E}_0^{\infty\,1}} - \overline{\text{O E}_0^{\infty\,2}} = 26$ volts.

But, the resistance of the whole circuit being r^2; the resistance of the primary coil proper, r^1; the E. M. F. consumed by the resistance of the line, $r^2 - r^1$, is :

$$\overline{\text{O E}^{1\infty}} - \overline{\text{O E}^{\infty\,2}} = 60 - 12 = 48 \text{ volts};$$

that is, the line consumes 22 volts pressure less than in an equivalent continuous current circuit.

I need not remark that the consumption of energy in the line is the same for continuous currents as for alternating currents of equal strength ; only that in the alternating system the greatest part of this energy is furnished by a shifting of phase ; in the continuous current system it must be furnished by a drop of potential. This is especially marked, where the line is of low self-induction, and the working apparatus of high self-induction. If the working part is of low self-induction (for instance incandescent lamps), and the line has a considerable self-induction, just the opposite phenomenon appears the line consumes more potential than its resistance accounts for, and the difference of phase between current and potential difference increases, when approaching the dynamo alternator.

But these phenomena of self-induction, I suppose, are so well understood, that I need not dwell upon them any longer.

TESLA'S ELECTROLYTIC METER.

THE measurement of the quantity of current taken by consumers has given rise to a large variety of meters, one type among these being what are known as electrolytic meters. Probably the best known of this class is the Edison meter in which the quantity or weight of metal deposited from one plate upon another affords a measure of the current passed through the circuit. In other forms the quantity of gas decomposed by the passage of the current gives the desired indication.

In seeking to employ the electrolytic deposition of a metal for this purpose, but to avoid the manipulation required in weighing the plates in order to ascertain the loss in weight, Mr. Nikola Tesla makes use of an electrolytic cell, through which extend two conductors parallel and in close proximity to each other. These conductors are connected in series through a resistance, but in such manner that there is an equal difference of potential between them throughout their entire extent. The terminals of the conductors are connected either in series in the circuit supplying the current to the lamps or other devices, or in parallel to a resistance in the circuit, and in series with the translating devices. Under such circumstances a current passing through the conductors establishes a difference of potential between them which is proportional to the strength of the current, in consequence of which there is a leakage of current from one conductor to the other across the solution. The strength of this leakage current is proportional to the difference of potential, and, therefore, in proportion to the strength of the current passing through the conductors. Moreover, as there is a constant difference of potential between the two conductors throughout the entire extent that is exposed to the solution, the current density through such solution is the same at all corresponding points, and hence the deposit is uniform along the whole of one of the conductors, while the metal is taken away uniformly from the other. The resistance of one conductor is by this means diminished, while that of the other is increased, both in proportion to the strength of the current passing through them. From such variation in the resistance of either or both of the conductors forming the positive and negative electrodes of the cell, the current energy expended may be readily computed.

The accompanying diagrams show the meter in operative relations to a working circuit, and under slightly modified arrangements.

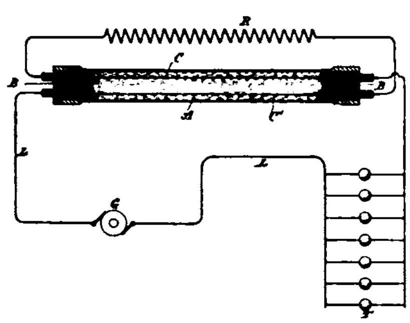

FIG. 1.—TESLA'S ELECTROLYTIC METER.

In Fig. 1, G designates a direct current generator. L L are the conductors of the circuit including lamps or other translating devices T. A is a glass tube, the ends of which are sealed by means of insulating plugs or caps B B. C C′ are two conductors extending through the tube A, their ends passing out through the plugs B to terminals. R is a resistance connected in series with the two conductors C C′, which by their free terminals are connected up in the circuit of one of the conductors L.

The method of using this device, and computing by its means the energy of the current, will be readily understood. First, the resistances of the two conductors C and C′, respectively, are accurately measured and noted. Then a known current is passed through the instrument for a given time, and by a second measurement the increase and diminution of the resistances of the two conductors respectively taken. From these data the constant is obtained, that is to say, for example, the increase of resistance of one conductor or the diminution of the resistance of the other per lamp-hour. These two measurements serve as a check, since the gain of one conductor should equal the loss of the other. A further check is afforded by measuring both wires in series with the resistance, in which case the resistance of the whole should remain constant.

In Fig. 2 the conductors C C′ are connected in parallel,

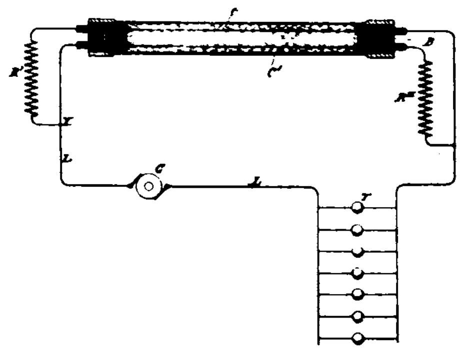

FIG. 2.—TESLA'S ELECTROLYTIC METER.

the current device at X passing in one branch first through a resistance R′ and then through conductor C, while in the other branch it passes first through conductor C′, and then through resistance R″. The resistances R′ R″ are equal, as also are the resistances of the conductors C C′. It will be observed that in the arrangement shown in Fig. 2 there is a constant potential difference between the two conductors C C′ throughout their entire length.

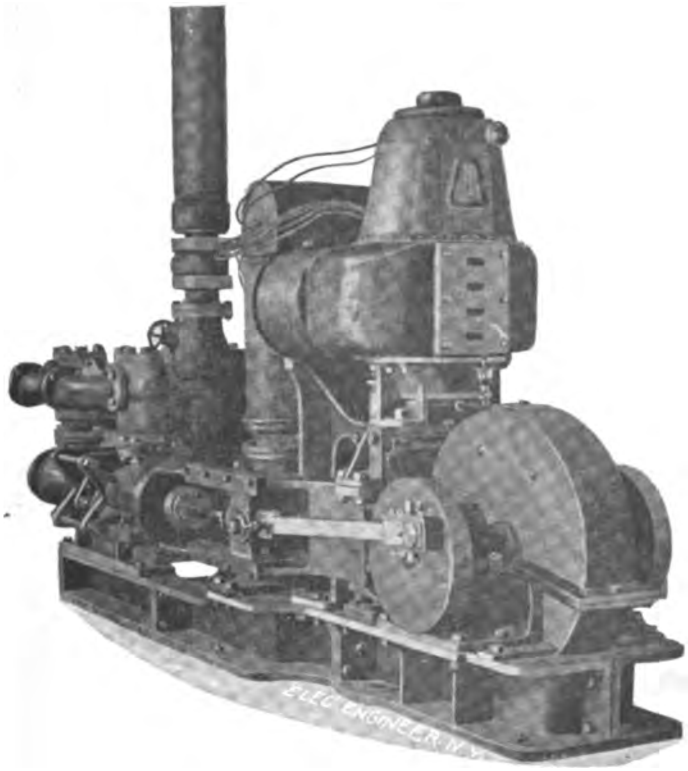
It will be seen that in both cases illustrated, the proportionality of the increase or decrease of resistance to the current strength will always be preserved, for what one conductor gains the other loses, and the resistances of the conductors C C′ are small as compared with the resistances in series with them. After each measurement or registration of a given variation of resistance in one or both conductors, the direction of the current should be changed or the instrument reversed, so that the deposit will be taken from the conductor which has gained and added to that which has lost. By this method it is possible to read off directly the amount of the energy expended by means of a properly-constructed ohm-meter, and without resorting to weighing the deposit; it is not necessary to employ shunts, for the whole of the current to be measured may be passed through the instrument; and the accuracy of the instrument, and correctness of the indications, are but slightly affected by changes in temperature. In addition to these advantages the arrangement possesses the merit of economy of energy, and simplicity in construction.

THE BERLIN ELECTRICITY WORKS.

THE work of constructing the stations of this company for the year 1890-91 is now finished. The stations in Markgrafenstrasse and Dorotheenstadt are completed, whilst in each of the two others the erection of two large machines will take place during this year. At the same time the distributing system in the inner portion of the town will be transformed into the three-wire system. The output of the stations at the end of the year is expected to reach 185,000 lamps. The number of consumers in 1885 was 28; in 1886, 146; 30th June, 1890, 862; 1st June this year, 1,310. The current supplied rose from 24,420,000 ampre hours in 1889, to 32,268,462 ampere hours in 1890.

THE EDISON ELECTRIC MINING PUMP.

One of the most important fields for the electric motor in mining work is that of pumping, and from the fact that electricity has already been very successfully used in or-



Edison Mine Sinking Pump.

dinary pump work, it is only fair to infer that in this newer class of operation its early promise will be fully justified, despite the severity of the conditions under which mining operations, where pumps are used, are generally carried on.

As an example of the manner in which electrical engigeers are attacking the subject, we illustrate on this page the combination that has been brought out by the Edison General Electric Co. of a 25 h. p. motor and a Blake double-acting pump, all on the same base-plate.

The motor is series wound, and designed to operate at 800 volts; it can be supplied, however, wound for any of the standard voltages. The field coils are divided into three sections, and the regulation of speed is effected by commutation of these sections by means of an ordinary car-controlling switch. The armature shaft is connected by a worm driving a large gear-wheel keyed to a pair of crank discs, one on each side of the machine. Wrist pins, placed at an angle of 90° with each other, carry the connecting rods operating the plungers of the double-cylinder pump, which is mounted on the same bed-plate with the motor. Each pair of plungers being connected together by outside rods, work together like one plunger, and the connection with the crank discs being at an angle, one pair of plungers is drawing while the other is forcing water, thus making them double-acting. The size of each cylinder is 5 inches diameter by 12 inches length. The following table gives the performance of this pump as obtained during a recent test.

The height given in the table below is the height of a column of water at 60° F., with the barometer at 30 inches, which could be supported by the given pressure per square inch. The actual height to which the given number of gallons per minute could be raised would depend on the length and diameter of pipe and the number of bends, and in any case would be less than its theoretical height.

CUTTRISS' PROCESS OF INSULATING CONDUCTORS.

A novel method of insulating wires for electrical purposes has recently been devised by Mr. Charles Cuttriss, of this city. Instead of a sheathing made up of woven material consisting of seperate strands, or one in which a fibrous covering is associated with an insulating material which serves to bind the fibres to the core, Mr. Cuttriss proceeds as follows:

Cotton in the condition in which it leaves the carding-engine—that is to say, in the state of a delicate flat narrow strip or ribbon called a "sliver"—is coiled down into a can with its convolutions continuously crossing each other, so that when the sliver is removed its parts do not adhere to each other. This sliver is passed through boiling water and then drawn through a contracted nozzle or die, by means of which its fibres are slightly compacted and matted, and its tenacity considerably increased. While in this condition it is wound spirally around a wire, and by rubbing-plates is compressed or packed, and becomes felted or matted around the wire. This is wound on a spool or bobbin, and while the cotton is still moist, the spool is immersed in a bath of insulating compound, which is maintained at a high temperature until the air and moisture are driven out from the cotton sheathing, and the latter fully saturated with the compound. A sheathing made in this way and saturated with a compound composed, for example, of gum-copal or shellac and carbolic acid, or resin and resin-oil, will, it is claimed, insulate and protect a wire very perfectly, be flexible, dense, and durable, and hard and horn-like in character, without tendency to unravel or fray.

REACTING OR RECIPROCAL DRIVING AS APPLIED TO ELECTRIC PROPULSION.

BY

D. W. Mott

Early in 1879 I began to speculate, as inventors frequently do—positive in outgo, potentially negative in income—on a subject which has since gained, and will continue to gain, in importance,—in fact, stands to-day without a parallel in the industrial history of the world—that of electric traction as applied to the general subject of railway propulsion. The importance this subject has lately assumed in view of its possible adoption for the metropolitan rapid transit lines, warrants me in sending to you some of the results of my early labor in this particular direction, which may be suggestive in the evolution of this problem as well as interesting to some of your numerous readers.

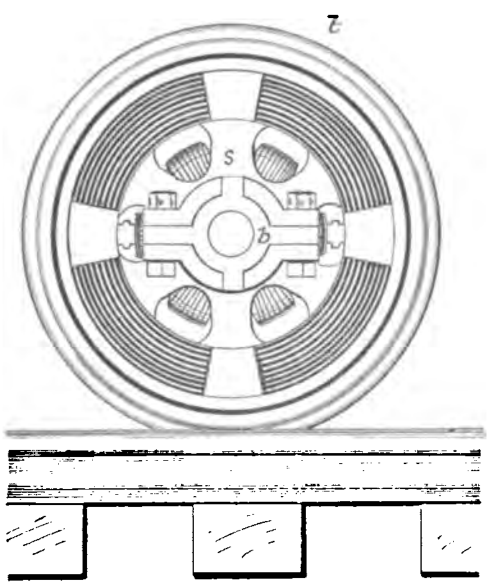

Fig. 1.

Up to the time mentioned I had never seen an induction motor, at least to know it as such, and was familiar only with the early forms of electromagnet motors, several of which I had access to at the time in the School of Science of Princeton College.

The making of each car unit self impelling, in other words distributing the power throughout the train, as distinguished from haulage, thereby securing the traction due to weight of train and dispensing with 30 to 60 tons dead weight of machinery, with the incidental advantage of many pulls or *multitorque* instead of one pull of a locomotive, was one of the early maxims I adopted in my work, and from present appearances it is fast becoming, if it is not already so, one of the axioms of electric traction. Among other minor features which I then incorporated in my plans, were inflexible coupling of cars, in order that the train would move as a unit, avoiding jerking or jamming when starting or stopping; distributing automatically the strength of current or motive power proportionally to each car according to the tonnage of each, whether it was loaded with passengers or freight, thereby avoiding the drag of one car on another and assisting to uniform movement throughout the whole; also the same feature with regard to magnetic brakes, they being supplied with power in proportion to the load, every train being controlled from one point, and each car capable of isolated and independent operation. I looked upon these general features at that time quite apart from

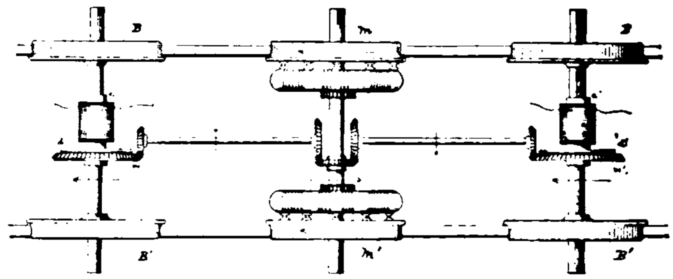

Fig. 2.

the comparative economy of electricity and steam as a motive agent, as affording one of the strongest arguments for its adoption, and I may say I have not since had cause to change that opinion.

I quite realized in 1879, as I do now, that the torque of a number of armatures without reduction to start a train from a position of rest under all conditions of load, was not in itself sufficient for the work, but did believe that it would suffice to keep up the motion after the car was started, and this led me, in 1880, to make drawings in which a simple mechanical arrangement of car starter played an important part in overcoming the *vis inertia* of the car, the motors being mounted upon one axle of each truck, and several other features convenient for the purpose working up the two in conjunction. The car was started and stopped mechanically, and electrically controlled while in motion.

In this same combination of motors applied directly to axle with car starters, I had also a form of epicyclic train for the reduction of speed, the same in principle as that illustrated in The Electrical Engineer of September 17, 1890, though different in arrangement.

The arrangement I worked out, though simple, I did not feel was the solution of the problem I was looking for. I thought there must be a way to multiply a small power into a great force for moving a car, in some way analogous to the simple lever, when great resistance or weight is to be overcome by the application of an insignificant force. I saw at once it was only a question of relative speed for a given time. There was plenty of speed, and to spare, but little pull. I wanted to reverse this, and was led to utilize the reaction in the motor, *i. e.*, to allow the two elements of the motor, the armature and the field, to revolve, and then, if I could bring this dual and reverse motion to bear at the same point, or at another point of traction through other axles or wheels, I would at once double the pull of a motor, and have twice the speed in the motor as at the point of traction; or in other words, *one* pound torque of armature would, on the principle of the simple lever, give *two* pounds pull to the car.

I then devised a number of mechanical methods of carrying this idea into practice, in some of which I used gears, in others no gears, and in either case was enabled to still further increase the statical or moving pull by the purely physical action of the current up to any degree of useful application. Of the several ways of carrying this reactive or reciprocal driving into effect, I will illustrate from my early drawings typical examples of each, (1) with gear, (2) without gear, (3) by cable. The accompanying illustrations come under the first head. There are three ways of motor mounting shown; the first, Fig. 1, is the electromotive wheel, where the motor is incorporated into, and forms part of, the supporting wheel of a car. This may have disadvantages in practice, depending upon the conditions and surroundings, but has this advantage under all circumstances, that the motive power adds practically nothing to the weight of the train, it being substituted for the ordinary wheel.

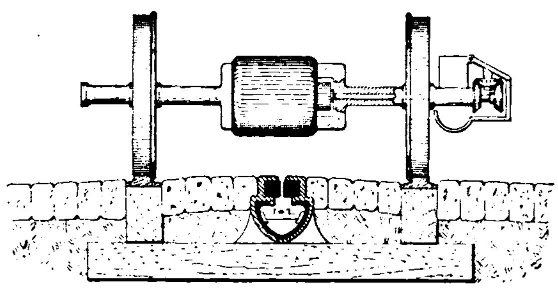

Fig. 3.

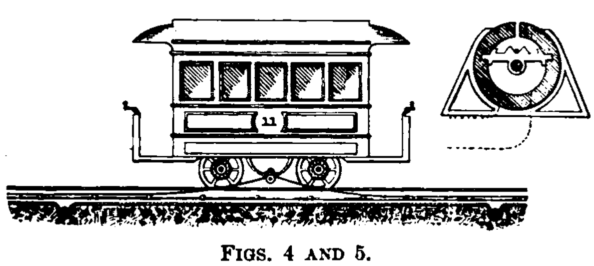
In Fig. 2 there are shown two motors on one axle but four or six drivers, as the case may be, the reciprocal action of the armature being communicated to the adjacent axle by the counter-shaft. Magnetic adhesion clutches are shown, which allow the armature free revolution; but these, it will be observed, are not necessary, and they were entirely done away with. The motor is of the multipolar type, with flattened ring armature of the Schuckert-Mordey type, mounted to an ordinary paper car wheel. The direction of motion of the several parts is indicated by arrows.

In Fig. 3 the motor is mounted at the centre of axle, the field magnet is hinged, and the armature mounted in such a way upon its shaft as to be readily dismantled. In this case, with the bevel wheels at the right and all of the same diameter, the speed between the armature and the field is twice that of the axle upon which the driving wheels are mounted, and the statical or moving pull of the motor is just double what it would be if mounted in the ordinary way. The armature shaft which runs through the driving axle is made subject to torsional elasticity to give the desired flexibility between the power and the point of its application, which idea is now in almost universal use in one form or another.

The street system of line and feeder shown in Figs. 3, 4 and 5 has, I believe, some meritorious points. The insulat-



Figs. 4 and 5.

ing conduit, Fig. 5, in which lie the feeder and working conductor, is made of concrete, cement, asphaltum, fire clay, etc. This conduit, it will be observed, may be nearly filled with water, and still preserve the insulation of line if properly put down; but of course it should be drained in the usual way. The supports of the working and feeding conductor act as braces to strengthen the conduit. The working conductor, made of silicon bronze or other material to resist abrasion, corrosion or oxidation, is lifted up through the slot to the trolley underneath the car as the car progresses, trailing back into the conduit as the car recedes. One car may be run faster than another and in either direction. There are no rigid sub-surface connections, but the drop conductor may be hauled around independent of the conduit, as at switching, etc.

Take the wheels out from car and replace by ordinary wheels, and we have the ordinary type of car. Throw the bevel wheels on the right, in Fig. 3, out of gear, and the field and armature will revolve together.

THE PITTSBURGH FIRE-ALARM SYSTEM.

About a year ago the Pittsburgh city councils gave the superintendent of the bureau of electricity permission to entirely refurnish the police and fire-alarm system, which at that time was in a totally antiquated and unfit condition. Mr. Morris Mead, the superintendent of that department, who had long been alive to the wants of his bureau, immediately set himself the task of giving the city the best system to be had, and has succeeded in designing one of the finest and most complete fire-alarm services in the United States. The accompanying illustration shows the interior of the office. The fittings are all of the best workmanship, and embody the latest improvements in this class of electrical apparatus. The cabinet work is of dark mahogany throughout, and tastefully hand carved. No less than 40 Breguet galvanometers indicate any defect or irregularity in the system, in addition to which a large upright galvanometer indicates the condition of the alarm circuits.

Central Office of the Pittsburgh Fire Alarm Service.

The annunciators, one for each signal circuit, are placed between the upper line of switches and the ornamental cap of the board, and are so constructed as to be restored by one movement, at the will of the operator, and the relays, furnished with rubber magnet covers and having platinum contact points, are mounted in compartments in sections of five, on marbleized slate bases.

All the work has been executed in the most workmanlike manner, under the personal superintendence of Mr. Mead, and was completed without any interference with, or interruption to, the working of the fire-alarm system.

PROJECTED ITALIAN ELECTRIC RAILWAY.

A scheme has been laid before the Italian Minister of Public Works for the construction of an electric railway from Aosta to Pré-Saint-Didier, that is to say, from Aosta to the Helvetian-French frontier. The project, which owes its origin to Signori Farrinet and Garrone, will, if carried out, bring into existence the largest electric railway in Europe. It is proposed to utilize local watercourses as the means of producing motive power

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed*, EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XII. NEW YORK, JULY 22, 1891. No. 168.

Not in a week, or a month, or a year, but by the lives of many souls, a beautiful thing is done.—Ruskin.

THE EDISON LAMP DECISION.

OUR readers have already received the Extra, in which, immediately after the handing down, we published Judge Wallace's decision in the great and important Edison lamp litigation. They know, therefore, that another of the critical campaigns in electrical warfare has been fought out, and that the future of one of the foremost electrical industries has been pretty clearly defined. At first reading, the decision in Mr. Edison's favor is not so very impressive, but the fact grows upon one with later perusal that it is fairly entitled to be called broad and sweeping. The patent is sustained, and it appears to control the situation.

There are a great many aspects to this long and costly litigation. It seems to us a matter for general congratulation that an electrical patent has once more been sustained. It may be said that Judge Wallace's decision will be promptly appealed. No doubt; but Judge Wallace's decisions have the reputation of being appeal-proof. If electrical patents of this fundamental nature were to be voided every time they came to the test, there would be a long farewell to advance in the electrical arts. Most of the stimulus to invention would be withdrawn; little inducement to capital would remain. Let us suppose, for example, that the Bell telephone patent, the Morse telegraph patent, the Brush storage battery patent, the Brush double arc lamp patent, the Edison incandescent lamp patent, had all gone down before the onslaught. Would there have been any material gain in the way of incentive to brains and money to become interested in new electrical ideas? None, but on the contrary, the feeling of confidence and permanence that lies at the bottom of all great industries would have died away, leaving little hope behind.

Next to inventors as a class, we may look at the inventor who in this case receives his reward. He certainly may be felicitated upon such an occasion, and if we judge him aright will value the vindication of his genius and his priority far more than he does the royalty that may come to him. Before and without Edison, there was no incandescent lamp; and while many aimed at the goal, it was his genius that turned failure into success, and gave to the world another of those beautiful, priceless things which, as Ruskin says truly, are the outcome of many years and many lives. If our readers would see how the work of Mr. Edison has been regarded by his friends, we would advise them to glance over the magnificent closing argument printed in our columns, of Mr. Grosvenor Lowrey, whom we may describe as the discoverer of Edison and his eloquent protagonist.

It is somewhat difficult to predict the immediate results of the decision in regard to the public and as affects electrical manufacturing interests. A great deal depends on the shape of the decree, which has not yet been entered. A great deal depends on the attitude of the Edison General Electric Co. A great deal depends on other inventors and their new departures. While there are accountings to be made, it is to be borne in mind that such a process is not one of the easiest or quickest things in the world. The game may be hardly worth the candle. Moreover, it is a notorious fact that while the Edison lamp business has been conspicuously successful, the industry as a whole has not been signalized by any great profit. Another peculiar feature is that for a time the patent upheld was actually in abeyance owing to the decision against it on the ground of foreign limitation; and during that period a great many lamp concerns started up which can plead good faith and immunity for at least that term. As to the attitude of the Edison General Co., we can only hope and believe that the corporation will exercise its victory with the moderation which is always the best proof of the right to power, and which will be only a further proof of the skill that has throughout been manifested in the direction of its affairs. Possibly the company, having spent so many hundreds of thousands of dollars to sustain its rights, may consider it necessary to "make an example." The phraseology of the decree will probably do much to determine its action. In some instances, there is really no change of conditions at all. For instance, the Thomson-Houston Co. has been paying royalty under the Sawyer-Man patents. It will be in practically as good a position should it simply pay that royalty into other coffers. In fact, we look for an interesting readjustment of relationships in the long run, with ultimate good to the whole electric lighting industry.

But as we have said, a great deal depends on that which is to be. Inevitably the drift of invention will now be towards the improvement of the incandescent lamp, and towards the introduction of forms that do not infringe. It is here that such work as Mr. Tesla's, so recently brought to notice, assumes a new and wonderful value. We mention Mr. Tesla, not because he stands alone as an innovator in this field, nor because he has altogether "arrived," but because his work is the most striking illustration of the possibilities that lie before us. Mr. Tesla gave us a motor without a commutator; and it would be strangely in keeping if he gave us now a lamp without a filament. Meanwhile the Edison Co. will enjoy the rich fruits of a great and hard-won victory.

Such, then, is the situation. While there are now probably few who will seriously deny that the modern system of incandescent electric lighting, one of the greatest achievements in the arts, originated in the world-renowned laboratory at Menlo Park, and while it may be admitted that, as a matter of abstract justice, the rewards and profits of the invention during the term of his patent, ought rightfully to fall to Mr. Edison, yet the fact should not be lost sight of, that even Judge Wallace was compelled to pronounce the specification of his patent a "perplexing" one, and to remark that it "leaves to be found by inference from generalities what the elements are of the combinations included in the extremely elastic terms of the two important claims." When we consider further, that for want of a vigorous and far-sighted executive, more than five years were permitted to elapse before the first step was taken by the old Edison Company towards obtaining a judicial determination of the meaning and scope of this patent, and that, as the law stood prior to the decision of the Supreme Court in the Bate case, the public were justified in the belief that the Edison patent must be held to have expired under the provision of the statute relating to prior foreign patents, a view in which Judge Wallace himself judicially concurred—when we consider all this it will be evident that the manufacturers of incandescent lamps who have invested large amounts of capital in their business, must in fairness be considered to stand in a far different position from that of wilful and inexcusable infringers. It would seem, therefore that, should the decision of Judge Wallace be affirmed by the Appellate Court, it might be an eminently wise and judicial policy on the part of the Edison Company to permit its competitors to continue in business, under an equitable royalty, at the same time fixing the minimum price of lamps to consumers at a remunerative figure, thus compelling future competition to be conducted on a basis of quality rather than of price. Such a course, while it could not fail to be exceedingly profitable to the Edison Company, would not only be less detrimental to the business interests of the community than a more arbitrary course, but would obviously be of direct and positive advantage to the true interests of the consumer.

THE WESTINGHOUSE REORGANIZATION.

With much pleasure we note that, as we ventured to predict last week, the Westinghouse reorganization has become an accomplished fact. This reorganization is the more striking for the reason that it was completed in full knowledge of Judge Wallace's decision upholding the Edison lamp patent; and the only inference possible is that the men of affairs and of leading who thus assume control by the investment of a large sum of money, are well satisfied as to the outlook. We are ourselves inclined to look upon the Westinghouse Company as now one of the most formidable in the field, and as being far more likely to-day to get business and do it profitably than it was in the time of its inflation and extravagance. It has stripped off superfluous burdens, and with obligations cut to the quick can market its product on a very favorable basis for securing good profits. We believe and hope that the company, and its rivals no less, has gone utterly beyond the "free lunch" period, of which the main idea has been that of doing business as a charity to the public, making goods for nothing and giving them away "gratis."

ELECTRIC HEATERS ON STEAM ROADS.

The problems connected with train lighting and heating are by no means few, and apparatus that has answered most of the requirements has been found to fall short in regard to others. The idea of using electricity for lighting is one that has been tried with varying results. While it has been a failure quite often, the actual data in successful instances is such as to promise that electrical methods will be predominant in the near future. This promise is greatly helped toward realization by the resort to electricity also for heat, on steam railroad cars, as some very cumbrous and delicate apparatus, piping, etc., is at once dispensed with, and the same attendant is every way competent to attend to both systems. We are very glad to note in our columns, this week, the fact that one of the largest and most influential steam roads has decided to adopt Burton electric heaters for some of its special first-class trains. This seems to us an event of the highest significance, and one of bright augury for the traveling public. The success of electric heaters in cars on electric railways has been notable, and this new work is simply an extension of present methods. The popularity of electric heating is young, but growing fast. We know of one instance where heaters have been ordered for a large block of apartment houses in a Western city. Evidently there are enormous advantages in a method that, using the same wires on which are placed the lights or fan motors of a house or office, furnishes also heat by the mere turning of another switch. In fact, with our changeable climate, a system that will thus give us cooling breezes one day and warm air the next, with kodak instantaneousness, is a great desideratum and boon.

THE MANUFACTURE OF OZONE.

The discovery of ozone by Schoenbein over 40 years ago was followed by a variety of experiments, and although it has been applied in isolated cases for commercial and sanitary purposes, no systematic attempt has thus far been made to reduce its manufacture to a commercial basis. We have therefore deemed it well to bring to the attention of our readers the efforts which are now being made in Germany towards this end; and a description of the apparatus given by Dr. Frölich, which appears in another column, will give a good idea of its simple character. The uses to which ozone can be put are quite numerous and the availability of high tension alternating currents has now placed us in a position to carry out practically the manufacture of ozone on a commercial scale.

Scientific Note Making.

WHILE a good memory is probably the best endowment for the student or worker in any field, the multiplicity of new ideas and inventions brought out by workers all over the world at the present day, makes it impossible for a single individual, however gifted, to keep in mind the facts which he may be called upon to employ at any time. It therefore becomes necessary to supplement the memory by some means, and thus relieve it of a strain which might in the end lead to serious results. The making of notes on such matters as one is likely to have occasion to refer to on subsequent occasions, therefore becomes an absolute necessity, and, for those who adopt a systematic course in this respect, the labor spent upon it will prove to be an excellent investment. In connection with this subject we desire again to call attention to the admirable index to electrical periodical literature which is now available, and which has been published since the beginning of 1887 and known as Fortschritte der Elektrotechnik. While not taking the place of an individual index such as every one must of necessity require for his own use, it places in the hands of the student the complete record of current electrical literature, and its value cannot be over-estimated. It will be noted that in our last issue, Mr. J. S. Brown published an admirable article showing how every man may get up just such an index for himself in his chosen lines of work.

Printing the Edison Lamp Decision.

IN keeping with its precedent in such matters, THE ELECTRICAL ENGINEER issued the Edison lamp decision immediately upon its handing down, on Tuesday last, in the shape of an Extra, and by Thursday afternoon had put forth some 10,000 copies of that document. The extra is paged so as to bind up in proper sequence with the other numbers of the paper, and we shall be glad to send a spare copy to any subscriber who may need another for that purpose. We are glad to know that our promptness in the matter and avoidance of delay of the regular current issue of the paper has been favorably regarded. One letter on the subject says: "Allow me to congratulate you on your enterprise. I remarked but yesterday that the case afforded an opportunity for one of the electrical papers to score a 'beat,' and I am glad you have appreciated the opportunity." THE ELECTRICAL ENGINEER has been the only paper to publish a report of the arguments of counsel in this case. It also printed the patent in full in its issue of June 10.

Electrolytic Meters.

THE simplicity of electrolytic forms of meters has always made them a favorite department of work with electricians, and though what may be termed motor meters have lately gained considerable ground, we nevertheless see continued efforts to improve those of the electrolytic type. As an example of this, we describe on another page a meter devised by Mr. Tesla, in which the indications are obtained by measuring the change in resistance of the electrodes due to the deposit of metal from one upon the other. This method adds one more to the available means for measurement of the electric current.

The Frankfort Electrical Congress.

THE interest which has been aroused by the Electrical Congress to be held in Frankfort next September is well shown by the list of papers already announced to be read, which will, no doubt, be considerably augmented as the day of the Congress approaches. This list, which will be found on another page, includes a wide range of subjects, and the papers will probably give rise to interesting discussion. Prof. Heinrich continues to give in his correspondence some very interesting glimpses of the exhibition itself.

Rights to be Respected.

IT is satisfactory to note that the Mayor of New York has been unable to wreck the Subway Company at his will. The Corporation Counsel informs him that he cannot seize their plant as he wished. It is a pity that similar restraint was not put upon Mr. Grant when he began his chopping down of wires and poles.

A ROUGH-AND-READY DYNAMOMETER FOR SMALL MOTORS.[1]

BY JOHN HOSKIN.

Mr. Hoskin began by explaining that the device he was about to describe was by no means new, but that it was deserving of more attention from electricians than it had apparently received. A rough-and-ready, portable dynamometer, inexpensive and readily used, is, he continued, much needed in cases where bulky and elaborate apparatus being alone available, the efficiency of small motors, etc., is very often left to guess-work.

The dynamometer described by Mr. William Warby Beaumont before the Institution of Civil Engineers of London Nov. 13, 1888, seems to fill this need.

Its construction requires only the use of a leather belt with a spring balance attached to one end and a suitable weight at the other. The belt is to be thrown over the belt pulley of the motor, the spring balance is fastened to the floor base or support of the motor to be tested, and the weighted end hangs pendant on the side of the pulley, which, when in motion, will tend to lift the weight. When the motor is at rest the strain of the weight should be read off on the spring balance. This reading we will call W. When the current is switched on and the motor runs at speed the spring balance should again be read off, since the friction of the pulley on the belt will have a tendency to raise the weight; this reading we will call W'. The difference between W and W' in pounds, multiplied by the circumference of the pulley in feet (including one-half the belt thickness on each side), and this by the number of pulley revolutions per minute, will give the foot-pounds of mechanical energy, which can be compared with the electrical energy required to produce it, in the usual manner. Thus, in a few minutes with the aid of a speed counter or tachometer, a voltmeter and an ammeter the efficiency of a motor can be determined, and its ability to do a desired amount of work ascertained at once.

The speaker then referred to the value of the Waldron rotary pump for use as a dynamometer. This pump is operated by rotary piston blades working in a chamber, without leakage, and with but small friction, the amount of which can readily be ascertained and calculated for use as a "constant." Its capacity per revolution and the number of revolutions being known, as also the pressure against which it works, which can be regulated by a pressure gauge, the foot-pounds of work are at once arrived at.

This method of measurement will correctly register the work done, although the speed may be irregular; and its results can be made more accurate than that of the friction dynamometer, because not subject to the irregularities arising from differences in lubricants, temperature, etc., which makes it necessary to use adjusting screws in most forms of friction-brake dynamometers.

1. Abstract of a paper read before the Electrical Section of the Franklin Institute.

THE COMMERCIAL MANUFACTURE OF OZONE.[1]

BY DR. O. FRÖLICH.

THE generation of ozone by electricity, as well as a large number of its interesting reactions are well known, but the introduction of ozone for commercial purposes has not yet been undertaken on account of the lack of suitable apparatus for generating it in large quantities. The best method of generating ozone electrically, as is well known, is by means of the silent discharge, and as early as 1857 W. von Siemens designed his well-known ozone tube, which is still in use in laboratories.

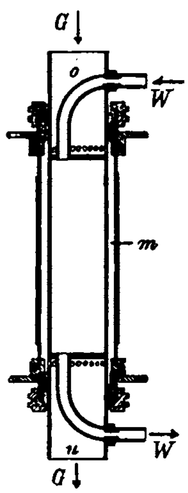

FIG. 1.

The same idea has been embodied in the apparatus recently designed at the works of Siemens & Halske, of Berlin, for commercial purposes, and its construction is shown in the accompanying engraving Fig. 1. As will be seen, it consists of an inner metal tube which is surrounded by an outer one forming the dielectric tube. The top and the bottom of the metal tube are closed, and the space between these two covers is filled with cooling water kept in circulation by tubes W W., reading from the top and bottom. Above the top and below the lower covers there are rows of holes through which the gas to be treated G is drawn from the upper space *o* into the space *m* between the dielectric cylinder wall and the inner metal tube. From there it passes to the lower end *u*, and out. The dielectric cylinder is made of hard rubber or celluloid, and leather rings serve to connect the parts.

Fig. 2 shows a set of these tubes as arranged for commercial work. The apparatus is so arranged that the cooling water passes through all the tubes, and so that a tube in case of rupture can be readily replaced.

The author has employed continuous currents, interrupted by a special rotating commutator at a rate of 600 per second. By this means far more ozone is generated than with an alternating current machine and induction coil, having only 50 to 100 reversals per second. However, when the number of ozone tubes is increased, this relationship is reversed and the alternating current exceeds in efficiency the continuous interrupted current. Further investigation seems to show that the generation of ozone is largely dependent upon the nature of the alternating current and that the steeper the curve, the more efficient it is. The generation also depends upon the mean E. M. F. in the tube; thus, up to 4,000 volts, using a glass tube, no ozone is generated. With increase of potential, other things being equal, the generation increases rapidly until finally the tube bursts, so that care must be taken not to exceed a certain limit. It was also determined that transformers with open magnetic cores as in the ordinary Ruhmkorff coil are more efficient than those with closed magnetic cores. Experiments have shown that with 2 horse-power, 2.4 milligrammes of ozone per second can be produced.

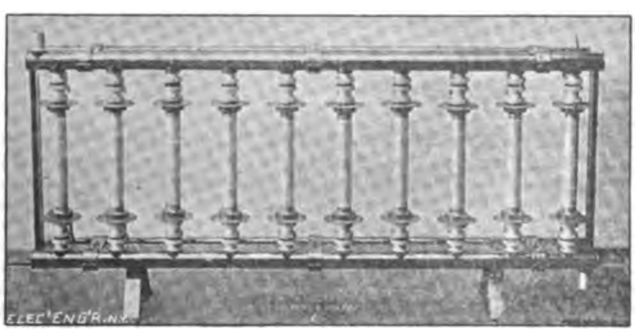

FIG. 2.

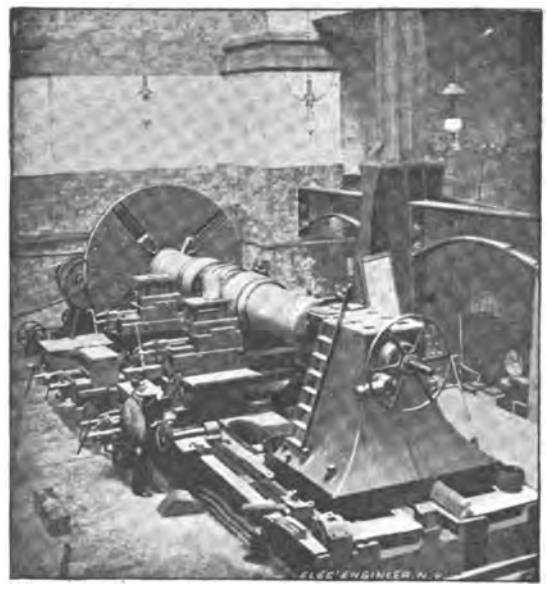
Among the many applications to which ozone lends itself, the author mentions particularly the disinfecting and sterilizing of water, there being good reason for assuming that the worst natural water can be made potable by ozonizing. He also refers to its application in bleaching processes and in the curing of wines, and, generally, for disinfecting purposes, its action on all bacteria and small insect life being very destructive.

1. Abstract of a paper read before the Elektrotechnische Verein of Berlin.

MONSTER LATHE AND SHAFT AT THE FERRANTI DEPTFORD STATION IN LONDON.

OUR readers have already been informed of the remarkable character of the electrical engineering undertaken by Mr. Ferranti at the Deptford Station in London. There are already in operation there two engines of 1,500 h. p. each, but the station is arranged for additional engines of far greater capacity, and there are now in course of construction two units with an ultimate capacity of 10,000 h. p. each. These enormous dynamos are of special construction, and the design chosen by Mr. Ferranti embodied a shaft no less than three feet in diameter. As no engine building firm would undertake the complete manufacture of such a shaft, Mr. Ferranti boldly set about to build a lathe specially for that purpose, and the accompanying engraving, made from a photograph placed at our disposal by Mr. John Van Vleck, chief engineer and electrician of the Edison Electric Illuminating Co. of New York, gives a good idea of the enormous proportions of this tool. The engines will be compound, with cylinders 44 and 88 inches in diameter and 6 feet 6 inches stroke. The moving parts of each generating unit, including the armature, will weigh 225 tons, and when finished will, without question, be by far the largest electric generating unit in existence. We may add that Mr. Ferranti, notwithstanding the criticisms which were made upon his work in the beginning, is fully satisfied that the course adopted by him was the correct one, and that the general tendency to larger and larger units bears out the truth of his early arguments.

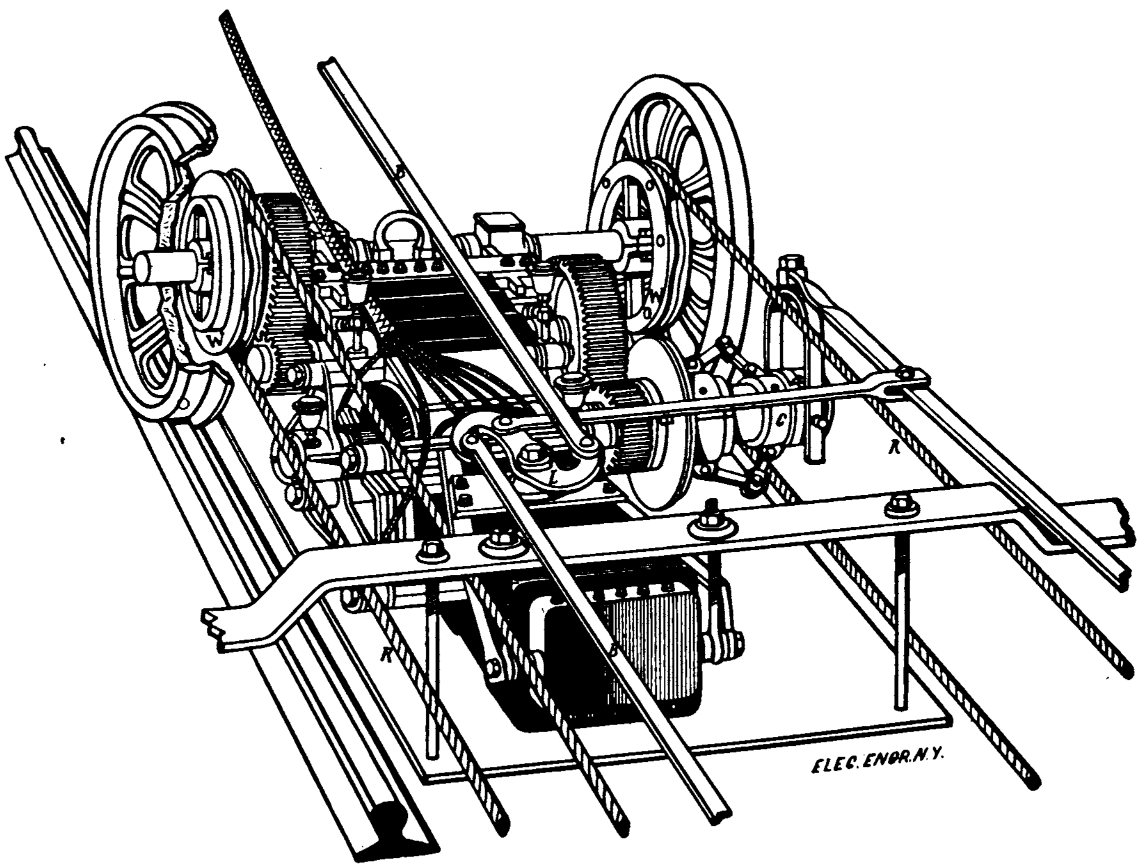


LATHE AT THE FERRANTI DEPTFORD STATION, LONDON.

THE WINKLER ELECTRIC CAR GEAR.

In a recent issue we had occasion to describe a novel type of dynamo, designed by Mr. C. F. Winkler, of Troy, N. Y., and this week we are enabled to place before our readers an ingenious method of operating electric cars invented by Mr. Winkler. Recognizing the losses due to the heavy draught of current taken by the motor when starting from dead rest, Mr. Winkler has started out with the idea of maintaining the motor on the car in continuous operation and throwing it in gear with the driving axle when starting, thus avoiding the heavy rush of current, and at the same time utilizing the momentum of the armature for starting. He has also devised an ingenious method of driving both axles from a single motor, which will be clearly understood by a glance at the accompanying engraving.

The motor which revolves continuously, is thrown in and out of gear by means of the levers B, which are connected to either platform of the car, and acting through the link L, throw in or out, the clutch C, which connects the armature shaft with the driving gear. Mounted on both axles are a pair of pulleys which are connected by means of the rope gearing R. The grooves on these pulley wheels W, however, it will be noted, instead of being straight, have a gentle sinuous curvature. The wire rope takes this curve and hence is enabled to exert a practically unlimited pull without slipping; the arrangement being somewhat after the nature of the well-known form of cable grip. In the experiments made with this car, it was shown that the car could be readily started with the momentum of the armature alone by shutting off the current and operating the clutch. The car has been in experimental operation on the Troy and Lansingburgh Electric Railway.



Truck Equipped with the Winkler Electric Car Gear.

THE GREATHEAD SYSTEM IN LONDON.

The project of building a deep tunnel railway on the Greathead system from Bayswater to the City, about an equivalent for the distance from Harlem to the Post Office in New York, seemed threatened, says the London correspondent of the New York *Times*, with a lot of opposition, but on examination this has shrunk to such proportions that a committee of the Lords has passed the bill without a single restrictive clause. The Commons committee has also passed the scheme for a Greathead tunnel under the Forth to run close to the Forth Bridge and to be utilized in connection with railway traffic over the bridge. The issue of these schemes has been watched with much interest, and their success establishes the system as the popular English solution of the rapid-transit problem.

MR. PREECE ON ELECTRIC LIGHTING AND GAS.

Mr. W. H. Preece (chief electrician to the G. P. O.) delivered recently, says our London correspondent, a very interesting and popular address before the Incorporated Association of Municipal and County Engineers, at the Institution of Civil Engineers in London. Addressing the members rather as a gas shareholder than as an enthusiastic electrician, he said the questions they had to decide were principally such questions as the following: What was the capital involved in a particular industry, what was the profit derived, and what had the consumer to pay? He was not going to put before them any fanciful figures, but figures which were published and which any one could check. In Manchester a ton of coal produced 9,611 cubic feet of 20 c. p. gas—rather in excess of the average of the country, which was not more than 15 c. p. From this it followed that in Manchester 1 lb. of coal would produce 4.29 cubic feet of gas, and if 4.29 cubic feet of gas were burnt per hour it gave an illuminating power of 17.2 candles. On the other hand, 1 lb. of coal burnt in a boiler to produce steam would give in electrical energy in the form of a glow lamp, such as was used in houses, 48 candles, and in an arc lamp, such as was used for street lighting, 288 candles. So that they started with the fact that 1 lb. of coal distilled into gas in Manchester gave a light of 17.2 c. p., and 1 lb. of coal converted into electrical energy would give 48 candles with a glow light and 288 candles with an arc light. In Manchester, during the twelve months ended March 30th, 1890, the income derived from gas was £434,851, and the expenditure was £360,804, showing that a balance of just a little over £73,000 was derived from gas, which was devoted to paying interest on loans, depreciation and cost of public lighting. The cost to the corporation of Manchester now of producing light equal to 4,000 candles by gas was 2s., and having obtained a provisional order to enable them to erect a central electrical-generating station, the corporation were now considering whether they should carry it out themselves or transfer it to another body. As to the cost of electricity, there was now more reliable and truthful information than there were, perhaps, as to anything else connected with electricity, and from figures in the possession of the Board of Trade, who had such a powerful control over the electric lighting interest that there could be no "shuffling" with their accounts, there was not a shadow of doubt that at the present moment the "Kilo-Watt," which was the Board of Trade unit of electrical energy, could be produced for 4d., which meant that as against 4,000 candles of light produced by gas for 2s., 4,000 candles could be produced by electricity in the form of the arc light for 8d. and in the form of the glow lamp for 4s. Having shown that what was nominally 15 candle gas was reduced to 10 by reason of dirt in the burner, draughts and the flickering of the light prevented the combustion of the gas, and that gas was wasted by being left flaring unnecessarily, Mr. Preece proceeded to argue that there would be no such waste with electricity. Taking the figures of the nine chief towns of England, he showed that the average price paid by the consumer for gas per light per annum was 9s. as against 10s. for electric light, calculated on the 200,000 lamps at present in use in London. Those were rather startling figures, as most people were under the impression that the cost of electric lighting was very much more than that of gas, and he was very much surprised to find that in his own house, where for the last eight years he had had an engine and accumulators and generated his own electricity, the price he paid for his lights amounted to less than 10s. per lamp per annum. He had had tabulated the revenue derived by each of the London electric lighting companies per 33 wall lamps by which it appeared that the Metropolitan derived a revenue of 12s. per lamp; the Chelsea, 8s. 6d.; the Kensington and Knightsbridge, 9s. 2d.; the House to House, 11s. 6d.; the St. James' and Pall Mall, 9s. 6d., and a company in Brighton derived an average revenue of 8s. 6d.—the mean revenue for 200,000 lamps in London being 10s. In Manchester, where gas was cheaper than in London, the average price paid per lamp per annum was 7s. 6d. as against 8s. 4d. for the electric light. In London the Electrical Supplies were charging 7½d. in some instances and 8d. in others. In Bradford they commenced by charging 5d., but they had now raised the price to 6d. In Newcastle-upon-Tyne they were charging the public 4½d. and allowing considerable discounts on that 4½d. to large users of electricity. In the case of the post office at Newcastle, for instance, there had been a discount of 20 per cent., so that in that town the cost of electric lighting very nearly approached the price of gas. In Bolton, at Messrs. Horrocks' mill, which had for the last six years been lighted by electricity, the cost worked out at 4s. ½d. per lamp as against 5s. 6¾d. when they used gas. In Manchester, again, there was under the Exchange a very large restaurant which used to be unbearable when lighted by gas, but with the electric light now the manager found that he was not only saving £800 a year in the cost of illumination, but that his business had doubled by reason of the atmosphere being cleared so that people were able to eat their meals in comfort. When the association visited the Royal Naval Exhibition they would see that the electrical energy used for the whole exhibition was generated by one engine and one dynamo coupled together. At Deptford they would find space for electrical machinery sufficient to light a million lamps, although at the present moment only about 200,000 were kept going. One of the greatest merits of electric machinery over gas machinery was the small space that was occupied by the former. Whilst a space of 100 ft. by 50 ft. was required for the machinery necessary to manufacture a million cubic feet of gas, the same space would contain electrical machinery sufficient to light up the whole of a big town. The adoption of the electric light in houses would remove a source of deterioration to goods and chattels, to one's books and pictures, and it would do away with that which destroyed decorations and dirtied ceilings and would introduce something which encouraged cleanliness, and which would add materially to one's comfort and cheerfulness. Nothing would add so much to the cheerfulness of this life as the electric light, and he felt quite satisfied himself that if he had not had the electric light in his house for the last eight years he would not have been addressing the association at that moment. The chief controller of the post office told him that on Christmas Eve the electric light had enabled them to get through the work quicker than they had ever done before, and that it was equal to 200 men. In the savings bank department of the post office the cost of the electric light had been paid for by the increased service that was got out of the staff there. It had diminished the number of hours of absence by two hours per head per annum; and that put at 10d. per hour, the ordinary overtime rate in the Government service, amounted to a saving of £680 a year, and as the cost of the electric light was £700, it really amounted to £20 a year out. It was argued by many in England that electric light was only for the rich. He wanted them as engineers to persuade the corporations they represented to look to the introduction of the electric light so that it might become the light of the poor.

New Type-Setting Machine Operated by Electricity.—Mr. C. L. Redfield, of Chicago, has invented a new form of type-setting machine, which is claimed to have remarkable features of practicability and simplicity. The power for making an impression with the type is furnished by an electric motor. The impression is made by the type on card-board, especially prepared for this purpose, which costs a trifle more than ordinary paper. The impression on the card-board leaves a matrix ready for pouring in the electrotype composition to form the plate. The machine on actual test was shown to do work equivalent to ten ordinary compositors. The company controlling the invention is the Chicago Matrix Machine Co., E. B. Springer, president; P. H. Gunckel, vice-president; William Tuckington, secretary and treasurer.

Literature.

Histoire d'un Inventeur. A Record of the Discoveries and Work of G. Trouvé in the Domain of Electricity. By Georges Barral. Paris, 1891. *Georges Carré*. 610 pp., 6½ x 10 inches.

There is probably no name better known among electrical workers, and amateurs especially, than that of Gustave Trouvé, and if we take into consideration the enormous number of ingenious devices and inventions due to this electro-mechanician, his celebrity is not to be wondered at. There is hardly a branch of applied electricity which Mr. Trouvé has not taken up and in which he has not done some good work. The history of such a man, as well as the complete record of his work, cannot fail not only to interest the reader, but to go far towards instructing him in various methods of applying the better-known phenomena of electricity.

Mr. Trouvé was born at La Haye-Descartes in the Arrondissement of Losches in the department of Indre-et-Loire on the 1st of January, 1839. From his early youth he showed great aptitude for mechanical work and delighted his playmates by his skill in making toys. One of his very first machines was a small steam engine driving a trip-hammer, which he built when he was only seven years of age, and which was constructed entirely of wood, lead, and tin. These were followed by other inventions of a mechanical nature, but very soon Mr. Trouvé was fascinated by the possibilities of electricity and from that time on devoted most of his attention to work in that department. It would take us too far to mention even the principal and most important apparatus devised by Mr. Trouvé and admirably described and illustrated in the work before us, but, as we have said before, there is hardly a branch of electrical work which Mr. Trouvé has not gone into and which has not been enriched by the product of his brain and hand.

The practical electrician, no less than the electrical amateur, will find this work not only instructive, but highly entertaining. It is profusely illustrated and contains an admirable index, not only of the contents of the book, but of the original publications in which all of Mr. Trouvé's inventions have appeared.

Appointments, Etc.

Mr. E. D. A. Brady, of New York City, who has been an agent of the Gamewell Fire-Alarm Tel. Co., has been appointed electrical engineer of the Frackville & Gilberton Electric Light, Heat and Power Co., of Frackville, Pa., which is going to install an extensive plant.

Mr. N. S. Possons, formerly superintendent of the Brush Electric Co., has become the general sales agent of the Eureka Tempered Copper Co. from July 1st. His large experience in electrical and mechanical matters will make him a very valuable acquisition.

Mr. E. W. Dutton, who has had charge of the Thomson-Houston electric light plant at Atlanta, Ga., has become master mechanic of the Atlanta consolidated electric railway lines, with charge of repairs, new construction and all mechanical work.

Mr. John Protzman, electrician of the electric light company at Streator, Ill., has gone to Bessemer, Ala., to take charge of a large plant started there by Mr. E. J. Stiles, of the former city.

Mr. W. G. Meloon, who has installed a great many Thomson-Houston plants, has accepted a position with the Thomson-Houston Co. at Cincinnati.

Mr. O. E. Rundahl, late of the Hutchinson, Kansas, Water, Light & Power Co., has taken charge of the electric light plant at Cañon City, Col.

Mr. M. W. Thayer has resigned from the charge of the electric light plant at Winchendon, Mass., and has been succeeded by Mr. Skerry.

Mr. Frank T. Robinson has been chosen general manager and treasurer of the Johnson Electric Train Signal Co., of Woburn, Mass.

Mr. A. J. Martin has been appointed the manager of the West End Electric Co., of Philadelphia, which has lately put in a large plant.

IT "FAR EXCELS."

A correspondent at Carthage, Mo., writes us:—"I received a sample copy of The Electrical Engineer last December from our local news agent. I had been taking several other publications but quit them, and now have The Engineer from Jan. 1 up to this week's number. I think it far excels all the rest in illustrations and in the descriptions, which are the life of any scientific paper."

Society and Club Notes.

NATIONAL ELECTRIC LIGHT ASSOCIATION.

The Citizens' Committee of Montreal are pushing forward the completion of their plans for the entertainment of the National Electric Light Association with the vigor for which the good people of that city are so noted. The corporation of the city has just voted the appropriation of a large sum of money, to be placed at the disposal of the Citizens' Committee.

The use of quite a number of yachts has been tendered by private gentlemen of Montreal especially for the pleasure of the ladies attending.

President C. R. Huntley, of the Association, informs us that a new feature will be introduced this year, as suggested by the Executive Committee, which will add to the interest and the diffusion of practical information on the details of work in connection with the operating of central station and other plants. A "Question Box" will be placed at headquarters in Montreal for the reception of written questions upon any pertinent subject. This box will be opened prior to each session, the questions read in open convention, and answers requested from those who are willing to speak upon the subject. This plan will, no doubt, be very favorably received, and will give excellent practical results.

College Notes.

THE OHIO STATE UNIVERSITY.

An advertisement in another column calls attention to this excellent institution. The State has adopted a policy of just liberality toward it, and it is advancing rapidly to a place among universities of the first rank. The range of instruction includes courses in arts, philosophy, modern languages, science, and agriculture; in civil, mechnical, electrical and mining engineering; and in veterinary medicine and pharmacy. Two new buildings are to be erected the coming year. Three new departments have just been created, and two more professors in agriculture and botany are soon to be added, making the total number of teachers forty-five. It seems certain that Ohio is at last to have a university of ample resources and facilities.

It will be well for all interested in securing a good training for students in electrical engineering to send for the large and instructive catalogue issued free by this popular school, located at Columbus, Ohio.

JOHNS HOPKINS UNIVERSITY.

MR. HERMANN S. HERING, who has for the past five years been professor of electrical and mechanical engineering at the Manual Training School of Philadelphia, has just been appointed to the position of associate in electrical engineering at Johns Hopkins University, in Baltimore, where he will begin his duties in October, associated with Dr. Louis Duncan. In his former position Mr. Hering originated the course in the Manual School, and made it a very creditable one, especially so considering the extremely limited resources of the school in apparatus and laboratory room.

PRATT INSTITUTE, BROOKLYN, N. Y.

A few months ago we published an article by Mr. A. C. Boughton on the electrical work doing at the Pratt Institute. The catalogue just received shows that the electrical course is being maintained and developed on excellent lines. The course is in charge of the Department of Mechanic Arts, of which Prof. C. R. Richard, is director, while Mr. F. W. Dunbar, B. S., is the instructor in electrical construction.

UNIVERSITY OF PENNSYLVANIA.

The university has announced its decision to increase the time given to mechanical and electrical engineering by providing additional courses on these subjects, extending over four years. Examinations for admission will be held September 21. Full information can be obtained from the dean of the college department or from the professor of mechanical engineering at the university.

UNIVERSITY OF MINNESOTA.

Mr. George B. Shepardson, late instructor in the electrical laboratory at Cornell, has resigned his position to take charge of the new department of electrical engineering at the University of Minnesota.

Reports of Companies.

SUCCESSFUL REORGANIZATION OF THE WESTINGHOUSE CO.

At a meeting of the stockholders of the Westinghouse Electric Company on July 15, it was unanimously decided to accept the plan of reorganization recently proposed.

The following new board of directors was elected: Charles Francis Adams, Boston; Lemuel Bannister, Pittsburgh; August Belmont, New York; A. M. Byers, Pittsburgh; Charles Fairchild, New York; Marcellus Hartley, New York; George W. Hebard, New York; Henry B. Hyde, New York; Brayton Ives, New York; George Westinghouse, Jr., Pittsburgh.

By the plan of reorganization adopted $4,000,000 of 7 per cent. cumulative preferred stock is created, of which $3,000,000 has been taken at par by the reorganization syndicate to care for the company's floating debt and provide additional capital.

The assenting stockholders give up 40 per cent. of their stock, aggregating over $2,500,000, par value, for the use of the company, and are given upon the 60 per cent. of stock which they retain a 7 per cent. preference over the very small amount of non-assenting stock remaining out. The company is doing a large, progressive and profitable business, and bids fair to become a more formidable competitor than ever in the electrical field.

UNITED ELECTRIC SECURITIES CO.

The United Electric Securities Company, of Boston, invite proposals for sale to the company of $50,000 first series collateral trust sinking fund 5 per cent. bonds. This call is in addition to previously issued call for $30,000 first series and $20,000 second series bonds.

DIVIDENDS.

THE SOUTHERN NEW ENGLAND TELEPHONE CO. have declared a dividend of 1 per cent. payable to stockholders of July 16. The capital is $1,500,000. This is the first dividend in over two years, but the company hope to pay 1 per cent. quarterly from this time out.

MIDDLETOWN, CONN. The Middletown Electric Light Co. has declared a semi-annual dividend of 2 per cent. in spite of the damage done by the ice storm, amounting to $1,000. The old officers have been re-elected.

Financial Market.

QUOTATIONS ON ELECTRICAL STOCKS.

F. Z. Maguire & Co., Electrical Securities, of 18 Wall street, this city, report the following quotations of July 18, 1891, from New York, Boston and Washington:

Legal Notes.

EDISON INCANDESCENT LAMP LITIGATION.—VI.

ARGUMENT OF GROSVENOR P. LOWREY, ESQ., (CONCLUDED).

Mr. Lowrey said he would pass the parliamentary investigation, only reading what had been said by Tyndall and by Sir William Thomson. Professor Tyndall must have been supposed to have known all that anybody knew of the King lamp, but nevertheless he did not think incandescence was worth while in respect to lighting in small centres—he did not think there was much in it. Mr. Conrad Cooke, editor of *Engineering*, in speaking of Edison, had said, "His nephew told me himself that he has seen over 200 lights in one circuit. I must say that I should like to see it myself." Then Sir William Thomson; that great authority, that really wise man, the sort of man who probably did not understand Ohm's law; who, if you had asked him, would probably have said he once thought he did, but was finding out so much every day he was not sure now, had said: "It is quite possible that a plan of using electrical energy for light may yet be found, in which ten feebler lights will give a sum equal to that obtainable by the same energy in one concentrated light." That had not been found. Edison did not find, nor did any one ever find, that one could divide that lamp of 1,000 candles into ten and retain the total of 1,000. What Edison had done was to find that it could be divided and get ten lights of ten candles each, in ten places where they were wanted, and find a money-making business in supplying them. It had not occurred to Sir William Thomson that there were several ways of getting around a stump; that way had to be found out from this practical fellow at Menlo Park, who was so ignorant. He (Mr. Lowrey,) had often thought what an awful thing it would have been for the world, if Thomas A. Edison had the misfortune to be educated at Stevens Institute. Then he would have known, as they all knew, the mathematics, and then he would have known too, what things could not be done. There was reason to be grateful that it was not everybody to whom the fortune of a liberal education came, because in this business of investigating nature, a liberal education often enslaved the mind. There was Professor Elihu Thomson; he understood him to be of the opinion that it had been a mere matter of electrical engineering to make this lamp; all the required laws were known and the rest was mere ciphering. Now Prof. Thomson was an expert cipherer; he was a professor in Pennsylvania; an inventor; a man of excellent ability, he had been engaged in the search after a small light before Edison began, but it had never once occurred to him to sum up all these outstanding unused laws, which he knew so much about, and evolve the light before us.

All this time they had had Mr. Edison underground looking for this thing; he had sent up from time to time various little things he had hit upon, by way of indicating what progress he was making. Various discoveries had been made, patents had been sent to the upper ground, and in all of them high resistance had been insisted on. Mr. Edison in his testimony had said:

What we desired at that date [November or December 1878] and had concluded as the only possible subdivision of the electric light was, that the lamps have a high resistance and small radiating surface, so as to be capable of being worked in multiple arc commercially; and our calculations showed us that the lamps must have at least 100 ohms resistance to compete successfully with gas; otherwise if the lamps were of low resistance the cost of main conductors would be so great as to render the system uncommercial.

Mr. Lowrey said that the latter part of this quotation seemed to be a great comfort to his friends on the other side. There might be something else requiring his attention, but he believed the 100 ohms was now their sheet anchor. Mr. Edison had frequently used the term "calculation." Evidently General Duncan supposed that he had meant that the mathematicians had made calculations and now he was going to fix Edison with the responsibility. But Edison saw what it meant and he said: "I don't mean that I made figures; I don't mean that I made calculations"—and with a sudden burst of scorn—"I find the mathematicians are always wrong." Mr. Edison had there given expression to what he (Mr. Lowrey) believed to be perfectly true statement, as to the intuitive way of genius in ascertaining these things. In dealing with a subject like this, when Edison saw the elements which composed it, the mathematical results were instantly before him, not in figures nor on paper, but he realized the whole thing, and he sent the mathematicians back to figure things over again to prove his intuitions. It was then that Edison had come to Ohm's law. He had been called down from his laboratory,—where he had been no doubt at work on things interesting to himself—and had been asked questions until he thought he had answered all that could be fairly asked, and then came this notable answer about Ohm's law.

Mr. Edison had first taken up platinum for the reason that carbon under the old conditions was not good; his first utterance on the subject had been a lament that carbon would not serve, because of its known tendency to unite with oxygen in a state of incandescence; so he had turned his attention to platinum, and he (Mr. Lowrey) could conceive that he had done it with a longing eye cast back all the time towards carbon. Mr. Batchelor had said that he would say: "Oh, Batch! if carbon could only be made stable!"—stable under the stress of high incandescence, and when used in quantity necessary to give high resistance and small radiating surface; so he had taken up platinum. His Honor would perceive the trouble which the inventor had been put to to overcome the evil tendencies of platinum. He had been compelled to provide an air chamber and a thermo-regulator to prevent overheating by automatically shutting off the current.

When Mr. Edison had returned with his lamp in his hand from his investigation of the foundations of this recondite subject, he had been met with various kinds of greetings, which were valuable, as showing what science had then thought about what he had professed to have discovered. Without stopping to read these, Mr. Lowrey said, he would call his Honor's attention to a published interview from which his Honor would find that Prof. Morton thought very little of the little carbon. He says that what Edison had to do was to find out whether it would last; that was exactly what Edison had been finding out. He had found disintegration to be the result of high incandescence, until it had been protected in that high vacuum which nobody before had tried. Mr. Sawyer too, after the publication of Edison's discovery, had offered to bet large sums of money that the little carbon would not last twenty minutes in a proper vacuum.

Turning to another branch of the case, Mr. Lowrey said that there were remaining certain very pertinent questions relating to the construction of the patent, as well as certain questions of law affecting the state of the art and its influence, under the special facts of the case, upon the rights of this inventor. The defendants appeared to be making three defences to the first two claims of the patent; *first*, that both claims were void, because it was no invention to substitute superior for inferior materials in making one or more, or all of the parts of a thing; *second*, that those claims were further void for want of invention, because it was not invention to change the degree of a thing, or one feature of a thing; *third*, that in the light of the state of the art and of the descriptive part of the specification, the claims must be so construed as that the defendants did not infringe.

In searching for the nearest approaches in the prior art two fields must be explored; the prior plans for illumination by carbon burners and those by platinum burners. The defendants had contended that the Adams lamp was to be found in the first field, and if so, it constituted the nearest approach to the invention of the patent. For the purposes of the argument they might consider that it was an abandoned invention, and not merely an abandoned experiment. In the second field of the prior art defendant had contended that Edison's platinum lamp was to be found; if so, it undoubtedly constituted the nearest approach from that side, to the invention of the patent. The complainant contended that this was not a part of the prior art, but for the purpose of the argument they might assume for the present that it was. Mr. Wetmore had argued that it was a part of the prior art; *first*, because the American patent, though not granted until after the patent in suit, ranked in point of priority as of the date of its prior application, April 21, 1879, and *second*, because the French patent of June, 1879, though granted to Edison himself, as truly constitutes a part of the state of the art as if it had been granted to a stranger. The complainants denied both these propositions of law. Mr. Lowrey then cited authorities in support of the proposition that it was well established, where a patent is sought to be used as a club to defeat another patent, that it dates as to the date of its issue and not of its application. As to the second ground, they would admit that if the French patent had been granted to a stranger, it would have been part of the prior state of the art. Mr. Wetmore had sought to draw a distinction between the invoking of the prior French patent to negative the novelty of the patent in suit, and of invoking it as a part of the state of the art to limit the scope of the patent in suit, but he had ignored the distinction between invoking a prior foreign patent to the same inventor, and one granted to a stranger as a part of the state of the art, limiting a later American patent to the same inventor. He (Mr. Lowrey) believed that no precedent on that point had been established. His Honor must therefore determine whether the first half of section 4887 R. S. operated to protect an American patentee against having his prior foreign patent turned against him in court. Defendants had sought to treat the French patent as a part of the state of the art, by claiming that it was not like the patent in suit; then having on that ground obtained its admission into the state of the art, they had shifted their contention, and urged that it was substantially like the patent in suit. These clearly inconsistent positions could hardly be approved by the court. Complainants therefore contended that the platinum patent should be excluded from the state of the art while construing the patent on the carbon lamp. Now for the sake of the argument, he would assume the contrary, and regard the platinum patents as the nearest approach to the invention of the patent from the platinum side.

His Honor inquired whether there was any material difference in the description between the American and the French patent on the platinum lamp.

Mr. Wetmore said the French patent was a little fuller.

Mr. Lowrey remarked that the American platinum patent, being of later date, was by express decisions out of the state of the art.

His Honor observed that he had not supposed the American patent had any bearing on the state of the art, but had held different views as to the French patent.

Mr. Wetmore called his Honor's attention to a case in the Patent Office; the only one he had been able to find. In *Ex-parte Holt*, it had been distinctly held that when an application had been filed which would support a broad claim, and the applicant had made a narrow claim, he could not, unless he put in a saving clause, or else filed the application simultaneously with it, get a second patent for the broad claim.

General Duncan said that the relation between the two patents seemed to be very much like that found by the Supreme Court in *Hayden* vs. *Suffolk Company*, in which it had been held that the first patent was limited in view of the broad claim obtained in the second patent; a fact, as it seemed to him, of very great importance as bearing on the question of construction in the present case.

Mr. Lowrey, resuming his argument, said, *first*, the rule that it is not invention to substitute superior for inferior materials, in making one or more, or all of the parts of a thing, was a general rule, subject to certain exceptions which were as well established as the rule itself. The courts had applied that rule only in cases in which the adaptability of the substituted material had depended upon well-known characteristics and qualities. The exceptions had been so numerous that they have even led Justice Bradley to say that there was no rule of law, that the substitution of one material for another was not patentable. Mr. Lowrey then cited a number of cases in support of his contention that the substitution of carbon for platinum had involved a new mode of construction, and had developed new uses and properties in the lamps. He could see no escape from the conclusion that the substitution by Edison of carbon for the incandescent platinum material of the earlier patent, did abundantly constitute invention. To banish a substitution, at once so surprising and so successful, from the domain of invention, would be to go counter to all decisions ever rendered by the Supreme or Circuit courts on the subject, and counter to the whole purpose and spirit of the patent laws.

His Honor observed that it was, of course, well-known in the state of the art at the time, that carbon had these peculiar qualities of resistance and infusibility.

Mr. Lowrey replied that nevertheless it had not been known that it had the quality of resisting disintegration when properly protected, and that the proper protection had been discovered.

His Honor replied that the difficulty in these cases lay in the application of recognized and familiar principles of law to the peculiar facts of the case.

Mr. Lowrey, resuming, said that the invention resided in the combined use in the new carbon burner of the three facts in question; two of those facts had been known prior to Edison's day, as isolated facts, but the third one had been discovered by him. The patentability of the substitution of carbon for platinum did not reside alone in the newly-discovered fact, but in its combination, in the lamp, with the two known facts of the high specific resistance and of the infusibility of carbon. It had clearly required invention to correlate the two old facts and the one new one, and to utilize those facts in electric lighting by substituting carbon for platinum in an exhausted glass globe. He would close this part of the argument with Mr. Edison's own accurate and comprehensive statement of the whole matter:

> The discovery I made was, that a fine filament of carbon, under the conditions I had, did not disintegrate to any extent. That was the discovery as set forth in my patent; but the patent has also, in addition to discovery, some invention as well as discovery; in other words, it required invention to carry out the discovery which I made.

Mr. Edison might be ignorant of physical science but he was certainly a good lawyer, and could not have stated his case better.

His Honor remarked that Mr. Edison had compressed the whole argument in a very brief way.

In the "feeder" case—continued Mr. Lowrey—Sir William Thomson had been asked: "Suppose there had been a lamp at a certain time known to you, how would you have advised a person to place the conductors?" He said: "I cannot assume this knowledge without other knowledge that became public between 1878 and 1881. I cannot assume a reversal of the history of science; a displacement of the order of discovery, and the formation of ideas founded on discoveries in science;" and so he would have said that the discovery of the disintegration of carbon, under certain condilions, had been deferred by Providence until it could be made in its due order, as one of a succession of steps.

His Honor here remarked that he had not been impressed with the convicton that there was no invention in what Mr. Edison had done. The question was rather as to how much he had done, and what was the extent of his invention, for the purpose of determining what interpretation was to be put upon his patent.

Mr. Lowrey said he would speak next of the utility of the filament. He did not know whether he had sufficient time to fill the long-felt want of his brother Duncan; a definition of "filament" that would suit him. Justice Butt had not seemed to find much trouble; be had found the filment in the thing done, not so much referring to what had not been done. He had said a "thread" was a thread and a "rod" was a rod; and it had been found that rods and threads, under the engineer's calipers, had classified themselves into widely separated grades. The chasm which had been leaped under the impulse of Mr. Edison's discovery had been from 16 to 69; a leap from the shore of failure to to the shore of success.

Two controlling and essential conditions had been constantly insisted upon in the patent. It plainly taught that the greater the resistence and the less the radiating surface in any individual conductor, the better. Mr. Edison had brought over from his platinum experience, the notion of the difficulty of overcoming the fluctuation of the current by putting a great length of conductor into the lamp, and then masking it by coiling it away.

The first results of experience had taught him that that was not necessary, but not before he had given evidence of its influence, in giving color and form to his ideas, by making the drawing of the patent.

Gen. Duncan inquired whether Edison could have got that resistance by any process of carbonization known to the art at that time.

Mr. Lowrey replied that there was no reason to suppose that he could not have done so. Resuming, he said that his associate had reminded him that he had passed a point, to which he would for the moment return. He would cite several cases establishing the general rule that it was not invention to change the degree of a thing, or one feature of a thing, but those had all been changes of degree, having some utility for the particular purpose in view, but in each case it had been obvious before the change had been made, that the result desired could have been obtained by the change in degree. So far as Edison could be said to have merely reduced the cross-section and increased the length of such a carbon as that of King or Adams, he was yet far outside the rule, because those changes had operated cumulatively to enormously increase the resistance of the carbon, and had, moreover, resulted in a revolutionary change in the mode of operation, not only of the lamp, but of the entire system.

His Honor inquired whether there was proof in the record of any use of filaments made merely of the carbonized thread described in the patent.

Mr. Lowrey replied that none had been made except for purposes of experiment.

Mr. Curtis observed that Mr. Batchelor had said that he knew of no tar-putty lamps except some made for experiments in Paris.

Mr. Dyer pointed out that Professor Barker had said that one manufacturer used silk thread. He believed that it was admitted that the defendants had used silk thread.

Mr. Curtis said that the thread had been subjected to a peculiar process patented since.

His Honor remarked that he was anxious to know whether there was anything in the record showing the use of a filamentary thread made under any one of the modes described in the specification.

Mr. Lowrey replied that such had been made, but not for commerce.

Mr. Dyer said that it appeared that paper, a material referred to in the patent, had been used early by Mr. Edison. He called his Honor's attention to the fact that two of the defendant's lamps in evidence had carbons of paper.

Mr. Curtis added that the evidence also showed that the paper had been subjected to special mode of treatment—the Maxim hydrocarbon treatment—invented after the issue of this patent.

Mr. Lowrey in reply contended that this had been done, not to make a filament more a filament, but to protect the stability of the thing and produce uniformity of resistance. Both Dr. Morton and Mr. Shallenberger, had said that it was a misfortune that they had to do it. Mr. Lowrey said the complainants had used paper without treatment.

Gen. Duncan replied that the complainants had treated it electrically and had carbonized it on the pump. The patent had nothing to say about it, but as a matter of fact if they did not do it, they could not make the burner. Mr. Edison had said in his Canadian affidavit, that none of this material could be used without hydrocarbon treatment, except by processes which he himself knew, and could alone practice, but could not communicate to others, even to Batchelor, by any statement in words.

Mr. Lowrey remarked that the chief value of the Maxim treatment was to so far spoil the lamps that they might perhaps cease to be an infringement.

Resuming his argument, Mr. Lowrey said that the only essential thing was high resistance and small radiating surface. There was nothing essential about coiling; that was only a subterfuge to cheat nature out of some of the efforts she was making to keep the inventor back. The table of dimensions which had been put in showed that defendants' three lamps partook of the extreme characteristics of Edison's filamentary lamp, and not at all of the characteristics of the old lamps. While it was true that the knowledge of the particular laws of nature which had been utilized by Edison in making that change in the incandescent carbon, could be traced backward to times anterior to his work, it did not follow that in utilizing those laws by means of a compound change in degree of the prior incandescent carbons, he had exercised nothing beyond the expected skill of the electrical engineer; that skill had been expected a long time and had not arrived. Among the criteria which served to distinguish skilled electrical engineers who were *not* inventors, from those who *were* inventors, none was more striking than the fact, that merely skilled persons are invariably inclined to follow in the footsteps of their predecessors, while inventors are continually inclined to take new departures. If that criterion were applied to the case in hand, they would find that down to the latest date when anything had been published upon this subject, before the issue of the patent in suit and of the French platinum patent, the word of the most advanced who were not inside of Mr. Edison's laboratory had been: "Get your resistance down." Edison had changed both those degrees so radically as to increase the resistance of his carbon twenty-fold or more. A change of degree so extensive as this had been foreseen by Edison to involve radical and extensive changes in the mode of operation of the lamp, and in the words of Lord Justice Lindsley, "to turn failure into success." Such revolutionary plans were neither found nor executed by mere electrical engineers.

It might be said with truth, that defendants' methods of analysis and comparison of what Edison had produced with the laws of nature before known, if they had been applied to the Bell telephone or to the Morse telegraph, would have abundantly negatived the presence of invention in either of those marvelous contrivances.

His Honor here took occasion to observe that he had not been much troubled about the question of invention; his trouble had been to find out whether the invention had been patented.

Mr. Wetmore had contended—continued Mr. Lowrey—that the first claim of the patent was so limited in several of its features by the descriptive part of the specification, as to enable the defendant to escape the charge of infringement. The most noticeable of these features was the spiral form of the carbon. The complainants had contended that a carbon filament, having substantially such a resistance, and such a radiating surface, as that described in the patent, was substantially like it, whether it were coiled or otherwise arranged. In support of this legal position Mr. Lowrey read extracts from the decision of the Supreme Court in *Winans* vs. *Denmead* and in *Lake Shore R. R.* vs. *Car Brake Shoe Co.* In the present case the third claim expressly called for the coiled carbon. If the first claim were to be so construed by implication, then it must be identical with the third; a highly improbable conclusion.

Mr. Wetmore's contention that the method of cementing the filament to the leading-wires must be imported into the first claim by the words "secured to metallic wires as set forth" appeared to him to be unreasonable, because the claim undoubtedly covered a manufactured article and not a process of making such articles. There was no statement nor implication in the patent that the filaments could not be joined to the wires in any other way. The remaining limitation which Mr. Wetmore sought to import into the first claim made it call for a filament of carbon of high *specific* resistance, but even this could not enable the defendants to avert infringement, for all their lamps contained such filaments, in the only sense in which the quality of high specific resistance could be ascribed to the filament of the first claim. There was a bold and limitless audacity in counsel, in alleging that they had not got carbon of high specific resistance, because they had taken a carbon made by complainant's plan, and spoiled it by reducing it, although its resistance was still enough to give them a profit derived by the form they had learned from complainants. Mr. Wetmore had sought to limit the second claim by attaching four limitations to its first element, the carbon filament; namely, spiral form; high total resistance; high specific resistance, and the particular method of attachment described. The spirality of the carbon was a matter of form and not of substance, and therefore could not be imported into the second claim by implication any more than into the first claim. A carbon filament, moreover, was not necessarily definable in terms of total resistance. It might have a low total resistance and still be a filament within the definition of the English Courts, provided its resistance was high in proportion to its radiating surface.

A great deal had been said about 100 ohms, as if a lamp could never be made without a resistance of 100 ohms; the lamps were various, according to candle-power. If the carbon was cut short they got a less total resistance, and a less candle-power, but out of the same filament, acting by the same law. How absurd to suppose that Mr. Edison intended to disappoint and oblige these infringers, by never supplying to the public lamps with less than 100 ohms resistance! But even were the limitation of high total resitance implied in the second claim, none of defendants lamps were less than 40 ohms, and hence they could not thereby escape from the claim, for that was a high resistance relatively to 4 ohms. It was high, in the sense that it enabled users of the lamps to operate them on the plan contemplated by the patent, whereas the older low resistance carbons could not have been operated upon that plan. It was illogical to assert that a statement that a particular object came within a particular category, excluded other objects from that category, differing from it only in degree, and that to an immaterial extent, in respect of the purpose and mode of operation of the thing under discussion. Mr. Lowrey said, following the decision in *Tilghman* vs. *Proctor*, in the Supreme Court, that the defendants had not averted infringement by giving to their filament a resistance as low as 40 ohms, because that the patent was satisfied with "great resistance" as compared with the resistance of one to four ohms of the prior art. Mr. Lowrey contended further that the carbon filament of the second claim was not necessarily definable in terms of specific, any more than of total, resistance; but even if that limitation were attached by implication to the first element of the second claim, none of defendants' lamps would fall outside of that claim, for their specific resistance was not low enough to prevent their offering a great resistance in proportion to their radiating surface. Mr. Wetmore's contention that the particular method of uniting the filament to the wires must be implied in the second claim, is even more unreasonable than that it must be attached to the filament of the first claim. Whatever method of union was sufficient to enable the current to pass, satisfied the conditions of the second claim, and it would be extremely unreasonable to confine it to the particular union described. Thus it plainly appeared that even if there were any ground for importing those limitations into either of the claims, they were nevertheless abundantly broad to cover all the lamps of the defendant.

In the case at bar—continued Mr. Lowrey—the question of infringement to be decided was whether Mr. Edison should hold or should lose the fruits of his genius or his labors; or whether he should hold his due portion of the fruits of that genius and labor in the field of electric lighting. It was impossible that he should hold all those fruits, because they were so extensive and so splendid that the whole civilized world was participating, and would always participate, therein.

The final defense to which it yet remained to reply was the defendant's contention that the patent was void because the description was not in such full, clear and exact terms as to enable any person skilled in the art to make and use the carbon lamps of the patent.

This was a question of evidence, and not of construction. It could only be supported by evidence of persons skilled in the art to which the invention pertained, therefore he would merely call the attention of his Honor to the portions of complainants record wherein such evidence as the defendants had taken to support that defense had been totally swept away.

In conclusion, Mr. Lowrey said that his brother Wetmore had eloquently appealed to his Honor not to punish the twenty millions of capital which had been invested in this business. He would not reply to any such argument, but should ask his Honor to consider those greater millions that had been invested in this business, subject to all the effects of these piracies, and which were being used in the prosecution of an honorable and legitimate industry. Mr. Edison had said that he makes his calculations intuitively; he sees the inner motions and processes of nature. Those men who had money to invest had a like genius for their occupation; they saw intuitively how much it was worth while to risk in an unlawful course for a great profit. They knew what they were about and they took their chances; they did not require in that respect, the protection of any court.

Ever since he had come into the case, concluded Mr. Lowrey, he had been under the influence of a deep sentiment. The day that Benjamin F. Thurston had died, he had been in this city to confer with the counsel in this case in respect to the very duty which he (Mr. Lowrey), had now performed. When that heavy task had fallen from Mr. Thurston's relaxing hands and had been confided to his own feebler strength, it had seemed to him that looking his Honor in the face, who had been the friend of both, and the friend of their associates and adversaries, that he could never speak in his place with the idea that he had been deservedly chosen for any such function. Personal pride had seemed to forbid it; but it also seemed that he must put his name—by this reference, since it was not otherwise there—into this great record of the case which he had really loved, and which he had perfectly trusted and believed in. On that day, as Emerson had said: "Envious death robbed us all, to aggrandize one funeral." He had undertaken to perform that duty as well as he could, and he had done his best.

ANOTHER SILVER MEDAL FOR THE CLARK ELECTRIC COMPANY.

At the fourth annual exhibition of the Amateur Photographers Society of New York, held in May, 1891, the Clark Electric Company was awarded a silver medal of excellence for their arc lamp for electric optical lantern apparatus. This is the first and highest medal ever issued by the society for electric light for optical purposes in photography.

This opens up another channel of usefulness for the Clark apparatus.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED JULY 7, 1891

Alarms and Signals :—

Annunciator, M. Garl, 455,316. Filed Sept. 26, 1890.
A needle annunciator.

Electrical Watchman's Clock, H. S. Park, 455,352. Filed July 1, 1890.

Watchman's Time-Detector, A. Newman, 455,410. Filed Mar. 11, 1890.

Watchman's Time-Recorder, J. A. Lannert, 455,440. Filed Jan. 5, 1891.

Grave Annunciator, W. H. White, 455,446. Filed May 22, 1890.
For the relief of persons buried alive.

Clocks :—

Self-Winding Electric Clock, F. L. Gregory, 455,532. Filed Apr. 2, 1891.
Electro-magnetic device for winding a weight-actuated clock.

Distribution :—

Transmission of Alternating Currents of Different Phase, M. Von Dolivo-Dobrowolsky, 455,683. Filed Mar. 28, 1891.
Claim 1 follows:
The combination of a dynamo-electric machine having a plurality of coils or sets of coils in which independent alternating currents of relatively differing phases are induced, a transformer provided with as many primary coils as there are induction-coils or sets of coils in the dynamo, and with a smaller number of secondary coils, separate connections between the induction-coils of the dynamo and the primary transformer-coils, and mains connected to the secondary coils of the transformer.

Dynamos and Motors :—

Friction-Gearing for Dynamos, F. L. McGahan, 455,488. Filed Dec. 26, 1890.

Multipolar Dynamo, A. L. Riker, 455,517. Filed Feb. 7, 1891.
Relates to the construction of field-magnets which are laminated.

Carbon Brush and Holder Therefor, A. L. Riker, 455,518. Filed Mar. 25, 1891.
Holds the carbon brushes against the commutator with yielding pressure.

Pulsating-Current Reciprocating Electric-Engine System, C. J. VanDepoele, 455,520, Filed Mar. 23, 1889.
Relates to improvements upon the inventions patented Apr. 2, 1889, No. 400,809, and April 9, No. 401,231.

Electric Motor, L. G. Goode, 455,711. Filed Aug. 22, 1890.
Relates particularly to a reciprocating motor.

Electric Motor or Generator, W. F. Brown, 455,726. Filed Aug. 21, 1890.
Has two armatures upon a common shaft, an intermediate cummutator upon the shaft, the several windings of the two armatures being connected respectively to the opposite ends of the commutator segments.

Galvanic and Thermo-Electric Batteries :—

Galvanic Battery, H. C. Sample, 455,693. Filed Dec. 2, 1889.
Especially designed for small batteries of the portable kind. By a tilting motion of the battery cell the electrodes are immersed in the fluid or withdrawn.

Lamps and Appurtenances :—

Combined Fuse-Block and Incandescent Lamp, H. E. Swift, 455,366. Filed Sept. 29, 1890.

Lamp Socket and Switch and Circuit Closer Therefor, H. P. Ball, 455,55 Filed Dec. 16, 1890.

Electric Arc Lamp, J. W. T. Olan, 445,576. Filed Jan. 12, 1891.
Relates to the class of arc lamps in which the arc is operated in a vacuum or in a chamber containing a rarefied inert gas.

Measurement :—

Electric Meter, J. J. Wood, 455,524. Filed Oct. 30, 1890.
Claim 1 follows:
The combination, with an electric meter as a means for correcting the registry thereof, of a shunt around the meter and automatic means in the nature of a rheostat controlled by the current being measured for diverting through said shunt varying proportions of current from time to time as the total current varies, such rheostat being so proportioned that the current so diverted shall be graduated for each quantum of current proportionally to the normal overregistry for such quantum, whereby the registry is reduced to direct ratio to the current.

Electric Meter, J. W. T. Olan, 455,575. Filed Dec. 29, 1890.
Employs, as a measure of current, a rotator propelled by gas produced by decomposition of an electrolyte.

Medical and Surgical :—

Electric Belt, C. A. Bogardus, 455,680. Filed Feb. 24, 1891.

Metal Working.

Method of Electric Welding, E. Thomson, 455,420. Filed Feb. 19, 1891.
Employs a local cooling effect to the work in the heating portion of the circuit near the points of application of the contacts and between them and the welding points.

Securing Metal Bands on Wooden or other Articles, E. Thomson, 455,421. Filed Feb. 24, 1891.
Welds the bands, by electricity or otherwise, after they are placed in position.

Miscellaneous :—

Electrical Walking Toy, J. B. Kibler, 455,545. Filed Mar. 17, 1891.

Apparatus for the Defecation of Saccharine Juices by Electricity in the Manufacture of Sugar, E. Maigrot & J. Sabates, 455,631. Filed Apr. 15, 1889.

Switch-Board for Electric-Fence Stations, D. H. Wilson, 455,696. Filed Aug. 25, 1890.
For use in connection with wire fences in which an electric current is employed for the detention of fugacious cattle.

Railways and Appliances :—

Electric Locomotive, N. C. Bassett, 455,298. Filed Oct. 30, 1890.
Relates particularly to the class of motor cars designed to draw passenger cars. Motor is mounted directly upon the truck axles with its weights supported upon springs; variable friction gearing is provided for varying the speed of the locomotive.

Trolley-Pole Stand, J. R. Griffiths, 455,322. Filed Jan. 20, 1891.
Permits a sweep of the trolley pole to a horizontal, front or rear, and a sufficient side movement.

Conductor for Electric Railways, W. H. Knight, 455,339. Filed May, 11, 1885.
Employs a slotted conduit flush with the street and having its inner surface adapted to shed water away from the slot; the conductors have a bare contact surface parallel with the slot.

Electric Railway, W. H. Knight, 455,340. Filed May 11, 1885.
Relates to a conduit system; provides, through a swiveling connection, for the free lateral movement of the contact device, so that it may accommodate itself to irregularities in its path.

Electric Railway, W. H. Knight, 455,341. Filed Apr. 29, 1887.
Supports the conductors as far as possible above the bottom of the conduit.

Electric Railway, W. H. Knight, 455,342. Filed Oct. 16, 1888.
Provides a transverse movement of the plow or contact device, in a conduit system, whereby it may pass entirely across from one side of the car to the other.

Electric Railway Plow, W. H. Knight, 455,343. Filed Mar. 5, 1889.
Relates to the method of supporting the contact device.

Conduit for Electric Railways, W. Bradley, 455,447. Filed Nov. 24, 1890.
A construction adapted to prevent the entrance of water or dirt.

Electric Railway, E. W. Rice, Jr., 455,454. Filed Mar. 30, 1891.
Employs two or more supply conductors along a road each carrying a different voltage, and devices by which the circuit of the motor may be completed through either of the different supply conductors.

Train-Signaling Apparatus, L. F. Jordan, 455,510. Filed Nov. 16, 1889.
For establishing communication between the engineer and the conductor.

Electric-Motor Car-Truck, J. F. Seiberling, 455,581. Filed Mar. 9, 1891,
A method of sidgle reduction gear.

Power-Gearing for Vehicles, E. A Sperry, Reissue 11,177. Filed May 18, 1891.
Original No. 434,098, Aug. 12, 1890.

Telegraphs :—

Telegraph Key, R. W. Green, 455,320. Filed Feb. 10. 1890.
A self-closing key.

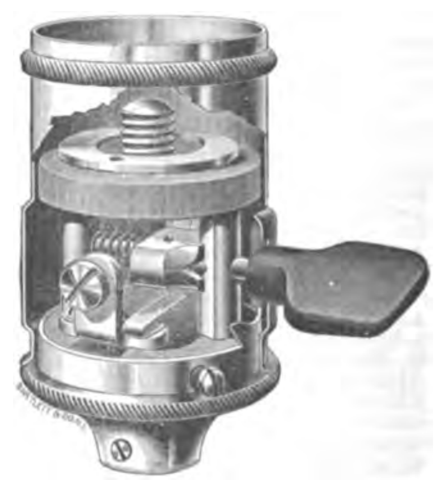
Quadruplex Telegraphy, C. D. Haskins, 455,398. Filed Nov. 19, 1887.
Relates to means for avoiding false signals upon the neutral relay by reversals of current.

Telephones and Apparatus :—

Support for Telephones, W. J. Myers, 455,722. Filed Jnne 3, 1890.

UNION ELECTRIC MFG. CO'S. NEW SOCKET AND ROSETTE.

The Union Electric Manufacturing Company, of Bridgeport, Conn., have recently brought out a new and improved socket, which is meeting with general approval, on account of its



A New Socket.

mechanical and electrical excellence. Our illustration shows the general design so well that description is unnecessary. There are very few parts to it, the chief novelty being in the method of holding the key in position by peculiarly shaped projections on the key, pressed up against one of the frame posts by a spring. In the most recent form the contact ring on the top is done away with and two screws are substituted, one going into each of the frame posts. The whole socket can then be easily taken apart for repairs when necessary.

A new rosette which the same company is manufacturing is having a large sale. The silk cord is fastened into the lower half in the usual manner, and the projecting lugs are inserted under the small brass pieces in the base, and fastened by screws, forming an excellent contact.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

An advertiser is always the first to get out of a trade calm, because his sails are set ready for the favoring breeze.—Confucius.

THE ELECTRIC GAS-LIGHTING CO.'S IMPROVED PENDANT BURNER.

WE illustrate in the two accompanying engravings a new pendant electric gas-lighting burner, which possesses a nnmber of improvements over any other form. It has been called the double contact and pass-by ratchet burner. Fig. 1 shows the burner

FIGS. 1 AND 2.

ready for lighting, which is done in the ordinary way, but with this advantage, that the lower end of the German-silver electrode comes in contact with a little projection on the disc, which makes a positive connection to the ground, and thereby prevents all possible trouble with an imperfect ground caused by an accumulation of grease on the gas-cock. This projection also serves to prevent the German-silver electrode from passing through the flame on the back stroke, as shown in Fig. 2, so that there is no danger of the electrode being held in the flame either purposely or accidentally, whereby it would lose its temper and conductivity. The burner is manufactured exclusively by the Electric Gas-Lighting Company, of Boston.

BERLIN IRON BRIDGE CO.

The new works of The Berlin Iron Bridge Company, of East Berlin, Conn., are now completed; the company have all the machinery placed and are now running full time, employing in all departments 400 men. The building is made entirely of iron, no woodwork being used about the construction except for the window sashes. The roof trusses are all provided with trolley cars with which to move material back and forth about the building, and three lines of narrow-gauge tracks extend the entire length of the building—these three tracks being connected at each end of the building by a transfer table. There is a skylight on each side of the roof, extending the whole length of the building, and for a distance of ten feet down from the eaves of the building on all sides it is made entirely of glass, so that the interior of the building is thoroughly lighted. The company have purchased a large amount of new machinery, and are now prepared to furnish all kinds of structural ironwork, including iron buildings and iron roofs for electric plants, on very short notice. Their large experience in this class of work and their improved facilities insure first-class work at a reasonable price.

MR. LEE L. MURRAY, of Melbourne, Australia, has been in Boston for a few days looking up electrical devices for adoption in Australian cities. Mr. Murray is particularly anxious to find a good alternating motor and arc lamp, as most of the lighting in that country is done on alternating circuits.

ALUMINIUM CARBON CO.

The above company, a recent comer in the field of arc-light carbon production, is attracting considerable attention, not only by its new departure, but by the excellence of its manufactures. It has established itself with headquarters at Room 69, Coal and Iron Exchange, Buffalo, N. Y., and carries on its factory at Lancaster, N. Y. The company has as its officers Andrew Cant, president; R. J. Getz, vice-president; Fred V. Doty, secretary and treasurer; and W. H. Boulton, as superintendent. The list is such we think as to inspire no little confidence among "old time" central station men, who know what good carbons are and who have been the makers of them. Mr. Doty, it may be added, is also the general manager. The company write us: "We are now producing a superior line of carbons to those now on the market, and can safely guarantee that they will burn 25 per cent. longer than any carbon now on the market, and also will produce a perfectly white and steady light." Evidently, a company that has this faith in its product means business and will get no small share of trade.

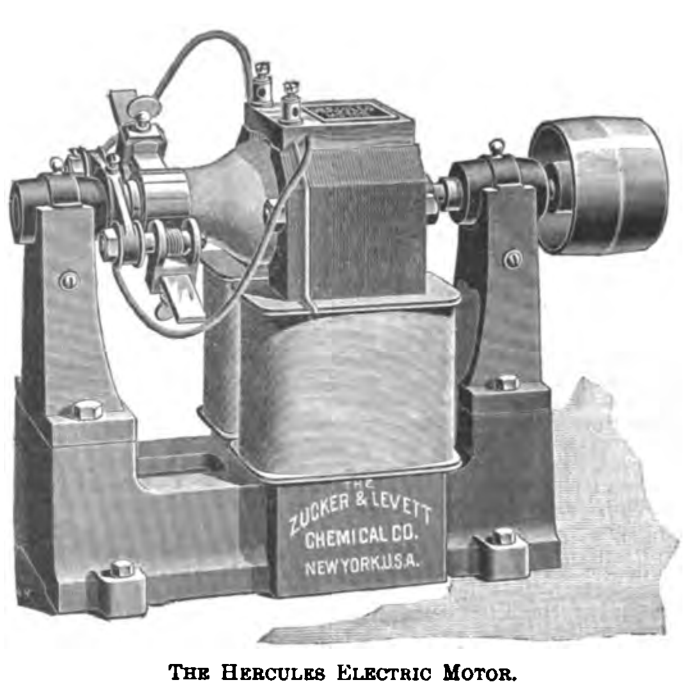
THE HERCULES ELECTRIC MOTORS AND DYNAMOS.

THE accompanying cut illustrates a new motor just brought out by the Zucker & Levett Chemical Co., of this city. The motor is of the inverted horseshoe type, in which the whole of the magnetic circuit is stamped out of one sheet of best Swedish iron, the sheets being bolted together to form the magnet frame.

The plates are thoroughly insulated to prevent the generation of Foucault currents and consequent heating. The field coils are separately wound on brass spools, and the distance between the magnet cores is slightly larger than twice the depth of one coil, thus allowing the same to be slipped over the core.

The plates of the armature, which is of the modified Siemens type, have teeth forming longitudinal channels on its periphery, in which the coils are wound. These teeth, besides reducing the magnetic resistance to a minimum, entirely prévent the coils from shifting and consequent burning out of the armature, due to short-circuiting. The magnet frame is bolted to an iron base, having iron standards and self-coiling bearings even in the smallest size of machines. By this method of construction a highly efficient and simple form of motor is obtained.

There is no sparking if the commntator and brushes are kept in fair condition, the magnetism of the field greatly overpowering that of the armature even when the machine is working at full load. The automatic motors are usually plain shunt wound with an armature of extremely low resistance. The fan motors are plain series wound and run a six-blade 12-inch propeller fan at 1,600 revolutions per minute, taking one ampere at 120 volts.

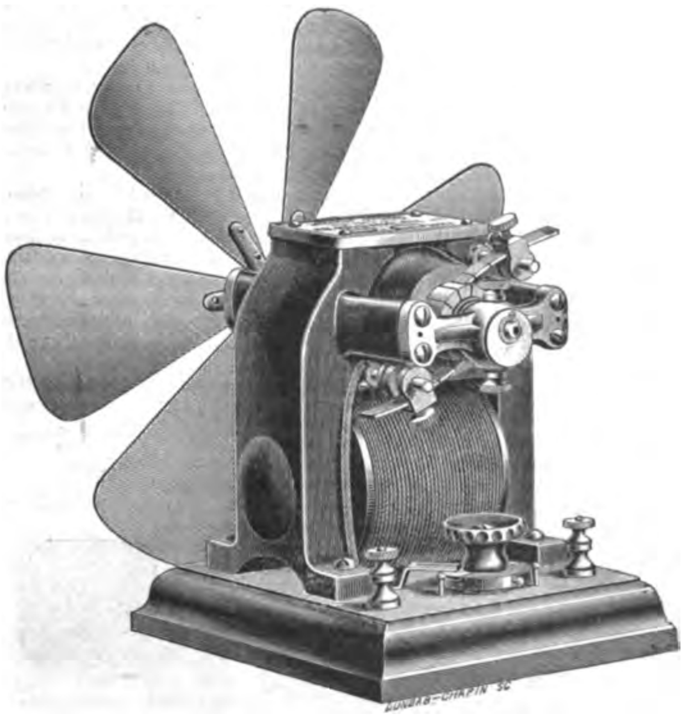


THE HERCULES ELECTRIC MOTOR.

The mechanical details of these machines have been very carefully worked out and all parts are adjustable. Quite a number of the Hercules fan outfits are in daily use and are giving general satisfaction. These machines will be manufactured in all sizes from one-eighth horse-power up, for both light and power.

THE HOLTZER-CABOT "BONNIE BREEZE" FAN MOTOR.

THE Holtzer-Cabot Electric Co of Boston, Mass., well-known manufacturers of standard electric bells, annunciators and general electric supplies, have recently added to their already extensive works a department for the manufacture of electric fan motors. We illustrate the Holtzer-Cabot ⅛ h. p. motor with fan on this page. The machine shown in the cut has a Norway iron field core with malleable cast pole pieces, a drum armature with a very substantial commutator (nothing but mica insulation being used). It has self-oiling bearings, with phosphor bronze journals and in mechanical detail is claimed to be more nearly perfect than anything heretofore attempted in the small motor line. It has been found, it is said, to require no more current to drive a 12 inch fan at its slow speed than was found necessary to drive the ⅙ h. p. motor of another make when running free, so perfectly lubricated were its journals and so well balanced magnetically its armature. It is provided with a switch giving three changes of speed to the fan and is wound for circuits of any potential. It is heavily japanned and furnished plain or nickel-plated. The drum type armature was selected as being the most durable and efficient, it having been decided to sacrifice on account of cost no feature which rendered it possible to obtain greater durability or higher efficiency in the motor.



THE "BONNIE BREEZE" FAN MOTOR.

The company does not believe that the demand of the present day is for a fan motor whose special merit is that it can be easily repaired, but rather that the demand is for one that does not get out of repair, and they have here made one which they are ready to guarantee to be permanently serviceable. Especial attention, however, has been given to making the machine interchangeable in every part, which is true of all apparatus manufactured by this company, so well known for the high and "standard" quality of its work.

We are informed that the Holtzer-Cabot Electric Co. have secured the services of Mr. E. S. Pillsbury in this department of their works. Mr. Pillsbury has had an extended experience in the line of small electric motor manufacturing, having had employment with both the pioneer manufacturers of fan motors, viz., the "C. & C." Motor Co. and the Crocker-Wheeler Motor Co.

ELECTRICAL FIBRE CARBON CO.

A few weeks ago we made reference to the formation of this company. It has now fitted up a very fine factory at 1234 to 1236 Michigan avenue, Detroit, Mich., and is pushing the manufacture of its new carbon battery and other specialties produced by its new processes for the treatment of raw carbon. The company is in excellent hands, John R. Markel being president, John H. Davis, vice-president, and Eugene Klein, secretary and treasurer, the last named being also an expert chemist. Mr. Markel is an old electric light representative, while Mr. Davis is a pioneer in the carbon industry.

CENTRAL ELECTRIC CO.

The Central Electric Company have recently taken some very large orders for electroliers and other electric light fixtures for several public buildings in the Northwest. They report a large trade in these articles and that the demand is for better goods than have heretofore been supplied.

At a recent life test of 100 Packard lamps by a superintendent who is generally considered extremely finical on the question of lamp efficiency, the average life was found to be 2,118 hours. The Central Electric Company are handling these lamps in the West and report that their sales are constantly increasing. The capacity of the factory is now being doubled to meet this new demand

The Central Electric Company are showing samples of a new porcelain insulator, which they will place upon the market within a few days.

THE WIGHTMAN ELECTRIC MANUFACTURING COMPANY.

A number of the railway motors of the Wightman Company, a description of which appears in another column, are already running very successfully in Auburn, N. Y., and in Scranton and Easton, Pa., and large orders from these and other places necessitate the running of the factory night and day. The great increase of business has compelled the company to erect new buildings, which will soon be completed. The following letter indicates the reception with which these motors are meeting at the hands of railway men:

AUBURN, N. Y., June 29, 1891.

The Wightman Electric Manufacturing Co.,
Scranton, Pa.

Gentlemen:—We ran your car yesterday with heavy loads and are more than pleased with it. It is very fast and makes no noise whatever, and seems about as near perfection as anything can be.

Very truly yours,
AUBURN CITY RAILWAY CO.
(Signed) G. W. WELLS, Superintendent.

The work of this company is characterized throughout by simplicity and durability, and it is rapidly gaining a reputation for the superior quality of its products.

WANT THEIR OWN NEW COMPANY.

During the convention of the Order of Railway Telegraphers in St. Louis the newspapers were allowed to have only so much of the proceedings as the Press Committee thought should be printed. Since the adjournment it has been learned that one of the most important subjects considered was the formation of a new telegraph company, to be owned and controlled by operators. This matter was discussed, and is said to have been put in a fair way for final accomplishment. The new company is to capitalize at $2,000,000 and be organized, officered, and manned by men of known standing and ability in the telegraphic profession. The money required will be forthcoming, judging from the declaration of certain supporters of the scheme, who say that the order had the cash and time to devote to it.

MESSRS. DUBOIS & DUBOIS, of Washington, D. C., have secured the *Journal of Useful Inventions* and have merged all its rights, title and interest with the *Inventive Age*, which, it may be expected, will be more helpful and instructive than ever.

OKONITE ON SHIPBOARD.—The White Star Line steamer "Teutonic," which sailed recently for Europe, carried among its passengers Captain Willard L. Candee, of the International Okonite Co., Limited, New York.

NEW YORK NOTES.

MR. W. R. MASON, the general manager of the Electric Merchandise Co., Chicago, favored us with a call a few days since. He reports a most encouraging outlook for the live company which he represents, several large contracts having been taken during the last few weeks. The Merchandise Co., as selling agent for the Burton Electric Heater, of which company Mr. Mason is president, has been doing good work in calling attention to the merits of that device, and the visit of Mr. Mason to New York was by appointment with some of the leading officers of one of the largest steam roads, whose management have decided to heat some of the special first-class trains by the Burton Electric Heater. After consultation with Mr. S. Dana Greene, who is consulting electrician of the company, with reference to the best plan of equipping the cars, arrangements were made and the patrons of at least one road will ride next winter in safety, having no fear of either being roasted or scalded in case of an accident.

MR. W. F. D. CRANE, of the Engineering Equipment Co., reports considerable demand for the Kellogg pole, which his enterprising company is energetically pushing into the electric railway field. Mr. Crane has just returned from a trip which carried him as far as Chicago, and he says that advertising undoubtedly pays. As he expresses it, "Our pole 'ads.' tell so much that some people seemed to know as much, if not more, about its good and bad points and desirable features than I did. Its characteristics had evidently appealed to them, and they recognized a good thing when they saw it." The company has also done good business with the Boston trolley, line materials, Habirshaw wire and other specialties for which they are agents, several nice orders having been received lately.

MR. CHARLES A. SCHIEREN has left on the steamer "Fürst Bismarck" on a short trip to Europe. The principal reason for his going is to visit the International Electrical Exposition at Frankfort, where he will inspect the various devices for transmitting power by belting exhibited there. From a letter obtained lately we learn that the "American" leather link belt, exhibited by the American Leather Link Belt Co., attracts universal attention, and is so much superior to all European link belts exhibited, that the other exhibitors have actually withdrawn all link belts from the exposition.

SCHIEREN BELTS.—Orders for their perforated electric belting have been secured by Chas. A. Schieren & Co., Ferry street, this city, from the Columbus Consolidated Street Railway Co., Columbus, O., which takes six 18¼-inch double belts. They have also furnished the belting for the Worcester, Leicester and Spencer, Mass., Street Railway Co., namely, one 40-inch and five 12-inch belts. They report quite a fair demand for the perforated belt for street railway purposes.

E. G. BERNARD & CO., Hall Building, Troy, have recently installed a neat isolated plant in the country residence of Mrs. W. H. Hart, at Fernwood. A United States dynamo is driven by a Case engine, and is supplemented by a set of 30 cells from the Electrical Accumulator Co. The plant is in the care of Mrs. Hart's gardener, and runs 76 lamps, all told. Dynamo and engine are connected by the Evans friction cone system.

MR. J. W. PACKARD, general manager of the New York & Ohio Company, of Warren, Ohio, paid us a visit this week and reports business very good indeed. He had just received a telegraphic notice of an order from St. Louis for 4,000 Packard lamps, 2,000 52-volt lamps and 2,000 104-volt lamps, making 4,000 in all. Mr. Packard came to New York with a view of attending the meeting of the Lamp Manufacturers' Association.

NEW ENGLAND TRADE NOTES.

THE JEWELL BELTING COMPANY, of Hartford, don't appear to feel the general dullness of trade, but, on the contrary, Mr. Newton reports that they have never had so many orders, especially from electric light plants. That the Jewell belt is meeting with hearty approval is abundantly proven by the amount of new business that they get, and by the warm letters of appreciation which they daily receive from their customers. Among their most recent sales are the following: Cedar Rapids Electric Street Railway Company, Cedar Rapids, Iowa, complete equipment; Springfield Electric Light Company, Springfield, Vt., complete equipment; Omaha Electric Street Railway Company, Omaha, Neb., complete equipment, embracing one 48-inch double belt; Jamestown Electric Light Company and Jamestown Street Railway Company, Jamestown, N. Y., complete equipment; Amsterdam and Rockton Street Railway Company, Amsterdam, N. Y., complete equipment; Wautaûga Lighting and Power Company, Johnstown City, Tenn., two 39-inch double belts.

THE EDISON ELECTRIC ILLUMINATING COMPANY, of Boston, have purchased a large lot of land on Atlantic avenue, for the purpose of building a large central station, where they can use compound condensing engines. No settled plans have yet been adopted, as they will not commence building for some time, owing to present leases. Should they commence building soon, however, it is probable that the vertical compound engines and generator combined, manufactured by the Edison General Electric Company, and recently described in THE ELECTRICAL ENGINEER, would be adopted.

MR. F. E. PETTINGELL, of the Pettingell-Andrews Company, has at last got sufficiently recruited to be able to attend to business once more, and his numerous friends are all glad to see him back in his usual place. Mr. Pettingell has had quite a serious sickness since his return from Europe, and has not been able to attend to business for over a month.

THE PETTINGELL-ANDREWS COMPANY, of Boston, have added a new department to their already existing large business, namely, that of bells, batteries, push-buttons, switches, office and annunciator wire, &c., and will carry a complete line of these light goods, in addition to their large stock of the heavier supplies for electric light and railway purposes.

THE REDDING ELECTRIC COMPANY, of Boston, have taken the selling agency for the Hyer-Sheehan electric motor, described in the last number of THE ELECTRICAL ENGINEER. They have also in view the agency of the Columbia incandescent lamp, and are making arrangements for the agency of a first-class wire. With these the Redding company will be well equipped to do a general electrical supply business, and will be pleased to furnish prices to all enquirers on any line of electric specialty. The sale of the Star Electrix goods still keeps brisk.

THE RUSSELL ARC LAMP continues to attract many new customers, and the Russell Electric Company have all they can do to fill their orders. The "Baby" lamp is anxiously awaited, as they have numerous orders for it, but have been delayed somewhat in the machinery for making them. When the machinery is ready, a large business is expected, and the "Baby" lamp will have the same excellent workmanship as the larger lamp, and all the parts will be interchangeable.

MR. O. K. STUART, a gentleman well known in electrical circles, has now got thoroughly settled down as treasurer of the Germania Electric Company, of Boston, and reports his company as making active preparations for fall trade. The Germania company are at work on a number of new devices, which when perfected will prove valuable accessories to their present large business. Mr. Peter Claus, of New York, has taken the agency for New York City and State.

THE NEW HAVEN INSULATED WIRE COMPANY, of New Haven, Conn., the manufacturers of the well-known Helmet brand of insulated wires, recently sold by the Empire City Electric Company, of New York, will continue to manufacture their goods, as there is a large demand for them, and will hereafter supply dealers and central stations direct. Messrs. Hague and Bean will continue in the management.

M. J. FRANCISCO & SON and the Rutland, Vt., Electric Light Co. have opened large new offices in Rutland, taking the entire first floor and basement of the *Herald* building in that city. The fittings and appointments are most luxurious and handsome, and electric lights, electric motors, &c., add to the general comfort The opening was made the occasion of a reception recently.

PHILADELPHIA NOTES.

MR. B. FRANK JOHNSON, the general agent of the Interior Conduit & Insulation Company, has received a letter from Gov. Gorham, secy. of the old Point Comfort Hotel Company, in which he states that they have found no necessity for inspection of their new building in which an entire conduit installation was recently made; that their insurance agent has placed over $150,000, covering owner's as well as builder's risk, and has required nothing of them, the directors. The contract for the new Betz office building, on South Penn Square, has been awarded to Allen B. Rorke, builder, of this city, and work of tearing down the old church and erecting the new building will be begun at once. The contract for the electric work has not yet been awarded, but the system of the Interior Conduit & Insulation Company has been called for in its entirety for the lighting of the building.

MR. CHARLES H. FISHER, agent for Chas. A. Schieren & Co., reports business as excellent. He has recently received orders from the following companies for their famous perforated belting: Home Electric Light and Power Co., Tyrone, Pa.; Jenkinton, Pa., Electric Light and Power Co.; Shamokin, Pa., Electric Railway Co.; Merchants' Electric Light Co., of this city, and the Edison Electric Illuminating Co., of both Bellefonte and Lebanon, Pa.

THE STAR ELECTRIX CO. are about to move their office and factory from Wallace street to the large Warner Building, 641 Broad street, where they will occupy several floors, and with the addition of more machinery they will double their present capacity for turning out the specialties so favorably known to the trade.

MESSRS. WALKER & KEPLER are busily at work on the jewelry store of J. E. Caldwell & Co., of this city, which when finished will doubtless be the handsomest lighted store room in the country. The Interior Conduit Company's tubing will be used throughout the building.

THE EUREKA TEMPERED COPPER CO., of North East, Pa., has kept its factory running on full time, notwithstanding the general dullness in business circles, and has orders on the books for an output of at least sixty days.

MR. G. A. WILBUR, the Philadelphia agent for the Fort Wayne Electric Co., has sold a Wood 60-arc light dynamo to the Southern Electric Light and Power Co., of this city.

MR. W. C. WRIGHT, of Wright & Starr, has just been granted a patent on a fluid clutch which can readily be adapted as a hydraulic motor or a fire pump.

Mr. Wright has had an application pending for over two years for a conduit system for electric railways which has just been granted.

MR. CHARLES P. PEROT has been elected a director of the Equitable Electrical Construction Co., of this city.

MR. S. ASHTON HAND, first vice-president of the Equitable Electrical Construction Co., is spending the summer at the Bellevue Hotel, Wayne, Pa.

MR. NORMAN MARSHALL, secretary of the Star Electrix Co., sailed for Europe last week on a short business trip.

MR. G. A. WILBUR, agent for the Fort Wayne Electric Co., has contracted to furnish the Franklin Electric Light Co. with a 1,000-light Slattery alternating dynamo with full station equipment. He has also installed two 40-light Wood arc dynamos and 75 2,000 c. p. lamps for Geo. Kelly & Co., 810 Market street.

WASHINGTON NOTES.

THE "GLEN ECHO" ELECTRIC RAILROAD has been started with current from the power-house of the Georgetown & Tennallytown R. R., their own station not yet being finished. Large crowds go out daily to enjoy the "feast of reason and flow of soul" set out at our own "Chautauqua." By-the-by a series of lectures on electricity is to be delivered during the summer at this resort. The road makes the grounds so easy of access that there should be no lack of interest.

J. W. BURKET & Co. are wiring the new addition to the U. S. Treasury Dept. The addition will be occupied by the draughtsmen of the Supervising Archtects' office and over each desk will be a 50 c. p. lamp with a McCreary ground-glass reflector. The building is ventilated by means of two C. & C. combination exhaust fans, andmotors furnished by the Washington Construction Company.

THE CHESAPEAKE & POTOMAC TELEPHONE CO. have recently executed a large mortgage on their property to obtain money for their extensive underground work. As an officer of the company expressed it: "They are providing for the 20th century in more ways than one."

THE U. S. ELECTRIC LIGHTING CO. have broken ground for a new building on the lot adjoining the present station. It is purposed to erect a counterpart of the old station, thus doubling their capacity.

THE PRIMARY BATTERY "INVENTOR" has caught this town once more, and as a consequence no less than six different companies are ready to outdo the dynamo and steam-engine.

S. C. CLUM & Co., of Philadelphia, have erected a complete electric power plant for the new lumber warehouse of Barber & Ross on 18th street. The U. S. system has been used.

WESTERN TRADE NOTES.

INTERIOR CONDUITS.—The following will give our readers a general idea of the great advancement that has been made during the past four months in the way of interior conduiting buildings for electric light wires as well as telephone and other wires, and all of which is due to the untiring endeavors of Mr. H. M. Underwood, the General Western agent of the Interior Conduit & Insulation Co., of New York. Up to July 10th the approximate number of public and office buildings for which he has made arrangements for the "interior conduit" system foots up to 22 buildings, for the distribution of about 58,105 incandescent lights. In addition to this there are five private residences which vary from 160 lights to 700 lights each, and two or three installations of concealed wires for about 150 arc lights. Two out of the above five private residences have all wires run in conduits, *i.e.*, bell, fire-alarm, etc., and one has speaking-tubes. About four of the office buildings out of the 22 have wires for telegraph, telephone, message service, etc., run in conduits, and one has the speaking-tubes.

THE ELECTRIC MERCHANDISE CO., of Chicago, through their traveling representative, Mr. D. B. Dean, have secured the order for all the overhead line material of five miles of road for the Vancouver Electric Railway and Light Co., of Vancouver, B. C. They have also received an order for six miles of overhead fixtures for the Citizens' Electric Railway, Light and Power Co., Mansfield, O., for their new equipment. Mr. D. B. Dean has sent in orders during his last Western trip for over 150 of their well-known rawhide pinions.

MR. W. R. B. WILCOX, of the Electric Merchandise Co., of Chicago, has just returned from the East, where he has been making an extended trip in the interests of the Burton electric heater, for which the Electric Merchandise Co. are the agents. This well-known heater is attracting widespread attention and interest, and especially so with reference to its introduction for heating cars on steam railroads, and it will only be a short time before it will be very generally used for this purpose.

MR. D. W. HIGGINS, president and general manager of the National Electric Tramway and Lighting Company, of Victoria, B. C., was in Chicago last week. He is looking up street railway matters and spent considerable time here with the Electric Merchandise Co.

KOHLER BROS. & GRIER, the agents for the Eddy Electric Motor Co., have just placed another 15 h. p. machine. The orders for these motors are now coming in so rapidly that they have determined to carry a stock of all standard sizes immediately, thereby enabling orders to be filled with the greatest possible promptitude.

THE ELECTRICAL SUPPLY CO. are gradually getting settled in their spacious new quarters at No. 102–104 Michigan avenue, and notwithstanding the immense amount of work involved in their change of location, they are handling their usual large amount of business with the promptitude and celerity for which they are noted.

MR. W. R. MASON, manager of the Electric Merchandise Co., of Chicago, started for New York last week on a short business trip, having some important matters regarding the Burton electric heater to attend to in the East.

KANSAS CITY NOTES.

ENGLISH, MORSE & CO., the well-known engine, belting and general machinery dealers, of Kansas City, are doing a large and prosperous business, and their business in electrical work is brisk and increasing all the while.

THE FRANKLIN ELECTRIC CO., although they have but recently started in business, are doing remarkably well. They are dealers in general electrical supplies of all kinds, and also pay especial attention to electrical construction and repair work. The promoters of the enterprise are able and energetic business men, thoroughly conversant with the requirements of the electrical trade, and at the same time thoroughly well-posted electrical engineers. Mr. W. H. Blood, Jr., was for a long time associated with the Thomson-Houston Electric Co., at Lynn; Mr. G. E. Chaflin is well known in electrical circles from his association with the Westinghouse Co., and A. M. Miller is a mechanical engineer of large and varied experience in the construction and equipment of electrical power plants.

. THE GATE CITY ELECTRIC CO., dealers in electrical supplies and agents for the famous Okonite wire and specialties, are having a good trade in all lines. Mr. W. D Greene is the manager of the company, and he is pushing the business in first-rate shape.

MR. J. W. MASON, formerly manager of the Gate City Electric Co., has now established himself at 527 Delaware street, where he is handling a general line of electric supplies for electric light, power, telephone and other work. He is also special agent for the "Safety" insulated wires and cables, which are meeting with such well-deserved success.

THOS. F. CLOHESEY, New York Life Bldg., Kansas City, electrical engineer, reports that he is handling a large amount of new electrical work and receiving numerous inquiries for propositions all the time and the outlook is very encouraging. He is interested in a new storage battery which will very shortly be manufactured in the West and placed on the market.

GRIMES BROS., 807 Main St., Kansas City, are placing on the market a new spark arrester and bug screen for arc lamps, which is being very rapidly adopted by central station men. It will be found of great use in connection with lamps as a preventive from sparks escaping and setting fire to property and keeping bugs from getting into the lamp, and its merits are well worthy of investigation.

MR. ALLEN R. FOOTE, the special Census agent for electricity, gave an entertainment recently at his residence, in Takoma Park, Washington, to twenty-four other veterans of the Civil War. The occasion celebrated the thirtieth anniversary of his enlistment as a Union Soldier. Comrade W. H. Nelson read an original poem.

A READER of THE ELECTRICAL ENGINEER in San Francisco writes: "I am thoroughly satisfied with your paper and acknowledge it as the most valuable reading matter in our profession. I shall forward you subscription for one year as soon as my trial trip runs out." Another reader in St. John, New Brunswick, writes: "It is not only keeping up its record as a leading electrical journal, but can be fairly dubbed as 100 per cent. efficiency."

THE
Electrical Engineer.

VOL. XII. JULY 29, 1891. No. 169.

THE FRANKFORT INTERNATIONAL ELECTRICAL EXHIBITION—III.

BY

Richard O. Heinrich.

THERE are always a great many disadvantages offsetting the advantages which an electrical exhibition offers. The inventor or manufacturer, who exhibits intends to instruct the public, and to educate it to the use of new things which are to lighten the burdens of this short life. Then he wants to show to the prospective buyer and to the engineer what there is in the market; and finally he wants to go through a competitive examination with his brother inventors and manufacturers. The intentions are good enough, but only too often they remain on paper only. The general public sees an immense number of puzzles, thinks the phonograph and telephone great, the light effects beautiful, the little measuring and testing instruments "just too nice for anything" (which they often are), and finally retires, completely worn out, to a shady place where it can find the beloved brown nectar, which can be imbibed more readily than electrical science, and which goes to the spot. The scientist or engineer is just slightly better off; he can see and learn some new things, especially about the law of the conservation of energy, if he asks the exhibitor for the efficiency of his machines. Of course there is no inferior article to be found in an exhibition; every exhibitor says so, for his is the best in the world. After all, the technical public will leave with the impression that it has seen a good deal and learned very little.

But what about the poor man, who is doomed to sift good from bad and tell his confreres, who are smart enough to stay at home, all about the immense progress of the

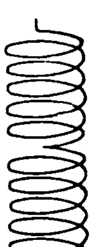

FIG. 1.

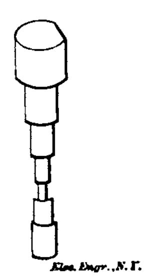

FIG. 2.

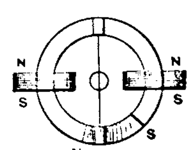

FIG. 4.

science, and about the wonderfully new and revolutionizing inventions, which the exhibitor tells him he has? The greatest advantage of such an exhibition should be found in the reports of a competent committee of judges. It is doubtful whether the work of such a committee can be very thorough, judging from the time which will be given for the purpose. The names of the gentlemen in charge, however, certainly guarantee the value of such work. It will not be too difficult to find a number of prominent experts to take charge of the different sections and to accomplish, within a reasonable time, the task, the result of which would be highly interesting to the electrical engineer and scientist. If it shall be possible to obtain some reliable data on the practical value of the continuous current transformer system, as exhibited by Lahmeyer & Co., the three-phase alternating current (Drehstrom) system, and of sundry different propositions made for long-distance transmission of electrical energy, and finally on commercial measuring instruments and electric meters, it will be all that can reasonably be expected.

FIG. 3.

FIG. 5.

Since it is to be hoped that the future will bring us some revelations on the question of dynamos and motors, I shall postpone somewhat my notes on this subject, and begin with the smaller fry, which are to be found at the north end of the exhibition grounds in the building for "Science and Electro-Medicine," and in the separate building of the Weston Electrical Instrument Company, and of Hartmann & Braun, instrument makers. This latter exhibit is one of the most complete of its kind. There are not so very many essentially new things to be seen there, but a number of improvements in their commercial measuring instruments and in some of the instruments of precision will make a more detailed account of value.

Voltmeter and Ammeter.—Externally a difference is scarcely detectable between the old and the new types of commercial meters manufactured by that firm. The voltmeter is the very same which has been introduced to some extent in America during the last four or five years. It has soft iron in its movable parts, controlled by gravity. The divisions are not proportional. The makers claim that this type of voltmeter can be used equally well for continuous and alternating currents; that the difference in the indication for continuous and alternating current does not amount to more than ½ per cent., and that the magnetic lag may be taken at 0. 6 per cent. The makers are to be congratulated on this result with soft iron, however small the quantity; but I must confess that I would rather wait until the committee of judges reports, or until I can convince myself, as I am somewhat sceptical.

The ammeters show a few radical innovations. Prominent amongst these is the controlling spring. The steel spring is wound right handed for one-half of its length and left handed for the other, as shown in the illustration, Fig. 1.

With this arrangement, it is claimed, the zero point is always constant, and change of temperature has no influence on the indication of the instrument. To this spring is fastened a soft iron core, which is drawn into a solenoid of heavy copper wire, or turned in the form of a spiral from a solid piece of copper. The soft iron core is wound of thin sheet iron, as indicated in Fig. 2. Its shape may be varied in such a way that the scale divisions are either proportional to the current, or so that the greatest space between divisions may be obtained at any desired part of the scale. The attractive force of the solenoid is considerable, 1,000 to 1,500 ampere turns. The instrument is fairly dead beat, but may have some lag, judging from the quantity of iron used, which, however, is nearly eliminated on account of the great attractive force used. The accuracy obtained for the voltmeter is 1 per cent.; that for the ammeter, 2 to 3 per cent.

FIG. 6.

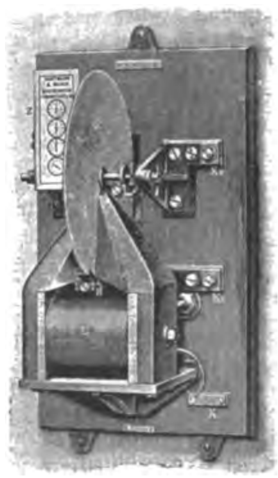

FIG. 7.

Among the instruments of quite novel construction are the torsion galvanometer and torsion watt-meter and electro-dynamometer.

The torsion galvanometer, shown in Fig. 3, is very similar to the Siemens torsion galvanometer, and answers the purpose of volt and ammeter combined. But, instead of being a zero instrument, as the Siemens torsion galvanometer is, it is made direct reading, the controlling force being a torsion spring, and the earth's magnetism partly. The movable magnet, Fig. 4, is of circular form and made of steel tubing; the two poles come near each other and are connected by a piece of soft iron to effect a magnetic circuit. The solenoids are wound in such a way that a passing current produces the polarity indicated relatively to the magnet. The position of magnet and solenoids effect a deflection proportional to the current, so that the scale is very even and direct reading. The magnet is supposed to remain reasonably permanent by means of the magnetic circuit formed.

The electro-dynamometer and wattmeter of Hartmann & Braun, shown in Fig. 5, are almost identical, except that the ring magnet is replaced by a solenoid of almost circular shape, suspended, like the magnet, by a silk fibre, the current being taken to and from the solenoid by a very fine silver spring with very wide convolutions in order to reduce the torsion. By having the stationary solenoids of low resistance in the main circuit, and the movable one of high resistance in shunt, the instrument forms a direct-reading wattmeter. The movable system is effectually clamped by large aluminum vanes. The total range of these instruments is given at 0.1 to 150 volts direct and to 1,500 with additional resistances; 0.01 to 1.5 amperes direct and 150 amperes with shunts; the wattmeter reads to about 120 watts.

The electric meters made by this firm are only designed for continuous current. In the clock meter, Fig. 6, S is a solenoid through which the main current passes and acting simply as an ampere meter with proportional deflections. Every minute the clockwork makes a contact to energize the electromagnet M, which in turn attracts the S-shaped armature. The deflected pointer of the ammeter limits the distance through which the S-armature can travel, the larger the deflection the larger the distance of the armature travelled over. When the armature is attracted the registering train commences to operate, and stops registering as soon as the limiting position of the pointer is reached; neither does it register when it goes back in its old position.

The motor meter, Fig. 7 (Wilkes' system), utilizes the reciprocal action of a current passing through a movable conductor in an intense magnetic field. The main current is taken off by means of mercury contacts from the centre to the circumference of an easily rotating copper disc. An electromagnet in shunt to the main line produces rotation of the disc when a current is passing. The eddy currents generated in the rotating copper disc produce a retardation in such a way that the number of revolutions are proportional to the strength of the current; the registering dials indicate directly in ampere hours. The whole is surrounded by a dust-proof casing. A later type has two copper discs instead of one, and the electromagnet is changed accordingly.

The clockwork meter is used up to 30 amperes, the motor meter from 50 to 1,000 amperes for any voltage required. In the beginning the meter registers somewhat too low, but is said to be strictly proportional from 15 per cent. of the total range for the old form, and from 6 per cent. up for the new type of motor meters. More exact data may be obtainable later on.

Among the galvanometers exhibited are some very sensitive and very dead-beat instruments of the Thomson astatic and of the Wiedemann type. The copper dampers employed are all very narrow, but have their greatest extension in the direction of the poles of the bell magnets, the usual form employed. This allows the coils to be brought close to the magnet, and answers the purpose of dead-beating perfectly. Among the new instruments are those illustrated in Fig. 8 and Fig. 9. The first is a dead-beat galvanometer of the Deprez-D'Arsonval type, the magnetic field being formed by a number of horseshoe magnets fastened with the same poles to common pole-pieces. The frame with the wire winding is suspended by a fine metal wire, the electrical connection being made below by a very fine wire spiral with negligible torsion. A silk fibre below keeps the coil from vibrating. Fig. 9 is a combination of a differential mirror galvanometer with a balanced reading telescope and scale.

FIG. 8.

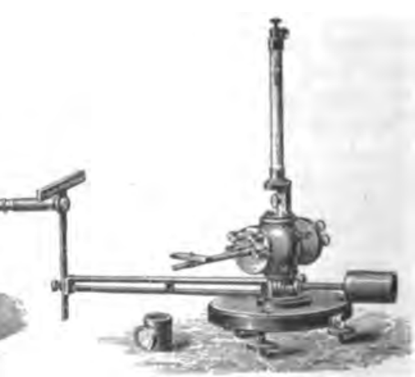

FIG. 9.

A very convenient and novel instrument for studying magnetic fields is shown in Fig. 10. A thin bismuth wire, chemically pure, is wound bifilar fashion in the shape of a spiral, and the ends brought to terminals at the handle of the instrument. The whole spiral is fastened between two small mica sheets, so that the turns are insulated from each other. This spiral serves, according to Lenard, to investigate the intensity of a magnetic field and is small enough to be introduced between the pole-piece and armature of a dynamo, being only $\frac{3}{4}$ in. in diameter and $\frac{1}{32}$ in. thick. With a change of the intensity of the magnetic field the resistance of the bismuth will be changed by a measurable amount. A change of 1,000 lines of force per square centimetre corresponds to a change of about 5 per cent. in the resistance of the spiral; a curve usually accompanies the instrument, from which the intensity may be read directly.

The exhibit of the firm showing a complete electrical testing laboratory is highly creditable. I must also mention the use by this firm of a manganese nickel-bronze for resistance instruments, which has a very small negative temperature coefficient. The time test of this alloy has not been extended enough to fully substantiate the good features claimed for this material for instruments of high precision.

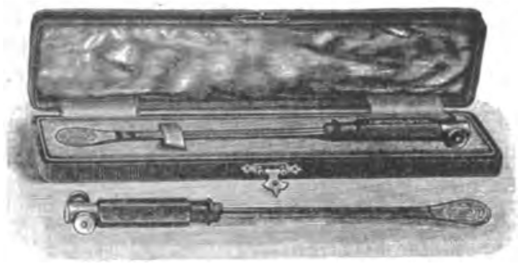

FIG. 10.

ELEMENTARY GEOMETRICAL THEORY OF THE ALTERNATE-CURRENT TRANSFORMER.—IX.

BY

Chas. Steinmetz.

C. Dependence upon the Cross-section g, and the Length l, of the Iron Circuit, upon the Frequency N, and the Magnetic Resistance ρ.

If we increase the cross-section g, of the iron, but without changing any one of the other constants, l, r, r_1, etc., the resulting M. M. F., $\overline{OF}$, necessary for the production of the magnetism M, that is, the induced E. M. F.'s E_1 and E_1, decrease inversely proportional to g.

Hence, for increasing g, the resulting M. M. F., F, travels on $\overline{OF}$ from F in the direction to the centre point, O.

Hence the impressed M. M. F, $\overline{OK}$, decreases with increasing g, also, $\overline{KF}$ being parallel to $\overline{OA}$; and K travels towards O on the line $\overline{OK}$, or rather on the curve k, which gives the dependence of the angle of magnetic lag, $\alpha = $ KOF, upon the magnetization, OF.

This curve k may approximately, inside of certain limits of the magnetization (*not* for very low magnetization, and for magnetic saturation) be replaced by the cubic parabola, $\overline{KF} = \gamma \sqrt[3]{\overline{OF}^2} = \gamma\, \overline{OF}^{\frac{2}{3}}$, or $\overline{KF}^3 = \gamma^3\, \overline{OF}^2$, γ being the coefficient of magnetic lag.

In Fig. 17 this cubic parabola is shown, together with a true curve of magnetic lag, as found by actual tests. The magnetization used in American transformers (working with high frequency, $N =$ 100 to 140) is marked at I. The magnetization used in European transformers (working with low frequency, $N = 42$) is marked at II on the curves.

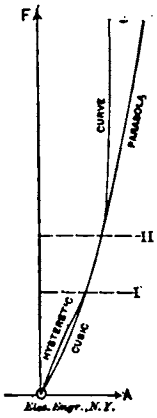

FIG. 17.

In Fig. 18, the transformer diagram is given for the iron cross-section, $g = 10$ square inches, and $g' = 20$ square inches.

As seen, the primary M. M. F., L, moves on a cubic parabola l, parallel and congruent to the cubic parabola k, and E and E_0, the primary E. M. F.'s, on cubic parabolas e and e_0, similar and proportional to the parabola k, as shown in Fig. 18. A, C, C_1, etc., are derived in the usual way.

If, as a rough approximation, we neglect the angle of magnetic lag, α, all these cubic parabolas become straight, vertical lines, as shown in Fig. 19.

The difference of phase between primary current and impressed E. M. F., decreases with increasing g, and the decrease of the "leakage current," C^{∞}, is almost inversely proportional to g. That is, an increase of g increases the efficiency, and especially the all-day efficiency of the transformer, and makes it work more economically. Hence g must be chosen as large as possible.

The length of the iron circuit, l, has an influence almost exactly opposite to g. If we neglect the variation of the magnetic susceptibility of the iron, as we have done until now, an increase of l has exactly the same effect as a proportional decrease of g. Hence a decrease of l decreases $\overline{OF}$, and thereby causes K, L, C, E, E_0, to travel on their respective cubic parabolas, which in this case are vertical lines downward, increasing the efficiency.

Hence l must be as short as possible, and it must be considered a mistake to leave a hole in the centre of ring transformers.

The specific magnetic resistance of the iron, ρ, acts somewhat similarly to l. Its decrease increases the efficiency,

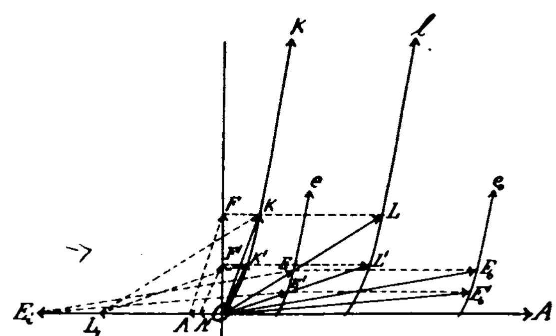

FIG. 18.

but a change of ρ means a change in the kind of iron used, and such a change also gives a different value to the coefficient of magnetic lag, γ, that is, a different angle of magnetic lag, $\alpha = $ KOF.[1]

A change of N, the number of periods per second, has the same effect as an increase of g, so that the higher the frequency, the smaller the resulting M. M. F., and the shifting of phase, and the higher the electric efficiency becomes, so far as the transformer proper is concerned. An increase of N reaches farther than an increase of g, and increases the self induction in line and machinery also, which increase of self induction may, under certain circumstances, more than counterbalance the gain in the transformer proper, the more as the loss of energy by eddy-currents increases with the square of the frequency N, and therefore, even if imperceptibly small with low frequencies, may become serious with high frequencies.

A proof of this increased loss of energy by eddy-currents is afforded by the fact, that in the transformers of Ganz & Co. in Austria, which work with 42 periods per second, the loss due to eddy-currents is negligible, while in American transformers, which work at three times as high a frequency, although these transformers are built at least as carefully as the European converters, the loss caused by eddy-currents is quite perceptible.

D. Dependence upon n and n_1.

We now consider the influence of a change of the number of turns n and n_1 of the transformer, but such a change,

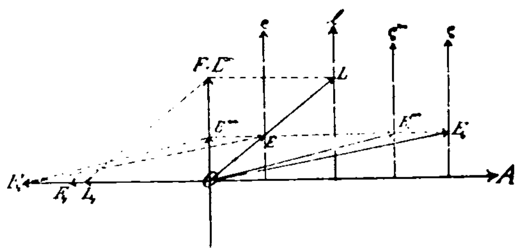

Fig. 19.

that the ratio of induced E. M. F.'s, that is $\frac{n_1}{n}$ remains the same : $\frac{n_1}{n} = \frac{3}{4} = .75$.

The other constants are again supposed to remain the same as before.

Let us, for the sake of simplicity, in Fig. 20, neglect the angle of magnetic lag. Then, for increasing n, n_1, the points L^∞, C, C^∞, E, E^∞, E_0, $E_0{}^\infty$, move downwards on vertical lines, e, e_0, etc., while L_1 moves on the horizontal line from the right to the left. L travels on a hyperbolic curve, l.

When taking into consideration the angle of magnetic lag, these vertical lines have to be replaced by cubic parabolas, as before. The ratio of transformation, $\frac{E_1}{E_0}$ approaches the limit, $\frac{n_1}{n}$ more and more, for increasing n, n_1, if the primary resistance is very small.

Especially remarkable is the rapid decrease of leakage current C^∞, and of the primary current for half-load, with

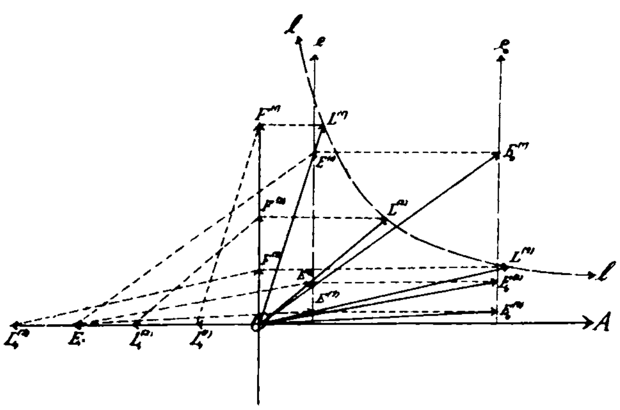

Fig 20.

an increasing number of turns n, n_1. Therefore the all-day efficiency increases very considerably with increasing number of turns n, n_1.

This fact may account for the higher all-day efficiency of some types of open circuit converters, because the much higher magnetic resistance of open circuit necessitates the use of a larger number of turns n and n_1.

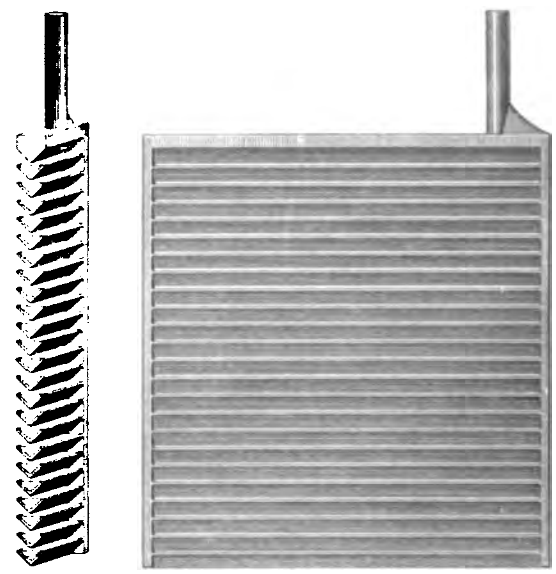
In Fig. 20 the diagrams are given for the number of turns:

1. $n = 40$, $n_1 = 30$, hence : $\frac{E_1}{E_0} = .476$.
2. $n = 80$, $n_1 = 60$, " $\frac{E_1}{E_0} = .581$.
3. $n = 160$, $n_1 = 120$, " $\frac{E_1}{E_0} = .588$.

$$\frac{n_1}{n} = \frac{3}{4} = .75.$$

THE WINKLER STORAGE BATTERY.

In addition to the dynamo and the electric car gear already described in our columns, Mr. Charles F. Winkler, of Troy, has recently brought out a type of storage battery, the construction of which, he claims, enables it to withstand the hardest usage and thus insures it a long life. The plan upon which the plate is constructed will be readily seen from accompanying illustrations, which represent respectively a section and side view of the plate.



The Winkler Storage Battery.

It will be noted that the grid consists of a vertical row of V-shaped troughs within which the active material is contained. This method of construction gives considerable area of contact and at the same time allows the active material to contract and expand without affecting the shape of the plate, and hence avoids buckling. At the same time the space between the troughs allows the liquid to circulate freely, and thus permits of a thorough utilization of the active material.

On a recent test the battery was made to give successively 40, 45, and 60 amperes at the beginning, the time being about 10 to 15 seconds in each case. For an instant the battery was short-circuited, the pointer of the amperemeter leaving the scale at 200 amperes. The battery was charged after the first discharge for 10½ hours at 10 amperes without intermission; the regular discharge was begun at 1.35 p. m., and continued at the rate of 18.5 amperes until between 6 and 6.15 p. m., when it gradually fell to 17 amperes at 6.30. After a rest of an hour the discharge started at 17.5 amperes and in 42 minutes had dropped to 14.5, when the wires were disconnected. The entire discharge amounted to 97 ampere hours, giving an efficiency for this discharge of 93 per cent. When the cell began to discharge the difference of potential was two volts, and at the end of the discharge 1.78 volts. In the cells arranged for this test the plates consisted of 5 positives and 5 negatives, and were new, having received their first or forming charge of 10 amperes for 26 hours. The following gives the weights of plate and active material:

Weight of plates alone, 16 lbs. 2 oz.

" " " with active material, 25 lbs. 6 oz.

Weight of active material, 9 lbs. 4 oz.

Where it is desired to obtain lightness, Mr. Winkler purposes to make the grids of an acid-proof, non-conducting material, such as celluloid, and to provide each of the V-shaped troughs with a metallic conductor, and to connect all the wires of one plate together so as to form the electrode. Mr. Winkler usually employs as the electrolyte in his batteries a compound of sulphuric acid, silicate of soda, and sulphate of ammonia. The compound is poured in in liquid form and after a short while congeals into a gelatinous mass, which keeps the plates firmly in place and at the same time avoids the spilling of the liquid, which might occur when the batteries are used for traction purposes.

THE NEW BOSTON TELEPHONE EXCHANGE.

The inadequacy of the facilities for their constantly growing business in Boston some time ago forced upon the New England Telephone and Telegraph Co., the necessity of enlarging their central exchange and they determined to erect a building specially adapted to the wants of a telephone exchange and equipped with the most modern apparatus. After careful and minute planning this building was begun, and on July 11 the old exchange was transferred to the new without the slighest interruption of services.

The new exchange is situated in the new building of the American Bell Telephone Co., at the corner of Milk and Oliver Streets, which occupies a lot 90×100 feet. The building is nine stories high with an additional story of smaller dimensions than those below. The building is constructed of brown brick and Scotch brown sandstone, and is of fireproof construction throughout, so that should a fire originate in any of its apartments it could not spread or do any damage beyond that place.

Of the nine stories, the lower five will be rented for business purposes. Upon the sixth are the executive offices of the American Bell Telephone Company, as well as the treasurer's office, and the office of the legal department. Upon the seventh floor are the offices of the electrical and patent departments, the archives, and the offices of the auditing and statistical departments. The eighth floor is occupied by the business offices of the New England Telephone and Telegraph Company, consisting of the general executive offices, the office of the Boston division, the treasurer's department, and the offices of the electrician, engineers, and the auditor and secretary. The ninth story, and the small tenth story already mentioned, are entirely occupied by the operating department. The corridor floors are all laid in mosaic, and the dado work is of the finest polished marble.

The basement contains the heating and ventilating apparatus, the dynamos for the electric lights with which the entire building is equipped, and the elevator machinery, beside affording storage room for the supplies of the New England Company. The electric light plant is one of the most compact and complete of its kind to be found anywhere. The steam plant, from which the power is derived, consists of a battery of two Whittier Machine Company's boilers of 55 h. p. each. There are two high-speed Ide engines of 70 and 40 h. p., respectively and two Western Electric Company's incandescent light dynamos, one with a capacity for generating current for 500 lights, and the other for 800 lights.

One of the most prominent features of the building and equipment is the conduit and cable system employed. All the wires enter the building through underground cables. From the Milk street conduit there are 50 ducts that enter the subway, each duct capable of accommodating a cable carrying 120 wires. At the corner of Milk and Oliver streets what is known as the State street conduit enters the subway. This has 27 ducts for cables. On the Oliver street side, near the south end of the building, the Oliver street conduits are reached. These have 70 ducts, of like cable capacity with the others.

The subway is lined on either side and overhead with iron racks on which are hung brackets to support the cables entering the buliding from the various conduits. Not only this, but under the concrete flooring of the subways there are a number of ducts which are employed for the same purpose. All the cables received into this subway are carried to or converge into the cable shaft at the south end of the building. This shaft is 5x10 feet in area, and is carried up from the basement to the ninth story, a distance of over 100 feet, between solid brick walls, where the various wires which are comprised in the cables are connected with the switchboard apparatus of the operating room.

The ninth floor of the building, a plan of which is shown in Fig. 1, is entirely given over to the operating department. The cables carrying the lines come from the ducts in the street up through the shaft provided, as stated, specially for them in the body of the building, and enter the distributing room, part running through ducts in the walls

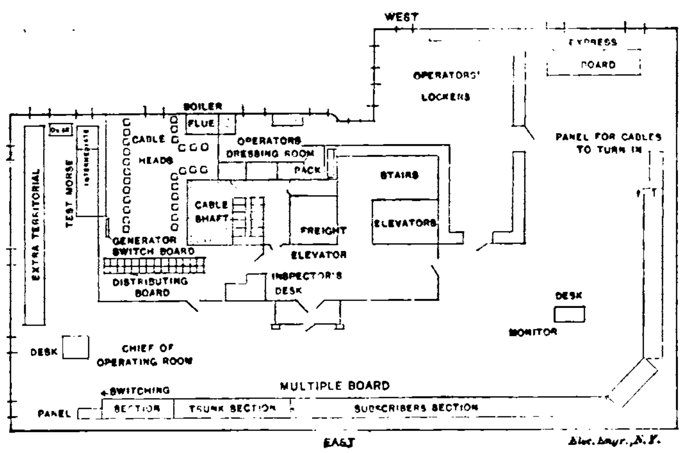


FIG. 1.—PLAN SHOWING ARRANGEMENT OF MAIN OPERATING ROOM.

near the floor to the lower row of cable heads, and part through ducts in the ceiling to the upper row of cable heads. They are so arranged that they do not cross each other in any part of their course, so that any cable may be removed and replaced without disturbing any other cable.

The cable heads are in two rows, an upper and lower one, mounted on an iron framework placed a few feet from the walls of the room, so that the cable heads and the protectors may be accessible from both the front and the back, Each conductor in the cable ends in a binding post insulated from the iron of the cable head. From each binding post an okonite-covered wire runs to a Hayes combination strong-current protector which protects the switch apparatus from both strong and weak currents. From the protector, each circuit passes through a cable under the flooring to the outer terminals of the distributing or cross-board (shown in Fig. 1) which is of the latest Hibbard pattern, built of iron rods and tubing, and arranged so that in one division the wires shall be carried in a vertical direction and in a second division behind the first, so that they shall be carried in a horizontal plane.

The distributing board is 15½ feet long, 2½ feet wide and 9 feet high, has an ultimate capacity of 6,400 pairs, and is provided with a platform under which the wires come from the cable heads and run to the switchboards. At present the board is not wired to its full capacity, the terminals at one end being used for wires leading to extra-territorial apparatus, and at the other for wires leading to the local subscribers' apparatus, the space in the middle being left for future growth. To the inner terminals of the distributing board are connected the conductors running to the switchboards.

In describing the switchboards, it will be best to begin at the extreme right and describe the board in turn to the extreme left.

On the extreme right is a test and combination loop-board (Test, Morse, Fig. 1) with capacity for 1,020 telephone wires and 102 combination loops. The test-board is for the purpose of locating troubles by testing lines and for interchanging lines. At the board, the Circuit Manager, provided with telegraph and telephone instruments and galvanometer and rheostat, tests every line every morning, and gives orders to his men and the different managers to remove trouble located by him in their territory. The combination loop-board is for the purpose of handling combination loops.

Next to the Combination-Board is placed the Intermediate Switchboard (Intermediate, Fig. 1), having an ultimate capacity of one hundered and fifty pairs of wires for long-distance subscribers and ninety local trunk lines for connecting extra-territorial boards together. The eight Extra-Territorial Boards (Ex-Territorial, Fig. 1) are situated on the other side of the alcove. At these boards the extra-territorial and long-distance work is carried on. The regular multiple-board situated on the east and north side of the room takes the local subscribers', grounded and metallic, and suburban trunk lines. The board is made to grow from right to left and is built with an ultimate capacity of 6,000 subscribers' lines and 600 trunk lines, and is at present wired for 3,600 subscribers and 300 trunk lines. It is at this board that all the local exchange and suburban trunk-line connections are made and that the local subscribers are connected to the Long-Distance boards for ex-territorial business.

On the extreme right of this board is the extra-territorial switching section, provided with an end section on each

FIG. 2.—MULTIPLE SWITCH BOARD AND CHIEF OPERATOR'S DESK.

side for the convenience of the operators on the regular sections (Switching Section, Fig. 1). There are four operators on this section ; one connects the subscribers on the multiple board to the extra-territorial boards, two connect the extra-territorial boards to the regular multiple subscribers' board, and the fourth operator makes connections between suburban trunks.

Next in order come the trunk sections where all the suburban trunk lines end (Trunk Section, Fig. 1). These lines first multiple through the board and then come back to the trunk section to the drops and end in a double cord. There are three sections of trunk lines, a hundred lines to a section, and three operators to a section. At the left of the trunk sections are the fifteen subscribers' sections, shown in Fig. 2, with three operators to a section and eighty subscribers to an operator, and showing the Chief Operator's desk.

To each operator's telephone set, a circuit runs to the Monitor's Desk (Monitor, Fig. 1), and shown in perspective in Fig. 3; the monitor may cut in and hear if any impoliteness is being shown either to, or by, a subscriber.

The express board situated across the end of the room (Express Board, Fig. 1) on the extreme left of the board is for handling the express business. This express service is peculiar to Boston. There are six hundred subscribers for this service which consists only of calling expresses. No connections are made; the subscriber simply gives the order to the operator through a hand telephone. The

FIG. 3.—MULTIPLE BOARD AND MONITOR'S DESK, BOTH WITH CONNECTIONS UP.

operator puts the order on a slip and hands the slip across the board to the sending side. The operators on the sending side sort the slips and call up the different express companies and deliver the orders.

The drops on the regular multiple board are all placed in a trough to economize space, and the board is provided with an intermediate distributing board for interchanging the circuits between the multiple and the answering jacks. The drops on the intermediate board, the extra-territorial board and the express board are on the face of the board.

The battery and generator rooms are in the tenth story, a half story, to which the freight elevator runs. Three hundred cells of gravity battery will be placed in these rooms for the circuit manager's instruments and the busy test, etc.

The transmitters on the boards will all get their battery power from a four-cell accumulator which takes the place of 250 gravity cells. This accumulator is charged by a special dynamo run by a motor which gets its power from the regular lighting circuit. The 12 metallic circuit generators are run by the same motor that drives the accumulator dynamo. The generator circuits are provided with a switchboard of the cross-bars and pins pattern by means of which the circuits are interchanged and manipulated with perfect ease. The battery circuits to the different operators' sets are provided with fuses to protect the instruments from overcharge from the accumulators.

The engraving Fig. 4, shows the back of the board, exhibiting the cabling and iron and wood supports, the back of the cord shelf and the intermediate distributing board.

Three competent switchboard inspectors are constantly employed in testing and keeping in order the wires of the switchboard, the extent of which can be judged from the fact that the number of soldered wire connections in it are 448,856, and the number of feet of copper wire 14,943,868, or 2,745 miles of wire, all in comparatively short pieces. There are 133,126 distinct moving parts in the switchboard apparatus, and this only includes such separate pieces as are capable of being moved and require to be moved in position in the regular operation of the board.

The photographs from which our illustrations are made are the work of Mr. Willard Vandelip, of the engineering department of the New England Telephone and Telegraph Co.

While the general work connected with removal of the exchange was carried on under the supervision of General Manager J. M. Keller and his assistant, Mr. W. J. Denver, who has immediate charge of the Boston division of the company's business, the laying out of the routes of the cable conduits and supervision of all the underground work was in charge of Mr. Clarence J. Perkins, the

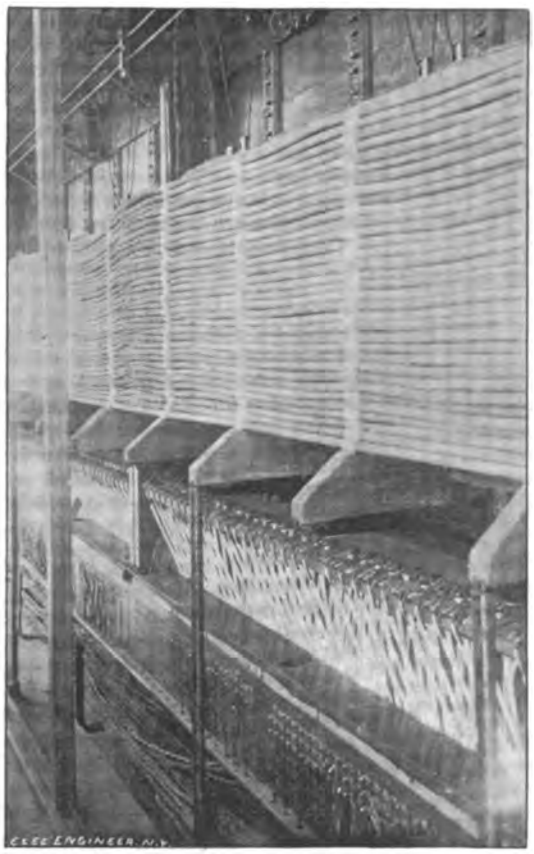

FIG. 4.—BACK OF SWITCH BOARD, SHOWING CABLING, SUPPORTS, CORD SHELF AND INTERMEDIATE DISTRIBUTING BOARD.

engineer of the company. The details of the electrical work, including the switchboard and its connections, were made under the direction of Mr. I. H. Farnham, the company's electrician.

The officers of the New England Telephone and Telegraph Company are: Thomas Sherwin, president; Henry S. Hyde, of Springfield, vice-president; S. W. Leedom, auditor and secretary; William R. Driver, treasurer; F. A. Houston, attorney; J. M. Keller, general manager; W. J. Denver, assistant general manager; I. H. Farnham, electrician, and C. A. Perkins, engineer.

REPLACING PLATINUM IN INCANDESCET LAMPS.

Word comes from Vienna that a Capt. Walter has discovered a method of amalgamating glass with other metals besides platinum, enabling manufacturers of electric lamps to make them at a cost much less than at present. The platinum wire used in the construction of the bulb is expensive, but it has nearly the same rate of expansion as glass. Changes of temperature cause both to change bulk at nearly the same rate, so that if the platinum wire once fills the holes through the glass it always does so, and thus prevents the inrush of air, which would be fatal to the life of the carbon filament. Reports have been current of similiar advances here, notably by an inventor at Louisville, Ky.

ADVANCES IN ELECTRIC HEATING.

BY

W. H. Mullen.

THE practicability of electrical heating has recently been receiving its conclusive demonstration. The time has come when apartments, wherever situated, on land or sea, moving or stationary, may be warmed by electricity. The uses to which electrical heaters may be put are far more numerous than those persons not interested in that particular branch of the electrical industry appreciate. The wide range of their usefulness comes home, perhaps, more forcibly to those engaged in the work of their commercial distribution. Hints, propositions, happy suggestions, incidentally remarked, bring forth delightful pictures of comfort, which, like good architects' sketches of some proposed edifice, are accurate representations of what is to be.

The thought that all the useful effects of combustion, as employed for the comfort of man, may by a slender wire be brought into our homes, thereby doing away with the customary periodical transportation of fuel, while at the same time all the disagreeable and even dangerous products of combustion, such as smoke, gas, and flame, are carried away a hundred feet above our heads by the tall chimneys of some power house, itself, perhaps, many miles distant, has no inconsiderable charm.

In any electrically heated house, the absence of clumsy heat and smoke conveying apparatus is noticeable, and in May, the month of universal house-cleaning, it would be still more noticeable, for no soot can be shaken from a No. 16 copper wire. In warm weather the electric heaters take the place of gas and oil burners for doing small cooking. Without the disagreeable dirt and odor of the latter, they perform within a few minutes such services as boiling an egg, warming a cup of tea or coffee, toasting crackers or bread. Put to this use upon train or shipboard, the results are especially pleasant. While at all times abundant warmth may be obtained from electrical heaters, they furnish, when desired, less warmth than those in present use. Thus upon cool spring and autumn evenings, when it is not cold enough for a fire in a furnace or stove, yet is disagreeably chilly, they render a delightful service. There is no arranging of fuel, regulating of draughts, or removing of ashes. Within a few minutes after the simple act of turning a switch is performed the chill disappears from the air. The heaters occupy but little space and may be formed into more shapes than stoves and other heating appliances at the present time.

What the incandescent lamp is to artificial lighting, the electrical heater is to artificial heating. As are the lamps, so will the heaters be distributed over the walls of our theatres and concert halls, shedding their warmth uniformly throughout the room as the former do their light, forming, it may be, the panels in some elaborate wainscoting or included in some ornamentation; they may not only provide warmth for our bodies, but also be the cause for the removal of the cumbersome, inartistic radiators, registers and steam pipes, which are forever obtruding themselves upon our vision. In general use, their safety, neatness, and labor-saving qualities recommend them to all who have at hand the electric current or convenient means for generating the same. It is not unreasonable to predict that by the time the idea of electric heating is as old as that of electric lighting or of electric traction, power stations for that particular purpose will also be erected.

While in such stations where the power is derived from steam engines, the expense of the heaters connected therewith may be somewhat in excess of that of coal, oil, or gas heaters, still that excess is no more than a just price for the increased convenience and comfort received therefrom. But in many places water-power is utilized for dynamo work. In such localities people easily recognize the economy of heating by electricity, and especially is this so when in those same districts the cost of fuel is great. Thus the Canadians, with whom the price of coal is high, while swift-running streams provide abundant mechanical power, are anticipating with enthusiasm the installation of power stations for supplying the adjoining territory with current solely for heating purposes.

Nearly all ocean steamships now are equipped with apparatus for electric lighting. Within a few years their dynamo capacity will be increased so that they may provide heat as well as light. One system of wiring will then perform the combined work of conveying light and heat and the necessity for the present expensive and difficult system of steam conductors will no longer exist.

There is, however, a more urgent necessity for electrical heaters in the railway world. Electric roads, such as traverse the streets of our cities, are beginning to utilize the means so convenient for them of heating their cars. With them, not only the actual cost of heating is reduced, but the incidental expense of caring for stoves and fuel on the cars is entirely removed. The greatest boon, however, will accrue by their use upon steam roads. Already there are roads taking active measures to place them upon their trains. A prominent representative of America's leading trunk line remarked a few days since that stoves and steam for heating purposes must give place to electricity, if the latter proved at all practicable. Railroad men realize that accidents are in some cases unavoidable; that their evil, at best, is great; but it will be appreciably lessened when the danger of death by burning or scalding is removed. The time is not remote, we believe, when a dynamo car will be as necessary an appendage to a train as the tender. It will contain one or more electric generators with accompanying steam plant. In fact, it will be a power station complete in every respect, having its own separate attendant.

Thus does the electrical heater bring to us increased convenience and comfort, cleaniness and safety. And it is not by great expenditure that this improved condition of affairs may only be secured. A foreign journal of recent issue contains the remark that the one obstacle in the way of the early introduction of electrical heaters into everyday use is their excessive expense. No greater obstacle can present itself than the reiteration of such erroneous statements. Both by repeated experiments and by actual service their economy has been proven. Of novelities people are suspicious. Unless complete success attend their first appearance they wrongfully are considered failures. However, the electrical heater, like all meritorious inventions, will survive such thoughtless suspicions, and even now includes itself among our economical modern improvements.

THE FATIGUE OF METALS.

WITH respect to statements that occasionally appear on the subject of the fatigue of metals under long-continued stress, a report that has recently been published regarding two similar suspension-bridge links is worthy of notice. A square iron link, 12 inches wide, 1 inch thick, and about 12 feet long, was taken from a bridge at Kieff, then about 40 years old, and tested against a similar link which had lain unused in store ever since the building of the bridge. The means of comparison were, therefore, excellent, and the result should go a long way to show whether or not iron really does lose any of its strength in prolonged service. The effect of the tests was to determine for the old used link an ultimate tensile strength of 21.8 tons per square inch, an elastic limit of 11.1 tons per square inch, an elongation of 14.05 per cent., and a contraction of 17.35 per cent. at the point of fracture. For the unused link, the tensile strength was found to be 22.2 tons per square inch, with an elastic limit of 11.9 tons, and elongation and contraction at fracture of 18.42 per cent. and 18.75 per cent. respectively. The two pieces of iron were, therefore, of practically identical strength; for the small difference actually observed is well within the ordinary range of variability of similar pieces of the same metal.

ELECTRICAL DEVELOPMENT IN THE SANDWICH ISLANDS.

BY

Jno Cassidy

As far as I am aware, little or nothing has ever been said about electrical development in the Sandwich Islands. I will therefore venture to tell the readers of THE ELECTRICAL ENGINEER, which is very well known in this part of the globe, what we have, what is needed, and what could be supplied with profit from the United States.

The Sandwich Islands are famous for their beautiful water-powers, and this power is being utilized for electrical work. The streets of Honolulu are lighted by 92 arc lights of 2,000 c. p. of the Thomson-Houston system, and the dynamos are driven by water-power. The same station furnishes 800 incandescent lights for residences and stores. This plant is the property of the Hawaiian Government. The Queen's Palace has a private plant of one Armington and Sims engine and two Thomson-Houston low-tension dynamos with a capacity of 600 lights. The Honolulu Iron Works have a plant of 75 lights, operated by a Mather incandescent dynamo. The Union Iron Works have an Edison plant of 75 lights. This enterprising concern have a Thomson-Houston motor in their pattern shop, and have now ordered a welding machine. The Oahu Railway has a private plant. The Waianae Plantation runs an arc system, not only out in the cane pieces but in the sugar mill. Nearly all the island steamers are furnished with electric light plants, annunciators, &c. The residences of planters on the other islands are also well supplied with the electric light.

Besides this, Mr. James Campbell, a wealthy land-owner, has installed at his Wikiki residence an accumulator plant furnished by the Edco Co., of Philadelphia; and Mr. Wilder, of the Wilder Steamship Co., has an accumulator plant at his residence. This is not a bad showing for the electric light.

The telephone industry is also in good condition. Honolulu itself has a population of 22,000 and a telephone system of 1,200 subscribers. On the island of Hawaii there are two telephone companies—the Hawaii Telephone Co. and the Hilo Telephone Co. The Maui Telephone Co. is on the island of Maui, and the Kaui Telephone Co. is on the island of Kaui. The telephones in use are from the American Bell Telephone Co., of Boston. The large plantations have also extensive private telephone service of their own. All telephone instruments and material are free of duty when entered by the company itself, giving the company an advantage over the merchants in the importation of electrical goods. Copper wire is extensively used in the construction of telephone lines, because of the salt air. A No. 12 iron wire circuit 9 miles long has been known to fall to pieces in less than two years, owing to the chemical action of salt water spraying on the galvanized iron.

There is also a general use of the telegraph in the island, and one hears a great deal about submarine cables between the Sandwich Islands and the American Continent. The great need of the kingdom is inter-island cable communication.

I might add that THE ELECTRICAL ENGINEER, with its well-filled pages of electrical knowledge, news and advertisements, is a familiar periodical, found on every island of the group, in the workshop and the plantation, in government offices and in the importing houses of merchants, through whose agencies a large quantity of electrical goods is imported.

THE NEW MATHER MOTORS AND POWER GENERATORS.

RECOGNIZING the demand for power transmission by means of the electric current, the Mather Electric Company has brought out a series of machines for that purpose which, while embodying the essential features of the well-known Gramme ring type, can be more readily insulated against the high potentials required for power service.

One of the essential features of the old type of Mather machines was a field magnet having the form approximately of the magnetic lines of force and consisting of one piece. In the new type the cores of the field magnet are straight, permitting the use of coils of wire that can be wound separately on a machine, while the rest of the magnetic circuit is practically a ring, and the whole, including the cores and pole-pieces, is cast in one piece without a joint.

The motors are built in sizes of 1, 3, 6, and 10 h. p. with two poles, and 20, 30, and 40 h. p. with four poles.

The generators are built up to 30,000, 50,000, and 75,000 watts with four poles, and 180,000 watts with six poles. Drum armatures are used in all the machines. In the four-pole machines the winding is such that the current has but two paths through the armature wires, and by a special method, devised by Prof. Anthony, no two wires having any great difference of potential are brought near each other.

The engraving, Fig. 1, which represents the 75,000-watt generator, shows the general character of all the four-pole machines, with the field magnet in one casting. In the 180,000-watt six-pole machine the field magnet is cast in two halves, but divided through the middle of two opposite poles instead of across the magnetic circuit.

The engraving, Fig. 2, shows the two-pole form adopted for motors up to 10 h. p. These small motors are wound and kept in stock for 220 volts, but can easily be wound for 110 or 500 volts, when desired. The winding is such that in no case is there a loss in the armature of more than four per cent., and the speeds run from 1,500 revolutions for the 10 h. p. to 2,500 for the 1 h. p. The variation in speed from full load to no load is never more than four per cent.

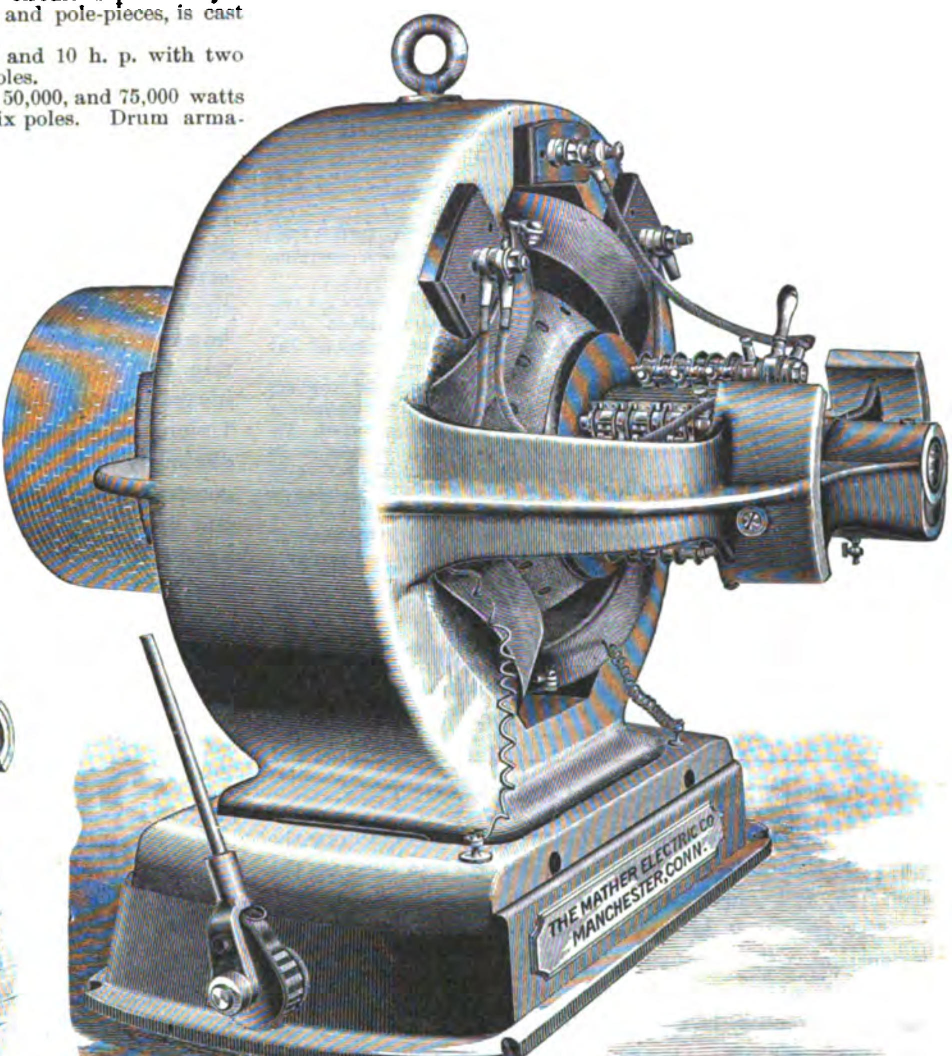

FIG. 1.—NEW MATHER 75,000 WATT GENERATOR.

CONSTRUCTION OF NON-INDUCTIVE RESISTANCES.

PROFESSOR AYRTON and Mr. Mather at the last meeting of the Physical Society presented a paper, says our London correspondent, on the construction of non-inductive resistances. In making some transformer tests about three years ago, the authors had occasion to consider the construction of electric conductors, the impedances of which should be practically equal to their resistances. This condition could only be fulfilled by making the inductance small in comparison with the resistance, and as the former does not depend on the material employed (excepting iron), it was important to use substances of high specific resistance. Carbon or platinoid being available, the latter was chosen on account of its low temperature coefficient. One form of resistance exhibited consisted of strips of thin sheet platinoid about 6 metres long and 4 centimetres wide. Each was bent at the middle and doubled back on itself, thin silk being placed between the contiguous parts, and narrow ribbon used to bind the parts together. Twelve such strips arranged in series had a resistance of 2.95 ohms, and would carry a current of 15 amperes without changing its resistance more than $\frac{1}{10}$ per cent. This strip resistance was made by Messrs. C. G. Lamb and E. W. Smith, who at the time were students in the Central Institution. Another form of resistance designed for portability consisted of bare-wire spirals, each length having a left-handed spiral placed within a right-handed one of slightly larger diameter, and the two being connected in parallel. This device was found to reduce the inductance to $\frac{1}{10}$ or $\frac{1}{20}$ of that of a single spiral, according as the diameters of the spirals approach towards equality. When the spirals are made of platinoid wire the ratio of inductance to resistance is very small, averaging about $\frac{1}{500000}$.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, *150 Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XII. NEW YORK, JULY 29, 1891. No. 169.

It is not alone to the actual inventions which have been made under the stimulus of the patent law that we must look for the fruits of that law; it is also to the power which has been acquired to make future inventions, to the patience and skill and intelligence which have been developed.—Chauncey Smith.

THE INCANDESCENT LAMP SITUATION.

WHILE the decision of Judge Wallace sustaining the Edison lamp patent has done much to clear up the situation, and must be looked upon as an award of substantial justice, it is easy to see from the proceedings in connection with the settlement of the decree that Judge Wallace himself entertains very fully the views that we set forth last week as to the desirability of moderation on the part of the victors. Our report in another column of what transpired shows him to believe that not a little consideration is due the vanquished, and that as far as he is concerned they are likely to get it.

Two expressions of opinion on the part of the court are very striking. As to the temptation to innocent, or even justfiable, infringement, it said: "The greatest cloud that hung over the patent was in its claims—in the language of the patent itself. *He did not much blame any infringer for assuming that he could go on and make any sort of an incandescent lamp without fear of that patent.*" Elsewhere, criticising the delay in testing the validity of the patent, as against infringement, Judge Wallace remarked: "What had influenced him very much * * * was the circumstance that there had been a long delay in the prosecution of the suit and the additional circumstance that the patent was one very well calculated to engender doubt in the minds of people who were making lamps as to whether it was good for anything, and then there was the fact that during this time a large amount of capital had been invested and a great many men were employed in making the lamps." Such language coming from the judge who has himself sustained the patent is, to us, most significant as an intimation of what he thinks should be done in the premises.

Unfortunately there are grave and serious difficulties in the way of such a settlement as we would like to see arrived at between the holders of the patent and other manufacturers of lamps. These difficulties consist chiefly in the fact that the Edison General Electric Co. has formal contracts with some seventy large sub-companies or licensees, giving them the sole right to the use of Edison apparatus in their respective territories. These territories, so far as we are informed, comprise most of the choice lighting area in this country, and evidently under this decision, these local companies inherit what can only be described as a "bonanza." It is a vested right of a very desirable character for them, and it is only natural and to be expected that they should seek to conserve and maintain that which would give them the virtual monopoly of incandescent lighting in the large towns and cities of the Union. We state the case broadly, because the point is obviously most important, and no one could blame local companies for trying to get the benefit of their contracts and investments. Local companies of whatever system have rights, and we are only sorry to say that parent companies in their "deals" have but too often forgotten the claims that their licensees had on them. Still, we are fain to believe that a wise and skillful policy will find a way out of the difficulties hinted at, and which certainly exist; and we must put on record our conviction that such a *modus vivendi* for the remaining two years of the patent ought at once to be sought for and found.

THE STORAGE BATTERY DECISION.

THE decision by Judge Coxe sustaining the patent of Mr. C. F. Brush on the employment of an active material mechanically applied to a storage battery plate, and thus reaffirming his former decision in a suit of like character, might reasonably have been expected, as the present case differed but slightly from that decided in Mr. Brush's favor as against the Julien Company. Judge Coxe's decision, however, contains a number of points which the inventor and intending patentee cannot too strongly impress on his mind. For instance, he emphasizes the care required in the drawing not only of the claims, but of the specification. Thus he alludes to the wording of the patent as being unnecessarily prolix and calculated to confuse the electrician as well as the lawyer, and hence introducing an element of doubt which might in some cases militate against the proper appreciation of the scope of the patent and its judicial construction. As he remarks, the ringing of changes upon a few given elements and the coining of new phrases and words do not constitute invention as contemplated in the patent law. While granting broadly to Mr. Brush the application of active material to the plate, Judge Coxe decides that there was no invention in the application of red lead in view of the fact that red lead is a form of oxide of lead, and, according to the inventor himself, an inferior material. The decision dwells at length upon the Italian patent granted to Mr. Brush, in which he describes a particular form of storage battery, and which, having expired, was brought forward as an argument for the expiration of the American patent. Setting on one side the recent decision of the Supreme Court on this point, Judge Coxe takes the view that the Italian patent was not intended to cover the same points as those claimed in the American patent, and hence he gives to the latter the broad character contended for it. Throughout the decision it is evident, and is so expressed, that the Court was disposed to give Mr. Brush the benefit of any doubts, and this action appears to be in keeping with a practice now becoming general in this respect. The same action can be traced in the recent decision of Judge Wallace in the Edison filament suit, and is, we are glad to believe, an indication that our courts are willing to protect an inventor in his rights independent of small "technicalities." It is to be hoped that this decision may finally place the storage battery in such a position that its commercial exploitation will no longer be retarded, as it certainly has been in the past, by the fear of legal complication arising to the user. Indeed, indications are not wanting to show that this will be the case in the immediate future.

A NEW PHASE OF ALTERNATING CURRENT LITIGATION.

Appearances indicate that the last word has by no means been said on the question of controlling patents in the alternate current system of distribution. A very general impression has prevailed in electrical circles that this matter was practically settled by the defeat of the Westinghouse Company's Gaulard and Gibbs patent, in the suit brought under it against the Sun Company, of Woburn, Mass., and decided by Judge Colt in 1888. In this case, it was in substance held that at the date of the patent there could have been no invention in the employment for a different purpose of a known variety of converter which transferred energy from high to low potential as distinguished from a conversion from low to high, but that something further was required to solve the problem of a successful system of electric distribution; that the Gaulard-Gibbs patent was limited to an organization for distribution in which the converters were arranged in series, and hence that the defendant, which used a multiple-arc arrangement, did not infringe. Now it appears that the Westinghouse company did not place their sole reliance on the Gaulard-Gibbs patent, but had also taken the precaution to secure Kennedy's invention of 1883, based on his discovery of the self-regulating properties of converters when arranged in multiple-arc, which was patented in this country in 1889. This patent, which we reprint in another column, is the one on which the Westinghouse Company has now brought suit against a local electric lighting company in Vermont, as mentioned in our legal notes a few weeks ago. The Kennedy patent covers in terms the essential principle of arranging converters in multiple arc, the only method, so far as we now know, of any great practical value; and in view of the language of Judge Colt's decision in the Sun case, it can hardly fail to be held to be a patentable invention. It would seem, therefore, that the issues involved in this latest suit are scarcely less important to electric lighting interests than those presented in the incandescent lamp case.

ELECTRIC POWER DATA.

American trade catalogues and publications have long since acquired a reputation not only for their typographical excellence and the beauty of their illustrations, but also for the large amount of valuable information which they contain and which not infrequently makes these publications a valuable treatise on the state of the art to which they appertain. This is, we think, specially applicable to the publications in the electrical trades, and we have on more than one occasion found space for their extended notice. That the value of such work is becoming more and more recognized is evidenced by the fact of its continuance, and two recent publications of this nature which have reached us, deserve, we think, special notice. The subject of power transmission by stationary motors, and for electric railway work, has now reached an importance second not even to that of electric lighting, and hence data on these two subjects, especially if of a practical, commercial character, will be welcomed by many. In the former domain, a recent publication of the C. & C. Electric Motor Co., from which we give copious extracts on another page, presents an excellent résumé on a question which has from the beginning given rise to much thought on the part of station managers. The proper basis of charge for the power supplied by electric motors must of necessity vary somewhat with the local conditions, but where these conditions are alike, the experience of one station will be an excellent guide for others who contemplate undertaking this class of work. The variety of methods offered as a basis, as well as the variety in character of the work of the motor, are excellently shown, and in this connection we would again call attention to the excellent paper by Mr. Lufkin read before the National Electric Light Association at Cape May in August, 1890, entitled "A Proper Basis for Determining Electric Motor Rates." The discussion of the relative merits of constant potential and constant current circuits also brings into strong relief the advantages of the former, but the existence of many continuous current circuits which now remain idle in daytime would make it appear that notwithstanding the objection cited, there is some room for a profitable utilization of this method of transmission in many cases where power distribution has not yet been attempted and where it can be done with practically little investment for new wires.

The data on electric railway work, compiled by the Field Engineering Company, gives an excellent idea of the cost of installation of such roads. It also brings out prominently the relative cost and economy of the high-speed and low-speed engine, as well as the single, compound and condensing engine, showing that in this respect too great care in the designing of a station cannot be exercised. Where the general information on all points connected with power distribution is still so meagre, such publications as those above mentioned are not only of value from the technical standpoint, but they indicate clearly the fact that the industry, as a whole, is now so well established that exact data is forthcoming, and that calculations based upon it can be relied upon in commercial enterprises.

ON THE MECHANICAL ACTION OF ELECTRICAL WAVES PROPAGATED IN CONDUCTORS.[1]

BY H. HERTZ.

AFTER studying various forms of apparatus to determine the forces to which a conductor is subjected when placed in the path of a series of electrical waves, and obtaining results that were quite concordant in respect to the points at issue, I adopted that used by Mr. Lecher, and shown in Fig. 1. Here A A' is the primary conductor, formed of two square plates of 40 centimetres side, joined by a brass wire 60 centimetres long. This wire is interrupted in the middle of its length, where the spark gap is placed. A small induction coil is used as exciter, worked by two accumulators, and producing sparks four centimetres long. The

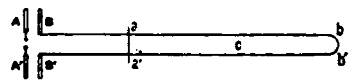

FIG. 1.

simple discharge of this little coil is certainly less powerful than that of a larger one, but the rapidity of the discharges compensates for the defect.

Facing the plates A A', at a distance of 10 centimetres, are the plates B B' attached to two parallel wires B *b*, B' *b'*, placed at 10 centimetres from each other. These wires are each 6.8 meters long, and their ends are connected at *b b'*. At a distance B *a*, which is variable, the two wires are also connected by a bridge piece *a a'*. For a certain position of this bridge, at a distance of about 1.2 metres from B B', a very energetic oscillation is produced at *a a'* and *b b'*. This represents the half length of a stationary wave, and, as Mr. Lecher has shown, it is produced by resonance between this vibration itself and the primary vibration produced in the air, between A A' on the one side and B *a a'* B' on the other. A displacement of the bridge augments the period of one of these vibrations, and at the same time diminishes that of the other, so that with this arrangement the proper position of the bridge is determined in a very precise way.

The forces to be observed being small, all extraneous electrostatic actions due to the presence of conductors must be carefully eliminated, which may be readily accomplished with this apparatus, as the wires form a system of continuous conductors. If, in our experiments, the active parts be surrounded by a metallic cage connected with the nodal points, *a a'* and *b b'*, they will be still more completely protected without altering their vibrations. The vibration is of the same character, independently of the form or position of the two wires.

For the measurement of the mechanical action of the electric force, I have used a little cylindrical tube of gilt paper 5.5 centimetres long, and 0.7 centimetres in diameter. This tube was suspended horizontally by a thread of silk. A minute magnet was affixed for controlling purposes, and a small mirror was used to indicate the deflections. The entire system was suspended in a little glass box, and is indicated in Fig. 2. When it is submited to the influence of the vibrations, the tube deviates and tends to set itself in the mean direction of the electrical force. To obtain greater deflections, I brought the two wires near together in the neighborhood of the apparatus, and reinforced their effect near the extremities of the body tested by two small plates, as Fig. 2 indicates, for a special case. Under these circumstances it was possible to obtain initial swings of over 100 scale divisions.

The results obtained differed by only a few per cent. As examples of the possibility of applying these deflections to purposes of measurement, I indicate two series of observations. The first shows the action of resonance. The apparatus was placed at *c*, the antinode of the vibration, and the wires *a b* and *a' b'* were brought near one another, as indicated in Fig. 2. The bridge piece *a a'* was then placed at different distances *e*, measured from B B', the induction coil was set working, and the value of *i*, the first swing was observed. The corresponding values of *e* and *i* in the neighborhood of the maximum were as follows :—

e	8,	90,	100,	110,	120,	130,	140,	150,	160 cms.
c	5.3,	10.0,	21.8,	51.2,	44.1,	19.3,	10.3	5.7,	4.2 div'ns.

The curve plotted from these values is very regular, and shows a maximum between 110 and 120 cm. The impulsive swing reached a maximum value, $i = 60.6$ divisions, for $e = 114$ cm.

The second series of tests was made with the view of showing the diminution in the intensity of the vibrations from the antinode *c* to the node *b*. For this purpose, the distance between them was divided into 12 equal parts, and the apparatus was successively placed at the 13 points of division so obtained. The following observations were made :—

No. =	1	2	3	4	5	6	7
i =	80.5 ...	80.5 ...	79.0 ...	77.0 ..	65.0 ..	57.8 ..	50.0
No. =	8	9	10	11	12	13	
i =	38.5 ...	27.5 ...	17.5 ..	7.0 ..	1.0 ..	0	

These values vary in a sufficiently regular manner for the purpose of judging the form of the vibration, and for making it evident that it differs in a very noteworthy way from a simple sinusoidal oscillation.

The result of other experiments on the direction of the electrical force in the neighborhood of the wires show that the extremities of the little tube seem always to be attracted toward the nearest portion of the wires.

For the study of the magnetic force, a ring 65 millimetres in diameter was used. This was suspended, as shown in Fig. 3, so that it could turn on one of its diameters, and furnished with a magnetic needle, a mirror, and a glass cage. Contrary to what might be expected, the ring does not remain at rest under the influence of the oscillations, but is acted upon by forces of the same order of magnitude as those evidenced by the action of the cylinder when placed at the antinode of the vibrations. Moreover, the direction of the deflection shows that the force between neighoring parts of the ring and cylinder is not an attraction, but a repulsion.

The repulsion is due to the oscillations, and its magnitude must depend on resonance, according to the same law as the electrical actions. The ring always sets itself perpendicular to the plane of the wire, whatever its position with reference to it, provided it lies within the contour *b b'*. We can deduce, therefore, from these experiments alone that, in addition to the electrical vibration, there exists a vibration of another kind whose nodes coincide with the antinodes of the former, and that the directions of the two classes of vibration are perpendicular to each other. Referring to the experiments, we can easily recognize the new vibration as magnetic. The rapidly oscillating magnetic force must, by induction, produce a synchronous alternate current in the closed metallic ring, and the reaction of this current produces a deflection. The magnetic force is a maximum at the nodes of the electric vibration, and at these points its direction is normal to the plane of the wire. That the action between neighboring portions of the ring and wire is a repulsion is easy to account for. The current induced in the ring is such as to neutralize within the ring the effect of the inducing current in the wire. The two currents accordingly flow in opposite directions and repel each other.

If the ring be moved away from the node *b* toward the antinode of vibration, the repulsion diminishes to zero, and then becomes an attraction, increasing until the antinode is reached. In a particular case the repulsion deflection at *b b'* was 20 divisions; it disappeared altogether at about 95 centimetres distance from the ends, and became an attraction, the maximum value of

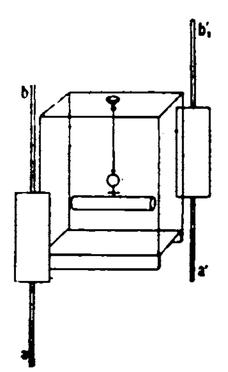

FIG. 2.

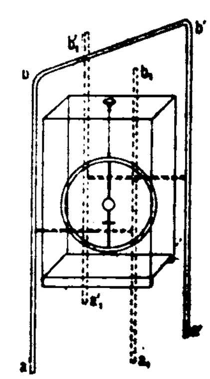

FIG. 3.

which was measured by 44 divisions. In order to explain these results it is necessary to consider the simultaneous action of the electric and magnetic forces, the former being greatest at *c*, and the latter at *b b'*. We can verify this explanation by investigating the variation of the magnetic force after having eliminated the action of the electric forces. With this view, place parallel to the wires *a b*, *a' b'*, two other wires of about 20 centimetres length, arranging the four wires symmetrically with regard to the equilibrium position of the ring as indicated by the dotted lines in Fig. 3. Also join *a b* to a_1 b_1 and *a' b'* to a_1' b_1'. In this way the electric action is evidently almost annulled, while the magnetic action is very little altered. We now observe a repulsion of the movable ring for all distances, diminishing to a minimum at the antinode of the electric vibrations. The minimum value is found to be four divisions. If the electric vibration was sinusoidal, the magnetic force would have disappeared at the node. The distribution of the electric force has already shown us that

1. Abstract of a translation from *La Lumière Electrique*, March 28, 1891.

this hypothesis is not exactly correct, and we can thus understand the existence of magnetic force even at the antinode. The mechanical actions of the electric and magnetic forces, as theory indicates, are in general of the same order of magnitude. The predominance of one or the other depends essentially on the mutual actions of the nearest parts of the ring and the solid conductor. The more nearly these are like infinitely short wires, the greater is the relative importance of the magnetic force; while the greater the surface of the conductors, the more the electric force predominates. From the above experiments on conductors of very simple form, it is evident that a conductor of any form, when placed in the path of a train of electromagnetic waves, is subjected to forces of a very complex character.

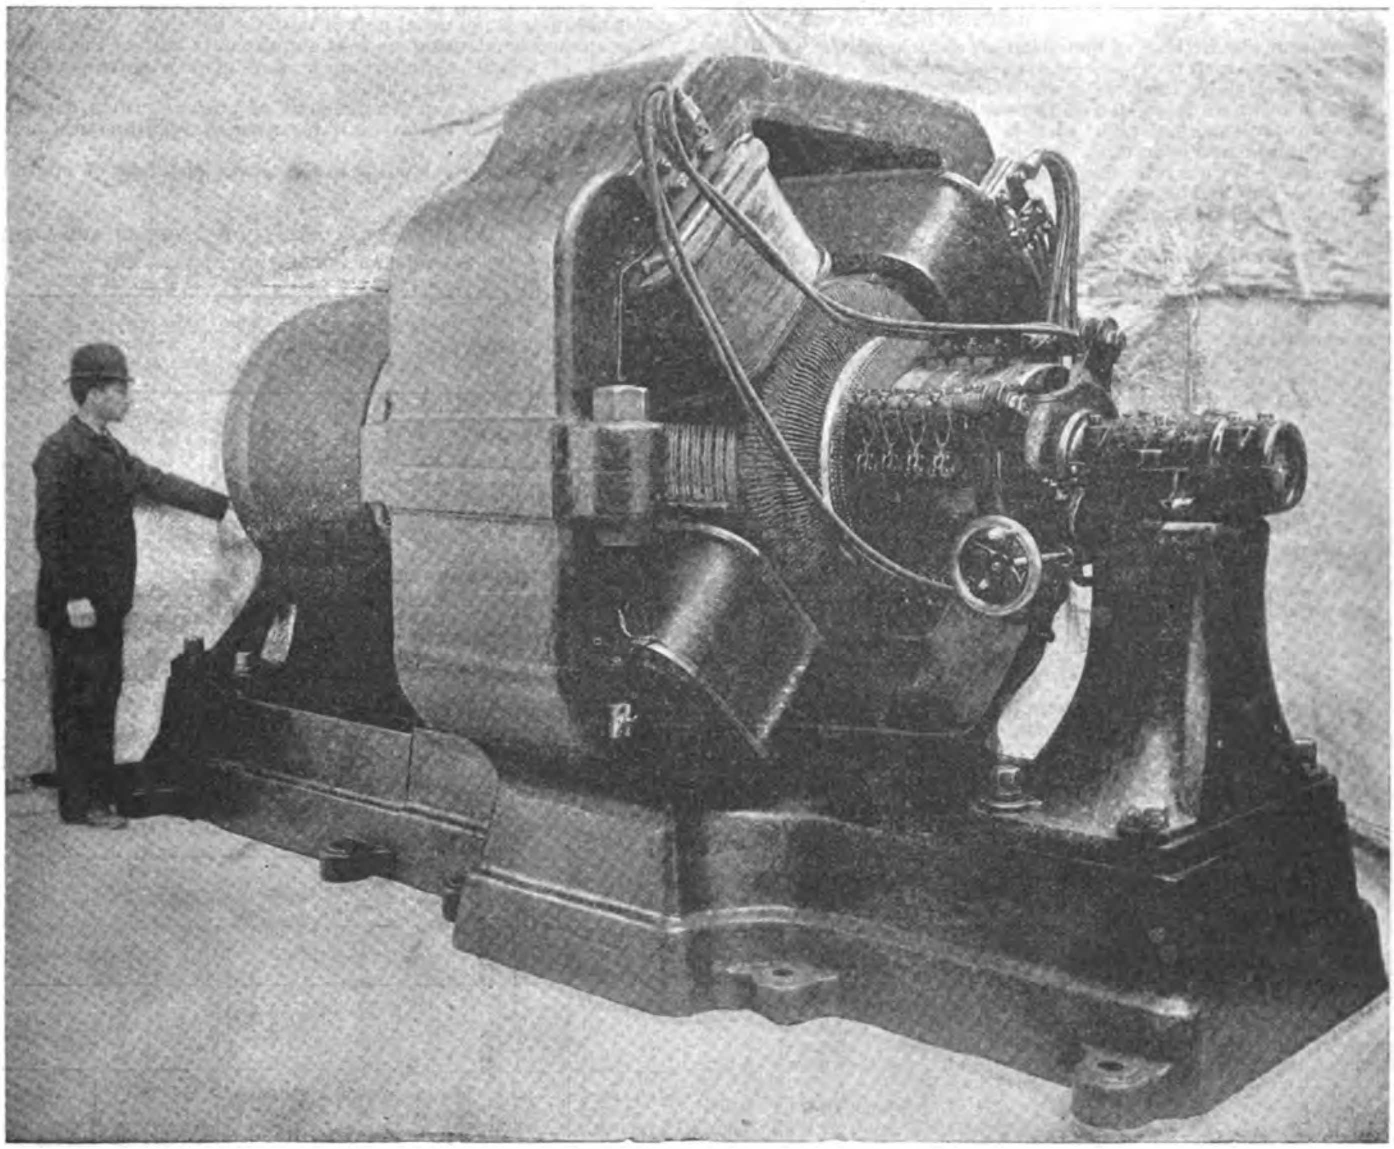
THE THOMSON-HOUSTON 250 H. P. GENERATOR.

The erection of power stations of large capacity for operating electric street railways in our large cities has created a demand for generators of greater output than have been heretofore employed. The first type of railway generator brought out by the Thomson-Houston Electric Company was a two-pole machine of the motor type pattern, having an output of 62,000 watts, which was followed by a four-pole machine of 75,000 watts capacity, which in turn has been followed by a generator of the same type, having an output of 250,000 watts.

The general construction of this machine will be readily seen from the accompanying illustration. The armature is of the Gramme ring pattern and so constructed that opportunity is afforded for the best insulation and the danger due to great difference of potential between any two of its conductors is avoided. This is a most valuable and important feature, as in case of accident or injury to any coil, it can be easily repaired without affecting in any way the remaining coils. The construction of the armature affords excellent ventilation, which is very necessary in dynamo machines, particularly as their size is increased, for the reason that the radiating surface does not increase in proportion to the size of the mass.

One of the most important features of this generator is the arrangement for lubrication and good alignment of the bearings. The boxes are made in two parts and are entirely separate from the stands. On the top of the stand is a seat into which the spherical surface of the box fits and in which the box is free to move. The bolts which secure it to the stand are smaller than the holes which are drilled through the box, so that a slight play of the box in the seat is permitted. The bearing shells or linings are removable, and are made in the following manner: A skeleton shell of brass is made, the interstices of which are filled with Magnolia metal. This is then bored and reamed to size, oilways being cut so that the oil circulation begins at the point where the oil rings touch the shaft. This method of manufacture permits of a perfect circulation of oil, ensures the cool running of the bearings, and greatly reduces the care and attention required by the dynamo when in operation. This type of box and bearing lining has proved so satisfactory that it is now being introduced in machines of smaller size, and will in future be used on all machines of large capacity. Whenever it is necessary to examine bearing linings, the armature is jacked up about one-sixteenth of an inch, so that the bearing is relieved of the weight, two bolts removed from each stand, and the entire box taken out. In case it is not desired to remove the box, the cap can be taken off and the bearing linings readily removed.

The movement of the brushes is effected by means of the shaft on which a small worm is attached, and which in turn works in a rack fastened to the yoke. By means of this a very fine adjust-



New Thomson-Houston 250 H. P. Multipolar Generator.

ment of the brushes can be made. The worm locks the yoke so that it cannot be moved except by hand.

In order that the conductors inside the armature may be held securely in place, an adjustable internal wire support has been designed. When the armature is being wound the wires are forced into position so that they cannot sag, vibrate, or chafe the insulation. All tendency to short-circuiting is thereby avoided and the position of the wires assured.

The commutator has 180 sections. In practice, the generator will have its fields separately excited, although the connection at the switchboard is so arranged that by throwing a switch the dynamo can be made self-exciting, should emergency require it.

The total floor space occupied by the 250 h. p. generator is 13 ft. 3½ in. x 7 ft. 1 in. The height of the machine is a little less than 8 ft. The pulley is 48 in. in diameter and has a 35 in. face. The speed is 400 revolutions per minute and the dynamo, complete, weighs about 21 tons.

FIELD'S DATA ON ELECTRIC RAILWAY WORK.

WHILE the method of operation of electric railways and the advantages which they possess over other forms of traction are now getting to be fairly well understood, there are still a large number of those interested in the subject to whom a handy résumé of the principal data, such as the power required, cost of construction and operation, etc., of electric railways would be welcome. With a full recognition of this desideratum evidently in mind, the Field Engineering Co., of this city, have recently published an excellent little folder, from which we take the following data:

The cost of an electric car equipment, including two motors, truck and car body complete, is from $3,200 to $3,500. There should be installed in generating capacity for power plant twenty to twenty-five horse power per car operated, which will give reserve power. The cost of generating power is from three to five cents per car mile. A car uses under average conditions one h. p. per car mile per hour. That is, a car operating at a speed of five miles, five h. p., at eight miles, eight h. p.

Cars are generally equipped with two fifteen h. p. motors. The tendency at present time is to slower speed motors, thereby reducing amount of gearing. The attainable speed with electric motors is limited only by condition of road-bed and local requirements; 130 miles an hour has been attained experimentally. Electric traction means rapid transit and increase of traffic of from 40 to 200 per cent. and moderate reduction in operating expenses per car mile.

One mile of single-track construction will cost complete with sixty-five pound girder rail, ties two and one-half feet on centres, bonding of rails, paving, etc., $9,000 to $10,000. The cost of the electric part of power plant, including generators, switchboard, etc., installed, is $35 to $45 per h. p.

Line construction per mile, complete, including track bonding, plain pole work, cross-suspension or bracket with feed wire................	$2,000 to $2,500
Sawed and painted poles,......................	2,500 to 3,000
Iron poles, concrete setting, cross suspension, double track, feed and guard wires............	6,500 to 7,500
Same with centre poles.........................	4,500 to 5,500

An electric car averages 100 to 125 miles a day.

The accompanying table gives the

COST OF ELECTRIC EQUIPMENTS FOR STREET RAILROADS.

No. of cars.	Steam plant. H. P.	Capacity of generators. K. W.	Steam plant.	Station electrical equipment.	Car equipments, bodies, trucks and motors.	Line construction ½ mile of double track per car.	Total equipment (omitting track).
6	120	80	$7,000	$6,400	$19,500	$15,000	$47,900
10	225	150	11,000	10,500	32,500	25,000	79,000
15	375	240	17,500	15,000	48,750	37,500	118,750
20	450	300	22,000	17,500	65,000	60,000	164,500
30	675	450	28,000	22,000	97,500	90,000	237,500
50	1,125	750	50,000	33,000	162,500	187,500	483,000
100	2,025	1,350	90,000	60,000	325,000	375,000	850,000

The above figures are approximate only and based on the best city railroad practice.

The cost of steam plant complete is for high speed $45 to $55 per h. p., and for Corliss, $65 to $75 per h. p. The number of units of power in power plant should be as few as is consistent with safety and economy of operation, but not less than two.

Engines operate at a piston speed of 600 to 800 feet per minute, high speed, so called, having in general the lower piston speed and shorter stroke and higher rotative speed or number of revolutions, and the Corliss the reverse. Corliss engines generally operate at 75 to 100 revolutions, and larger high speed, 150 to 225 revolutions. Belt generators direct to engines with Corliss and high speed, thus making each unit independent of all others; one generator to each engine is preferable.

Avoid use of counter-shafting by the above methods, and make belt centres as long as practical; 20 to 30 feet for high speed, and 40 to 50 feet with Corliss.

Engines on railway work should be built very heavy, and have ample fly-wheel capacity to relieve the working parts of the excessive strains due to changes in load.

Compound engines should not be run non-condensing on railway work; the loads are too variable.

Every effort should be made in locating power plant to obtain facilities for condensing, and operate plant wth compound condensing engines.

Ten to thirteen sq. ft. of heating surface evaporating 30 lbs. of water per hour is the usual unit of h. p. for boilers.

Compound condensing engines require only half of the boiler capacity of single cylinder ones, and give a corresponding economy in coal consumption.

On the designing and arrangement of power stations depend the economy of operation both for present requirements and future developments.

The best practice is tending to the direct coupling of engine and generator.

THE RELATIVE COMMERCIAL ECONOMY OF ENGINES AND COST ARE AS FOLLOWS:

Type.	Lbs. of coal per h. p. hour.	Cost per h. p. sizes over 100 h. p.	This is based on an evaporation of 9 lbs. of water per lb. of coal.
High speed single	4 to 5	$11 to $13	
" " compound	3 " 3½	14 " 16	
" " " condensing	2¼ " 2½		
" " triple	1¾ " 2	18 " 22	
Corliss single	3½ " 4	16 " 18	
" compound condensing	1⅔ " 2	22 " 25	
" triple	1½ " 1⅔	27 " 30	

THERE ARE THREE CLASSES OF BOILERS:

1. Horizontal return tubular, which is the most general in use, and costs $9 to $10 per h. p.

2. Vertical tubular (Corliss or Manning), which is a vertical tubular boiler with water leg, giving an internal fire-box, economical in floor space, largely used throughout New England. Cost, $10 to $12 per h. p.

3. Sectional or water tube boiler, of which Babcock & Wilcox is the best known, especially adapted for higher pressures and safety. Cost, $17 to $19 per h. p.

CAPACITY OF ENGINE REQUISITE FOR DIFFERENT GENERATORS.

Generators.	Engine.						
		High speed.			Corliss.		
Watts.	H. P.	Size.	Speed.	Wt. 2 fly wheels.	Size.	Speed.	Wt. 2 fly wheels.
50,000	75	12 x 12	280	7,000 lbs.			
80,000	125	15 x 16	225	9,000 "			
150,000	225	18½ x 18	200	15,000 "	20 x 36	90	25,000 lbs.
2-150,000	450				24 x 48	80	50,000 "

Steam pressure, 100 lbs.

All information here given represents the more advanced standard of construction, and the prices quoted are for the highest class of work and materials.

NEW FORMS OF INCANDESCENT LAMP.

As intimated in our columns last week, the Edison lamp decision is stimulating work on forms that will not infringe, and various rumors are current. It is stated from the West that a new lamp will very shortly be placed on the market which will not infringe on any of the incandescent lamp patents in force. Further particulars are promised at an early day, and their publication will be very eagerly awaited.

C. & C. DATA ON ELECTRIC POWER TRANSMISSION.

A most interesting and valuable pamphlet has just been issued by the C. & C. Electric Motor Co., devoted entirely to the discussion of questions connected with the transmission of power electrically for stationary motor work. One portion of it is practically a reprint of Mr. Lufkin's admirable paper read before the National Electric Light Association on "A Proper Basis for Determining Electric Motor Rates," and includes the tables or diagrams proving his argument as to the necessity of making rates on "maximum readings." Another very valuable section includes a series of forms of contract for motors and power current. A third section embraces the various rates charged for electric power. We have ourselves published a number of such rates before, but are glad of the opportunity to give these:

NEW YORK.

	INTERMITTENT WORK. Per month.	FREIGHT ELEVATORS. Per month.
⅛ h. p........	$3 00	......
¼ "	5 00	......
½ "	8 00	......
1 "	12 50	$10 00
2 "	22 50	15 00
3 "	30 00	18 33
4 "	36 66	21 66
5 "	43 75	25 00
6 "	50 00	28 33
7 "	56 88	31 66
8 "	63 33	35 00
9 "	69 37	38 33
10 "	75 00	41 66
15 "	100 00	60 00
20 "	125 00	......
25 "	145 83	......

Based on maximum readings.

Continuous work, 50 per cent. extra.

METER RATE.

10 cts. per h. p. per hour with discounts as follows:

	Horse power hours per month.	
On bills for	100 to 200	....20 per ct.
" "	200 to 400	.....25 "
" "	400 to 600	.....30 "
" "	600 to 800	.....35 "
" "	800 to 1,000	.....40 "
" "	1,000 to 1,500	.....45 "
" "	1,500 or over	.... 50 "

CHICAGO, ILL.

Applicable to classes of work in which the rate of power consumption is uniform, or nearly so, such as operating ventilating fans.

	Per month.		Per month.
¼ h. p. ...	$5 00	7 h. p.....	$65 45
½ "	8 50	8 "	78 20
1 "	14 00	9 "	81 45
2 "	25 00	10 "	90 00
5 "	50 75	15 "	135 00
6 "	57 90		

Applicable to classes of work in which the rate of power consumption is variable, such as operating machinery for printing, sewing, embossing, wood and metal working, pumping for hydraulic elevators, coffee grinding, baking, etc.

	Per month.		Per month.
⅛ h. p.....	$3 00	6 h. p.....	$42 60

5 "	18 00
7½ "	25 00
10 "	30 05
15 "	40 00

A great many excellent points are made in the discussion of electric power. With regard to dynamos it is said:

In selecting a dynamo for a commercial power circuit a series or constant current machine should not for a moment be considered. The argument that it requires less copper for the circuits is a snare. A constant potential dynamo of 500 volts pressure (or less where limited areas are to be covered) is the only dynamo which should be considered, and the size should be as large as the prospective supply of power will warrant. There are, however, conditions found in special transmissions of power where a potential of 1,000 volts or even higher may to advantage be employed. Let us for a moment compare these different types of machine. To approximate the output of a 50-light constant current or series dynamo we will analyze the duty which it performs. One arc lamp (10 amperes, 45 volts) consumes 450 watts of energy, or a total energy of 22,500 watts consumed in the 50 lamps. In a circuit of 10 miles of No. 5 B. & S. wire there would be a resistance of about 17 ohms and a consequent loss in energy of 1,700 watts in the circuit carrying 10 amperes of current, which, added to the 22,500 watts consumed in the lamps, makes the total output of the dynamo 24,200 watts. To develop this energy of 24,200 watts (50 arc lights) the average series or constant current dynamo requires 50 h. p., indicated in the engine in the station.

With this same 50 h. p. indicated in the engine we will guarantee to deliver with one of our constant potential power dynamos from 30,000 to 35,000 watts at the dynamo terminals according to the loss in friction in the engine. In other words, approximately 25 per cent. greater output of electrical energy for the same indicated horse-power in the engine. This saving of 25 per cent. in engine and gross dynamo capacity will more than pay for the difference in cost of copper for the constant potential circuit, besides requiring 25 per cent. less fuel for the continuous operation of the plant. Again a potential of 500 volts is incapable of doing serious bodily harm, and for this reason, if for no other, should commend itself for almost universal use.

On the subject of rates, the disquisiton is very pithy: To establish an equitable power rate has been a somewhat difficult task, in the first place because of the unwillingness of both the company supplying the power as well as the user to rely on a meter measurement of the power consumed; and in the second place, the difficulty of correctly estimating the power which will be used in driving a given lot of machinery for ten hours each day, and on this estimate basing a contract rate. This condition of affairs first led to the adjustment of power rates solely on the basis of the possible or rated horse-power of the motor employed. While, in general, rates established on this basis are unsatisfactory and even unjust to the consumer, they are necessary in the case of motors on series or constant current circuits for the protection of the station, it being a fact that the fluctuations in power on the circuit show littl eeffect in the saving of the initial power in the station. Not so on a constant potential circuit, and the method of rating just described was soon discarded for what is generally known as a "Maximum Reading" rate, the customer being charged for power on the basis of the maximum reading shown on an ampere meter placed in series with the motor from time to time as the circumstances of the case required, or on the addition of any new machinery. In some of the contract forms is a clause giving authority for making this reading from time to time. From records obtained from all parts of the country and from many different classes of machinery being operated by electric motors, it has been determined beyond a chance of error that the general average use of an electric motor does not exceed 40 to 45 per cent. of its rated capacity, while the average maximum load carried by the motor as shown by these same records does not exceed 65 to 70 per cent. of its rated capacity. To make this possibly a little more clear: On a circuit to which is connected 100 h. p. in rated motor capacity, the electrical horse-power supplied to this circuit in the station will not exceed, as a maximum, 70 h. p., and the average power supplied will not exceed 45 h. p. On one circuit with which we are familiar this maximum of 70 per cent. was only reached once during a stated month and then but for a period of about five minutes. On several circuits the average station reading is as low as 25 to 30 per cent. of the gross motor capacity connected. Hence, it will be seen that a motor rate based on 70 per cent. of the indicated horse-power of any given motor of high efficiency to be supplied with current will obtain for the station a high rate for the power. The conditions here outlined cannot be obtained with cheap and inefficient motors. In a recent case a 25 h. p. motor of our make was installed in place of a 15 h. p. of another make, the duty required of the motor being increased about 25 per cent. over that required of the 15 h. p. machine, the station supplying the power increasing their charge per month in proportion. The records on this motor show that the current supplied at present is no more than was supplied to the 15 h. p. machine, while the station is receiving a 25 per cent. increased revenue. In establishing a contract rate for electric power this matter of efficiency and and reliability of the motor will be found an all-important factor.

An electrical horse-power in the station should not cost to exceed 1¼ cents per horse-power per hour, or at the rate of $45 per year per horse-power with coal at $3.50 to $4.00 per ton. On this basis of cost in the station and adding 10 per cent for loss in the circuit and 10 per cent. for loss in the motor, it makes the cost of an actual horse-power delivered to the user $54.45 per year, or $4.54 per month. Taking the rates of the Brooklyn Edison Co. on a 10 h. p. motor, published in this pamphlet as an illustration, they being the cheapest rates we know of where steam power is used, we will illustrate the method of charging before referred to, and the profit to be derived at the Brooklyn rate for power. The cost of coal in Brooklyn averages about $8 per ton:

Motor in use, 10 h. p.
Maximum reading on motor, 70 per cent., 7 h. p.
Average power delivered by motor, 45 per cent., 4½ h. p.
Rate for 7 h. p. per year.......................... $470 00
Cost of 1 h. p. delivered per year.................. 54 45
Cost of 4½ h. p. delivered per yer.................. 245 02
Profit.. 224 98

ELECTRIC LIGHTING BY MUNICIPAL AUTHORITIES.[1]

BY PROF. HENRY ROBINSON, M. I. C. E., M. I. E. E.

A REVIEW of the subject of public lighting, which concerns municipal authorities very closely, shows that for the lighting of streets arc lamps are the most economical. The smallest made require five amperes of current, but it is not desirable to use less than six. The candle power varies with the angle at which it is measured, 40° below the horizontal line being a maximum for constant current lamps. The following table gives the approximate candle-power at various angles. The height of the lamps should be arranged so as to give an angle of not less than 7° to the most distant point which it is intended to serve:

LIGHTING POWER OF ARC LAMPS.

Current in amperes.	Horizontal.	At angle of 7°.	At angle of 10°.	At angle of 20°.	Maximum at angle of 40°.
	c. p.	*c. p.*	*c. p.*	*c. p.*	*c. p.*
6	92	175	207	322	460
8	156	300	350	546	780
10	220	420	495	770	1,100

The following table gives the cost of working arc lamps:

Current in amperes.	Average candle power at angle of 20°.	Watts required.	Units used per hour.	Cost of current at 3½d. per unit.	Cost of carbons .50 and fixing .16.	Total cost per lamp hour.	Cost per average candle-power per hour.
				Pence.	*Pence.*	*Pence.*	*Pence.*
6	322	300	0.3	1.05	0.66	1.71	·00531
8	546	400	0.4	1.40	0.66	2.06	·00377
10	770	500	0.5	1.75	0.66	4.21	·00313

The last column in the table gives the cost per candle-power per hour, and these figures are arrived at by dividing the "total cost per lamp hour" by the figures representing candle-powers "at an angle of 20°" (given in the table of lighting power), which represents a fair average of the power from arc lamps.

Arc lights should be placed high up on account of their high candle-power and great distance apart, because the light thrown down at an angle is much greater than that cast horizontally, and because the light given horizontally is not so steady as that which is thrown down at an angle.

The following data enable the coefficient of minimum lighting power in streets to be determined:

Let P=candle-power of lamps.
L=maximum distance from lamp in feet.
H=height of lamp in feet.
X=a coefficient.

The light falling on a unit area of pavement varies inversely as the square of the distance from the lamp, and is directly proportional to the angle at which it falls. This angle is nearly proportional to the height of the lamp divided by the distance. Therefore,

$$X = \frac{P}{L^2} \times \frac{H}{L} \quad \text{or} \quad X = \frac{PH}{L^3}.$$

The usual standard of gas lighting is represented by the amount of light falling on a unit area of pavement 50 ft. away from a 12-c. p. gas lamp 9 ft. high, which gives a coefficient as follows:

$$X = 12 \times 9 \div 50^3 = \cdot 000864.$$

Adopting the above coefficient, I calculate that the before-mentioned sizes of arc lights will give the same standard of light at the heights and distances stated in table A.

1. Abstract of a paper read before the London Meeting of the Association of Municipal and County Engineers.

TABLE A.

Current in amperes.	Height of lamps.			
	20 ft.	25 ft.	30 ft.	35 ft.
	Maximum distances served from lamp in feet.			
6	160	175	190	203
8	185	202	220	235
10	205	225	243	260

Table B gives the corresponding distances, assuming the minimum standard to be doubled, thus bringing the coefficient up to .001728, which represents the amount of light on a unit area 50 ft. away from a 24-c. p. lamp 9 ft. high:

TABLE B.

Current in amperes.	Height of lamps.			
	20 ft.	25 ft.	30 ft.	35 ft.
6	130	144	155	166
8	150	165	180	193
10	170	190	205	220

The distances apart of the lamps would, of course, be double the distances mentioned in tables A and B.

One arc lamp will take the place of from three to six gas lamps, according to the locality, arrangement, and standard of light adopted. A scheme of arc lighting, based on the substitution of one arc light on the average for 3½ to 4 gas lamps, would double the minimum standard of light, whilst the average standard would be increased 10 or 12 times.

ELECTRICITY vs. THE HORSE, IN BOSTON.

The following statistics concerning the comparative operation of the West End Street Railway as respects horses and electricity in the months of April and May have been given out. The West End, it is to be borne in mind, is as yet imperfectly equipped electrically, buying its power where it has not had time to complete its own plant, and has labored under the many organization disadvantages arising from so great a change as from horse to electricity:

APRIL STATEMENT.

	Electric.	Horse.
Gross receipts	$134,321	$344,896
Net earnings	48,487	67,449
Per cent. operating expenses	63.86	80.62
Earnings per mile run	34.05c.	31.77c.
Net earned per mile run	12.30c.	06.22c.

MAY STATEMENT.

	Electric.	Horse.
Gross receipts	$144,638	$374,605
Total operating expenses	84,163	269,556
Net earnings	60.475	105,049
Per cent. operating expenses	58.18	71.95
Earnings per mile run	38.43c.	34.22c.
Net earned per mile run	16.07c.	09.60c.

The long electric cars make an even better showing than the above. They are operated by the same sized Thomson-Houston motors as the smaller cars, and by reason of increased capacity earn considerable more per mile. The company is operating seventy-five of these cars now, has seventy-five more in the shops awaiting adjustment of trucks, and will eventually have many more in operation. These long cars earned $83,000, or forty-four cents per mile operated, in May, and forty-six and nine-tenths cents per mile operated in the first half of June, the latest obtainable figures.

When the West End has finished its own power houses it is calculated that it can reduce expenses of operating its electric cars to at least twenty cents per car mile, and with the long cars, earning above forty cents per car mile, it can considerably extend the long car service and still operate them upon a basis of fifty per cent. for expenses.

The West End service covers about 18,000,000 car miles run per annum, and it is not difficult from this fact and the data above given to figure that the change from horse to electricity is more than worth the expenditure upon capital account.

The net earnings of the West End gained over the previous year $15,000 in May, and though the figures are not yet made up, it will probably show a gain of $30,000 net for June. The net earnings of June and July should be about $200,000 for each month.

KAPP, RECKENZAUN AND JARMAN AT THE ENGLISH TRAMWAY INSTITUTE.

THE Tramway Institute at their annual meeting gave a fair opportunity to the discussion of electric traction and I think, writes our London correspondent, it may have some good results. The Institute is fortunate in possessing a president who is well acquainted with traction work in America; therefore he could bring experience to bear upon any discussion which might arise. Electric traction was represented by such men as Kapp, Reckenzaun, Holroyd Smith, Gordon, Jarman. Mr. Kapp presented a paper on the Lineff system. It was a little fuller than the paper read at the British Association last year. The lecturer referred to the conditions of closed conduit and compared it with the slotted rails at Buda-Pesth, where there is an underground conductor. The author maintained that such an underground open conduit system is rather expensive and was objected to by the general public and by tramway men. Lineff's system, therefore, in his opinion, offered advantages, both in cost and convenience, over the older rival. Overhead conductors would not be started in England, and storage-battery cars were too heavy, as the power necessary to propel the vehicles was in the proportion of 11.5 to 6.5, the larger figure represented the energy requisite for the battery car over a car deriving its current from a metallic conductor. This not only affected the coal bill, but also the depreciation and interest upon the larger plant required. The estimated cost of Lineff conduit was about £2.500 per mile of double track. It contained two conductors, the current being returned by the tram rails and the earth. Regarding the efficiency of the system, it was ascertained that 14 per cent. of the power is lost through exciting the large magnet which actuates the movable conductor; another 4 per cent. is wasted in propelling the said magnet over the line, and the other loss estimated at 1 per cent. is due to leakage on the straight surface. All other loss, such as that due to resistance, is the same as any other system requiring conductors. The insulation resistance in the channel had been materially improved. In the original line it was 4475 ohms per mile, and that was obtained when the entire surface of the conductor was resting upon the bottom of the channel. The present improvement consists in supporting the metal strip upon divided insulators, whereby the surface of contact is enormously diminished, with the result that this resistance has been increased to 85,000 ohms per mile. Further improvements might be effected by blowing air from the channel, and thus effectually carrying off any accumulated moisture.

Mr. J. Sturgeon contended that the line on which the results had been obtained was too short for any definite information to be given of the system. Mr. Reckenzaun, in rising, said he was bound to take exception to several of Mr. Kapp's statements with regard to the insulation measurements of Mr. Lineff. It appeared to him somewhat premature considering that the tests were made on an experimental track some 70 yards long, and in the condition of laboratory experiment. The possibility of leakage increases with the length of the line, especially in those cases where sections of conducting rails are periodically in actual contact with the roadway, which after a soaking rain must be a good conductor. Moreover, the minute cracks in the conduit, which are likely to result from abnormally heavy traffic will readily establish sources of leakage between the inner conductor and earth. Concerning the channel, Mr. Kapp had referred to the objection against slotted conduits, and he had also mentioned the Buda-Pesth tramway. The Buda-Pesth conduit was immediately underneath one of the rails, which must have slots for the wheel flanges to run in. There is therefore no additional opening in the road. What tramway men wanted nowadays were figures relating to the working cost of propelling cars by electricity, and he, Mr. Reckenzaun, had brought information from two important Continental lines. The total length of the electric tram-line of Buda-Pesth is 16 kilometers. It has been in operation for about 18 months. The popularity of the electric system is shown by the large number of passengers carried. The number per kilometer was 2,690. These increased in December of the same year to 3,631. The horse tramways of the same place, however, carried 2,730 and 2,267 passengers during the corresponding months, showing a material falling off. The maximum speed allowed by the municipality is 11 miles per hour. The expenses of the electric tram amounted to 45.4 per cent. of the gross revenues, whilst with the horse tramway of the same city the ratio between expenditure and income was 71.8 per cent., which corresponded with the best English tramways. Referring to the cost of construction and equipment of Austrian lines, it was shown that the horse tramways of Vienna have cost £4,100 per mile, steam tramways of the same city, £7,000, and the electric tramways of Buda-Pesth, £3,000 per mile, of which £1,400 was expended on the conduits and conductors. Electric traction expenses, inclusive of all charges, were, during the year 1890, 2s. 8d. per car kilometer. The other line which was in his mind was that of Frankfort, which has been in operation for about 7 years. In this case also comparisons can be made between horse traction and electric traction. The Frankfort tramway is worked with overhead conductors. It was built by the same firm as in Buda-Pesth, Messrs. Siemens & Halske. Last year the electric cars made 519,770 car kilometers at a cost of 2.73 pence per kilometer, whereas the traction expenses on the horse-car lines of Frankfort were 5.04 pence per car kilometer, showing a saving of 46 per cent.; but in the case of the electric tram-lines two cars were always coupled together, carrying only one driver and a conductor, consequently the comparison is not quite fair. On the other hand, the horse tramway has a very much greater traffic. It can easily be shown that if the electric tramway were worked on the same scale as the horse tramway and the car had its own motive power and attendants the saving would amount to at least 40 per cent.

In conclusion, the speaker said he wished to point out another error in Mr. Kapp's paper, and that related to the per cent. between the power required to propel a storage battery car and an electric car actuated with an overhead or underground conductor. It had been repeatedly found in practice that the energy necessary at the central station is practically the same for all cases under similar conditions. It is perfectly true that the storage car has from 1½ to 2 tons more weight to carry, and that the working efficiency of the cells is not much more than 70 per cent. But the plant at the central station, with conductor systems, must be large enough to respond at any moment to the greatest demand for current, and this is often three to four times as much as the average working rate. The fluctuations in power were enormous; within the space of a few seconds it may vary between zero and the utmost energy the engine may be capable of exciting. This is a serious disadvantage with the conductor systems, and entails waste which is infinitely greater than that usually accounted for as "loss on the line," etc. Storage batteries are, on the other hand, charged with a constant current, the engine and dynamo run all day at their best efficiency with a steady load, and the fluctuations occur only in the car, when the cells give out the energy demanded by the exigencies of road and load. The losses due to conversion of energy in the batteries and the extra weight are fully compensated by the steady working at a uniform rate of the charging plant.

A paper was then read on the Jarman system by the inventor. Experiments had been carried on since the year 1886 with storage-battery cars at Clapham, and the author had been working hard in perfecting the system. Since the description of the car which appeared last year important modifications have been made. One was in the car; the spur wheels were provided with fibre teeth which were durable and could be replaced easily and worked silently. The motor now used makes only 650 revolutions per minute when these cars run at the rate of 8 miles per hour. The brushes consist of 5 square carbon pencils abutting against the outer edge, the pencil carrying its own current through flexible connections. These brushes worked very satisfactorily. Mr. Jarman found that the accumulators which were originally set did not fulfill the requirements of electric traction, and he constructed a new kind of cell, which promises increased durability.

NEW YORK NOTES.

MESSRS. MILLIKEN BROS., of New York and Chicago, report business rushing. In the line of iron-roof work, of which this firm make a specialty, they have lately secured contracts for Allentown for the new electric line; for a large boiler house at New Orleans, La., and for the Newark, N. J., power house. After a sharp competition with their competitors they have secured contracts for their patent poles for the new electric line in New York City and at Providence, R. I. Both these contracts are large and desirable, and the fact that they secured them speaks well for the many advantages of their poles. At the suggestion of Mr. McIntire this firm has introduced a new form of eye bolt in tops of poles, which contains an additional insulator. It is made in the form of a fork, having a special porcelain insulator in the end. Parties interested in these matters should correspond with the above firm.

FAIRPORT, N. Y.—The proposed electric road to Fairport, as laid out by engineer John Skinner, shows light grades and easy curves, that reflect great credit on his skill, when the difficult nature of the ground is considered. It is not decided whether operations on this line will be begun this season or not.

MR. E. R. KNOWLES, C. E., who has long been actively connected with electrical work, has just been appointed chief electrician to the Schuyler Electric Co., with headquarters at Middletown, Conn., where the factory is situated. He will assume his new duties on August 1.

L. J. WING CO., of this city, so well known for their fan and ventilating apparatus, etc., are pushing their Regan gas or gasoline vapor engines, which are already familiar to the trade and in growing demand.

MR. JOHN MAC CORMACK, M. E., formerly connected with Van Zile, Mac Cormack & Co., of Albany, N. Y., has connected himself with the Heine Safety Boiler Co., of 45 Broadway, N. Y.

MR. P. CLAUS is the New York representative of the Germania Electric Co., manufacturers of the Schaefer incandescent lamp. His office is at 63 Broadway.

Society and Club Notes.

NATIONAL ELECTRIC LIGHT ASSOCIATION.

The Montreal *Star* of July 15 has the following: There was a meeting last evening at the Windsor Hotel of the executive committee of the General Citizens' Committee, formed in connection with the approaching convention of the National Electric Light Association of America. Prof. Bovey presided, and there were also present Prof. McLeod, Prof. Cox, John Kennedy, J. Fairman, J. A. U. Baudry, L. B McFarlen, J. Carroll, J. S. Shearer, S. C. Stevenson, and A. J. Corriveau. Prof. Bovey stated that the finance committee of the City Council had increased their recommendation for an appropriation from $1,000 to $2,000. A resolution was also passed thanking the Mayor, City Council and the finance committee for their generous appropriation. The formation of the reception committee was then discussed, and a number of names added to the executive committee. The remaining time of the meeting was devoted to a consideration of the entertainments to be given the visiting electricians. The conversazione at McGill College had been decided upon, and Prof. McLeod and Mr. Carroll were appointed to look after it. Should they give a ball or a banquet, or either? Mr. Fairman thought an estimate of the cost should be made before deciding, so as not to go beyond their means. This was agreed to. Prof. Bovey reported progress in regard to arranging garden parties and receptions. They could secure as many as they wished. It was suggested that a lacrosse match be arranged. Mr. Kennedy was requested to secure invitations from the Grand Trunk and Canadian Pacific Railway Companies for the members of the convention to visit their works. Mr. Fairman was to secure a similar invitation from the Dominion Bridge Company, and Mr. Stevenson was to report on a visit to the Forest and Stream Club's quarters. Other entertainments were discussed.

CHICAGO ELECTRICAL ASSOCIATION.

After a highly interesting meeting on July 14th, the Chicago Electrical Association adjourned until September 8th, when the regular fortnightly meetings will be resumed in St. George's Hall, 169 Washington street. This young society held its first gathering last April, when a number of young electrical workers decided to organize it. The score of members are taking active hold and the half a dozen meetings already held promise well for the future of the association. Having neither a lunch-room nor a life insurance connected with it, the Chicago Electrical Association stands apart from both the Electric Club and the Electrical Mechanics. Its chief aim is to bring the members together to listen to papers on various subjects and to discuss them. Half a dozen prominent houses are represented, and the discussions are both lively and thorough. The officers for the present year are as follows: President, J. F. Connor, of *Electricity;* Vice-President, F. R. McBerty, Western Electric Co.; Secretary, E. G. Hovey, Western Electric Co.; Treasurer, D. E. Webster, Electrical Supply Co.

College Notes.

McGILL UNIVERSITY, MONTREAL, CAN.

Prof. Bovey has been informed that the McGill University is to be the fortunate recipient of a very valuable electric light plant, consisting of dynamo and arc lamps. The plant is of the celebrated "Wood" system, manufactured and presented by the Fort Wayne Electric Co. Mr. W. J. Morrison, their general agent, together with Mr. A. J. Corriveau, president of the Canadian Electrical Construction Manufacturing Supply Co., representing them in Montreal, have been instrumental in securing this generous gift.

PURDUE UNIVERSITY.

During the vacation many changes are being made in the mechanical and electrical laboratories of Purdue University. The new mechanical laboratory building, together with the electrical building, will give Purdue the finest equipment in the West for practical instruction in electrical engineering. The new building is to contain a set of Westinghouse air-brakes and a Mogul locomotive, both of which will be used for experimental work. The collection of dynamos and motors is growing steadily, and a number of fine electrical measuring instruments have recently been added.

Reports of Companies.

ST. PAUL, MINN.—At the annual meeting of the St. Paul and Minneapolis Messenger and Telephone Co., the following directors were elected: F. D. Abbey, F. M. Schutte, and John A. Ebel. At a subsequent meeting of the directors the following officers were elected for the ensuing year: F. D. Abbey, president; John A. Ebel, vice-president and general manager; F. M. Schutte, secretary and treasurer. It was decided at the meeting to extend the lines of the company and make other needed improvements.

BANGOR, ME.—At the annual meeting of the Maine Telegraph Company the following officers were chosen for the ensuing year: Directors, A. W. Paine, C. E. Bliss, F. A. Wilson, A. C. Flint, John F. Colby, Arad Thompson, C. P. Stetson, Bangor; E. F. Littlefield, Winterport; George Bliss, Waldoboro; president, A. W. Paine; secretary and treasurer, J. Y. Ricker. A dividend of $2 per share was declared. A great many Maine people are interested in this company. It owns the important lines in Maine which are operated by the Western Union, the latter company leasing them.

Appointments, Etc.

MR. M. C. SULLIVAN, who for a year past has very successfully represented THE ELECTRICAL ENGINEER in New York, has resigned to become connected with a new and growing branch of electrical business. Mr. Sullivan's zeal, loyalty and perseverance are such as to make a mark anywhere, and his old associates can only wish for him the abundant prosperity which they know he will win for himself as an electrical engineer and business man.

MR. W. E. STOW, who for the past nine years has been connected with the electrical interests of New England, has been appointed the New York Agent for THE ELECTRICAL ENGINEER. Mr. Stow has been actively connected with the electrical industry since 1882, when he entered the employ of the New England Department of the Edison Electric Light Co. He will also be remembered by his New England friends as having thereafter been successively connected with the Thomson-Houston Electric Co., the Sprague Electric Motor Co., the Wright Electrical Engineering Co., and the Standard Electric Supply Co., of Boston.

Literature.

"ELECTRICITY."

There is no limit to the ambitions of Chicago, and it appears to be one of the resolves of the great metropolis of the West to have as many electrical journals as New York can boast of. We have received from that city a copy of the new paper *Electricity*, just issued there. It is in every way a commendable publication, tastefully got up, beautifully printed, well edited, and abundantly provided with that which is, after all, the journalistic staff of life—advertising. The paper has a distinct aim and that is to handle all electrical topics in a popular manner, yet so fully and accurately that the technical reader will also be satisfied. Clearly there is a mission for such a journal in this country, and *Electricity* bids fair to become a power if it lives up to its early promise. The names of the men connected with it are a guarantee of good and honest work. Mr. J. W. Dickerson is editor in Chicago, and Mr. George H. Guy in New York. Mr. W. S. Key is the manager of the Boston office, and Mr. C. McL. Paine of that in New York. The president of the company is Mr. W. H. Temple; the secretary and treasurer, Mr. H. S. Skilman, and the business manager, Mr. Irving Washington. *Electricity* will appear weekly, and at a subscription price of $2.50 per year offers full value. We can only wish every kind of prosperity to this latest electrical enterprise of the great and growing West.

THE STORAGE-BATTERY LAUNCH "MAGNET."

Mr. Fred. Reckenzaun, of West Hoboken, N. J., has recently sold his pioneer American storage-battery launch "Magnet" for use in California. It is to be placed by the purchasers, the Wieland Bros., brewers, of San Francisco, on Lake Tahoe. At the end of the season it will be removed to Sansalito, the headquarters of the San Francisco yacht clubs, to be run on the bay during the winter. The Pacific Electrical Storage Co., of San Francisco, has contracted to furnish a charging plant for Lake Tahoe.

Legal Notes.

THE KENNEDY PATENT ON ALTERNATE CURRENT DISTRIBUTION.

As a matter of general interest, we reprint below the patent of Rankin Kennedy, of Glasgow, Scotland, on which a suit has recently been brought by the Westinghouse Company against the Marble City Electric Light Co., of Rutland, Vt., the real defendant being understood to be the National Electric Manufacturing Co., of Eau Claire, Wis. Although the invention of Kennedy was made as early as 1883, having been fully described by him in the *Telegraphic Journal and Electrical Review* of June 9 and June 16 of that year, his application for the patent in this country was not made until November 13, 1888. This was early enough, however, it is said, to save his patent from the effect of the provision of the statute, that the invention must not have been two years in public use in this country prior to the date of application.

In the opinion of Judge Colt in the case of the Westinghouse against the Sun Company, in 1888, it was said :—

The most important improvement was made by Zipernowsky and Deri in their English patent of March, 1885. This patent describes minutely a system of distribution by induction through potential reducing converters combined in multiple arc, and it includes an alternating current dynamo generating a current of high potential.

Now as it was held, in the same opinion, that there was no invention in the reduction from high potential to low through a converter, it would seem, or is held, that while Kennedy had clearly not thought of this particular feature of a system of distribution, yet all that was essentially new in the apparatus of Zipernowsky and Deri, referred to by Judge Colt as the most important improvement which had been made in the art of alternating current distribution, was embraced in his discovery. The claim of the Kennedy patent, it will be observed, covers in the broadest terms the important principle of self-regulation, which is a direct consequence of his arrangement of the converters in multiple arc instead of in series, as had previously been the practice of Jablochkoff and Gaulard and Gibbs.

UNITED STATES PATENT OFFICE.

RANKIN KENNEDY, OF GLASGOW, COUNTY OF LANARK, SCOTLAND, ASSIGNOR, BY MESNE ASSIGNMENTS, TO THE WESTINGHOUSE ELECTRIC COMPANY, OF PITTSBURGH, PENNSYLVANIA.

SYSTEM OF ELECTRICAL DISTRIBUTION.

Specification forming part of Reissued Letters Patent No. 11,031, dated September 24, 1890. Original No. 407,291, dated July 16, 1889. Application for reissue filed August 28, 1889. Serial No. 322,251.

To all whom it may concern:

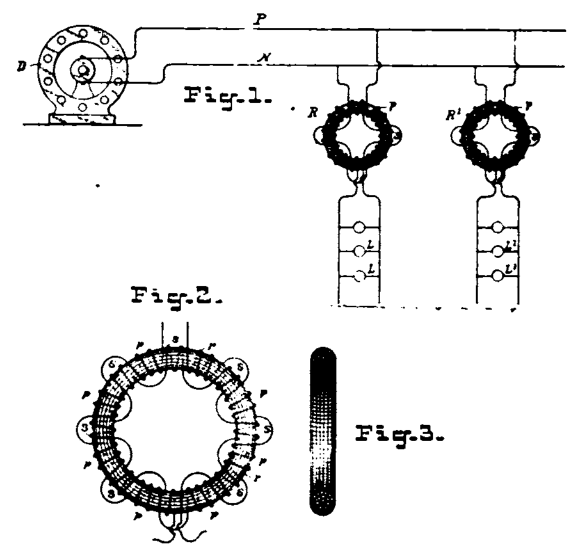
Be it known that I, RANKIN KENNEDY, a subject of the Queen of Great Britain, and a resident of Glasgow, county of Lanark, Scotland, have invented a new and useful Improvement in the Method of Distributing and Regulating Alternating Electric Currents by Secondary Generators (Case 232), of which the following is a specification.

In systems of distribution by alternating electric currents employing stationary induction-coils or secondary generators, it was customary, in the practical use of secondary generators prior to my invention, to connect all the primary coils in the circuit of the source of alternating currents in series. In such an organization the primary conductors of all the secondary generators are traversed in succession by one and the same current, and as a consequence any variation in the resistance opposed to the passage of the current through any one primary coil produced a corresponding variation in the current flowing through the primary coil of all the other secondary generators. It was found in practice that opening the secondary circuit of any of the secondary generators resulted in greatly diminishing the current delivered to all the others, and thus the entire system would be disturbed by turning off the lights at any one point. No entirely satisfactory method of overcoming this defect has been discovered. I have found that a counter electromotive force is set up in a coil of wire carrying an alternating current and wound upon an iron core, and this counter electromotive force is proportionate to the size of the iron core and the length of wire in the coil surrounding the core. I have also found that when the secondary circuit of a properly-constructed secondary generator is open or disconnected and an alternating electric current is applied to the primary coil, a counter electromotive force is developed in the primary coil which is practically equal to the applied electromotive force. When, however, secondary currents are allowed to develop in the secondary coil, the counter electromotive force is so modified that a primary current flows which varies approximately inversely as the resistance offered to the development of the secondary current. Availing myself of this discovery, I have devised a new method of distribution of energy by alternating electric currents, by which the secondary generators are rendered independent and self-governing, each receiving its appropriate current independently of all the others, and each deriving from the source an amount of energy proportionate to that which is actually consumed in the secondary circuit. In carrying this method into operation the primary coils of the secondary generators are connected with the source of energy in branch or derived circuits and the secondary coils are closed through the lights arranged in parallel arc. In such an organization each secondary generator receives its current independently of all the others, and the primary current in each secondary generator increases as the resistance in its secondary circuit decreases; or, in other words, the primary current increases as the current in the secondary circuit increases. From this it follows that the energy supplied to the primary coil or consumed by the secondary generator may be made nearly directly proportional to the work being done, and the whole system becomes self-regulating and flexible.

In the accompanying drawings, Fig. 1 is a diagram illustrating my improved organization of apparatus for electrical distribution, in which two secondary generators are shown connected with the source in parallel arc. Fig. 2 is a diagram illustrating the principle of construction of one of the individual secondary generators. Fig. 3 is a cross-section of the same.

Referring to Fig. 1, D represents a source of electric energy, which may be a dynamo-electric machine or other proper apparatus for producing alternating electric currents. Two secondary generators (which are a sufficient number to illustrate the principle of the invention) are shown at R and R'. These have their primary conductors *p p* connected in parallel between the main conductors P and N, which extend from the terminals of the source of electricity D. Groups of lamps are shown at L and L', placed in parallel and included in the secondary circuits *s s* of the respective secondary generators.

In order to obtain the counter electromotive effect which I have mentioned, I employ a secondary generator in which the size of the iron core and the length of the primary coil surrounding it are proportionate to the electromotive force applied thereto. An example of such a secondary generator is illustrated in Figs. 2 and 3. This consists of a core of soft iron composed of iron wire in the form of an endless ring, upon which two coils of insulated wire are wound. One coil constitutes the primary and the other the secondary conductor of the secondary generator. I have shown the primary coil wound in sections *p p p p* and the secondary in sections *s s s s* arranged alternately upon the cores. When two or more such secondary generators have their primary conductors connected in parallel arc and their secondary circuits disconnected or open, the counter electromotive force is so great that practically no current passes through the primary conductors; hence when no work is being done in the secondary circuits little or no energy is wasted. When, however, the secondary circuit of any given secondary generator is closed through a greater or less number of parallel branches containing lamps or other translating devices, then a secondary current is generated in the secondary wire, the effect of which is to neutralize the counter electromotive force proportional to the amount of work being done. These changes take place without modifying the value of the current traversing the primaries of the other secondary generators or affecting in any way the operation of the translating devices in their secondaries. The same is equally true of any of the other secondary generators or any number of them connected in the same manner, and it follows that the system is an automatically self regulating as well as a very economical one.



FIGURES IN THE KENNEDY PATENT.

I claim as my invention—

The method of distributing and regulating alternating electric currents by secondary generators, which consists in producing in two or more derived circuits constituting the primaries of two or more secondary generators a counter electromotive force which, when any secondary is open, is practically equal to the applied electromotive force in its primary and in controlling said electromotive force by the current flowing in the corresponding secondary when the secondary is closed in such manner that the current in the primary shall vary with and be approximately inversely proportional to the resistance in the secondary, substantially as described.

In testimony whereof I have hereunto subscribed my name this 27th day of August, A. D., 1889. RANKIN KENNEDY.

THE INCANDESCENT LAMP INJUNCTION.

Judge Wallace Grants a Respite.—Synopsis of the Proceedings.

ON Thursday, July 23, counsel appeared before Judge Wallace in chambers of the United States Circuit Court, to decide upon the settlement of the decree in the incandescent lamp case. Messrs. R. N. Dyer, G. P. Lowrey and S. B. Eaton appeared for the Edison Company, and Messrs. S. A. Duncan, L. E. Curtis and E. Root appeared for the United States Company.

Mr. Lowrey said that complainant was before his Honor with a judgment about to be entered, and a decision against the United States Company, and that company alone. That company was not a manufacturer, but a purchaser from the Sawyer-Man Company of the lamps with which it supplied its customers. Defendants had prepared affidavits with a view of inducing his Honor to suspend the injunction on account of public inconvenience. He thought there was no occasion for his Honor even to consider whether the operation of the writ of injunction ought to be suspended in the interest in some party differently situated. An order restraining defendants from carrying on the business would have no necessary effect upon the public, because lamps were made by others, who were competent until restrained, to supply them. Complainant expected to come to his Honor by-and-by to have one of those manufacturersres trained and expected then to meet all those reasons.

Gen. Duncan and Mr. Lowrey then handed to the court the forms of decrees which had been drawn respectively by counsel for complainant and for defendant.

Gen. Duncan in reply, briefly adverted to the operations of the United States Company. It had established in the United States some 1,050 incandescent plants, having a capacity of 350,000 lamps, and employing a little army of men. In most cases the United States Company were under contract to keep these plants supplied with lamps. Mr. Lowrey had strongly hinted that an injunction against the United States Company would be followed by applications for injunctions against all other manufacturers of incandescent lamps, which would involve a very serious grievance to the public. In New York 45,000 lamps were being operated upon the Westinghouse alternating system, which had been introduced about 1886, at a time when it was supposed, under the law as then interpreted, that the patent in suit had expired. Complainants' affidavits went to show that the Edison Company were not prepared to make satisfactory 50-volt lamps for the alternating system; perhaps for the reason that it was necessary, in lamps of low voltage, to make use of hydro-carbon treatment, a process owned and controlled by the United States Company, subject to certain contract arrangements with the Westinghouse Company. Moreover, the alternating systems served a territory not reached at present by the Edison plants. If by reason of an injunction, such plants were debarred from securing a supply of suitable lamps, the result would be the destruction of all the property invested in them. In view of the quiescence—he might say the acquiescence—of the Edison Company, from 1880, when defendant was publicly known to have been actively engaged in developing an incandescent lighting business, down to the time the suit was brought, he believed that if the bill had set forth the facts, a demurrer to the jurisdiction of the court would have lain. Mr. Hebard had said in his affidavit, that if the suit had been brought at once when the infringement began, and prosecuted promptly to a decision on its merits, defendant's investment in that branch of business would not have reached $50,000; whereas at the time the suit was brought it had reached $2,500,000, three-fourths of which had to do with incandescent lighting.

His Honor said that he had decided that complainant was entitled to an injunction; the only question was whether there were considerations which ought to lead to its suspension pending a decision by the appellate court. There might be a case, for instance, where the recovery of the royalty would be sufficient to indemnify for the infringement of the patent, while at the same time the granting of an injunction might cause tremendous inconvenience. What had influenced him very much, in the impression he had in the matter when he decided the case, was the circumstance that there had been a long delay in the prosecution of the suit, and the additional circumstance that the patent was one very well calculated to engender doubt in the minds of people who were making incandescent lamps as to whether it was good for anything, and then there was the fact that during this time a large amount of capital had been invested and a great many men were employed in making the lamps,

Mr. Lowrey said they had not expected that this question would arise here as against the complainant, and that he would rather not have it determined at this time, nor in this way, because he had not said what he had to say upon it.

His Honor remarked that if some one had a right to set up this patent against infringers, they should have commenced early and in the right time.

Mr. Lowrey said that people had not thought it worth while to spend their money, until the decision in Bate and Hammond had let them out. There had been no delay since then. No man was to blame when the law told him, "You have not got a right," for not prosecuting that right, if he had proceeded vigorously when the superior authority told him he had the right.

Mr. Root, for the defendant, said that the patent had been alive for five years, irrespective of Bate and Hammond, and the proof had showed that the agents of defendant had over and over again said to representatives of complainant, "Why don't you sue if you say this patent is controlling?" Defendant could not get into court.

Mr. Lowrey said he would read from Mr. Hebard's affidavit, in the light of the distinction that he should ask his Honor to make between acquiescence and not suing. The gentlemen had not been misled by acquiescence; they had thought they would not be pursued at law; they had misjudged, and now they wanted to get, as the reward of that misjudgment, what the court allowed people who had been misled—a very different thing.

His Honor said he was not thinking about acquiescence. Where parties did not assert their rights for several years, it looked as if they did not feel, either that there was any necessity for it, or that they had any rights.

Mr. Lowrey said that judicial discretion was governed by established rules, and that its exercise outside of an established rule was an error. It rested on two things, one the right of the party, growing out of laches or acquiescence of the party who pressed against him, and the other public inconvenience.

His Honor mentioned a case in the Supreme Court, where a stay had been granted, because great injury to the defendant would have resulted from an injunction and this without reference to the public rights at all.

Mr. Lowrey said defendants contended that they had put up a great many plants that would become valueless if they could not get lamps; but there was no difficulty in getting lamps from others; there was nothing justifying the application of those benevolent principles of law. He did not suppose his Honor was there to protect defendants from paying damages, which might be measured by the cost of going round the corner and buying the lamps in another shop. Complainants were entitled to this injunction by the force of logic, and nothing intervened to destroy the effect of that logic, because of the curious situation defendant was in.

Mr. Root said defendants would meet the real substance of the thing here. At some other time, before some other judge, complainants might ask for an injunction against some other company, and his Honor's decision refusing to stay this injunction would be presented as a sufficient reason why a preliminary injunction should issue. Defendant was under contract to deliver lamps, and procured them to be made by a licensee in order to deliver them. Defendant was under these great pecuniary obligations; with large amounts invested; with many corporations and individuals from the public involved; led into that position by the failure of complainant to bring the validity of this patent to an issue at a time when defendant could not bring it to an issue. Mr. Root then referred to the case of *Mackall* v. *Casilear* (137 U. S., 556), in which the bill had been dismissed on demurrer for want of equity, upon the sole ground of laches. The Supreme Court had there said that mere protest and assertions of right, and threats not followed by effective action, could have no effect whatever. The proofs showed that complainants had been fully aware of an active, vigorous competition during the entire time which had been supposed to be the life of this patent, and it now appeared by what had been said in regard to this cloud which hung over the patent that they—

His Honor interposing, said that he thought that the greatest cloud that hung over the patent was in its claims—in the language of the patent itself. He did not much blame any infringer for assuming that he could go on and make any sort of an incandescent lamp without fear of that patent. He noticed that no two judges who had had it before them had ever agreed about it. Perhaps two had; but only one delivered an opinion; if they had both delivered opinions, he presumed they would not have agreed. He was practically called upon to suspend this injunction for about six months, and he thought, in view of the facts that the suit had not been brought for five years after it could have been brought; that there was a fair doubt as to whether his own decision would be affirmed; that a large investment had been made by those who had probably thought that they could go on safely notwithstanding the decision; and that large numbers of men had been and still were employed in the manufacture of these lamps—he thought he should be justified, under all these circumstances, in the exercise of his judicial discretion, in suspending the operation of the injunction.

In answer to a question from Mr. Lowrey, his Honor said that the amount of bonds that should be given would be a matter for consideration. The stay would be limited to defendant's specified contracts; not to permit the doing of any new business.

Mr. Root said defendant had some millions of dollars invested in the manufacture of electrical apparatus, and wished to proceed with the sale of it. If the right to furnish lamps were cut off by injunction, the sale stopped, and the manufacturing practically ended; then, in case his Honor's decision were reversed six months hence, defendant's business would have been ruined.

His Honor said that he did not propose to allow defendants to go on and extend their operations; he would simply allow them to live up to contracts already made; he would protect them to that extent; but the decision must stand for something.

Gen. Duncan explained that the large capital was required, not for making the lamps, but for the other apparatus; only about 2¼ per cent. of the cost of a plant was in the lamps, and it was considered desirable that lamps and dynamos should be of the same make. If his Honor were to limit defendant's right of manufacturing lamps for the ensuing 3 or 4 months, defendant's manufacturing industry would be broken up and its skilled workmen scattered to the four quarters of the earth; the best of them would go into the employ of their rivals; and then if defendants were fortunate enough to secure a reversal of his Honor's decree, it would be impossible for them to recover their position. The question was, whether defendants could, by giving a sufficient bond, have protection for this limited period of time; of course this right, reserved temporarily, could be limited to the sale of lamps in connection with dynamos of their own manufacture.

His Honor remarked that he was inclined to be liberal.

Mr. Lowrey said that before being liberal, might his Honor allow him to suggest, that with companies allied as defendant's were, his Honor's liberality might be abused. They had only to transfer their sales of new dynamos to one of the other companies, and the lamp business would be carried on in the largest possible manner. The allowance to supply lamps to dynamos already sold would result in the selling of all the lamps they could get customers for.

His Honor said he was inclined to think that in case complainants get their royalty on all the lamps defendant sold, that they would get justice.

Some discussion then took place between counsel as to the amount of the bond. It was finally agreed that $50,000 would be an equitable amount, and that the United States Company should have ten days' time in which to execute the bond. Judge Wallace then signed the stay of the writ of injunction pending the result in the appellate court.

By the interlocutory of Judge Wallace, filed on the same day, the accounting of the profits of the United States Company, through its use since 1880 of Edison's patented invention, was referred to John A. Shields. The defendant company immediately filed its bond in the sum of $500 for the costs of an appeal from the interlocutory decree to the new Circuit Court of Appeals.

TELEPHONE PRIVILEGES MUST BE THE SAME TO ALL TELEGRAPH COS.—POSTAL TELEGRAPH CO. vs. DELAWARE & ATLANTIC TELEPHONE CO.

The long-pending suit for a writ of mandamus to compel the Delaware and Atlantic Telegraph and Telephone Company to put a telephone in the office of the Postal Telegraph-Cable Company in Wilmington, Del., was decided by Judge Wales in the United States Circuit Court at Wilmington, on Saturday, July 18. The case was originally brought in the Superior Court of the State of Delaware and thence transferred to the Circuit Court. The decision grants the writ of mandamus, but it is possible that the case will be carried to the Supreme Court of the United States, and that it will be a year at least before the Postal receives its telephone.

G. H. Bates, of Wilmington, and R. S. Guernsey, of New York, represented the relators, and Edward G. Bradford, of Wilmington, and Charles L. Buckingham, of New York, the respondents.

The decision is based mainly on the principle that if a patentee leases his inventions for a public, rather than an individual, use, he thereby gives the use to the whole public. In this case, the American Bell Telephone Co. might have licensed its patent to the defendant sub-company, so that it alone could have used it, but the sub-company was licensed to use it for the public, and in fact did so rent it to all who desired, excepting only the Postal Telegraph Co., on the ground of an exclusive contract between the parent American Bell Co. and the Western Union Telegraph Co. Moreover: "The respondent is a common carrier which has offered to the public the use of a telephonic system for the rapid conveyance of oral messages from one point to another; that one of the most important duties of a common carrier is that it shall serve all persons alike, impartially and without unreasonable discriminations, and that the performance of this duty cannot be avoided by a special contract made between the respondent or its licensor and one or more persons for the exclusive use of the system, such contract being void as against public policy, and that a patented device or devices, when employed for a public use, or by a common carrier in the prosecution of its business, will be subjected to the same rules and regulations which govern unpatented property under the same circumstances. The reasons alleged by the respondent for its refusal to furnish the relator with a telephone are therefore insufficient, and it is ordered by the court that the writ of mandamus be awarded."

THE PERKINS SWITCH IN LITIGATION.

A special dispatch from Hartford, Conn., of July 25, says: "Charles G. Perkins, of the Perkins Electric Switch Company, of this city, and the Perkins Electric Lamp Company, of Manchester, has a big suit against the Edison General Electric Company, of New York. Mr. Perkins said last night that the electric switch which the Edison people are manufacturing was patented by him in 1881. He understands that there have been 400,000 or 500,000 of these switches made by the Edison Company. The royalty due him on them would be about $100,000. He says that the Edison people admitted to him that they were manufacturing the switch which he patented. The case will come up in the September term of the Superior Court. Mr. Perkins has retained Charles L. Buckingham, of New York, as his attorney."

"BY FAR THE BEST."

In ordering some special copies of THE ELECTRICAL ENGINEER of recent date, a subscriber writes: "I want to bind in the arguments and decision in the Filament Suit, with my set of briefs. This is by far the best digest of the arguments."

J. H. BUNNELL & Co. have brought suit against the Manhattan Electric Supply Co., of this city, for alleged infringement of their Burnley dry battery.

THE BRUSH STORAGE BATTERY PATENT SUSTAINED.

THE BRUSH ELECTRIC CO. *vs.* THE ELECTRICAL ACCUMULATOR CO.

On July 23, Judge Coxe, of the U. S. Circuit Court for the Southern District of New York, handed down his decision in the above suit sustaining the Brush patent, and granting an injunction. The following gives all the main points of the decision:—

This is an equity action founded upon three Letters Patent, granted to Charles F. Brush for Improvements in Secondary Batteries, as follows: No. 337,299, granted March 2, 1886; No. 260,654, granted July 4, 1882, and No. 266,090, granted October 17, 1882.

These patents and one other, No. 337,298, granted March 2, 1886, were before this Court in *Brush Co.* vs. *Julien Co.*, 41 Fed. Rep., 6979. The Court there decided that No. 337,298 and No. 337,299 were for the same invention, and intimated, as the inventor and his expert apparently regarded the former as the broader patent, that the difficulty might be met by a surrender of the latter, or by a disclaimer of similar claims therein. This solution of the difficulty was thrown out as a suggestion merely, the final disposition of the patents being left till the settlement of the decree.

It was not the intention of the Court to decide that one of these patents was entitled to preference over the other. For the reason stated, and for convenience of illustration, No. 337,298 was given prominence in the discussion, but the conclusion would have been the same had the position of the patents been reversed.

Upon the settlement of the decree the complainant selected No. 337,299 as the patent upon which it chose to rely, and withdrew No. 337,298 from the consideration of the Court. This was done without objection by the defendant in that case. On the 15th of July, 1890, after the decree in the *Brush-Julien* case was entered, the complainant withrew No. 337,298 from this cause and an order was entered dismissing the bill as to that patent. The cause has since proceeded upon the three patents as stated.

In the prior litigations involving the subject matter of these patents the following propositions have been decided:

First.—That Mr. Brush was the first in this country to hold absorptive substance, in the form of dry powder, in place on the supports of a secondary battery by paper or equivalent material, and the first who rammed or pressed it into grooves or receptacles in the plates.

Second.—That No. 337,298 and No. 337,299 are for the same invention, and that the complainant was not entitled to both patents, but was entitled to one.

Third.—The complainant having elected to hold No. 337,299, it was decided, by the decree, that claims numbers one, two, three, six, seven, eleven, twelve and thirteen were valid, the word "perforations" in claims numbers six and seven being construed as synonymous with "cells or cavities."

Fourth.—That the claim of No. 260,654 was not infringed by the application of the absorptive substance to the grids by a trowel or spatula.

Fifth.—That the defendants, by the use of supports filled with rows of uniform square holes, did not infringe the "rib claims" of No. 266,090.

Sixth.—That claims numbers seven and fourteen of No. 266,090, the latter claim being limited to the "perforations" described, were valid and infringed.

Seventh.—That No. 337,298 (and by implication No. 337,299) was not invalidated by patents Nos. 261,512 and 261,995, granted to Mr. Brush, July 18 and August 1, 1882, respectively.

Eighth.—That No. 337,298 (and by implication No. 337,299) was not invalidated by the expiration of the Brush Italian patent. *Brush* vs. *Julien*, 41 *Fed. Rep.*, 679; *Accumulator* vs. *Julien* 38 *Fed. Rep.*, 126.

All of these conclusions were reached after careful study and mature deliberation, and now, after having been re-examined in the light of the present record, arguments and briefs, except as to claims numbers eleven and thirteen of No. 337,299, are reaffirmed. No useful purpose would be subserved by again discussing them, as such a task would only involve a repetition of what has been said already in the other cases.

The proof of infringement is substantially the same as in the *Brush-Julien* case. It is more complete as to the manner in which the active material is applied to the plates, but in this respect it only emphasizes the former decision as to the non-infringement of the claim of No. 260,654. That claim is as follows:

"The method of forming the plates of a secondary battery, consisting in forming receptacles for oxide of lead in its surface, then applying oxide of lead to the plate and within such receptacles, and afterwards subjecting the oxide of lead to pressure."

The claim clearly contemplates not only the treatment adopted by the defendants, but *afterwards* subjecting the oxide to pressure. The defendants apply the oxide to the plates and within the receptacles with a wooden trowel in the hands of the workman, and there they stop. They do not subject the oxide to pressure afterwards.

The questions arising upon the expiration of the Italian patent, and as to the validity of the "red lead claims" are, however, presented by this record in a new and different aspect and may, with entire propriety be examined *de novo*, together with the question, not heretofore considered, relating to the effect of the Brush patents Nos. 260,653 and 276,155 upon the broad patent in suit.

First.—It is thought that claims numbers eleven and thirteen of No. 337,299—the red lead claims—are void for lack of invention. The specification, after referring to lead oxide as the active material, which is primarily and mechanically applied to the plates, proceeds:

"Peroxide is the best oxide of lead to use in the preparation of the plates; but as this is rather expensive to prepare, red lead or minium may be used."

If the record contained nothing but this statement the claims could not be upheld. After the invention of a support primarily coated with mechanically applied oxide of lead, merely coating the plate with the commonest, cheapest and best-known form of lead oxide did not require the exercise of the inventive faculties. Especially is this so when the patentee himself asserts that the best results can be obtained by using peroxide. It would seem that the use of red lead would at once occur to any one who had even a superficial knowledge of the art. There is no more novelty in using red lead for the coatings than there is in using cast lead for the plates. (*Brush* v. *Julien, supra, p.* 692.)

Patent No. 337,399, at least as far as its broad claims are concerned, is not invalidated by anything contained in the Brush patents No. 260,653 and No. 275,155. The application for the former (No. 260,653) was filed June 15, 1882, a year and two days after the application of No. 337,299.

No one can read the specification of No. 260,653 without being impressed with the fact that the inventor intended to confine the patent to a single point, namely the form of the electrodes. He expressly says so.
The claim is:

"In a secondary battery, an element consisting of a structure of etagère-like form, containing in the spaces between its shelves lead in a finely-divided state, substantially as set forth."

It is true that the broad invention is described, but it is equally true that it is not claimed. It was hardly possible for the patentee to describe the subsidiary invention without disclosing his main invention. An infringer, with the statements on the face of No. 260,653 before him, would scarcely have the hardihood to assert that he supposed the broad invention was released. No court would listen to such a plea. The claims of that patent did not protect Mr. Brush in the use of the broad invention. A person who did not use an "etagère-shaped" plate, could, if no other patent prevented, use the broad invention with perfect impunity. No. 337,299 was intended to prevent such use. The court has not been able to discover an authority holding a broad patent invalid in such circumstances. None has been cited by counsel.

What is true of No. 260,653 is also true of No. 276,155. Mr. Brush was the first in this country to make the broad invention as stated above. He is entitled to the fruits of his invention. It is the policy of the law to reward him.

Where the Court can see that the patentee has produced an invention of real merit, it should not be unduly industrious in endeavoring to discover some statement or act of his by which, on technical grounds, his rights may be forfeited. It should rather be sedulous to protect him. Whether or not the improvements patented by Nos. 260,653 and 276,155 are the same as the improvements covered by some of the claims of Nos. 337,299 and 266,090 it is, perhaps, unnecessary to decide, for none of the claims in issue and infringed are so affected.

It seems that in his anxiety to claim his invention in every conceivable form, the patentee has involved himself in a labyrinth of descriptions and claims in which electrician and lawyer alike are quite apt to become confused. What Mr. Brush accomplished in 1879 and 1880 can be embraced in a brief, clear and concise statement. What he actually did is the test by which his patents may be judged. He is entitled to what he invented and only this. His patents can receive no broader construction, because he described his inventions with irksome prolixity and gives to the same structure a wearisome variety of names. The nomenclaturist should not seek the reward for his labors in the Patent Office. A person is not entitled to a patent because he has invented a new word. The danger and impropriety of holding a number of claims relating to the same structure, and which can be differentiated only by the most abstruse and metaphysical distinctions, seem apparent. They are calculated to embarrass the inventor and mislead the public.

Did Patents Nos. 337,299 and 266,090 expire with the Italian patent?

The Italian patent was applied for July 28, 1882, sealed August 8, 1882, and was issued for a term of three years from September 30, 1882. It expired September 30, 1885, never having been prolonged, renewed or extended. No. 337,299 was granted March 2, 1886; No. 266,090, October 17, 1882; both were applied for in June, 1881.

Under Section 4,887 of the Revised Statutes, the test of identity between the foreign and the domestic patent, as established by the Supreme Court in two recent decisions, may be stated as follows:

Is the principal invention in each, is the thing patented abroad the same in all essential particulars as the thing patented here; would the home patent be infringed by a structure made in accordance with the provisions of the foreign patent?

In cases where these questions are answered in the affirmative the United States patent falls, and it will not be saved by the fact that it contains improvements not found in the foreign patent. *Siemens* vs. *Sellers*, 123 *U. S.*, 276; *Com. Co.* vs. *Fairbanks Co.*, 135 *U. S.*, 176.

Whether the expiration of a foreign patent for an improvement only will operate to overthrow a domestic patent for a broad invention, which contains also a claim covering the improvement, has not apparently been decided by the Supreme Court. The language of the Court in *Siemens* vs. *Sellers, supra*, is, perhaps, comprehensive enough to cover such a contingency, but this is a question which need not now be considered.

In the *Brush-Julien* case the Court commented upon the absence of expert testimony relating to the Italian patent. No similar observation can, with propriety, be made regarding the present record. It would indicate a lamentable want of appreciation on the part of the Court to ask for additional instruction and advice. Eight experts of greater or less prominence and attainments have testified upon this subject. Three of these, called by the defendants, have expressed the opinion that the divisions of the Italian patent describe everything claimed in the United States patents granted to Mr. Brush and that the inventions covered by the two patents, No. 337,299 and No. 266,090, are literally described and substantially claimed in the Italian patent.

On the other hand, five electricians, including the patentee himself, have testified that the Italian patent relates to inventions wholly different and proceeds upon totally dissimilar lines. In short, that it is but a progressive step in the Planté method, its object being to aid the process of electrical disintegration of the plates in the electrolyte, and not to supersede that process by placing the active material mechanically upon the plates prior to immersion in the battery fluid.

The mere fact that these gentlemen of conceded ability and learning, whose motive is to enlighten the Court, and who were all sworn to tell the truth, differ so radically regarding the meaning of the Italian patent, is of itself suggestive.

The defendants plead the defense of forfeiture. They must prove it by a preponderance of evidence. And yet upon the question of the identity of the patents in question there is a sharp difference of opinion among those who are most entitled to speak upon the subject. Is there not room for the assertion that the defendants have failed to sustain the burden in this behalf?

When this question was presented in the *Brush-Julien* case the mind of the court was in doubt, and now, having re-read the Italian patent in the light of the new testimony, it is still in doubt, but inclining more strongly to the opinion that the complainant's contention is correct. The Court is not prepared to hold, therefore, that the Italian patent is for the same inventions as those covered by the two patents in question. In fact, the more the Italian patent is studied, the more settled becomes the conviction that it is not for the same invention as No. 337,299.

Believing that Mr. Brush is entitled under our law to protection for a meritorious invention, the Court should not, unless fully convinced that the facts warrant such a course, destroy his patents upon grounds which do not go to the merits of the invention, and which, for want of a more accurate word, may be termed *technical*. Why a meritorious inventor, who is a citizen of this republic, should lose his rights at home because he has tried to protect them abroad is, on principle, not easy to comprehend.

It is said that the expiration of the Italian patent threw the invention into public domain. So it did into the domain of the Italian public, but if Mr. Brush had taken no patent in Italy the Italian public could have practiced the invention from the moment it became known there. Had he taken no foreign patents his invention would have been thrown into the public domain of every land but this. In this country his inventions would have been protected for seventeen years, outside of this country they could have been used with perfect impunity. The inventor applied for his patent here long before he applied abroad, but through the delay of the Patent Office the foreign patents were issued first.

Assuming the invention to be similar, the inventor has been guilty of no fault, the American public has lost no rights, and yet, under the provisions of this statute, which it is thought was never intended to apply to a case like this, a valuable monopoly is destroyed.

The question of how to dispose of No. 337,298 is, in view of complainant's position regarding it, more puzzling than ever. The rule which obtains in this circuit, requiring a disclaimer of invalid claims as a condition of a decree, has always seemed an arbitrary one. It certainly seems inequitable that the Court, at *nisi prius*, should compel the patentee to renounce forever a claim which may be held valid upon appeal. It is possible that this rule may be modified by the Circuit Court of Appeals.

In view of this contingency and of the extraordinary and distinguishing circumstances surrounding this case, the Court has concluded, if the complainant upon reflection still desires to assume the responsibility of retaining two patents for the same invention, not to require a surrender or disclaimer of No. 337,298 as a condition of a decree. It is thought, however, that pending an appeal it should be deposited with the clerk to await the further order of the Court.

An accounting having been waived, it follows that on filing a disclaimer of claims eleven and thirteen of patent No. 337,299, the complainant is entitled to a decree upon claims one, two, three, six, seven and twelve of this patent, and upon claims seven and fourteen of No. 266,090, for an injunction, but without costs.

W. C. Witter and W. H. Kenyon, for the complainant; Fred. H. Betts, for the defendant.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED JULY 14, 1891

Accumulators:—

Secondary-Battery Plate, J. R. Maclaughlin, F 455,968. Filed June 3, 1890.
Plate is composed of opposite end-bars, and transverse connecting bars, all of aluminum; the connecting bars are of hollow trough-like form with in turned edges, adapted to receive and hold active material.

Alarms and Signals:—

Thermostat, H. A. Chase, 455,788. Filed Oct. 29, 1888.
A circuit-changing lever is normally pressed by a spring against a block of paraffine or other easily fusible material adapted to melt at a given temperature.

Fire-Alarm Apparatus, H. A. Chase & H. F. Eaton, 455,812. Filed July 28, 1887.
A receiving apparatus adapted to the detection of false alarms from thermostats.

Thermostat, H. A. Chase & H. F. Eaton, 455,813. Filed Nov. 1, 1888.
Adapted for use in a closed circuit and arranged to open the circuit and thereafter close it again.

Signaling Apparatus, H. F. Eaton, 455,873. Filed Sept. 23, 1889.
Amplification of the invention patented to B. J. Noyes, Mar. 22, 1887, No. 359,688. Adapted to police signaling.

Conductors, Conduits and Insulators:—

Process of Manufacturing Insulated Conductors, C. Cuttriss, 455,789. Filed Aug. 6, 1890.
Consists in applying to, or winding upon, a conductor the loose fibres of a material such as cotton, and compacting them to form a felted or matted sheathing. The fibrous sheathing may be saturated or coated with a fusible insulating compound.

Insulated Electrical Conductor, E. D. McCracken, 455,904. Filed Mar. 5, 1891.
Winds a conductor with a paper tape composed of twisted paper or paper cord flattened.

Wire-Covering Machine, J. McCahey, 455,970. Filed Sept. 12, 1890.

Insulated Electric Conductor, E. D. McCracken, 456,120. Filed Mar. 4, 1891.
Employs air spaces for reducing static capacity. An insulating cord is wound round the conductor spirally with considerable space between each turn; an exterior insulating coating is afterwards applied.

Dynamos and Motors:—

Electric Motor, H. H. Porter, 455,765. Filed Jan. 17, 1891.
Has a three-pole armature revolving between two pole-pieces, obviating a dead point.

Alternating Current Motor, W. Stanley, Jr., and J. F. Kelly, 455,773. Filed April 10, 1891.
Employs a condenser, with a shunt-wound machine, to neutralize the effects of self induction.

Dynamo-Electric Machine or Motor, J. B. Entz, 455,790. Filed Nov. 24, 1890.
Relates to machines in which the field magnet system is situated within a ring armature, and in which either the field-magnets or the armature may be the rotating part.

Holder for Carbon Brushes of Commutators, C. H. Farrington, 455,856. Filed Oct. 21, 1890.

Armature for Dynamo-Electric Machines, E. W. Rice, Jr., 455,887. Filed Mar. 21, 1891.
Relates to means for holding the coils in place.

Electric Motor or Dynamo-Electric Machine, C. G. Curtis, 455,898. Filed Mar. 9, 1891.
A construction for multipolar machines adapted to reduce the vertical dimensions; especially applicable to street car motors.

Armature for Dynamos, F. L. McGahan, 455,971. Filed Dec. 26, 1890.
Relates to method of driving: armature is provided with an external friction rim, enabling it to be driven peripherally by a friction wheel.

Galvanic and Thermo-Electric Batteries:—

Terminal for Electric Batteries, H. V. Hayes and A. S. Hibbard, 455,986. Filed Jan. 19, 1891.
Employs an easily fusible soldered joint in lieu of thumb-screw connections.

Lamps and Appurtenances:—

Electric Cut-Off Apparatus, E. W. Rice, Jr., 455,800. Filed Dec. 15, 1886.
Contacts are separated by an insulating film and adapted to come together upon the destruction of the film through the heat of an arc abnormally formed.

Measurement:—

Electric Indicator, E. C. Eldredge, 455,855. Filed Feb. 9, 1891.
For current measurement.

Medical and Surgical:

Electro-Medical Lighting Apparatus, P. Oudin and H. O. Kratz-Boussac, 455,972. Filed Oct. 13, 1890.
For illuminating the different natural cavities of the human body for medical examination.

Apparatus for Administering Electricity, G. H. Bethel, 455,981. Filed Oct. 13, 1890.
Apparatus for electric medical baths.

Electric Belt, L. N. Fancher, 456,021. Filed April 6, 1891.

Metallurgical:—

Electro-Magnetic Ore-Separator, J. Wenstrom, 455,808. Filed Dec. 24, 1890.
Improvements on machines of the type patented to the same inventor Nov. 15, 1887, No. 373,211.

Magnetic Separator, J. Wenstrom, 455,809. Filed Dec. 24, 1890.
Further improvements, as next above.

Magnetic Separator, H. G. Fiske, 455,984. Filed Mar. 26, 1891.
Feeds the gangue through or across a magnetic field in a film or stream of regulated thickness.

Magnetic Ore-Separator, H. G. Fiske, 455,985. Filed Mar. 26, 1891.
Employs a feed belt or conveyor, a transverse belt or separator crossing the feed belt a short distance above the latter and a series of magnets with their poles in close proximity to the separator; the magnet poles alternate in polarity in the direction of the motion of the separator.

Miscellaneous:

Loop-Switch, W. M. Goodridge, 455,747. Filed Mar. 4, 1887.

Electro Phonometer and Phonoscope, I. H. Farnham, 455,815. Filed Feb. 13, 1891.
An apparatus for investigating disturbing currents, as upon telegraph or telephone lines, and for comparing their effects.

Electric Switch, C. G. Dahlgren & J. H. Svensson, 455,837. Filed Dec. 24, 1890.
A quick-acting switch.

Cut Out for Arc Lamps, C. E. Scribner, 455,953. Filed Nov. 4, 1890.

Lighting Arrester, C. S. Van Nuis & J. H. Vail, 455,955. Filed Oct. 16, 1890.
Relates to arresters of the class employing several fusible wires arranged to be thrown into circuit successively and automatically.

Railways and Appliances:—

Subway and Connection for Electric Railways, W. Osner, 455,763. Filed Oct. 13, 1890.
Uses the track rail as part of the structure of the conduit.

Electric Railway, R. M. Hunter, 455,796. Filed May 22, 1886.
A telpherage system.

Trolley for Electric Cars, W. H. Knight, 455,798. Filed Apr. 8, 1891.
Provides for sounding an alarm when the trolley wheel has run off the conductor.

Street-Car, F. W. Smith, Jr., and S. S. Williamson, 455,842. Filed Feb. 16, 1891.
In a car propelled by a local motor means are provided for arresting the movement of the car without stopping the revolution of the motor or of the driving-wheels; the car may be raised and supported independently of the driving-wheel.

Electric-Railway System, S. P. Wilcox and J. D. Partello, 455,956. Filed June 16, 1890.
A conduit system; includes the employment of conductors in sectional lengths in the conduit and a pair of continuous feeding conductors along the system.

Street or Station Indicator, W. T. Snedden, 456,006. Filed Jan. 14, 1891.

Railway Time-Signal, J. C. Dickover and W. Scott, 456,023. Filed Feb. 24, 1891.
A train register.

Street or Station Indicator for Cars, G. H. Tietjen, 456,098. Filed Jan. 20, 1890.

Motor-Truck for Elevated Railways, E. M. Turner, G. L. Van Beek and L. A. Brown, 456,103. Filed Oct. 2, 1890.
Adapted to a three-rail system in which the car is suspended from the upper rail.

Telegraphs:—

Automatic Circuit-Closer for Telegraph-Keys, J. W. Brown, 456,110. Filed Apr. 16, 1891.

PHILADELPHIA NOTES.

A LITTLE BASEBALL.—For some time past it has been evident that the employees of Partrick & Carter Co. were going to have a bad attack of baseball fever. The symptoms developed very rapidly and culminated in nines being selected from the store and factory, and the game was played on July 15, with the following result: Store 29; factory 11. It will be seen by the score that the factory was nowhere, which is easily accounted for when it is stated that Mr. Townsend was in the box for the store. He worked as hard as he would if he were chasing a $1,000 order, and the balls he pitched were of such high resistance that the heavy hitters of the factory couldn't get up enough voltage to make more than two safe hits, all their runs being made through leakage.

THE PARTRICK & CARTER CO. report business as very good for this season, their trade thus far being in advance of 1890 for the same period. Their King annunciator is a big success; the large dealers are having so many calls for them that they are making them a part of their regular stock. The new annunciator invented by F. S. Carter will be ready for the market very soon. It will unquestionably be the best thing in that line ever introduced by this firm, and will meet with the indorsement of the trade everywhere.

MR. J. W. PARKER has placed a 100 h. p. Ball engine with complete steam plant at the store of George Kelly & Co., Market street, which will operate a large arc light plant. He also placed an 80 h. p. Ball engine for the Ivy Brick Co., Ivy City, Washington, D. C.

MR. H. C. ROBERTS, of Vallee Bros. & Co., is in New Castle, Va., superintending the starting of an electric light plant which the above company has just installed in a large hotel recently erected in that town.

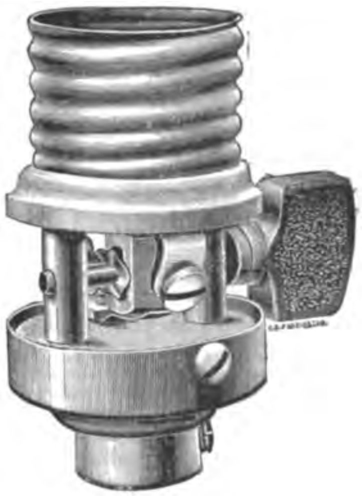
TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

Sweet are the uses of advertisements.—Mrs. Partington.

THE C. E. M. LAMP SOCKET.

THE accompanying engraving illustrates a new and improved lamp socket recently invented and manufactured by the Consolidated Electric Manufacturing Company, of Boston. The improvement consists in the method of making and breaking the contacts, so as to produce a quick and positive action, and so that the key is at all times either "on" or "off." This is done by means of a cam on the contact piece with four indentations into which a snap-spring fits, making the key turn quickly and preventing



THE C. E. M. LAMP SOCKET.

all possibility of short circuit or poor connection. The parts of the socket are all brass with porcelain insulation, and the workmanship is good and reliable. Already a number of large orders have been received, though the socket has but recently been put on the market, and the Consolidated Company are in receipt of many warm testimonials of its merit.

NEW ENGLAND TRADE NOTES.

MR. F. DAY VOORHEES, of the Norwich Insulated Wire Company, of New York, was in Boston this week, and reported good business in insulated wires. The Holtzer-Cabot Electric Company of Boston, have taken the agency for the Norwich insulated wires, and are already sending in large orders. The Norwich company have two factories in Brooklyn, but these are so overloaded with work, that they are now looking around for another factory, so as to increase their facilities for the fall trade. Their business in telephone cables alone is very large, nothing yet having been invented with so large an insulating resistance or so small an inductive capacity; but in addition to this staple line of goods the Norwich company are manufacturing large amounts of high insulation underground wires for electric light purpose, and are introducing a high grade line wire, which they are able to offer at very reasonable prices. They are also manufacturing a perfectly waterproof magnet wire and all kinds of house wires, which in addition to being waterproof are also thoroughly fireproof.

H. N. BATES & CO., of Boston, are having a large run on their goods for the equipment of central stations and other electric light plants, where first-class workmanship is required. Messrs. Bates & Company are sole selling agents for the United States of the famous Hunter friction clutch. Among their most recent contracts are the following: The new central station of the Concord Gas Company, Concord, N. H., which they are equipping complete with shafting, pulleys and friction clutches; the Woonsocket Electric Machine and Power Company, complete equipment of shafting, etc.; the Augusta, Hollowell and Gardner Electric Street Railway Company, Hollowell, Me., complete equipment of shafting, etc., and they are now engaged in remodeling the whole electric light plant of the Boston Post Office, installing Hunter friction clutches throughout.

THE SAFETY ELECTRIC LIGHT COMPANY, of Boston, which has for the past few months been making experiments with a primary battery for electric lighting, has so far perfected its battery as to put it to several practical tests that seem clearly to demonstrate its commercial value. The particular field in which the company has been working is the lighting of steam railroad cars, and several exhaustive and successful trials have been made by lighting the cars on long railroad trips. This week the directors' car of the New York and New England railroad, which has recently been equipped with the battery, made a short trip, affording an opportunity of witnessing the burning of the lights. There were eighteen lamps used, each of sixteen candle power, and these illuminated the parlor, the different staterooms, the kitchen and the other parts of the car. The battery cells were carried in a neat box beneath the car floor, and the place was so arranged that the cells could be removed and charged with fresh solution with very little difficulty. The wires from the battery lead to a convenient place in the interior of the car, where is located the switchboard, and from here the lamps on the different circuits can be lighted as well as turned to any degree of brilliancy from one candle to sixteen. The Safety Electric Light Company has been very conservative in its operations and is making every possible test to demonstrate the practicability of its light before placing it on the market. The trip last evening was most successful in every way.

THE UNION ELECTRIC MANUFACTURING CO., of Bridgeport, Conn., have now got thoroughly ready for business, and have already placed on the market a very handsome lamp socket and rosette, illustrated in our last issue. They are now manufacturing and will have ready for sale very shortly an excellent double-pole switch, which does not in any way conflict with existing patents. Their business is opening up in very good shape, though the company as yet are very modest in their reports, but well satisfied with what they have already done. The company are in receipt of numbers of letters of testimonial, and promise to the trade a line of goods which do not require *to be returned.*

MR. WILLIS L. ADAMS, of the Electric Merchandise Company, of Chicago, was in Boston, this week, looking up a number of his customers and friends in the interests of his company. In the midst of his calls he found time to drop into the Boston office of THE ELECTRICAL ENGINEER.

THE PETTINGELL-ANDREWS CO. report that they have decided *not* to go into the proposed combination to be known as the United Electric Company, which was outlined in our issue of July 8th. They will continue to do business as formerly under their own title.

WESTERN TRADE NOTES.

THE NEW CHICAGO HERALD BUILDING have placed an order with the Western isolated lighting department of the Thomson-Houston Electric Co. for a plant consisting of one 10,000 and one 15,000-watt arc dynamos with 50 double-carbon arc lamps, which will be novel in some respects. Special permission was obtained from the city electrician for the concealing of the arc light wires in this building, and a high grade of rubber-covered wire will be used, protected by "Interior Conduit" and laid in the cement flooring. A circle of six lights will be placed on the flagstaff so arranged that they can be raised or lowered at will with perfect ease by one man.

Special fixtures for suspending the arc lamps, a number of which will be placed on the front of the building, have been designed, and the wires leading to these fixtures will be brought through the building front. In order to accomplish this it will be necessary to drill in some places through five feet of brick and terra cotta, and in other places through about three feet of solid granite.

THE CHICAGO ELECTRIC MANUFACTURING CO., 73 W. Jackson St., Chicago, have just fitted up a very complete and elaborate testing-room for the calibration of ammeters, voltmeters and electrical testing instruments of all kinds. They are also making a specialty of electrical instrument repair work, and have excellent facilities for carrying on this branch of business with promptness and in the best possible manner. They are doing a large business in the manufacture of general electrical supplies and in experimental apparatus.

MR. WM. HOOD, dealer in electrical specialties, and Western agent of the Accumulator Company, is meeting with great success with the Jewel incandescent lamps, for which he is agent. His attractive exhibit in his handsome store window on La Salle street is exceptionally catchy, and must be seen to be appreciated.

☞ Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Miscellaneous, etc., will be found in the advertising pages.

THE FRANKFORT INTERNATIONAL ELECTRICAL EXHIBITION—IV.

BY

Richard O. Heinrich.

Building for Scientific Apparatus and Electro-Medicine.

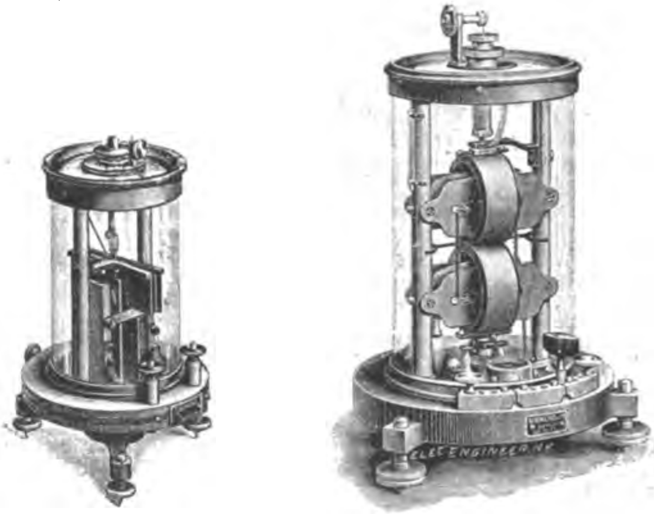
BY far the greater part of this building is occupied by Messrs. Siemens & Halske. This represents only a small part of the exhibit made by this firm in the different buildings, and it may almost be said that the exhibition is more or less monopolized by three large concerns, viz, Siemens & Halske, Schuckert, and Helios. The exhibit referred to represents a very complete testing and calibrating laboratory. It is interesting in its general design, and contains, besides the well-known types of instruments manufactured by this firm, quite a number of novelties of more than passing interest.

Five divisions are made, as follows: 1. Machine-testing room; 2. Cable-testing room; 3. Calibrating-room; 4. Laboratory for measurements of precision; 5. Workshop. A sixth addition is made at present in which it is the intention to show by means of vibrating flames and rapidly-rotating mirrors the vibrations made by the diaphragms of telephones, microphone transmitters, etc. The general idea followed throughout in this laboratory is to make the time required for technical tests a minimum by the employment of a bewildering multitude of switchboards and special arrangements. Some appear rather complicated and cumbersome, but all are of excellent workmanship.

The machines to be tested are placed on adjustable base-plates. A number of electric motors, of different capacities, are always in readiness to be belted to the machines under test. Time tests are made, and the E. M. F, current and resistance, hot and cold, of the dynamos are measured in an adjoining section. The instruments used for measurement are mainly the Siemens torsion galvanometer, Fig. 1, which is used as a voltmeter and ammeter; one instrument, with the necessary shunts and multiplying resistances, is used in the laboratory. The shunts and resistances are naturally of such dimensions that a multiplication of the scale divisions with a power of ten gives the respective values directly in volts and amperes; a switch enables the observer to take the two readings almost simultaneously with the same instrument. Resistances are tested with the Wheatstone bridge, or a modified Thomson bridge for very low resistances, and a sensitive mirror galvanometer.

As to the torsion galvanometer, apparently the standard instrument adopted in Germany, it may be said that the same measurements may be made with any very sensitive voltmeter, as, for instance, the Weston voltmeter, which is even decidedly preferable to the torsion galvanometer for a number of reasons. The torsion galvanometer has to be placed level on a rather solid foundation in a north-south direction. When a current is passing, the torsion-spring has to be adjusted until the pointer of the magnet returns to zero. The instrument is therefore, strictly speaking, not direct reading. It is true the resistances and the torsional force of the spring are chosen in such a way that each scale division corresponds to a whole or a simple fraction of a volt or ampere. The indications of the instrument are very much influenced by surrounding magnetic disturbances, or by a change of the magnetic movement of the bell magnet of the galvanometer itself. If such a change takes place the comparative direct reading can only be re-obtained by adjusting the torsional spring. There may also be a chance, even if very remote, of changing the torsional force of the spring by an overtwisting, or by giving a jerking motion to the magnet.

There is on exhibition an apparatus, or rather combination of apparatus, by which the torsion galvanometers are calibrated. It is the application of Poggendorff's method with some very practical modifications. The standard E. M. F. employed is a Clark cell. Temperature corrections are made directly with the adjustable rheostat, and checks,



FIGS. 1 AND 2.—SIEMENS TORSION GALVANOMETER AND ASTATIC ELECTRO-DYNAMOMETER.

if necessary, can be made with a silver voltameter. The whole combination of Clark cell, rheostats, and silver voltameter is mounted on one board, very handy for use. It is evident that the calibration of the instrument must be exceedingly correct (the possibility of reading off very inaccurately is not very great), since each instrument is said to be calibrated with the apparatus mentioned. The absolute constancy of the Clark cell, in inexperienced hands, may be a doubtful point, which, however, can easily be remedied or verified. The resistance of the instrument as a voltmeter is not nearly so high as, for instance, in the Weston instrument for the same ranges. To the American taste the instrument would appear flimsy and not very portable with all the shunts and series resistances.

Since this torsion galvanometer is not very well known in America, it may be well to be a little more explicit, Two types are manufactured, one with 1 ohm resistance in the galvanometer coils, the other with 100 ohms. If the instrument is to be used as a voltmeter, series resistances enclosed in a circular box give the different ranges of the instrument. With a 1 ohm galvanometer, for instance, there would go a resistance box, containing 9, 99, 999, and 9999 ohms. The following table would then represent all the necessary data about the instrument as a voltmeter.

Resistance of galvan. plus series resistance.	Sensitiveness.	Total range.
1 ohm.	1 on scale = 0.001 volt.	0 to 0.17 volts.
10 "	1 " = 0.01 "	0 to 1.70 "
100 "	1 " = 0.1 "	0 to 17. "
1,000 "	1 " = 1 "	0 to 170 "
10,000 "	1 " = 10 "	0 to 1,700 "

Using the instrument as an amperemeter, different shunts are necessary; usually $\frac{1}{9}$, $\frac{1}{99}$, $\frac{1}{999}$, $\frac{1}{9999}$ are furnished.

Shunt.	Total resist. of branch.	Sensitiveness.	Total range.
∞	1.	1 = 0.001 amp.	0.17 amp.
$\frac{1}{9}$	0.1	1 = 0.01 "	1.7 "
$\frac{1}{99}$	0.01	1 = 0.1 "	17 "
$\frac{1}{999}$	0.001	1 = 1 "	170 "
$\frac{1}{4999}$	0.0002	1 = 5 "	850 "
$\frac{1}{9999}$	0.0001	1 = 10 "	1,700 "

The resistance of the instrument as a voltmeter is rather low for the respective ranges in comparison with the Weston instruments, which have 80,000 to 100,000 ohms and more, for a range of 150 volts. The resistance as an ammeter is rather high. (Weston 15 amp. scale, 0.0022 ohm; 150 ampere scale, 0.00022 ohm.) In the first case the instrument will be subjected to heating errors, and also in the second an unequal heating of shunt and galvanometers will easily change the apparent ratio, since both are entirely separated, and if used with stronger currents, are not at all likely to have the same temperature.

The usual defense of our German confreres is that the instrument answers perfectly for all practical purposes! On the other hand it was seriously claimed in my presence that the Americans were not able to make instruments of precision. Suppose we cannot make them, then we have at least the common sense to appreciate a good and accurate instrument, and use it wherever necessary, regardless of price. An American central station manager of any conscience whatever appreciates the money-saving qualities of a voltmeter which is accurate within 0.15% under all circumstances, which is an impossibility with an instrument in which soft iron constitutes the moving parts. Ammeters of this type are excusable; but to make a general practice of using cheaply constructed voltmeters for incandescent light installations is certainly uneconomical and bad. If, as the makers, and often the users, claim, the magnetic lag, etc., in such instruments may be entirely neglected, they imply at the same time that a change in pressure of from 2 to 4%, and more, does not seriously affect the life of the lamps,—which remains to be proven.

In Fig. 2 is shown an instrument in which some of the weak points of the torsion galvanometer, and of the usual form of electro-dynamometer, are eliminated. It is an astatic electro-dynamometer. Two coils precisely equal in resistance and magnetic moment are united to an astatic couple and suspended by a fine silver wire. A torsional spring above and below controls the zero point, and the current is taken to the coils through very fine wire spirals, the torsion of which may be neglected. This astatic couple is movable about two stationary coils, as shown in the illustration; otherwise the instrument is identical with the usual form of electro-dynamometer. Instead of having a degree scale, and furnishing a table of the respective value, a scale giving divisions of the squares allows the reading to be made without computation. This instrument has the great advantage of being entirely uninfluenced by external magnetic changes. It is not very dead beat, and its sensitiveness is very small in the neighborhood of the zero point, as it is in all instruments in which the deflections are proportional to the square of the current.

THE PITTSFIELD, MASS., ELECTRIC LIGHT STATION.

BY

McSullivan.

THAT electrical progress has penetrated the poetic Berkshire Hills—the delightful strip of Western Massachusetts made famous by Hawthorne, Bryant, Fanny Kemble and others—and become firmly established, with all its improvements and conveniences, may not be known even to those whose names have become prominent in the electrical industry, and who at one time or another have claimed these charming hills as their home or resort.

Bountiful Nature seems to have poured out her richest treasures upon this favored section, and the introduction of electric light and power—those adjuncts now absolutely necessary to complete the list of appliances for comfort and convenience—leaves but little that could further enrich and render attractive its hills and valleys. Thus it is that the new central station at Pittsfield, Mass., is well worthy of attention. Situated in the heart of this largest town in

FIG. 1.—GENERATORS, PITTSFIELD, MASS., ELECTRIC LIGHT STATION.

the Berkshires, the station is in itself a model. It embraces features which are destined to be essential in the central station of the future, the principal one of which is its *composite* character.

Within walls of tasteful design are to be found the four divisions of the modern station, viz., incandescent and arc lighting, generators for supplying current for electric railways, and dynamos for furnishing electric energy to users for the various purposes to which electricity is now being adapted.

Electricity made its début in Pittsfield some six years ago in the shape of a single arc dynamo which was started to supply light to a few enterprising merchants who clubbed together for the purpose. From a small beginning this growing city has now realized a most perfect installation. The broadest streets are illuminated by arc lights, while the more shaded ones get their light from the little incandescent lamps connected in multiple series. To people visiting the town from the surrounding villages, notable among which is the far-famed Lenox, the perfect street lighting must be a revelation, as Pittsfield is one of the very few towns in the country which possesses this combined electric system for dispelling the gloom and darkness.

The station building is of a type known as "mill construction," and is considered fireproof. The term "mill construction," it may be said, defines a building in which the interior, or body of the building proper, is entirely independent of the side walls, thus minimizing the jarring

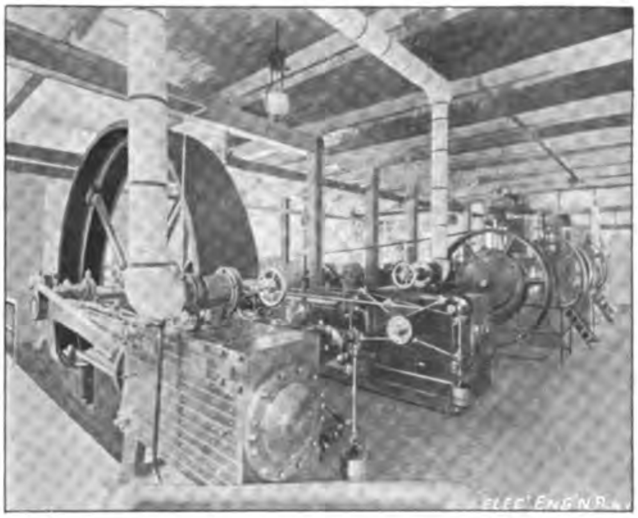


FIG. 2.—ENGINES, PITTSFIELD, MASS., ELECTRIC LIGHT STATION.

effect. It is a two-story building. The engines and dynamos are located on the first floor; the laboratory of Mr. Wm. Stanley, Jr., whose work in the alternating field is so well known, occupies the second.

There are now six Westinghouse alternating incandescent, two Thomson-Houston arc dynamos, and three Westinghouse constant potential, 500-volt, 50 h. p. generators. One of the latter is being used for the commercial power work, and the other two for supplying current to the street railway system. These are shown in our engraving, Fig. 1.

The motive power consists of one 400 h. p. Harris Corliss, and three Westinghouse engines of 100 h. p. each, shown in Fig. 2. The large Harris Corliss is used for the

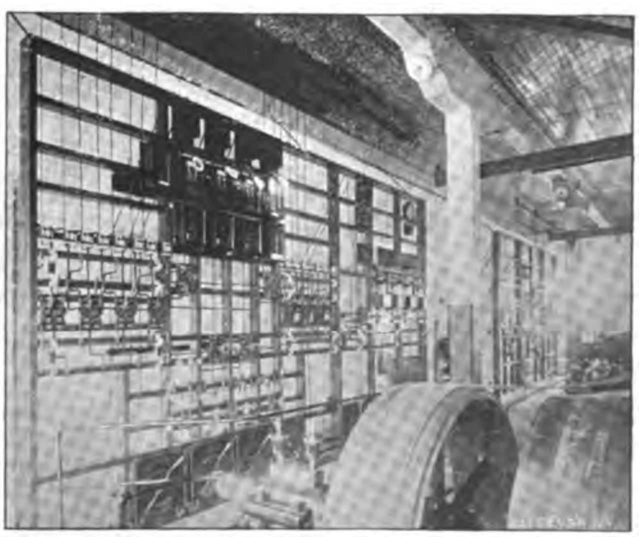

FIG. 3.—SWITCHBOARD, PITTSFIELD, MASS., ELECTRIC LIGHT STATION.

heavy work, while the smaller ones are reserved for light day duty. Power from the large engine is transmitted by a heavy belt to a shaft which extends along the west side of the building, on which are arranged tight and loose pulleys.

The switchboards, Fig. 3, occupy the entire north end of the room, directly in front of the offices. Between them and the wall is sufficient distance to allow of inspection from the rear without difficulty. The board is so divided that one side is for street and commercial incandescent lighting; the other half is devoted to arc light, motors and street railway power circuits.

Wires conduct the current from the generators to switchboard through tubing placed under the floor, and from there the wires to the outside circuits are led to a large pole a short distance from the station. Cross-arms on this pole are arranged in the form of a triangle, to which all the wires leading into the station are attached.

The laboratory of Mr. Stanley on the second floor is to be his future workshop. Here he has arranged one of the most complete laboratories to be found anywhere. It embraces a large chemical room, draughting department and workshop. The latter is a large, well-lighted room, and fitted up with all kinds of machinery for experimental purposes. Here it is that Mr. Stanley will carry on his work which has resulted in the past in so many valuable additions to the electrical industry.

The boiler-room, shown in Fig. 4, is a wing attached to the main building, 45 x 85 feet, at the end of which is the stack, 90 feet high, with 68-inch flue. The room contains

FIG. 4.—BOILERS, PITTSFIELD, MASS., ELECTRIC LIGHT STATION.

at present four boilers, built by Mr. H. S. Russell, of Pittsfield, having a capacity of over 700 h. p., and space has been reserved for additional ones for future demands.

The many advantages of the electric light are highly appreciated in Pittsfield, and its rapid introduction is surprising. As is well known, this beautiful old town contains some of the finest country residences in the Union. New ones are constantly being erected, and in nearly every case the new buildings have the electric light installed.

The electric street car system, lately inaugurated, will serve to emphasize the great superiority of this new form of propulsion. The village itself is greatly scattered. Embraced within its limits are several smaller hamlets devoted to manufacturing. From these outlying districts hundreds of people enter the village proper every night. Heretofore the horse cars have not been able to meet the requirements of rapid travel with heavy loads. Altogether Pittsfield is to be congratulated on its electrical facilities, and the success attained will no doubt lead other towns in that locality to follow its example. The road leads from the heart of the town to a pleasure resort called Pontoosac Lake, a distance of three miles.

CAPT. DE KHOTINSKY, whose name is well known in the field of electric lighting, will sail from Europe for this country in a few days, in the interest of the Germania Electric Co., of Boston, which controls his inventions here.

ELEMENTARY GEOMETRICAL THEORY OF THE ALTERNATE-CURRENT TRANSFORMER.—X.

BY

Chas. Steinmetz.

VII. Self-Induction in the Secondary Circuit.

Until now, we have considered the secondary circuit of the transformer as closed by a non-inductive resistance, so that there is no self-induction present except the magnetic leakage of the transformer proper, treated of in chapter V. If the secondary circuit is closed by an inductive resistance, for instance an electromagnet, the secondary current lags behind the secondary E. M. F. by an angle δ. To determine this angle, we proceed in the following way :

Let s_1 = the magnetic resistance of that magnetic circuit, which causes the self-induction of the secondary current. This secondary current may flow around this magnetic circuit in m turns. Then the M. M. F. of the secondary current C_1, exerted upon the magnetic circuit of the magnetic resistance s is, $F_1' = m\ C_1$, and hence the magnetism produced thereby is $M_1 = \frac{m\,C_1}{s_1}$.

This magnetism induces the maximum counter E. M. F.,

$$\varepsilon_1 = 2\,\pi\,m\,N\,M_1 = \frac{2\,\pi\,m^2\,N\,C_1}{s_1}.$$

The E. M. F. consumed in overcoming the secondary electric resistance is $\varepsilon_1 = C_1\,r_1$. Therefore the secondary E. M. F., ε_0, impressed upon this inductive resistance s_1, is derived in Fig. 21 from the parallelogram of E. M. F.'s $o\ \varepsilon_1\ \varepsilon_1\ \varepsilon_0$, where the heating E. M. F., $\overline{o\ \varepsilon_1}$ is perpendicular to the induced E. M. F., $\overline{o\ \varepsilon_1}$, as $\overline{o\ \varepsilon_0}$, and gives the impressed secondary E. M. F.,

$$\varepsilon_0 = \sqrt{\varepsilon_1^2 + \varepsilon_1^2} = C_1\ \sqrt{r_1^2 + \left(\frac{2\ \pi\ m^2\ N}{s_1}\right)^2},$$ and the

angle of retardation, $\delta = \overline{\varepsilon_1\ o\ \varepsilon_0}$; hence, $\tan\ \delta = \frac{2\,\pi\,m^2\,N}{r_1\,s_1}$.

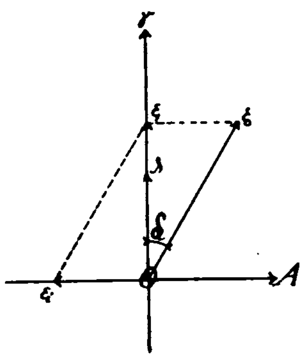

FIG. 21.

For producing the transformer diagram, in Fig. 22, we make as usual, $\overline{o\ F} = F$ the resulting M. M. F., $\overline{o\ E_1{}^1} = E_1$ the secondary E. M. F., produce a half circle with $\overline{o\ E_1{}^1}$ as a diameter, and make angle $E_1{}^2\ o\ E_1{}^1 = \delta$. Then $\overline{o\ E_1{}^2}$ is the resulting, or heating, secondary E. M. F.

Producing in the same way half circles over $\overline{o\ L_1{}^1}$ and $\overline{o\ C_1{}^1}$ as diameters, we get the secondary M. M. F., $L_1 = \overline{o\ L_1{}^2}$ and the secondary current, $C_1 = \overline{o\ C_1{}^2}$.

Completing the parallelogram of M. M. F.'s, with $\overline{o\ F}$ as a diagonal and $\overline{o\ L_1{}^2}$ as one side, $o\ L_1{}^2\ F\ L^2$, we get the primary M. M. F. as the other side, $L = \overline{o\ L^2}$, if we neglect the influence of hysteresis and eddies.

When taking into consideration hysteresis and eddies, by means of an ideal current, or rather ideal M. M. F., $\overline{o\ A}$, we have to produce this M. M. F. $\overline{o\ A}$ with the same phase as the secondary current $\overline{o\ C_1{}^2}$, and derive the point K, whence by the condition $\overline{F\ K} = \overline{o\ A}$ and $\overline{F\ K} \parallel \overline{o\ C_1}$.

This gives a somewhat different form of the curve of magnetic lag, k, as shown more particularly in the next chapter.

From the primary M. M. F., $L = \overline{o\ L^2}$, we get the primary current, $C = \overline{o\ C^2}$, and the primary heating E. M. F., $E = \overline{o\ E^2}$, and by the parallelogram of primary E. M. F.'s, $o\ E_1\ E^2\ E_0{}^2$ the primary impressed E. M. F., $E_0 = \overline{o\ E_0{}^2}$.

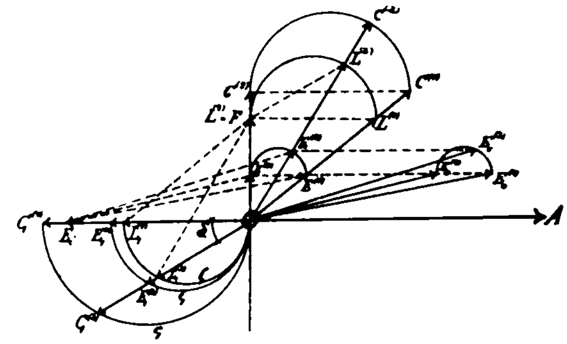

FIG. 22.

Now suppose the self-induction of the secondary circuit increases from 0 to ∞, then angle δ increases from 0 to 90°, and the secondary current, C_1, and the secondary M. M. F., L_1 travel on the half circles c_1 and l_1, from $C_1{}^1$, that is, $L_1{}^1$ to 0.

In the same manner L, C, E, E_0 travel on half circles, from $L^1, C^1, E^1, E_0{}^1$ to $L^2 = F$, that is, $C^2, E^2, E_0{}^2$, and we derive the following results :

If the self-induction of the secondary circuit increases, while the other constants remain the same, the phase of the primary current C increases, the phase of the primary impressed E. M. F., E_0 first increases, reaches a maximum, and then decreases again. Hence the difference of phase between primary current and impressed E. M. F. increases first slowly, then faster.

The difference of phase between primary current and secondary current, $C\ o\ C_1$, being almost 180°, increases very slowly, and reaches 180° for infinite self-induction. Any change of the phase of the secondary current therefore enforces a change of the phase of the primary current, so that both currents always have almost opposite phases.

Hence the transformer cannot be used for producing shifting of phases, but any self-induction or capacity, thrown into the secondary circuit, acts almost exactly in the same way upon the primary current, as when directly connected into the primary circuit, so that both currents always have very nearly opposite directions of equal phase.

ELECTRICITY AND ART.

MR. JAN VAN BEERS, in London, recently held a social gathering at the Continental Gallery to welcome his English patrons. Over a hundred guests sat down to supper, which in its way was unique. Astonishing effects were produced by the electric light. The supper table was made of glass, covered with an ordinary white table cloth ; underneath 300 incandescent lamps of various shades were placed, which suffused the table with light. Electric lamps were placed in every nook and corner of the room. The installation, which consisted of 575 lamps, was fitted up by Messrs. Mellier & Co., of Margaret street, Cavendish Square, under the superintendence of their engineer, Mr. W. Lowry. The whole of the work was completed by four men in one day.

THE SCHUCKERT TRANSFORMERS.[1]

After a series of studies undertaken to determine the most economical form to be given to converters, the firm of Schuckert & Co., of Nuremburg, Germany, have adopted the type illustrated in the accompanying engravings, Figs. 1 and 2. This will be seen to consist of a slotted ring, the coils being placed in radial slots, and the magnetic circuit completed by a ring-shaped cover which is bolted to the main core. Several advantages are claimed for this type of transformer. Thus, the coils may be wound in a lathe and insulation can be made perfect, and in case of accident to a coil it can be readily removed and a new one inserted. In order to obviate the jumping of a spark from primary to secondary, a sheet of copper is laid in between the two,

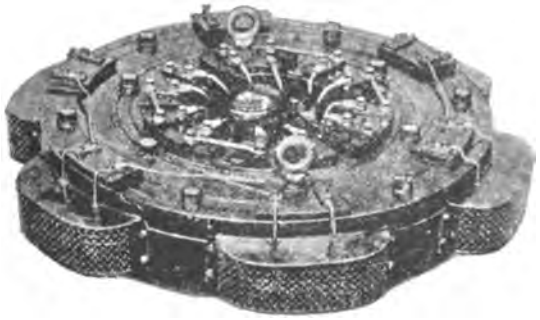

Fig. 1.—Schuckert Transformer.

and connected with the iron ring on one side, and the iron ring is permanently connected to earth, so that it can always be handled with impunity. The spark would therefore have to pass through the copper sheet first, and would reach the ground before entering the primary. The smallest number of slots which could be given to such a transformer is four; and in this case the complete ring represents two transformers entirely independent of each other. Larger rings built up of band iron are given a larger number of slots, as shown in the engraving, Fig. 2, in which

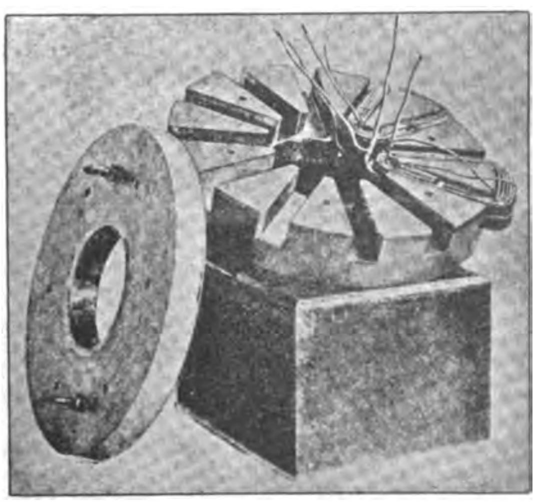

Fig. 2.—Schuckert Transformer.

the transformer has 12 slots, affording room for six individual and independent transformers, which can be coupled up in series or parallel in any desired manner. The flexibility of these larger transformers is thereby greatly increased, not only for laboratory work, but also for many practical purposes, where this subdivision presents many advantages. Thus the destruction of one coil would not by any means place the converter out of service. The peculiar construction of the transformer also makes it possible to obtain currents having any desired difference of phase; for example, taking the most simple case, that of a flat ring with four slots, as shown in Fig. 3. Here the primary windings are laid in slots 1 and 4, and 2 and 3, and the secondary windings, on the other hand, in slots 1 and 2, and 3 and 4. The secondary currents generated differ in

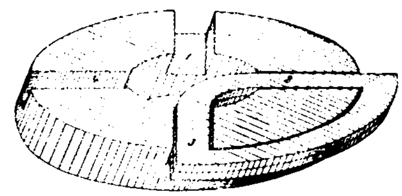

Fig. 3.—Schuckert Transformer.

phase 90° from each other, but differ only 45° with respect to the primary currents. These ring transformers are being exhibited by Messrs. Schuckert & Co. at the Frankfurt Electrical Exhibition, and are operated at 100 reversals per second.

SWINGING BALL LIGHTNING ARRESTER.

BY

F. H. Tidman.

In the summer of 1888 we had a severe lightning storm in the town in which we were operating an electric light plant, the first stroke of which entered a prominent store lighted by incandescent lamps on the converter system, and discharged upon the gas chandeliers, burning several sockets, and badly scaring the occupants. After this display the proprietor ordered all electric light wires off his premises, and did the electric light business great harm by telling people that blue flames shot out all over his store, and condemning the electric light as unsafe and dangerous to life and property. A short time after came another storm which shut down the plant by burning out the armature and destroying a number of converters. We concluded that if this was to be repeated every summer, there was little chance of securing a dividend for the directors, and that our customers would fall off. At about the same time another plant was nearly burned down on account of a comb lightning arrester with hard rubber base setting fire to a wooden partition, the brass comb having become fused together by the arc following, and short-circuiting the dynamo, the fuses of which did not burn out. The only thing which saved the station was presence of mind on the part of the engineer, who took an axe, cut down the partition, smashed the offending lightning trap and extinguished the fire.

With these facts before us, and having purchased the best arresters on the market, and being informed by the various arrester makers that all we had to do was to put their arresters in our station, one on each pole of the dynamo, we anxiously awaited another storm, which came while I was in the station at mid-day, while there was no current on the line. I saw a discharge take place on the station arresters, which I thought was rather heavy, and several others followed in rapid succession; the dynamo switches were open, and we thought the lightning had been carried to earth without doing any damage, but when we started up several complaints came in that lights were not burning, and one customer said there was a report like a gun in the box on the front of his house, and that the lightning struck it, and requested that it be removed at once, as his wife and himself had heard that the lightning had actually entered a store, the wires emitting blue flames. It then occurred to us that the lightning arresters were at fault, as our arc system received the same treatment, but to a lesser extent, which we attributed to its badly insulated condition, it being a very old line, which we intended to renew. We then studied all the works on static electricity, and reported effects of lightning, and were the first to conclude that we not only wanted arresters in our station, but also on our line. Having decided this important point, we cast about for an arrester which could be placed on the poles, and which would not ground our lines, needed no attention, did not cost much money, and was always ready, no matter how frequently the discharges took place. This we could not find; so we decided to make elaborate experiments in order, if possible, to supply our want.

We had before us all conceivable methods of producing rapid motion in a conducting body in order to break the following arc, and tried their practical value on our lines. Amongst other methods the pith ball was tried, suspended by a chain over a proper grounding device, and the chain connected to an arc-light circuit of 2,000 volts and 10 amperes. The arrangement was then attached to a powerful static machine, which would give a 19-inch spark in the air, and upon passing a discharge from the machine at a distance of about 3 inches from the discharging plates, the ball was violently thrown into motion and the following arc broken instantly. The experiment led us to make a complete outfit of these arresters, which were placed in wooden boxes and attached to a regular incandescent electric light circuit, with the result that no further trouble from lightning has ensued upon that line. Experience and time taught us that wooden boxes and galvanized iron covers with poor insulation gave trouble on account of effects of the weather upon the wood, which split and let in the rain, grounding

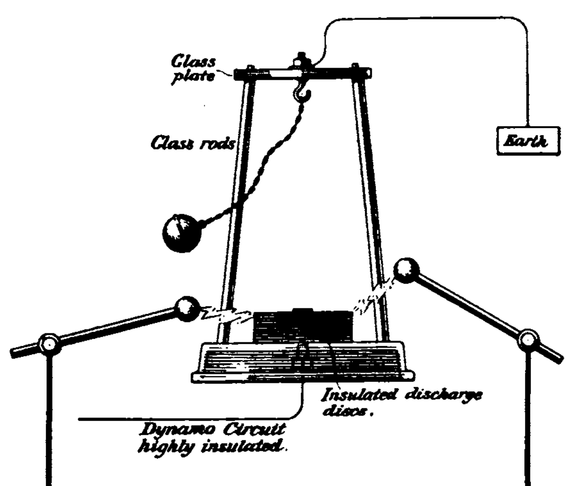

Fig. 1.—Swinging Ball Lightning Arrester.

the circuit; but we cared little for this, as they were evils which could be easily remedied by proper and careful construction. We then had the insulating material made of porcelain and the working parts covered by water- and dust-proof covers with brackets for attachment to poles, buildings, etc.

In order to enable those interested to repeat our experiment with the pith ball, I have made a sketch, Fig. 1, which explains itself to those who are familiar with the laws of static electricity.

We found that a metal ball would work in place of the pith ball, but that it must not be heavy or badly insulated from the opposite pole. It will be apparent to most of those who have to deal with heavy currents for light and power, that the following arc cannot exist under such circumstances. In practice it is found that the number of these arresters necessary to protect a mile of line with the average number of customers on a main street is 8, and it will be readily seen that a line provided with a number of discharging points, as shown in the accompanying illustration, Fig. 2, will never be troubled with broken lamps, converters, burnt-out motors, generators, etc., as the static charge from lightning is provided with points of lower resistance to ground than any part of the system.

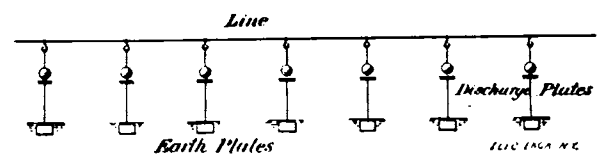

Fig. 2.—Swinging Ball Lightning Arrester.

Some persons ask, What would become of the arrester if the line were supplied with a current of 2,000 amperes and 500 volts? Our answer to such is, that the following current is instantly broken, and could not in any case burn out the arrester, even if the ball from any cause, such as careless installation, etc., failed to move, because the discharge plates, which are arranged as in the old-time telegraph and electric light arresters, would provide an insulation from a direct ground.

We may here state that the observed effect of a heavy and apparently direct stroke of lightning on an arc line was that the violence of the disruptive discharge was so great, that it blew the covers from the nearest arresters, leaving the swinging ball and discharge plate intact, and moving the ball in the arresters in the station to the same degree as in less severe strokes, and proved to the station operatives that they had nothing to fear from lightning of the most severe character.

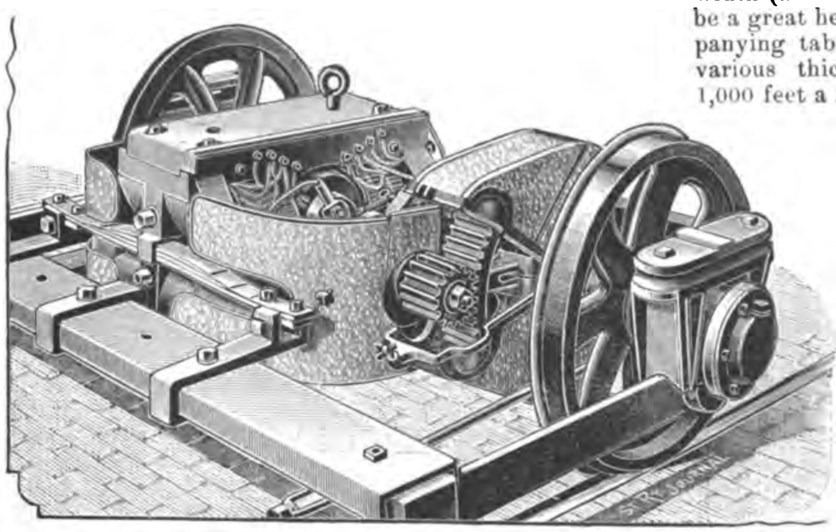
In conclusion, I would say that no station can afford to run without line arresters, which are the only safeguards against destruction to lamps, converters and motors; and further, that a single swinging ball arrester placed upon a large circuit is practically useless. It is, furthermore, against the laws of nature to expect lightning to carefully avoid lamps and motors and go gracefully to ground by the one arrester which we have heretofore provided at our stations.

THE FIVE-WIRE SYSTEM IN PARIS.

With the exception of the Vienna and Königsberg stations, the 45,000-light station, supplying the Place Clichy sector, which was recently inaugurated, is the only one of its kind in Europe. The Paris station has three floors, and covers a superficial area of 19,800 square feet. In the basement is the boiler plant, which comprises six of the Naeyer multitubular type. The ground floor is occupied by the steam piping, while on the first floor are placed the engines, dynamos and the distributing board. The generating plant comprises three 150 h. p. Armington and Sims engines, each belt driving two shunt-wound dynamos, and three 500 h. p. Corliss engines, running at 64 revolutions, and each of which is coupled direct to a 350-kilowatt (700 amperes at 500 volts) eight-pole machine The armatures of these dynamos are 11 feet in diameter, and the brushes bear on their exterior. A 250-cell battery of Laurent-Cely accumulators supplies current during the day. The district supplied by this station has an area of nearly two square miles, and the most distant feeding point is 2,750 yards away. To keep the pressure on the different branches at the proper value six sets of automatic apparatus are employed. The mains are all lead-covered, iron-armored Siemens cables. Aron meters are employed, and are modified to suit the exigencies of five-wire distribution, that is to say, the coils are arranged so that the current in the two outer leads exerts double the magnetizing influence of the current in the two adjacent leads, the central wire not passing through the meter at all. The Société Alsacienne de Constructions Mécaniques is responsible for the erection of the whole system.

THE WIGHTMAN ELECTRIC RAILWAY MOTOR.

In our issue of July 22 we described the improved electric car equipment now being manufactured by the Wightman Electric Manufacturing Co., of Scranton, Pa., and to



20 H. P. Wightman Motor Mounted on Truck.

the details already given we are now enabled to add the motor mounted upon the truck and the method of suspension. As will be seen in the accompanying engraving, the flexibility in suspension has been obtained by the use of a flat steel spring. The elasticity of this form of spring is greater than that of any other, and the tendency of the motor wires to crystallize and break on account of the jarring is reduced to a minimum.

The engraving also shows the Wightman Co.'s novel gear case. The construction is such that the gear can be exposed for examination at a moment's notice. The upper and lower halves of the case are hinged after the manner of a pair of shears. By loosening one bolt or thumbscrew the two halves swing one inside the other, in this way exposing the armature pinion, as shown. The pinion can then be removed without taking off the case.

The Wightman company have equipped a car with all their latest improvements, and fitted up as a drawing-room in the most exquisite taste. This car is intended to be taken about from place to place in order to demonstrate the value of the improvements introduced by the company.

ELECTRIC TRANSMISSION OF POWER AT FRIBOURG.

The municipal authorities of Fribourg are about to install a hydro-electric power transmission station at the Sarine dam, outside the town. The contract has been awarded to MM. Cuenod, Sautter & Cie., of Geneva, who will install two 150 h. p. 150 volt machines. Distribution will be effected on the three-wire system. The prices which it is proposed to charge are remarkably low when compared with the tariff elsewhere. Thus the charge for 1 h. p. during a year of 3,000 hours will be $69.00. In the case of a 5 h. p. motor, the charge will be $63.00 per h. p. per annum, and $39.00 per h. p. per annum for motors of 21 h. p. and upwards.

A HANDY RUBBER BELT TABLE.

BY

Every power user is confronted at some time with the problem of what belt width to get to drive his establishment, or certain machines therein, and very often his lack of proper information at first proves, after purchase, both annoying and expensive. To be able to pick out a belt width (and thickness) which will be just about right would be a great help; and such help is afforded by the accompanying table, which shows what width of rubber belt of various thicknesses is needed to transmit 10 h. p. at 1,000 feet a minute, with various arcs of contact on a cast-iron pulley. The belt joints are assumed to be made with single leather lacing. If other fastenings are used, there is a foot-note which enables due correction to be made. If the belt speed is double or treble that for which the table is made, only half or one-third the width will be required; and in like inverse proportion for other speeds. If the thickness for rubber belts offered for sale differs from those quoted, the widths required will be inversely proportional; thus, if the belt offered or contemplated be $\frac{7}{16}$ inch thick, there will be required a width between that demanded for $\frac{3}{8}$ and that for $\frac{1}{2}$ inch. Belt thicknesses are given in fractions of an inch instead of in "plies," because some makers' five-ply is not thicker than other makers' four, and some manufacturers make two or three thicknesses for each nominal number of plies. A few examples are here given:

1. It is required to know how many inches of belt $\frac{1}{4}$ inch thick (laced with single leather lacing) will be needed to carry 20 h. p. at 2,000 feet a minute, the arc of contact being 180°.

Table of Widths of Vulcanized Rubber Belts,

On Cast Iron Pulleys, with Various Arcs of Contact, to Carry Ten Horse-Power[1] at 1,000 Feet a Minute.[2]

(This table is for belts joined with single leather lacing [3])

Arc of contact.		Belt thickness in inches.				
		$\frac{3}{16}$	$\frac{1}{4}$	$\frac{3}{8}$	$\frac{1}{2}$	$\frac{5}{8}$
30°	$\frac{1}{12}$ cir.	25.77	19.32	12.88	9.66	7.73
45°	$\frac{1}{8}$	18.20	13.65	9.10	6.82	5.46
60°	$\frac{1}{6}$	14.40	10.80	7.20	5.40	4.32
75°	$\frac{5}{24}$	12.18	9.13	6.09	4.06	3.65
90°	$\frac{1}{4}$	10.67	8.00	5.33	4.00	3.20
105°	$\frac{7}{24}$	9.70	1.27	4.85	3.64	2.91
120°	$\frac{1}{3}$	8 85	6.64	4.43	3.32	2 66
135°	$\frac{3}{8}$	8.30	6.22	4.16	3.11	2.49
150°	$\frac{5}{12}$	7.80	5.85	3.90	2.91	2.34
165°	$\frac{11}{24}$	7.46	5.60	3.73	2.80	2.24
180°	$\frac{1}{2}$	**7.15**	**5.36**	**3.57**	**2.68**	**2.15**
195	$\frac{13}{24}$	6.93	5.20	3.47	2.60	2.08
210	$\frac{7}{12}$	6.72	5.04	3.36	2.52	2.02
240	$\frac{2}{3}$	6.4	4.79	3.20	2.40	1.92
270	$\frac{3}{4}$	6.18	4.63	3.09	2.32	2.65
300	$\frac{5}{6}$	5.90	4.42	2.95	2.21	1.77

1. For other horse-powers, use proportionate widths.

2. For other thicknesses or for other speeds, inversely proportionate widths are needed.

3. For single rawhide lacing, multiply widths in the table by 0.928; for double leather lacings, by 0.867; for double rawhide, by 0.813; and for riveted joints, by 0.565; because, other things being equal, the stronger the fastenings, the more a belt of a given width will drive; and *vice versa*, the narrower need be the belt, for a given horse power.

The table gives for 10 h. p., at 1,000 feet a minute, 5.36 inches. To carry 20 h. p., at 2,000 feet would take the same, practically a $5\frac{1}{2}$-inch belt.

2. For a $\frac{5}{16}$ inch thickness there would be needed the average between widths needed for $\frac{1}{4}$ and for $\frac{3}{8}$, that is, $(5.36 \times 3.57) \div 2 = 8.93 \div 2 = 4.465$; or practically $4\frac{1}{2}$ inches.

3. For 20 horse at 1,500 feet, only $\frac{2}{3}$ as much width, or 3.57 inches; a $3\frac{1}{2}$-inch belt would do.

4. For double rawhide lacing, $5.36 \times 0.813 = 4.36$; or practically a $4\frac{1}{2}$-inch belt.

THE COMMERCIAL PRODUCTION OF HYDROGEN AND OXYGEN FROM THE ELECTROLYSIS OF WATER.[1]

Numerous attempts have in the past been made to reduce to a commercial scale the electrolytic generation of hydrogen and oxygen, but up to within quite recently these attempts have not met with success. It seems, however, that more recent experimenters have attained a sufficient measure of success to warrant the belief that this method has now arrived at a state of commercial practicability. The problem has been worked out simultaneously by M. Latchinof, of St. Petersburg, Dr. d'Arsonval, and Comdr. Renard of the French Army. The principles adopted are almost identical, but the apparatus designed by Comdr. Renard seems to be the most complete from the commercial standpoint, and was described in a paper recently read before the French Physical Society.

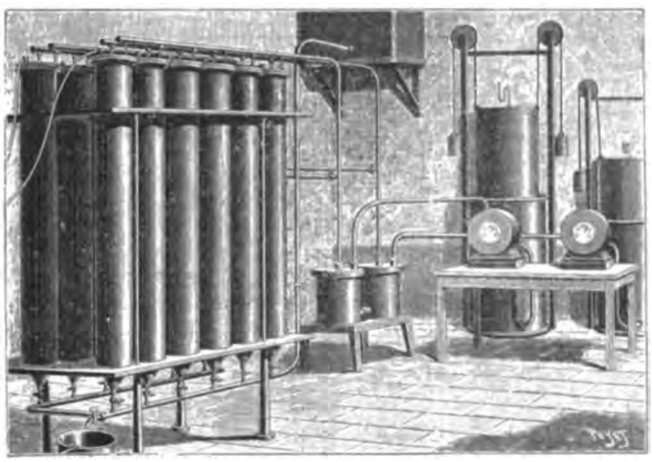


Fig. 1.—Commercial Manufacture of Oxygen and Hydrogen.

The new principles adopted in the construction of the large voltameters required are the following: First, the substitution of an alkaline solution instead of an acid, which makes it possible to employ electrodes of iron; second, the introduction of a porous partition between the electrodes, with the object of separating the gases. The experiments of Comdr. Renard have been made with a 15 per cent. solution of caustic soda, and a 27 per cent. solution of acidulated water; these are the proportions which give the maximum conductivity. Experiments made with the voltameter with platinum electrodes 3 to 4 centimetres apart have shown that for a given E. M. F. the alkaline solution allows a larger current to pass than the acidulated water; that is to say, it has a greater conductivity and is therefore more advantageous to use. The separating effect of the porous partition on the gases is due entirely to capillary phenomena. In order to prevent the gases from mixing through the partition above the level of the liquid, the partition must be made impervious above that line.

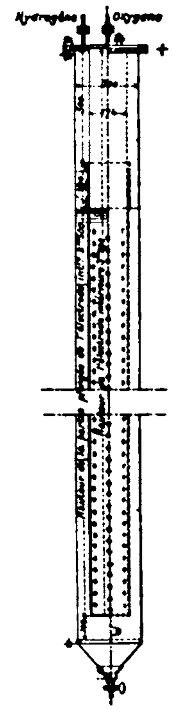

Fig. 2.—Commercial Voltameter.

The commercial apparatus employed by Comdr. Renard is illustrated in perspective in engraving Fig. 1, and Fig. 2 shows a section of one of the voltameters. The commercial voltameter consists of a large iron cylinder forming the outer electrode. The interior electrode is encased in a bag of asbestos cloth, closed at the bottom and attached by bands at the top. The inner electrode is pierced by holes, which allow the gases to ascend to the interior of the cylinder. The apparatus is hermetically sealed at its upper part, the two electrodes being, of course, insulated by a layer of rubber. Above the level of the liquid the interior electrode is continued and forms a receptacle for the gas. Hydrogen and oxygen escaping by the upper orifices are led to a compensator, which regulates the pressure within the tube. The apparatus is provided with cocks for filling with distilled water, which is placed in a reservoir above the voltameters, and for emptying. The size of the apparatus is as follows:

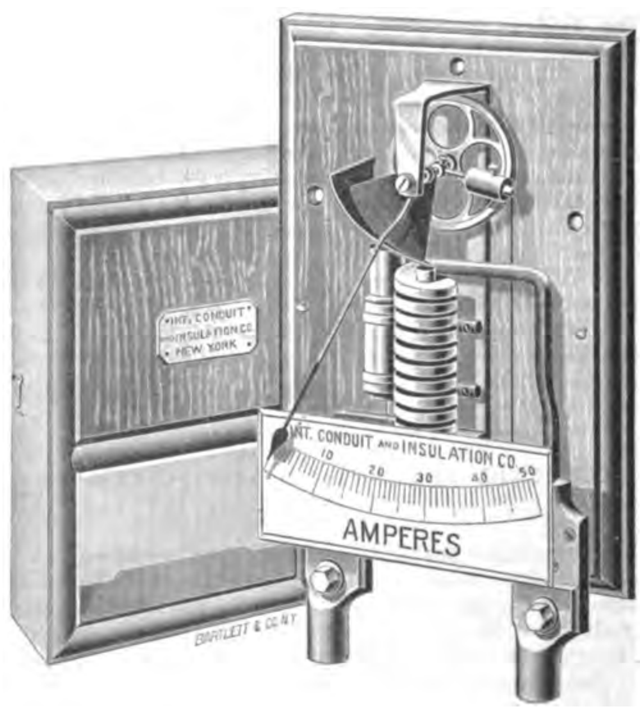
Height of exterior electrode,		11 ft. 4 in.	
" " interior	"	11 "	
Diameter of exterior	"		12 "
" " interior	"		7 "

The sheet iron employed is 2 millimetres thick. The electric resistance is about 0.0075 ohm. The current employed is 365 at 2.7 volts, and consequently takes a power of about one kilowatt. The production of hydrogen is equal to about 158 litres per hour.

1. Abstract from *La Nature*.

THE JOHNSON DEAD-BEAT AMPEREMETER.

The instrument illustrated in the accompanying engraving has recently been designed by Mr. E. H. Johnson for circuits in which very violent changes of current occur at frequent intervals, and where an instrument, other than one perfectly dead-beat would be of very little practical value. This amperemeter, as will be seen, consists of a soft iron



Johnson Dead-Beat Amperemeter.

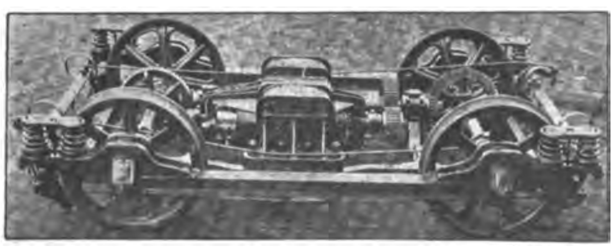
core wound with heavy bar copper, the magnet thus formed acting upon an armature having the shape of a sector, which is pivoted above the solenoid and provided with a pointer. The construction adopted for the armature is such that the scale divisions are practically uniform over the whole range of the scale.

This type of armature, while possessing in a marked degree the dead-beat quality, is, however, still further re-enforced in that respect by means of a dash-pot, shown in the engraving, the damping being effected by air-washing of the piston, no liquid being employed. The friction, therefore, becomes a practically constant quantity, and as the metal of the two interlocking pistons is never in actual contact, the delicacy necessary for accurate work is achieved.

The armature being under the influence of a strong electromagnet, is not influenced by currents in neighboring circuits. The resistance of the coil is also extremely low, that of the 25-ampere instrument measuring only .005 ohm. The qualities possessed by the instrument evidently make it peculiarly adapted for use in connection with motors and power stations, especially those devoted to railway work. This instrument, we may add, is now being brought out by the Interior Conduit and Insulation Company, of this city, and is designed for capacities varying from 10 to 200 amperes.

THE RAE STANDARD 40 H. P. RAILWAY MOTOR (TYPE B).

We have on several occasions described the successive improvements in the street railway apparatus of the Detroit Electrical Works, and are this week able to present to our readers an engraving of the new standard 40 h. p. railway motor designed by



Rae 40 H. P. Standard Railway Motor.

Mr. Frank B. Rae, the electrician and engineer of the company. One of the rules adopted at the outset by Mr. Rae was that an electric truck should have not more than one motor, which should be powerful enough to do all the work required of it, and the 40 h. p. motor truck illustrated is the outcome of this resolution. As will be seen, the motor gears directly with a shaft which runs lengthwise of the truck and is joined by beveled gears directly to the axle. These gears are accurately cut in special machines and have proved to be of excellent wearing qualities. The truck frame, it will be noted, is also of very solid construction, the entire truck forming one rigid frame, which keeps the motor and axles in proper position and avoids all wear due to jar and grinding.

KIND WORDS FOR "THE ELECTRICAL ENGINEER."

Mr. O. S. Platt, of Bridgeport, manufacturer of the "New England Electric Switch," writes us, under date of July 15, as to the result of his advertising in The Electrical Engineer: "Have received orders from all parts of the world, including all of the United States, the Southern Islands, Canada, England, France, Russia and Finland." * * * * "Have also found the efforts of your representatives to make me personally acquainted with those using goods in my line of great value, both socially and commercially, and am glad to acknowledge these courtesies."

Mr. H. A. Cleverly, the proprietor of the Cleverly Electrical Works, of 1018 Chestnut street, Philadelphia, has had a long and varied experience in the electrical field, and the fact that he has kindly sent us the subjoined will speak for itself: "Thanks for copy of Extra "Edison Lamp Decision." Its prompt issue and receipt are another evidence to the enterprise and push of The Electrical Engineer. It is the most valuable of the electrical journals. It is the only one I keep for future reference and am happy to say that I have every copy since its birth as the "Electrician," as well as under the present title. I wish you success and its full reward."

THE MILLER ELECTRIC RAILWAY CONDUIT.

A new departure in the arrangement of the several essential parts of an underground conduit system is that recently devised by Mr. John J. Miller, of Pittsburgh, Pa., and clearly shown in the accompanying illustrations.

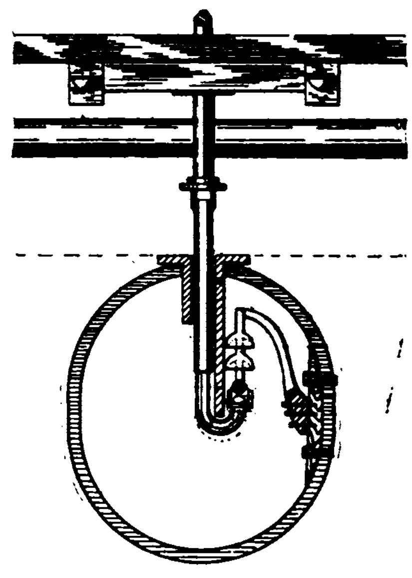


Fig. 1.—Transverse Section of Conduit, Miller System.

Here Fig. 1 represents a sectional and Fig. 2 a longitudinal view of the conduit. This is provided with slot rails, between which the trolley arm passes. The rail at the right, it will be noticed, extends below the wire, and protects it from any moisture that may find its way through the slot. The wire is suspended from a bracket, as shown, by means of a hard rubbber hanger. The trolley arm is provided at its lower end with a U-shaped extension, upon which is mounted the trolley. This prevents the moisture which may run down the rod from reaching the wheel.

It will be seen that the wire is suspended above all accumulations of water and rubbish in the conduit, and is protected from drippings by the double bell-hanger. Furthermore, the wire is doubly insulated from the conduit by means of the block and hanger, and there can therefore be no appreciable deflection of the current through the supports. The highest point of the bracket is at the point of its connection with the hanger, and therefore the bracket drains toward the side of the conduit and the hanger drains from the edges of its bells, thus preventing the wire from being connected with the side of the conduit by a film of water, and the wire is protected from an accumulation of moisture on its surface; the trolley is carried above the reach of water in the bottom of the conduit, and therefore there is nothing to interfere with a perfect contact between the trolley and the wire.

The Pittsburgh Underground Electric Construction Co. has been organized, with a capital stock of $300,000, for the purpose of

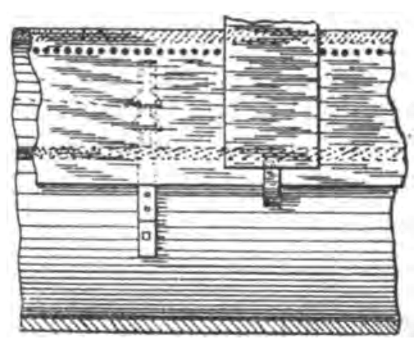

Fig. 2.—Longitudinal Section of Conduit, Miller System.

installing this system. The officers are Mr. C. D. Robbins, president, and Mr. D. J. Rex, secretary and treasurer. Mr. C. F. Shoemaker, Mr. F. A. Mann, of Cleveland, O.; Mr. F. J. Osterling, and Mr. John J. Miller, of the Robbins Electric Co., the inventor of this system, comprise the directory.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers*

VOL. XII. NEW YORK, AUGUST 5, 1891. No. 170.

It is a great thing to find out what cannot be done; it leads up to a knowledge of what can be done.—James Watt.

PREPARING FOR THE WORLD'S FAIR.

THE article from our Western representative, Mr. W. F. Collins, appearing in the present issue, gives an interesting account of the progress made in the preparations for the Columbian Exposition at Chicago. Some fears have been expressed as to whether Chicago will have everything in readiness by the appointed time in 1893. For ourselves we may say that we have no fears at all on that score, and the explicit statements made by Mr. Collins will go far to remove doubts that may be elsewhere entertained on the subject. It has been assumed by not a few people in the East that, to use a homely phrase, Chicago had bitten off more than it could chew. Nothing could be remoter from the truth. While we believe that it would have been well to hold the Exposition in New York, we believe also that Chicago offers many special advantages and inducements, and that what would otherwise be lacking will be compensated for by the courage and large spirit of the city which, even more than Boston or Philadelphia, is typically American. Chicago has not over-reached itself, and though some of its citizens may attempt to do foolish and vulgar things as if to prove that 400 years have not passed since Columbus made the first exhibition of American products, we all know that as a whole the Fair will make us proud of the enterprise and intelligence of the metropolis of the West.

But there is still much to be done, and it must not all be left to Chicago to do. Electrical manufacturers and electrical engineers are peculiarly concerned with this coming opportunity, and their great attempt should be to make every visitor carry away as the chief impression the idea that the Exposition signalizes more than anything else the triumphs of electricity in the arts and sciences. Not only must there be exhibits on a large scale, but the utilization of electricity for light and power should be sought in every possible manner. Moreover, the Exposition should be made the scene of an Electrical Congress as large and important as that of Paris in 1889. The American Institute of Electrical Engineers has, in fact, already laid the foundation for such a Congress, and it seems high time that steps should be taken to give form and life to the plan. The last Electrical Congress held in America was that at Philadelphia in 1884. Since that time an enormous development has taken place, and Chicago in 1893 should be made the next point of departure in electrical investigation and industry.

BIDDING FOR CONTRACTS.

WRITING in the London *Electrical Engineer*, Mr. Sydney F. Walker takes up the question of the abuses which have arisen from the practice of submitting tenders or bids for electrical work in England, and, considering the frequent expense to which firms are subjected in preparing these bids and specifications, pleads that they ought to be paid for by the firms asking for them. To overcome this difficulty Mr. Walker argues that all bids or tenders involving much expense should be charged for, the charge to be deducted from the amount of the contract by the successful competitor. We have adverted to this subject in order to point out the difference which exists in the practice in this respect here and abroad. To apply this rule here would, we think, be hardly practicable. The trouble which Mr. Walker complains of is, we believe, largely due to two causes: First, to the fact that in England, especially, any one who contemplates the installation of electrical work of any magnitude calls in a consulting engineer. The latter draws up plans and specifications to no special standard, working out each detail of the equipment to suit his own ideas on the subject, and then asks for bids on these plans. Secondly, it rarely happens, abroad, that a single firm is in a position to offer a bid on all the apparatus required for the equipment of an electrical plant. In both these respects our practice is diametrically opposite. With us it is a rare occurrence that a consulting engineer is employed, the intending purchaser applying directly to the companies to furnish him with apparatus to perform certain work. Then, also, our companies furnish everything, down to the smallest snap-switch required in an installation. It will therefore be seen, that the number of firms likely to enter into the competition for a piece of work is at once limited. On the other hand, the firms bidding have a standard system of apparatus throughout, and hence are not required to go into the minute details and calculations of cost, as would be the case where the apparatus required has been designed by an independent consulting engineer often with peculiar ideas of his own as to the best methods to be employed. To the latter cause, we believe, most of the trouble complained of abroad is due.

Which of the two methods of procedure is calculated to give the best results is a question quite open to argument. The value of a good consulting electrical engineer is undeniable in any project involving the expenditure of considerable sums of money, and we might even go so far as to say that a more general recognition of this fact would have prevented much loss and inconvenience in the past in many of our electrical establishments—loss from which many indeed are still suffering. On the other hand, however, we hardly believe it to be the province of the consulting engineer to act in the role of a designing engineer, an error into which he is frequently apt to fall. With the variety of apparatus now manufactured by different firms it ought not to be difficult to select, as it were, from stock such apparatus as will fill the requirements of any particular case, and we believe that this method of procedure will prove eventually to be the most economical both for the bidder and the consumer. There will still be plenty of work for the consulting engineer.

LIGHTNING PROTECTION FOR ELECTRIC CIRCUITS.

The troubles and diseases to which dynamo-electric machinery are subject, even in the best-regulated electric light stations, are of such a nature that ordinarily the remedy to be applied is a simple one; and the apparatus being under constant supervision, interruptions from causes which may be determined locally can be readily taken care of. But there is one frequent origin of trouble, which, in spite of its recognition at the outset, may be said to be still one of the principal sources of annoyance and loss in central stations. We refer to the effect of lightning strokes, which coming in on the line, enter the station, and, failing to be diverted to earth, ruin the dynamos. On the other hand, the frequent damage to lamps and converters connected to the outside circuits proves conclusively that the arguments brought forward by Mr. F. H. Tidnam in this issue are correct. It would indeed appear strange that the lightning charge should follow the line directly to the station which is protected against such charges and entirely ignore all the apparatus and the far greater number of paths open to it between the point where the line is struck and the lightning arrester at the station. Mr. Tidnam therefore argues that for thorough protection against damage by lightning, not only the station, but the line itself, should be provided at frequent intervals with lightning arresters. His experience and opinion will no doubt be that of many other station managers, and we are glad therefore to give space to an article which may result in the more thorough protection of all electric apparatus connected to overhead circuits.

Putting in Wires and Fixtures.

Trouble has recently arisen in one of the New England towns because the local electric light company that had hitherto put in wires and fixtures itself, at about cost, had decided to give up that branch of the business and restrict itself to the outside work. All inside work was hereafter to be done by concerns making a specialty of that class of work and approved of by the company. There are one or two sides to this question, as every local company knows. It should not be the business of an electric light company to put in wires and fixtures any more than it has been for a gas company to put in pipe and fixtures, yet many have assumed the responsibility and have often been very liberal in order to get custom. Somehow such generosity seems to carry a punishment with it, and, as in the present instance, a change of plan has been necessary. But the practice of leaving the work to outsiders also has its drawbacks, one of which is that bad wiring and poor fixtures bring curses on the light and on the head of the innocent company that wants only to supply the current. Much the same question arises as to motors. Shall a local company handle the motors itself, or shall it allow anybody to loop in any motors, or as many, as he chooses? One of the prime conditions of prosperous existence is that a company shall maintain the integrity of its circuits, but to do this it must have a pretty thorough control of all the work done by outside concerns that in any way affects those circuits.

Industrial Condensers.

The important position which the condenser is destined to occupy in the electrical distribution of the future makes the results of researches on the best methods of construction eminently timely. Recent work in this direction by M. Maurice Leblanc seems to prove that the action of alternating currents on condensers is actually to improve their qualities. But he also draws attention to the care required in their construction. Mr. Tesla has also referred in his recent lecture to a number of points which must be observed in order to prevent the destruction of the dielectric medium employed in alternating current work at high frequencies, one of the principal precautions to be taken being the thorough expulsion of all air, a point which is also indirectly hinted at by M. Leblanc.

A New German Transformer.

Although at first slow to adopt the alternating system, German electricians are now thoroughly convinced of its wide application, and have taken up its introduction with an energy characteristic of the faith with which they are imbued. The latest type of German transformer, which we describe on another page, embodies a construction which, though not entirely new, possesses a number of novel features which give it certain advantages. Principal among these will probably be the facility offered for obtaining difference of phase between the currents generated, which, for the purpose of electric power transmission with the alternating motor, will prove to be a valuable feature.

The Montreal Convention.

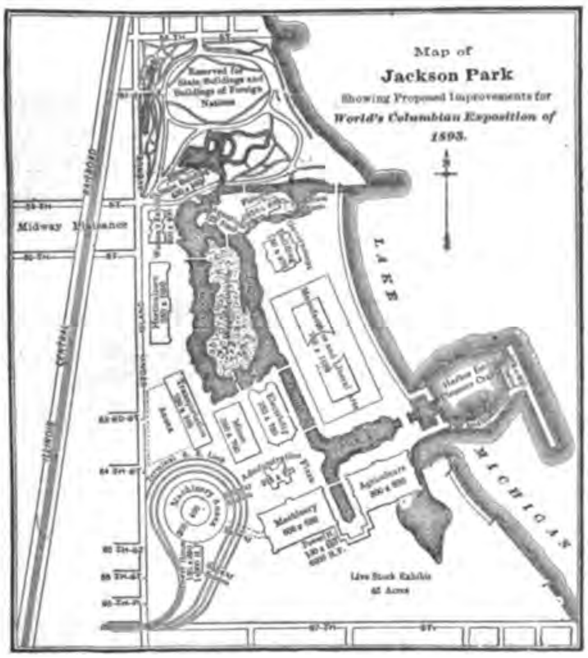
There is every indication now that the meeting of the National Electric Light Association at Montreal will be a great success, and it seems likely also that the exhibition will be one of the best yet given under the auspices of that body. It has been proposed to carry on the exhibition for several days and to charge gate-money, say 25 cents per head, the Association to take the first yield, but we trust that this scheme will be radically modified. The Association must stand distinctly aloof from all "hippodrome" business, and preserve its dignity and self-respect.

A VISIT TO THE WORLD'S FAIR GROUNDS.

BY

To any one in the electrical field or out of it who still remains at all sceptical as to the importance, size and scope of the Exposition in Chicago in 1893, a visit to the Fair Grounds will immediately be useful in dissipating any such ideas. He will be strongly impressed with the immensity of the arrangements made for the Exhibition and the remarkably rapid and thorough manner in which the work is now being pushed forward. The above remarks apply very pertinently to the electrical portion of the Exposition, and it may even now be said that this department will form one of the most important features, as electricity is to be used everywhere for all kinds of purposes in addition to furnishing illumination and motive power, in which operations it is already so well known in general every-day use.

One of the latest schemes for a striking display, but which appears somewhat impracticable at first sight by reason of the expenditure for construction and maintenance, and the difficulties inherent to such an undertaking, is the long-distance transmission of electrical energy from a power station situated at Niagara Falls and operated by that world-famed water-power. It might perhaps be carried out by the judicious use of transformers to



MAP OF THE WORLD'S FAIR GROUNDS.

raise and lower the electromotive force as required, although the thought of the valuable watts of electrical energy lost in the transmission over 500 miles of conductor is disheartening. Some of the would-be geniuses along the line might also take it into their fertile brains to tap the lines if they had the hardihood to dally with a probable 30,000 or 40,000 volt current. It may be in point here to suggest that it might be an excellent scheme to have all the condemned criminals electrocuted by the self-same current here in Chicago during the fair as a kind of side-show of morbid and thrilling interest.

Yet another "fad" is an electric firework display proposed by a French firm, and which has been submitted to the committee on ceremonies. Among the pieces proposed is The City of Chicago personified as a statue of fire, seated, and surrounded by figures of the States of the American Union. She will receive the great powers of the world, which will defile one by one before the assemblage of States. As each figure passes before the City of Chicago, it will halt, bow and then lay down its flag or shield at Chicago's feet and receive a palm branch of peace. This picture will form a grand firework, every point of which it is composed being of white or colored fire, and the successive appearance of the allegorical figures will be in multi-colored moving fire, presenting a marvelous kaleidoscopic appearance. The display together with numerous other pieces forming a background will present an illuminated surface of 21,000 square feet. The power necessary is estimated at 2,800 h. p., or $\frac{1}{10}$ of that if storage batteries are employed, and the effects are to be obtained presumably with incandescent lamps with perhaps some arc lamps; and probably the ever-willing motor will come in somewhere to operate the moving portions.

The contracts have been awarded, and actual work has commenced, on five of the buildings, namely, in the order stated, the Women's Building, the Electricity Building, the Transportation Building, the Mines and Mining Building, and the Horticultural Building. More will be started as soon as possible, and material is already on the way for the Administration Building and the Building for Manufactures and Liberal Arts.

A general plan view of the grounds in Jackson Park and the proposed improvements is shown in our illustration, the dimensions of the buildings being given, while the exact location of any one can be immediately determined.

The portion of the park where the fair is to be held has the appearance of a highly active battlefield. Men, material, freight-cars, railroad tracks, locomotives, dredges, and last, but by no means least, a whole army of kickers in the shape of the much-maligned mule, which having sold out of the street car business to go into landscape gardening, are to be seen on all sides, all busily working to the same end. To the uninitiated onlooker everything is in hopeless confusion, and he wonders how it is ever going to be all straightened out. But it will be.

More than 1,800 men are already at work, and this number is being rapidly augmented as the material arrives and new buildings are started. Over the construction tracks the engines are hauling material by carload after carload to the various buildings. The cheery hum of the saw-mill is also heard on all sides, those at present in operation being temporarily run by nondescript steam engines, which, however, will give place ere long to electric motors.

McArthur Bros., the contractors for all the grading and dredging, have six enormous dredges going merrily, completing the lagoons and lakes, which will form a veritable Venice of the grounds, and piling up the earth for hills and terraces, specially pleasing to the eye of the prairie-dweller.

The Woman's Building, in the northwest corner of the grounds, is well under way; the foundation timbers are in place, and the materials for the walls are on hand. This was the first building started, showing the energy and interest evinced by the women of the country.

The Electricity Building is situated at the south end of the lagoon, and is destined to be one of the handsomest of the buildings, as it undoubtedly will be the most attractive and marvelous to the sight-seer when the exhibits are all installed. The foundations are laid, the necessary material is on hand, and everything is progressing rapidly.

The grading for the Horticultural Building is completed. This Building will occupy the site just north of the temporary Administration Building, which is now being used as construction headquarters, and where the superintendents of departments, engineers and draughtsmen are busily engaged supervising and carrying out the work and making the various detailed plans. In the electrical part of the construction department the illumination details and the location of motors, etc., are being worked out. Work on the Mines and Mining Building is also progressing well, and here will be seen many interesting and practical exhibits of the adoption of electricity to mining of all kinds.

An immense amount of work has already been done on the lagoons, piers, and breakwater, the dredges running night and day cutting out the canal and connecting lakes; and a couple of steam pile-drivers are driving piles for piers and steamboat landings.

On the wooded island in the centre of the lagoon, at its south end, a temporary power-house for the generation of electric current, will be immediately built, and, in fact, work has already commenced. The plant will be in operation in five or six weeks. The station is laid out for an ultimate capacity of 600 h. p., of which 200 h. p. will be put in at once. This power will be employed for running dynamos for operating the arc lamps required for illumination of the grounds during construction, and also a large number of electric motors, which will be employed entirely for furnishing all the power for driving the various machinery, saw-mills, etc., used in constructing the buildings and performing any other work for which power is required. Incandescent lighting will also be run from this station wherever required.

The grounds are now intersected with railroad tracks in all directions, and a temporary pipe line for water supply has been laid. In every part the work is going on as expeditiously as possible, and no pains are being spared to have everything arranged in the best and most practical manner. The landscape architects are also exercising infinite care to beautify the grounds, which, when completed, will present a most artistic aspect, and, together with the magnificent buildings, will form a scene of unparalleled beauty and attractiveness on a scale unexcelled by any exhibition held in any country.

The thanks of the writer are due to Mr. Sargent, the electrical engineer of the construction department, under whose energetic supervision all the electrical construction and installation of plant are being carried out, for many particulars, and also to Mr. Geraldine, superintendent of the construction, for his courtesy in furnishing information.

THE GODFROY APPARATUS FOR INCREASING THE EFFICIENCY OF SUBTERRANEAN TELEGRAPH LINES.[1]

THE extensive development in France and Germany of subterranean telegraph lines has resulted in a demand for a device to render such lines as efficient as those carried overhead. To satisfy

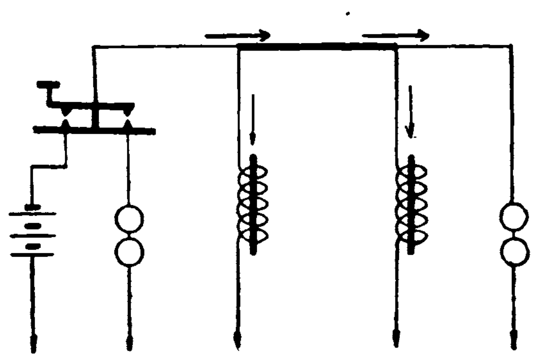


FIG. 1.

this demand, M. Godfroy has devised the arrangement shown in Fig. 1 of the accompanying illustrations, and first tested in the latter part of 1888.

The diagram, Fig. 1 (from an article by M. H. Cailleret, in the last number of the *Annales Télégraphiques*), shows an underground circuit arranged according to M. Godfroy's simple plan. When the transmitting key is depressed the electromagnetic shunt offers a considerable impedance, and the line is quickly charged. When the key is released, and during the instant when it is neither touching the front nor the back stop, the discharge current (now aided by the E. M. F. of self induction) goes quickly to earth through the shunt. Similar effects occur at the receiving end, and the net result is sharp, well-defined, Morse signaling. In 1888, the Paris-Angoulême line, 310 miles long, having a resistance of 5,000 ohms, and a capacity of 100 microfarads, was fitted with M. Godfroy's device. An ordinary Morse instrument, without either local or intermediate relays, attained a speed of 20 words a minute. The shunt circuit, which comprised an electromagnet with a closed magnetic circuit and a small auxiliary coil, had a resistance of 780 ohms and a coefficient of self-induction of 12 henrys. The battery consisted of 50 Callaud cells. The 1888 experiments showed that, in practice, it was not absolutely necessary to ensure a perfect balancing of the inverse effects of the capacity of the line and the inductance of the shunt. Thus one electromagnet gave equally good results on lines of from 150 to 200 miles in length, and another could be used on lines varying in length from 250 to 450 miles. It was only necessary to employ a battery suitable to the line, and either to adjust the resistance of the auxiliary coil, or to break the magnetic circuit of the electromagnet more or less thoroughly by altering the positions of the soft iron armatures.

Besides the French and German experiments some were carried out on an artificial line by Dr. Tobler at the Zürich Polytechnic.

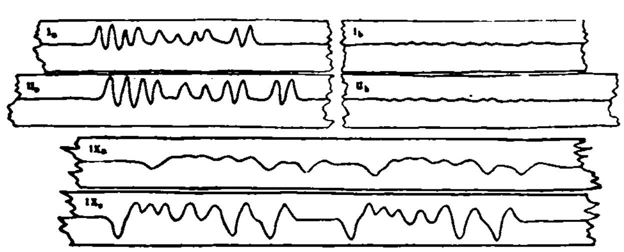

FIG. 2.

A syphon recorder was placed side by side with the receiver at the transmitting end, and registered the discharge currents from the line curves I*b* and II*b*, and curves I*a* and II*a*, Fig. 2, respectively, give an idea of the discharge currents at the transmitting end with and without the Godfroy electromagnetic shunt. The effect at the receiving end is shown in curves IX*a* and IX*b*. Curve IX*a* shows the signals received when the receiver was shunted by a resistance of 700 ohms. On replacing this inert resistance by one having considerable inductance, the curve IX*b* was obtained.

In France, some 20 long subterranean circuits, such as the Paris-Lyons (300 miles), Paris-Marseilles (650 miles) lines, have had Godfroy apparatus in regular work for the past 12 months and more; and recently it was decided to apply the device to 50 additional lines of over 125 miles in length. The apparatus is made in three sizes, having resistances of respectively 500, 750, and 1,000 ohms, and coefficients of self-induction of from 10 to 120 henrys.

1. London *Electrician*.

THE CONSTRUCTION AND PROPERTIES OF INDUSTRIAL CONDENSERS.[1]

THE development of the applications of alternating currents naturally draws the attention to the important subject of condensers, in which connection a brief account of the researches of M. Maurice Leblanc cannot fail to be of interest.

His first condensers were made of paper impregnated with paraffine heated to 70° C. These had a capacity corresponding to a specific inductive power equal to eight, but the residual charge amounted to nearly a quarter of the first discharge.

The capacity of the same condensers, when measured by the alternating current method, with a frequency of 75 periods per second, indicated a specific inductive power equal to one-third only of the above. On subjecting these condensers to a difference of potential alternating from 1,500 to 2,000 volts, with the same frequency, the heating produced was sufficient to melt the paraffine, to make the condenser hum, and to destroy it if the current were not quickly interrupted. With paper and paraffine specially selected for the purpose these results were not improved. By assimilating the paraffine with Poisson's dielectric, *i. e.*, a dielectric covered with conducting spheres, M. Maurice Leblanc found out the causes of the heating of the condenser, and of its great increase of specific inductive power, and discovered that by pre-

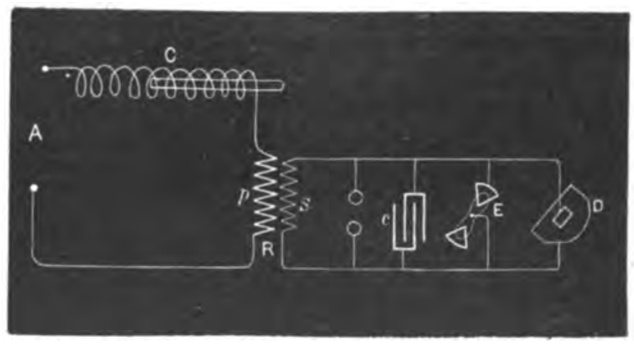

DIAGRAM OF EXPERIMENTAL CONDENSER.

A, Alternator; C, Choking coil; R, Ruhmkorff coil; *c*, Condenser; E, Electrometer; D, Dielectric tested.

viously heating the paper in the paraffine to the temperature of dissociation of the latter, the organic constitution of the paper is destroyed, and its fibrous structure entirely disappears. Condensers made in this way do not readily heat, and the specific inductive power falls to 2.56.

While these condensers were being made M. Leblanc made several experiments with the first ones, which, as he considered them defective, he used unsparingly, often subjecting them to differences of potential of 4,000 volts.

Having occasion later on to measure the capacity of some of them, he was surprised to find it much less than had been anticipated. The specific inductive power of the dielectric had become equal to 2.56. He examined them then to see whether the heating had not also decreased, and found that this was the case, as he had expected. These condensers, so faulty at first, no longer became heated, and had turned out excellent.

From the above it follows that excellent results may be obtained from paraffined paper; that we need not trouble about the quality of the material if we subject the condensers to a period of probation under the conditions indicated. They must be watched attentively while being used, and allowed to rest when they become heated to any extent.

This is a practical rule which is very easy to follow: A condenser runs no risk as long as it works noiselessly; when it begins to hum it is in danger.

It can easily be understood that what the action of heat had effected in a few hours (three on an average) would be brought about eventually by the electrical displacement produced in the centre of all the conducting particles contained in the mass. This is a fresh proof of that property of alternating currents which is now generally admitted, viz., that their action on dielectrics is beneficial rather than otherwise.

The ebonite condensers gave complete satisfaction. Their capacities, whether measured by the ordinary method or by the

1. London *Electrical Review*.

employment of alternating currents, were the same; the residual discharge was insignificant. Moreover, they do not become heated. The sheets of tin were gummed to the plates of ebonite with Chatterton's compound. The sheets of ebonite were kept on a hot plate until they became soft and very supple, when the sheets of tin were applied to them by means of an ordinary iron heated. Condensers made in this way form real plates of great solidity.

The thinnest ebonite that could be procured was $\frac{1}{10}$ of a millimetre in thickness; this was not split under the tension of 11,000 volts, the highest reached. It will be possible to manufacture this ebonite of a thickness of $\frac{1}{10}$ of a millimetre.

The accompanying diagram shows the experimental method used by Messrs. Labour, Hutin, and Leblanc, for studying the qualities of different specimens of ebonite from the point of view of their mechanical resistance to high potentials. An alternator, giving about 75 periods per second, is connected with the primary circuit of an ordinary induction coil, the trembler of which is suppressed. Into this primary circuit is introduced a self-induction coil, the inductance of which may be varied by introducing into it a bar of laminated soft iron, so as to vary the intensity of the primary current, and consequently the electromotive force induced in the secondary circuit. This induced electromotive force is, moreover, increased by connecting in derivation on this secondary circuit an ebonite condenser, capable of resisting the highest tensions produced in this secondary circuit, and measured by means of Sir William Thomson's electrostatic voltmeter. In derivation on this condenser were also established two balls mounted on a frame with a micrometer screw, enabling the disruptive distances corresponding to each potential to be measured. The dielectric to be tested is placed between the two secondary wires of the induction coil, and forms a sort of condenser, with the addition of two little pieces of tinfoil applied to its surface. It is thus easy to determine for each specimen at what potentials the successive signs of deterioration show themselves, viz., splitting, luminous glow, and the appearance of holes, with very bright and powerful sparks, which will set fire to the dielectric if it is inflammable.

THE C. W. HUNT CO. COAL CONVEYER.

In many electric light and power stations the important question of coal handling has often been neglected, as well as the cost of manual labor, that has to be added to the cost per ton of fuel consumed. This is a somewhat important source of expense, and one that may be quite considerably reduced by the following mechanism,—*i. e.*, a comparatively new conveyer for bringing coal into the boiler-room from either the railroad car or from the stock bin.

Referring to Fig. 1 it will be seen that the operating mechanism is run by pawls which push the chain along, thus obviating the use of sprocket wheels. An electric motor, suitably geared, can be placed at the end of the driving shaft and suitably boxed in to keep dust out. Fig. 2 shows the buckets and chain and the trucks upon which the conveyer runs. The buckets can be made of any size suitable to the kind and quantity of coal to be conveyed. An axle extends across from truck to truck between each pair of buckets, while the buckets themselves are pivoted upon a wheel-supported bearing at each side.

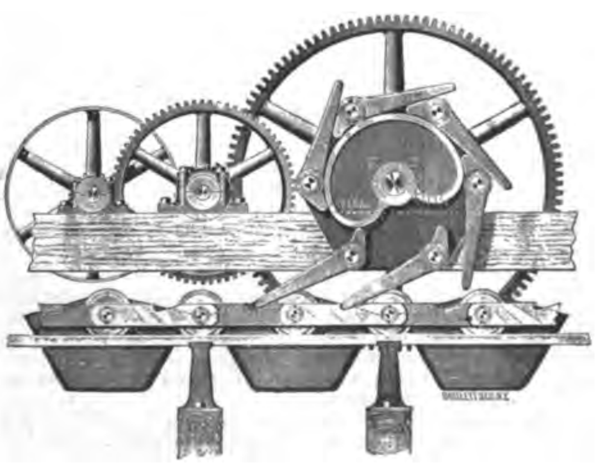

FIG. 1.—OPERATING MECHANISM, HUNT COAL CONVEYER.

The links forming the endless connection are held together and in free operative connection at the several wheel centres or axles. A pin at the side of each bucket answers as a trip for emptying purposes.

Fig. 3 shows one application of the system, and it will be seen that change of direction can be made as often as required in a vertical plane. With hoppers suitably arranged the coal is brought from the railroad car over the top of the boiler-room and dumped as required, the empty chain then going under the boilers, whence the ashes can be taken out automatically and dumped into railroad or other cars outside of the boiler-room.

The operative capacity is governed rather by the size of the buckets than by their speed of movement. The ordinary sizes are made with 28-inch links, and buckets of 2 cubic feet capacity. The regulation speed of this size of conveyer is 15 buckets per minute, delivering 40 tons of coal per hour.

FIG. 2.—DETAILS OF HUNT COAL CONVEYER.

These conveyers are now used by the Union Elevated R. R. Co., at East New York, and also at Fifth avenue, Brooklyn; at the coal docks on 20th and 56th streets, East River, New York; the Brooklyn Water Works, and many other points.

The application of the system to electric plants is proposed for the West End Street Railway Co. power station at Boston and

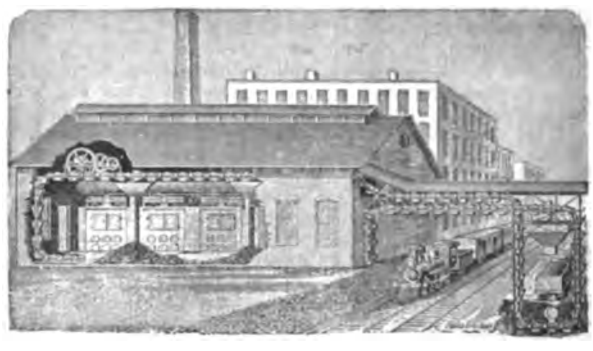

FIG. 3.—AN APPLICATION OF THE HUNT SYSTEM.

the Edison Electric Illuminating Co., in Brooklyn. The conveyer is manufactured and introduced by the C. W. Hunt Co., of 45 Broadway, New York, to whom we can advise any one interested to apply, and thereby possibly save themselves a considerable item in the cost of current production. It may be pointed out that the electric motor also furnishes a specially convenient means of propulsion for this mechanism.

AN ELECTRIC BELL FOR THE DEAF.

A "North Side" young man tells the following in the Chicago *Tribune:*

"Did it ever occur to you how a deaf and dumb man knows when his front door bell rings? I found out while making a call with a friend last Sunday. He invited me to go with him to visit a young married couple, both of whom were deaf and dumb. We made our way to a pleasant little flat building and my friend pushed the upper electric button. I asked him if they kept a servant, and when he said they didn't I inquired how they heard the bell. He said, 'They don't.' While I was wondering how they knew there was somebody at the door my friend's friend appeared. There was a little finger talk between them and he led the way upstairs. We talked awhile on pads of paper and then I told the young man I was curious to find out how he knew there was somebody at the door. He wrote: 'Come and look at our door-bell,' and led the way to the kitchen. Here I found a queer contrivance screwed against the wall about four feet from the floor. There was an electromagnet whose armature was connected with a pair of levers so that when the armature was attracted a catch was released and the hook tipped over. Hanging upon this hook was a section of a cedar post about eight inches in diameter and two feet and a half or so long. He pushed the armature against the magnet and the log dropped to the floor with a reverberating bang.

"'You can't hear that, can you?' I inquired.

"'No, I can't hear it, but we feel the jar when it falls.'"

METAL-COVERED INTERIOR CONDUITS AND ACCESSORIES.

In the wiring of buildings occasion frequently arises for insulated tubes sheathed with metal to afford better protection against mechanical injury and to prevent the action of alkalies when such tubes are run under floors or in other exposed places, and again, where they are liable to be subject to heat arising from external causes. To meet this demand the Interior Conduit & Insulation Co., of this city, have brought out the metal-covered tube illustrated in the accompanying engraving, Fig. 1, which consists of their regular tube covered with a metal sheath. Besides its fireproof and durable qualities, it possesses fine finish, which makes it readily available as a picture molding, in which case it can be held in position by screw wires or other supports, as shown in the engraving Fig. 2. For this purpose the tube is furnished in polished, oxidized and antique brass, nickel, copper, bronze, or any desired finish.

Where a double-tube system of wiring is employed as a substitute for wooden molding and concealed wiring, a twin metal covered tube can be employed to advantage. This tube is made with $\frac{5}{16}$ inch inside diameter.

In connection with the tubes, metal-sheathed junction boxes and all corresponding appliances are provided, so that the entire conduit system may be sheathed if desired. The internal appliances and fittings of the company are adapted either to the ordinary or metal-sheathed tube, but some of them are particularly adapted for the metal tube. Thus the "Universal" switch can be readily applied to this system, as shown in engraving Fig. 3, and is rendered quite unobtrusive and convenient, being in the direct line of the tube and requiring no separate branch for a switch.

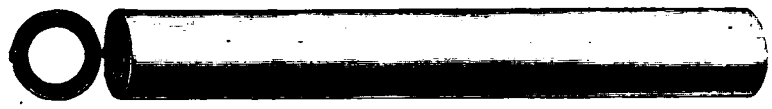

Fig. 1.

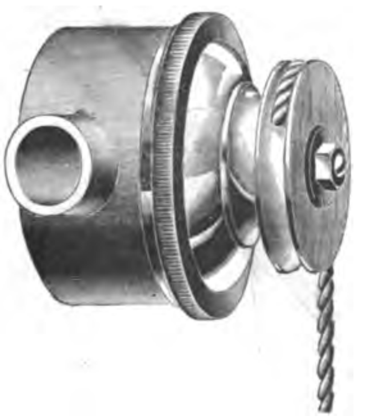

Fig. 4.

Fig. 2.

Fig. 3.

Metal Covered Interior Conduits.

Another form of switch which can be inserted directly in the circuit is shown in Fig. 4. It is especially adapted for conduit branch boxes and tubes. This is a pull switch, which can be made to operate mechanically from any convenient point by a bell cord and tassel attachment. The saving of wire and other advantages of this arrangement will appeal strongly to wiremen.

THE WHEELING, W. VA., CITY ELECTRIC LIGHT PLANT.

The city of Wheeling, W. Va., after sending a committee of its council on a tour of inspection for the purpose of selecting apparatus for the proposed city electric lighting plant, last week decided the question and voted to install the Wood arc light system of the Fort Wayne Electric Company. The plant will be equipped with 400 arc lights and will have an ultimate capacity for twelve 50-light arc machines. The motive power will consist of a 500 h. p. Hamilton-Corliss engine. The circuits will include 65 miles of pole-line construction and 100 miles of wire. Mr. John A. Seely, of this city, is retained as consulting electrical engineer by the city of Wheeling in the installation of this plant.

ELECTRIC RAILROADING AT LANCASTER, PA.

As another evidence of the increasing call for rapid transit throughout the country, the West End Street Railway Co., of Lancaster, Pa., may be cited. This company has amalgamated with the Lancaster City Electric Railway and now controls the entire street traffic of the city, the old horse system being replaced by electric power.

The power station, with car house attached, is a substantial brick building, the roof being of metal and slate, the latter being over the boiler-rooms. The dimensions of building, when first erected, were 235 x 60 feet. An additional car house has now been added, measuring 100 x 19 feet, together with an engine and boiler room, 135 x 35 feet.

The plant has been equipped by the Edison General Electric Co. and the whole of the work is of the highest order.

There are, at present, three 50 kilowatt compound-wound, self-oiling generators driven from a line of shafting furnished with Hill clutches by two 250 h. p. Reynolds-Corliss engines, built by E. P. Allis, of Milwaukee, Wis. The fly-wheels of the engines are 16 feet diameter, with 30 inches face. The pulleys are 56 inches diameter, with 16 inches face, and the pulleys of the generators are 26 inches diameter, with 16 inches face. Schieren belts are used, those for the generators being peforated.

Power is supplied from three 175 h. p. boilers furnished by C. R. Vincent & Co., Cortlandt street, N. Y. The mains from the machines are laid in troughs under the floor, supported on porcelain insulators. They consist of cable, manufactured by the Edison Machine Works, grade 4 being used. The switchboard is worthy of special mention. This is constructed of iron and slate, having two sides of iron and a top of slate. This is set on the floor and is easy of access from the rear. On the top slab are placed the different switches, safety fuses, etc., underneath being the rheostats, also with slated heads. The whole board is therefore perfectly fireproof. The positive mains are brought to a bus bar at the back of the board, from which they run to their respective switch, ammeter, etc., and thence on poreclain insulators to the tower, leaving the same through mica insulating tubes. The negative mains are brought to a common coupling, the ground wire leaving the building in the same manner as the positive mains. This ground is made directly with the rails. In addition to the ten cars which were first in operation, the company is now running eight 18 ft. and two 32 ft. cars equipped with two 15 h. p. motors each, together with six trailers. All these cars have been manufactured by the Brill Co., of Philadelphia. The company are at present operating 12 miles of track, one part extending to the little town of Millersville, five miles distant. It may be interesting to state that the mail to this town is carried by the Electric Co., and from thence by coach (also owned by the company) to Safe Harbor, 6 miles further.

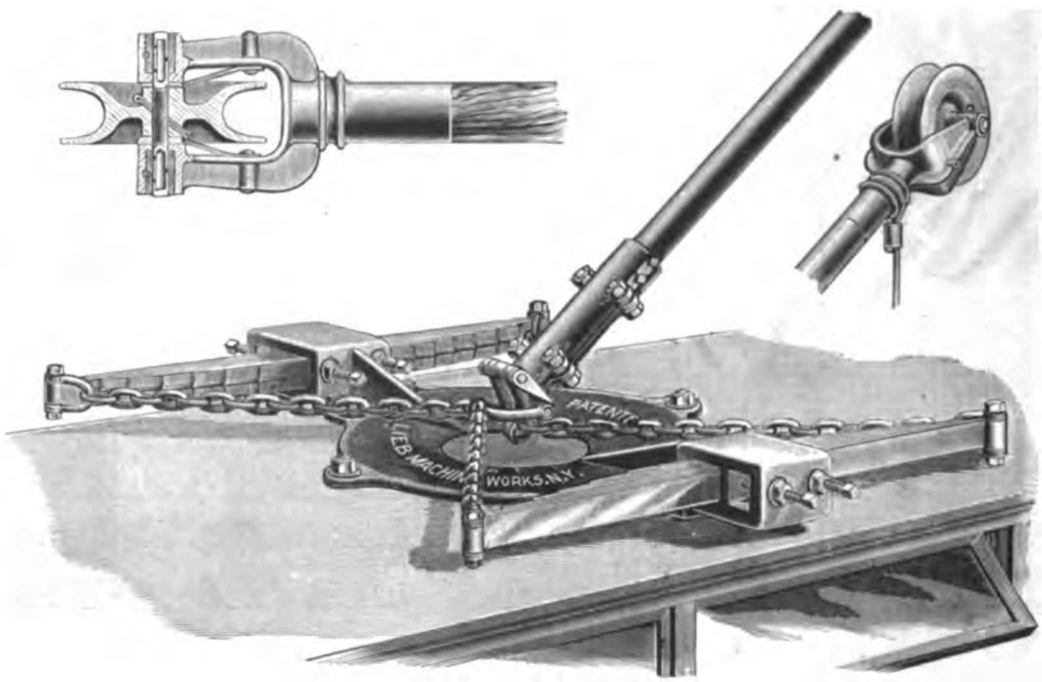
The officers of this company are as follows: John A. Coyle, president; Edward McGovern, treasurer; John Bausman, secretary; William Ring, general manager.

THE LIEB PERFECTED TROLLEY AND TROLLEY STAND.

THERE is probably no one detail of the many which go to make up the completely equipped electric car that has been the subject of more study and experiment than the trolley wheel and stand. The wheel being of necessity a small one, revolves at a high rate of speed, and is necessarily subjected to influences which tend constantly to its deterioration, and as a result much trouble has been experienced with this part of the equipment. In the Lieb perfected trolley, now being manufactured by the Lieb Machine Works, of 16 to 27 Vandewater street, this city, special precautions have been taken to avoid the difficulties heretofore met with.

The trolley, which is shown in section in the accompanying engraving, consists of a bronze wheel, which is pinned to a steel axle, so that both revolve together. The ends of the axle are bored and permit of the ready introduction of oil in the bearings, so that thorough lubrication is thus provided. The bearings are made of lignum vitæ, which material has proved to be the best adapted for this purpose. This wheel is guaranteed to run 5,000 miles.

The trolley stand, shown in the engraving, embodies several excellent principles. It will be noted that instead of employing the usual helical springs in order to obtain the proper tension, two flat steel wagon springs are employed, the four ends of which are connected to a special compensating joint. The arrangement is such that the tension or pressure of the trolley against the wire is alike in all positions of the trolley arm, and thus relieves both the car and the trolley wheel, as well as the wire, of all undue strain. The stand is so designed that the trolley wheel is able to pass under a line within five inches of the roof of the car.



LIEB TROLLEY STAND AND WHEEL.

It will also be noted that the connection between the wheel and the conductor leading to the motor is effected by means of discs pressed against the trolley wheel by springs, thus securing a firm contact.

WORLD'S COLUMBIAN EXPOSITION.

The Electricity Building, on which work has been started and is going on rapidly, will be completed about December 1st, 1891. The demand for space now aggregates something over 200,000 square feet, and in addition to this there have been received numerous preliminary applications not defining exactly the amount of space required.

Many of the applicants for space have given many interesting particulars what they are going to do, also in some cases stating the amount of money appropriated for their exhibits, and in no single case has this been less than $5,000. Such a figure as this shows the size and scope that electrical people intend giving to their exhibits.

It is estimated now that with the present space required and that called for in the preliminary applications—the latter being made on a very moderate basis, at the time of applying, as the parties were not informed that the space would be gratis—the entire Electricity Building and a portion of the Machinery Annex will be completely filled. It is, therefore, highly probable that some means will have to be devised to provide additional space, as the department of electricity will make a determined effort to give every one ample facilities. Of course, if necessary, the department will be compelled to use its prerogative in cutting down the spaces in order to make a fair and just allotment.

The Chief of Construction, Mr. D. H. Burnham, is preparing for Prof. Barrett ground floor and gallery plans and also sectional cuts of the Electricity Building, and these will be completed in the course of about two weeks. These plans will be sent out in printed form to all those who have made specific application for space, with a view to have all the applicants co-operate with the department in the final allotment of space.

ON THE ELECTROMOTIVE FORCES OF GALVANIC ELEMENTS.[1]

BY A. OBERBECK AND J. EDLER.

As amalgams in which the percentage is pretty low behave, so far as electromotive force is concerned, almost exactly as the metals themselves, an element consisting of the combination: mercury | electrolyte | amalgam was chosen, and the E. M. F. determined by the compensation method with the aid of a mirror galvanometer. The tests included the metals zinc, cadmium, tin, lead, and bismuth, in a large number of solutions of sulphates and chlorides of various degrees of concentration. In the result it appeared that the electromotive force depends principally on (*a*) the metal forming the electrodes; (*b*) on the electro negative constituent of the solution.

The order of the metals in the solution always remains the same, although their positions approach and recede from one another. The same is also true for free acids. The electromotive forces are greatest (and nearly equal) for sulphuric and nitric acids. For hydrochloric acid they are much smaller and nearly equal to those obtained with a neutral chloride. For solutions of salts the values of the E. M. F.'s follow the order: sulphate, nitrate, carbonate, chloride, bromide, and iodide. The electromotive forces only depend upon the metal of the salt in solution, when this metal is the same as that of the electrode. In this case the E. M. F. is smaller. If these results are compared with those published by J. Thomson on the heat equivalents of the above metals (except bismuth), a distinct correspondence between the differences of these equivalents and the observed electromotive forces will be noticed.

The authors arrived at the following conclusions:

1. The E. M. F. is to be calculated from the heat equivalent of the chemical process, taking into consideration the local evolution of heat that takes place at the electrodes.

2. Want of constancy in elements is due to the taking up of molecular layers of a dilute solution of the metal of the electrode. The degree of concentration depends upon many circumstances, which must be the subject of future experiments

1. *Wied Ann.*, Vol. XLII., Part 2.

COLUMBIA DYNAMOS AND MOTORS.

SINCE all dynamos and motors are based upon the same general principles, the differences in efficiency are due to the degree of correctness in design, accuracy of workmanship and quality of the materials used. Accepting this fact at the outset, the aim of the Columbia Electric Company, of St. Paul, Minn., has been to meet all these requirements, and their success is most gratifying.

The accompanying illustrations show two motors and a power generator built by this company. These machines have self-aligning bearings, self-oiling journals, and all sizes above 50-light dynamos and 5-h. p. motors have sub-bases and belt tighteners. Improved brush holders, both for copper and carbon brushes, are used on all machines, and, it will be noticed, have an independent action, as well as the double action, for placing them upon the commutator.

The power generators and dynamos, the general type of which is shown, Fig. 3, are of the same general form as the stationary motors, Figs. 1 and 2. The magnet cores of both are made of the

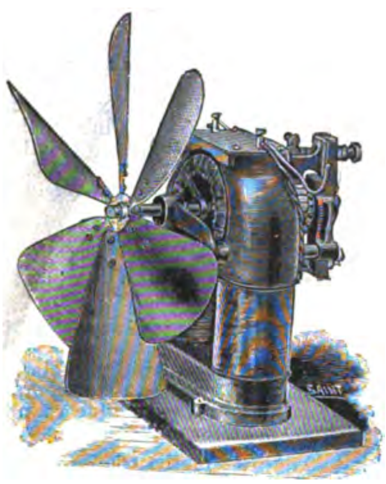


FIG. 1.

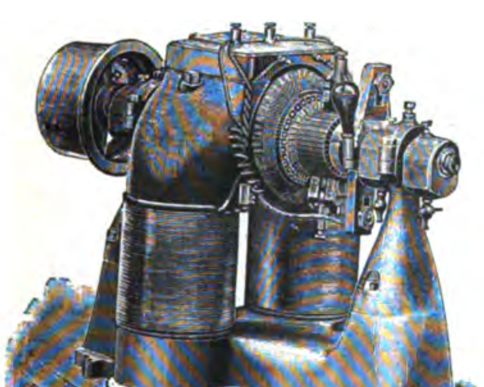

FIG. 2.

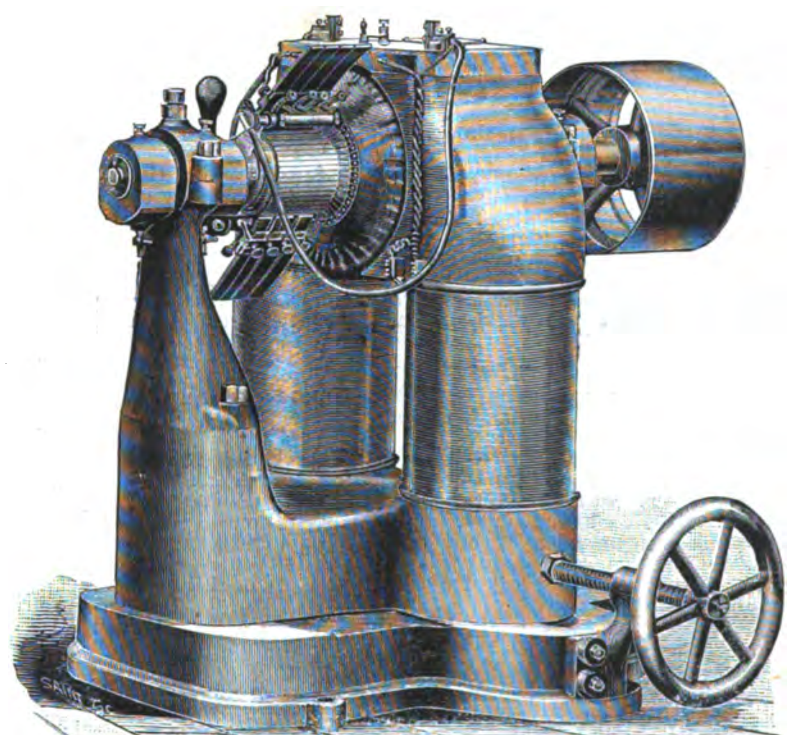

FIG. 3.

COLUMBIA MOTORS AND POWER GENERATOR.

best quality of charcoal wrought iron. The armature cores are thoroughly insulated with pure asbestos and mica, the same materials being used for insulating the spools upon which the field coils are wound. All commutators are insulated entirely with mica, and are so constructed that it is impossible for the bars to become loose.

These machines are wound either shunt or compound for any standard E. M. F., and the shunt machines and motors are provided with indestructible rheostats. The compound dynamos maintain a constant E. M. F. either at the machine or at the distributing point on the line.

In electrical efficiency and mechanical design these machines are claimed to be second to none. They are automatic in action and practically noiseless.

MR. H. T. PAISTE, the energetic and well-known switch manufacturer, has thrown off his business cares, and fled to the mountains of Virginia for a few weeks' recreation.

THE NEW WESTINGHOUSE ELECTRIC RAILWAY AT KANKAKEE, ILL.

AMONG the latest street railroads equipped by the Westinghouse Electric & Mfg. Company is that at Kankakee, Ill. This is a most charming summer resort, beautifully situated on the Kankakee River, between fifty and sixty miles from Chicago, and is becoming every day more popular with the city residents. In addition to its great natural beauty, which places it in the front rank of delightful spots for a summer outing, it is a solid and prosperous business town, having several big factories employing a large number of hands. The sporting element also has not been forgotten, as there is one of the finest race tracks in the country located there. The river a few miles above the town also is noted for its excellent fishing.

The advent of an electric street railway shows the progressive and enterprising spirit of its business men, and the growth of the town in population and new enterprises will increase rapidly, as is always the case where rapid transit is to be found.

The road is owned by the Kankakee Electric Railway Co., of which Mr. T. F. Andrews is president; Mr. T. W. Adams, treasurer; Mr. Carpenter, secretary, and Mr. Charles H. Cobb, general manager. The first car was started over the road on July 19th, but the formal opening took place on the 25th, when a party of people interested in such matters, among them representatives of the technical press, at the invitation of Mr. J. Livingstone Barclay, the manager of the Westinghouse Company in Chicago, and Mr. W. R. Mason, of the Electric Merchandise Co., went down to inspect the new line, which was unanimously voted an unqualified success.

The road built at present is somewhat over five miles long, with four motor cars now running. Trailers are to be immediately added, and additional lines will shortly be built.

The motor equipment was furnished by the Westinghouse Co., 20-horse power, 4-pole single-reduction motors being used. A noticeable feature of this system is that the gears are incased and run in oil, which renders them practically noiseless, and adds greatly to the comfort of the passengers. The principal streets on which cars are now running are Court, Harrison, East avenue, Merchant, Greenwood avenue, and Jeffries street.

All the line material and equipment supplies were furnished by the Electric Merchandise Co., of Chicago, who make the manufacture of, and dealing in, electric street railway supplies for all systems their exclusive business, and whose material is now to be found on almost every street railway plant in the country.

The cars were manufactured by the Pullman Company and are as handsome as any ever turned out. They are 16 feet long and mounted on "Hubbard" trucks, made by the McGuire Mfg. Co., of Chicago. The overhead construction was done by Mr. W. W. Hatch, of Kankakee, and the track-laying by Mr. C. E. Loss, of Rochester, N. Y. The work throughout has been done in the best possible manner.

The current for operating the road is furnished by a 500-volt 80 h. p. Western Electric railway generator, which is installed in a portion of the Electric Light Co.'s power house, and is driven by a 90 h. p. Paine engine, steam being supplied from the well-known Hazelton tripod boilers.

Reports of Companies.

AMERICAN BELL TELEPHONE CO.

The instrument output of the Bell Telephone Company for the month ended July 20, and the seven months of the company's fiscal year, is reported comparatively as follows:

Month ended July 20 —	1891.	1890.	Inc.
Gross	4,699	4,787	*88
Returned	4,638	2,887	1,751
Net	61	1,900	*1,839
Since Dec. 21—	**1890-91**	**1889-90**	**Inc.**
Gross	42,623	38,364	4,259
Returned	23,399	14,991	8,408
Net	19,224	23,373	*4,149

EASTON ELECTRIC CO.

The Sheriff has received an attachment for $15,000 against the Easton Electric Company, lately of 65 Broadway, in favor of Samuel Rowland on promissory notes of the company made a year ago, which were endorsed by P. Minturn Smith, the former president, and W. D. Perry, vice-president. Judgments for $2,395 have been taken against the company in favor of Murphy & Metcalf for professional services. The factory of the company was at 643 Kent avenue, Brooklyn. Ex-Mayor Wickham was its first president.

NORTH AMERICAN UNDERGROUND TELEGRAPH AND ELECTRIC CO.

There have been filed two executions aggregating $83,580 against the North American Underground Telegraph and Electric Company, formerly at 43 Broadway, in favor of Louis May, but no property could be found to levy upon. The company was formed several years ago with a capital stock of $5,000,000 to work the Johnstone iron conduit system for underground wires, but it was not favorably looked upon by the Board of Electrical Control.

DIVIDENDS.

The Thomson-Houston Electric Co. has declared a quarterly dividend of $1 per share, payable August 15.

The Eddy Electric Manufacturing Co. has declared a quarterly dividend of 2½ per cent., payable on demand.

Society and Club Notes.

ASSOCIATION OF EDISON ILLUMINATING COMPANIES.

The annual convention of this Association announced to begin on August 11, in this city, will be held at the Murray Hill Hotel, Park Avenue. The outlook is most promising, and recent events tend to give it far more than ordinary importance. The proceedings will begin at 10 A. M., on Tuesday, and during the day the following items of the programme will be taken up: Report of committee on the Prevention of Damage from Crosses of High Tension Circuits, by C. P. Gilbert, of Detroit, chairman; report of the committee on Lightning Protection, by A. E. Kennelly, of the Edison Laboratory, chairman, and the results of experiments at the laboratory on new forms of lightning arresters; report of committee on Grounding the Neutral Wire in Three-Wire Systems, by A. E. Kennelly, chairman; report of committee on Fuel Gas, by J. R. Markle, of Detroit, chairman. There will also be a visit to the office and stations of the Edison Electric Illuminating Company, of New York, in response to an invitation from the company to inspect the special features of their three plants, and plans for the proposed comprehensive station near the City Hall.

The following is the programme for Wednesday:

Address by officers of the Edison General Electric Company as to matters of commercial interest to the Association and the patent litigation; "How to get a Paying Load for Stations," by William D. Marks, of Philadelphia; "The Meters in Use in the Station of the Brooklyn Company," by R. S. White; "How can our Association best Serve Central Station Interests," by Frederic Nicholls, of Toronto; paper by W. L. Garrison, of the Brockton, Mass., Company; "Important Details in Underground Conductors," by Mr. Stevenson, of the New York Illuminating Company; "Some Practical Ideas on Distribution," by Leigh Carroll, of Birmingham, Ala.; paper by C. L. Edgar, of Boston; "Peculiar Features of the Edison Feeder System," by Wilson S. Howell; "The Success of the Mutual Insurance Idea in Electric Light and Power Stations," by secretary Jenks; paper by H. J. Smith, of the New York Illuminating Company.

Visit to the station of the Edison Electric Illuminating Company, of Brooklyn, in response to an invitation by the officers of that company.

On Thursday, the delegates will be given an excursion to Schenectady, by special train, by the parent company; and an opportunity will be afforded of visiting other of the manufacturing establishments around New York. Possibly the exercises may run over to August 14. The New York Electric Club, with its wonted hospitality, has tendered to the convention the privileges of the club-house during the week. The officers of the Association are: John I. Beggs, president; C. L. Edgar, vice-president; W. J. Jenks, secretary; and W. S. Howell, treasurer.

Appointments, Etc.

Mr. Gano S. Dunn, who graduated recently from the Columbia College electrical engineering course, has become associated with the Crocker-Wheeler Motor Co. as its electrical engineer, and is now actively engaged on important work for that concern.

Mr. D. C. Jackson, electrical engineer of the Chicago Edison branch office, has accepted the chair of electrical engineering at the State University of Wisconsin.

Mr. J. Harper, superintendent of the Jasper County, Mo., Electric Light & Power Co., has gone to Nevada to become treasurer of Asylum No. 3.

Mr. H. Coulter, of Kansas City, has been appointed manager of the telephone exchange at Leavenworth, Kansas.

Mr. H. L. Griffith joins the forces of the Dubuque Street Railway Co. as electrician.

Letters to the Editor.

THE GERMAN INDEX.

Regarding that most excellent index to periodical literature mentioned in your leader upon "Scientific Note Making," Vol. XII (No. 168), p. 92, issue of July 22, 1891, namely, "Die Fortschritte der Elektrotechnik," it may be well to state that the last number received to date by subscribers is the one for the last quarter of the year 1889, so that any one depending on it alone (and it is the best work of its kind) will be a year and a half behind the times, enough to put any one out of the race. It has further value than a mere index because of the abstracts of articles and its references to all reviews of electrical books.

J. STANFORD BROWN.

New York City, July 29, 1891.

ANOTHER ELECTRIC ROAD FOR BRAZIL.

A contract for an electric railway to be installed in Brazil was taken by Mr. Benjamin Blum, who will send a sample installation consisisting of one car with 25 h. p. motors; one 50,000-watt generator and all station apparatus and entire equipment for 1¼-mile track. This is for a narrow-guage road, and if successful, the entire road (consisting of 60 cars) is to be equipped by him.

Mr. Wm. M. Mordey, the English electrical engineer, arrived in this city from England on July 30, on a brief vacation. Unfortunately he will spend only a couple of weeks in this country, but proposes to make the most of his time in a flying excursion.

Literature.

Primary Batteries. By Henry S. Carhart, A.M., Professor of Physics in the University of Michigan. Sixty-seven Illustrations. *Boston. Allen & Bacon,* 1891. Pp. 193, ix ; $1.50.

In view of the fact that for half a century the primary voltaic battery constituted an essential part of every apparatus for the utilization of electricity, both for scientific and industrial purposes, it is certainly very remarkable that until now no one has apparently thought it worth while to prepare a special treatise in the English language on this subject. It cannot be truthfully affirmed that there has been no need for such a work, for notwithstanding the considerable amount of material of more or less value (generally less) to be found in the various treatises on the general subjects of physics, electricity, and telegraphy, and that embodied in papers scattered through technical journals, or entombed in the transactions of learned societies, the fact has been patent that most of the persons to whom the care of batteries has hitherto been committed have evinced an amount of ignorance of the subject little less than phenomenal. The Western Union Telegraph Company alone has in daily service more than 300,000 cells of sulphate of copper battery, under the care of some 20,000 different employees, not one per cent. of whom, it is safe to assume, ever received one word of intelligent instruction as to the most efficient and economical methods of management. The aggregate value of material consumed in these batteries must be nearly half a million dollars per year, at least one-quarter of which is absolute waste, due partly to carelessness, but much more to the total lack of intelligent instruction. The figures might be doubled by including the railway and other telegraphs, fire alarms, and signal and amateur batteries of various kinds.

It would afford us much gratification to be able to announce that Prof. Carhart's little book would be of great service to the benighted classes above referred to, but, on the contrary, we regret to be compelled to say, that while it is a most excellent treatise so far as it goes, its practical value is greatly lessened by the absence of detailed and specific instructions as to the care of batteries, the quantities and values of materials consumed in them, and other like information adapted to every-day use. From a theoretical standpoint, however, the work deserves hearty commendation. The distinction between electromotive force and potential, for example, which has always been a notorious stumbling-block in the path of the student, has been made so plain that the dullest cannot misunderstand it; and the fallacy of accepting as true under all, and even under most, practical conditions, the venerable dictum that the maximum effect of current in a circuit is obtained when the resistance, within and without the battery are equal to each other, is disposed of in a brief but admirable exposition of principles, which is a most valuable addition to electrical literature. The importance of making due allowance for the time-constant of the circuit in all electrical calculations is insisted upon, and is well illustrated by examples. Especially to be commended are the excellent chapters on Standards of Electromotive Force and on Battery Tests. In the latter the most recent and approved methods of determining the constants and electrical dimensions of different voltaic combinations, and of reducing the results to graphic curves, receive the attention which the practical importance of the subject demands. The descriptive matter relating to the different forms of cells in ordinary use, while excluding, as it should do, the innumerable ruck of inventions—new and old—which have neither utility nor real novelty to recommend them, in some instances leaves much to be desired. For example, it adds but little to the sum of human knowledge to be told, as we are on page 58, that the depolarizing solution of a certain commercial battery is "one of the best substitutes for nitric acid," so long as we are given not the slightest hint as to its ingredients.

The typographical execution of the work is praiseworthy, while the illustrations are generally sufficient for their purpose.

THE ELECTRICAL CENSUS OF THE STATE OF NEW YORK.

Upon the recommendation of Mr. Allen R. Foote, Hon. Robert P. Porter has appointed Mr. Horatio A. Foster special expert agent for the collection of statistics relating to the electrical industries for the State of New York. In making the appointment, it is the intention of the Census Office to complete the work for the State of New York, and to publish the results in a special bulletin at the earliest practicable date. It will therefore be the good fortune of this State, not only to have the benefit of the publication in advance of all other States, but also the honor of being first in the series of bulletins to give the results of the Electrical Census of the United States. For these reasons the Census Office, and all interested in this department of its work, are extremely anxious to have the report for New York complete and accurate in every detail. It is especially desirable that every person in the State in any way interested in the electrical industries shall cordially co-operate with Mr. Foster in facilitating his work, and furthering the general interests involved.

Mr. Foster will visit every electric central station, electric railroad, and the more important insolated plants in the State, and assist their superintendents in correctly filling the official schedule. All schedules that have been sent to Washington are put into his hands for correction and verification.

While the temptation will be very great to cause Mr. Foster to spend a little extra time at each station in talking over details of construction and management that are so intensely interesting to those in charge of stations, it is hoped that each superintendent will keep the fact in mind that one great point of value in Mr. Foster's work will be the quickness with which it can be completed. A very great service will be rendered by each superintendent if he will earnestly endeavor to assist in completing the work, so far as his station is concerned, in the shortest possible time consistent with accuracy. In a work as extended as this every half hour is valuable.

To assist in saving time it is suggested that each superintendent should have a correct memorandum for Mr. Foster, covering the following details :—

1. Average number of poles per mile.
2. Kind of wood.
3. Number of poles, part wood and part iron.
4. Total length of conductors on poles.
5. Total length of conductors on housetops.
6. Total length of conductors on bridges.
7. Total number of service connections.
8. Number of service connections on each alternating current main.
9. Total cost of all aerial conductors.
10. Total annual cost of maintaining all aerial conductors.

Mr. Foster will give each company due notice of the date when he will call for the purpose of finishing up its schedule and will give all the assistance that may be necessary.

It is the opinion, without exception, of all who know Mr. Foster personally, and of those who have read his recent articles on "Central Station Management and Finance," that no other person is as well fitted as he is, in all particulars, for the work he is to undertake. We congratulate the companies of the State of New York, and all interested in the electrical industries throughout the country, that this work is in such competent hands, and bespeak for him a cordial reception and every desired assistance from all persons upon whom he may call.

WOODHOUSE & RAWSON AT THE NAVAL EXHIBITION.

Among the numerous exhibits of private firms at the Naval Exhibition now open at Chelsea, London, is that of Messrs. Woodhouse & Rawson, United, Limited, of London. The exhibition

Woodhouse & Rawson Launch "Electric."

being primarily devoted to objects connected with naval warfare, we are reminded that this enterprising company have just completed to the order of the British Government the launch "Electric," of which we give an illustration. This has been specially designed for the conveyance of troops from one part of Chatham Dockyard to another, but it is intended to carry out with it an extended series of trials, so that the merits of electricity as applied to the propulsion of small vessels may be thoroughly investigated.

At the company's launch works, near Kew, there are at present several launches, varying in size up to 50 feet in length, in course of construction. Models are shown of some recently delivered, among which we notice one, the "Golondrina," 53 feet long, which has been built for the Mexican Government. Although some of these are steam launches, it is satisfactory from an electrical engineer's point of view to know that the demand for electrically propelled boats is increasing so rapidly that the company have felt it to be necessary to open a charging station near the works, where the accumulators may be recharged.

To show how easily electricity lends itself to launch propulsion the manager of the company's boat-building department has constructed a working model in which the screw is attached directly to the axle of the armature of the motor.

While search lights of all sizes are shown at this exhibition, the company has a model which they anticipate will soon find favor with the naval authorities. Instead of a mechanically worked arc, the light is obtained from an incandescent block of marble. This lamp was introduced some years ago as the "Sun" lamp, but owing to defects in design it did not meet with much favor. It has, however, now been perfected, and is about to be reintroduced. Its perfect steadiness and freedom from mechanism are its great merits.

The advantages of the single-stroke Jensen bell, particularly as adapted for signaling purposes on board ship, are shown, while it is almost needless to say that the quick-break switches for which the company is so well known are also shown. Both in the sample of the 1,000 ampere and the three-way 500 ampere types the sockets are arranged for "sweating in" the cables.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED JULY 21, 1891.

Clocks:—

Secondary Electric Clock Movement, B. Haberthur, 456,325. Filed Nov. 8, 1890.

Conductors, Conduits and Insulators:—

Flexible Conduit for Electric Conductors, C. H. Herrick, 456,271. Filed April 17, 1891.
Composed of a spiral lining, a protective wrapping applied to cover the separations between the turns of the spiral, and an inclosing envelope.

Conduit for Electric Cables, M. Delafor, 456,376. Filed Aug. 15, 1890.
Conduit has a removable cover, the joint between cover and conduit following a broken line transversely.

Lamps and Appurtenances:—

Cut-Out for Electric Lamps, W. F. Smith, 456,327. Filed Apr. 24, 1891.

Search-Light, W. E. Hadlock, 456,408. Filed Mar. 12, 1890.
A support and mounting for an electric lamp for search-light use.

Medical and Surgical:—

Electro-Therapeutic Apparatus, E. Grauert, 456,219. Filed July 16, 1890.
An electro-medical apparatus including a chloride of silver battery and special construction of parts.

Metallurgical:—

Magnetic Separator, H. G. Fiske, 456,507. Filed Mar. 26, 1891.
The mass of material to be separated is fed through the field of a moving series of magnets at a speed different from that of the magnets; the mass while traveling is subjected to continued reversals of the polarity of the magnets; the movement of the mass is in opposition to a current of fluid.

Metal Working.

Method of Welding by Electricity, J. H. Bassler, 456,540. Filed Aug. 16, 1888.
Applicable to the welding together of sheets, such as boiler plates, at their edges.

Method of and Apparatus for Electric Welding, S. L. Wiegand, 456,541. Filed Dec. 9, 1889.
Adapted to the welding of metal parts of such forms and dimensions as will not permit the entire weld to be effected simultaneously, but which require a progressive process.

Measurement:—

Method of Measuring Electric Currents, E. Thomson, 456,172. Filed Oct. 19, 1887.
Consists, essentially, in using an electrical current to generate heat, vaporizing a liquid by the heat, and noting the amount of vaporization as a measure of the electricity employed.

Miscellaneous:—

Electric Lock, A. S. Wiley, 456,182. Filed Apr. 9, 1891.

Insulated Contact for Electric Switches, O. S. Platt, 456,250. Filed June 4, 1890.
Employs porcelain buttons or bushings.

Operating Mechanism for Current-Regulators, S. H. Short, 456,253. Filed Mar. 10, 1891.
Relates particulary to rheostatic switches for the regulation of electric railway motors and operated from the car platforms.

Rheostat, J. Van Vleck, 456,280. Filed Jan. 19, 1891.
Designed to enable the coils of a rheostat to be thrown into or out of circuit by a small movement of the handle or lever.

Phonograph, T. A. Edison, 456,302. Filed Aug. 12, 1890.
Relates to the feeding devices.

Double-Contact Switch, T. H. Lovell, 456,493. Filed Dec. 2, 1890.
Especially adapted to use with currents of high potential.

Railways and Appliances:—

Trolley, J. E. Kinney, J. H. Brown & C. G. Wade, 456,148. Filed Oct. 20, 1890.

Connector and Support for Trolley-Wires, S. H. Short, 456,252. Filed Oct. 29, 1890.
Adapted for use with sectional trolley-wires.

Switch for Electric-Car Motors, S. H. Short, 456,254. Filed April 7, 1891.
Adapted for use upon electric railway cars equipped with four or more motors each, and provides means for connecting the motors in series, in multiple series, or in multiple arc.

Electric Railway R. M. Hunter, 456,513. Filed July 14, 1885.
Includes a contact device supported upon a laterally movable frame, the contact device having a self-sustaining, free-swiveling movement about a vertical axis.

Electric Railway, R. M. Hunter, 456,514. Filed Sept. 28, 1888.
Relates particulary to the arrangement of conductors upon a main line and a branch line.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED JULY 28, 1891

Accumulators:—

Electrode for Secondary Batteries, O. C. Flick, 456,558. Filed Jan. 3, 1887.
The electrode is made by casting or placing pure metallic lead into apertures or recesses, or upon the surface, of a plate of a metal or alloy not affected by the exciting liquid of the battery; then converting the metallic lead into a carbonate or other salt, and then converting the carbonate or other salt into spongy or granular lead while held in the cavities of the plate.

Secondary Battery, H. Pieper, 456,843. Filed Oct. 17, 1888.
Seeks to increase the capacity of batteries and facilitate their depolarization by maintaining within the battery-fluid gases in solution under pressure.

Alarms and Signals:—

Spout-Alarm for Grain-Bins, W. G. Adams, 456,667. Filed Dec. 18, 1889.

Annunciator, W. C. Dillman, 456,803. Filed May 6, 1891.
For use in connection with speaking-tubes.

Conductors, Conduits and Insulators:—

Cable-Head for Electric Wires, U. H. Balsley, 456,611. Filed Jan. 12, 1891.
Adapted for use with telegraph and telephone cables.

Attachment for Poles for Electric Wires, E. Verstraete, 456,663. Filed July 7, 1890.
Includes an insulating cap fitted on the end of a pole.

Distribution:—

System of Electrical Distribution, M. Feilbogen, 456,868. Filed Sept. 22, 1890.
A system for changing a constant current into an interrupted or pulsating current, adapted to a system of distribution employing converters.

Electric Circuit-Breaker for Secondary Generators, M. Feilbogen, 456,869. Filed Sept. 22, 1890.
Apparatus for use with the system noted next above.

Dynamos and Motors:—

Regulation of Dynamos Driven by Compressed Air, V. Popp, 456,598. Filed Apr. 7, 1888.
The output of the dynamo is controlled by an automatic regulator actuated by combined pnuematic and electric apparatus.

Electromotive-Force Regulator, E. M. Bentley, 456,612. Filed Oct. 21, 1890.
The method of regulating dynamos or motors consists in employing two sources of electromotive force and completing the circuit of each source through a variable portion of the other source.

Alternating-Current Motor, M. Von Dolivo-Dobrowolsky, 456,804. Filed Dec. 23, 1890.
Relates to the class of motors driven by a plurality of alternating currents of respectively differing phases.

Armature for Motors and Generators, N. C. Bassett, 456,925. Filed Feb. 27, 1891.
Relates to armatures of the type called "iron-clad." The coils instead of passing over the periphery of the armature core are passed through perforations near the periphery.

Ignition:—

Electric Gas-Lighter, A. Wunderlich, 456,684. Filed Apr. 7, 1890.

Automatic Electric Gas-Lighter, A. Wunderlich, 456,685. Filed Dec. 5, 1890.

Lamps and Appurtenances:—

Electric Arc Lamp, F. L. Sautter, 456,598. Filed Dec. 18, 1890.
Relates to the means of automatic regulation in focusing lamps.

Electric Light Crane, C. H. Shank, 456,859. Filed Jan. 10, 1891.

Medical and Surgical:—

Medical Induction-Coil, H. A. Voelkner, 456,746. Filed Jan. 28, 1891.
Employs two current-breakers vibrating at different rates of speed arranged in series in the primary circuit.

Metallurgical:—

Magnetic Separator, D. E. Lain, 456,622. Filed Aug. 2, 1890.
Combines a hollow cone of magnetic metal, two spiral rows of projections of magnetic metal from the external surface of the cone to form cores of electromagnets; a continuous spiral pole is provided for each of the two rows of cores.

Miscellaneous:—

Magnetized Head for Drawing Instruments, R. S. Carr, 456,553. Filed Aug. 4, 1890.

Coin-Controlled Electrical Apparatus, T. L. Brooks, 456,718. Filed May 19, 1890.

Clutch, W. H. Johnson, 456,827. Filed Apr. 1, 1891.
For use with dynamos.

Electric Condenser Regulator, J. McBride, 456,835. Filed Sept. 24, 1890.
Relates to apparatus for controlling automatically the supply of cold water to condensers in accordance with the quantity or pressure of the vapor to be condensed.

Show-Stand, J. W. Tyler, 456,865. Filed Mar. 12, 1891.

Electric Hoisting Machine, G. H. Reynolds, 456,908. Filed Dec. 27, 1890.
Especially applicable to elevators. Control is secured through the employment of variable resistances.

Railways and Appliances:—

Span-Wire Insulator, W. S. Jarboe, W. P. Siebert and J. White, 456,574. Filed Nov. 28, 1890.

Span-Wire Insulator, W. P. Siebert, 456,600. Filed Dec. 13, 1890.

Railway Signaling Device, W. Newcomb, 456,836. Filed Dec. 23, 1890.
Relates to visual signaling between moving trains.

Telephones and Apparatus:—

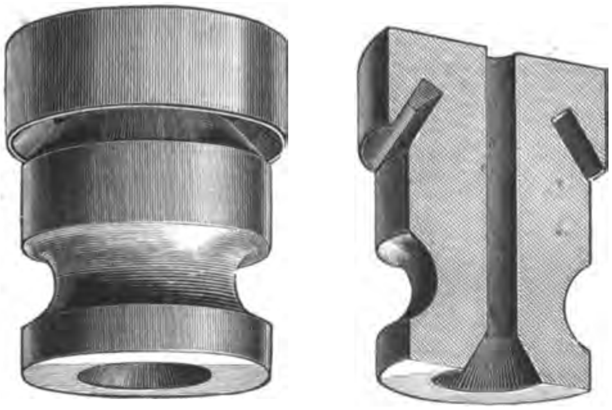
Electric Circuit-Changing Apparatus, H. V. Hayes, 453,817. Filed Feb. 3, 1891.
Relates to switching apparatus for use in connection with telephones; the apparatus shown was designed especially as a marine telephonic outfit for use on shipboard.

TRADE NOTES AND NOVELTIES
AND MECHANICAL DEPARTMENT.

"If you want to drop out of business, drop out of the papers."—C. M. Wilkins, of Partrick & Carter Co.

NEW CENTRAL ELECTRIC INSULATOR.

THE accompanying cut illustrates a porcelain insulator of new design. The slot around the base of the insulator, inclining

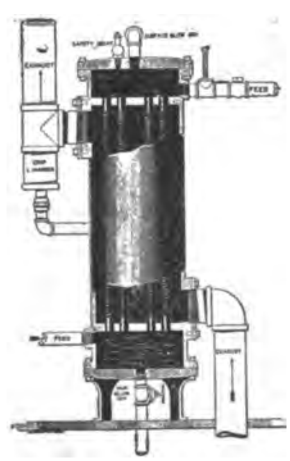


NEW CENTRAL ELECTRIC INSULATOR.

downwards, effectively prevents a line of moisture covering the insulator from the conductor to the supporting base. These insulators are highly glazed, have a countersunk base, and are spoken of very highly by those who have used them. They are being placed on the market by the Central Electric Company, of Chicago.

THE WAINWRIGHT CORRUGATED WATER-TUBE HEATER.

THE economic production of steam in an electric light or power plant is one of the most important factors of success, and results of the boiler, steam engine, and appurtenances largely control the question of dividends to the stockholders. Hence, every improvement to steam engineering applicable to electric plants is of interest to the electrical engineer, and we therefore illustrate in the accompanying engraving the latest type of corrugated water tube heater, designed and manufactured by the Wainwright Manufacturing Company, of Massachusetts, Boston. This heater has been designed specially and possesses many points of



THE WAINWRIGHT CORRUGATED WATER TUBE HEATER.

superiority, being provided with a settling chamber and a surface blow off.

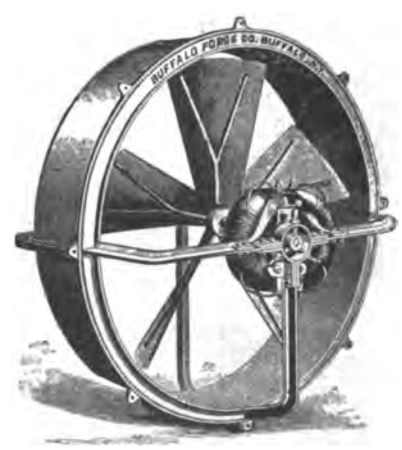
It is universally admitted that a straight tube heater, provided with proper means of blowing it off, and built so that it gives a chance for the impurities of the water to settle and be disposed of, is in every way by far better than a heater in which the water has no chance to settle, but allows all the impurities to pass into the boiler, there creating the chance of fouling and burning out the boiler.

An ordinary straight tube heater however, entails a heavy cost to prevent any possibility of leakage at the joints owing to the expansion of the tubes, but with the corrugated tubes it is entirely different, as the corrugations themselves take care of the expansion and contraction, and enable the manufacturer to make a heater which is practically perfect, and at the same time at a very low cost. The tubes are all of the best Lake Superior copper, and their durability is beyond question.

BUFFALO ELECTRIC DISC FAN WHEELS.

THE engraving herewith illustrates the improved electrical wheel just perfected and placed on the market by the Buffalo Forge Co., Buffalo, N. Y., U. S. A. As clearly shown, the motors are built as a part of the fan and require only a minimum power for driving. Any position suited to the maximum efficiency of the fan may be employed without affecting the arrangement of the motor. The fans are of high grade, carefully balanced, and the entire outfit is designed for quiet running at high speed. The motors are of the most approved style and type, especially constructed for fan propulsion, and capable of continuous use with little attention. The high speed at which it is possible to run these wheels gives them large capacity, so that a smaller fan, occupying little space, can be used to ventilate apartments of considerable size.

The above-named enterprising house not only build every type of fan and blower for all possible uses, but also manufactures a popular heating and ventilating system for all large buildings. It is known as the Buffalo "Hot Blast" or "Fan System" apparatus. Buffalo steel pressure blowers, "B" blowers, are well known to the trade as among the most durable blowing machines extant. Numerous Buffalo steel plate fans are now being used for the ventilation of mines with the greatest success. They are built both with single and double vertical and horizontal engines,



BUFFALO ELECTRIC DISC FAN WHEEL.

according to the work they are to perform. It is not uncommon to see these fans 20 feet in diameter when used for the above purpose. Aside from the above lines, this house manufactures a complete line of blacksmith tools, including portable and stationary forges, drills, punch, shear and bar cutters. It will be their pleasure to furnish complete catalogues covering the entire line of their manufacture.

THE SIOUX CITY ENGINE WORKS.

The Sioux City Engine Works report a constant improvement in their business, as indicated by an increased number of orders. They are still continuing their night force, and the indications are that it will be very largely increased in order to keep up the record, so far unbroken during the present season, of shipping everything ahead of contract time. They have recently shipped and are now erecting two 18 x 42 and one 12 x 36 Corliss engines for the Moline Plow Co., Moline, Ill. Two 12–22 x 36 compound condensing engines for the Waco Electric Light & Railway Co., Waco, Texas. One 16 x 36 to Leonard, Atkinson & Co., for their shoe factory, at De Kalb, Ill. One 16 x 36 to W. C. Ritchie & Co., for their box factory, Chicago, Ill. One 14 x 36 Corliss engine for a flouring mill at Savannah, Mo. One 9 x 14 Giddings automatic for electric lighting at Sioux City, Iowa. One 6–10 x 16 compound automatic for the factory of the New England Investment Co., Sioux City, Iowa. One 9 x 14 Giddings automatic for the Poch Mfg. Co., Leeds, Iowa. One 18 x 36 to the Northwestern Sewer Pipe & Tile Co., Sioux City, Iowa.

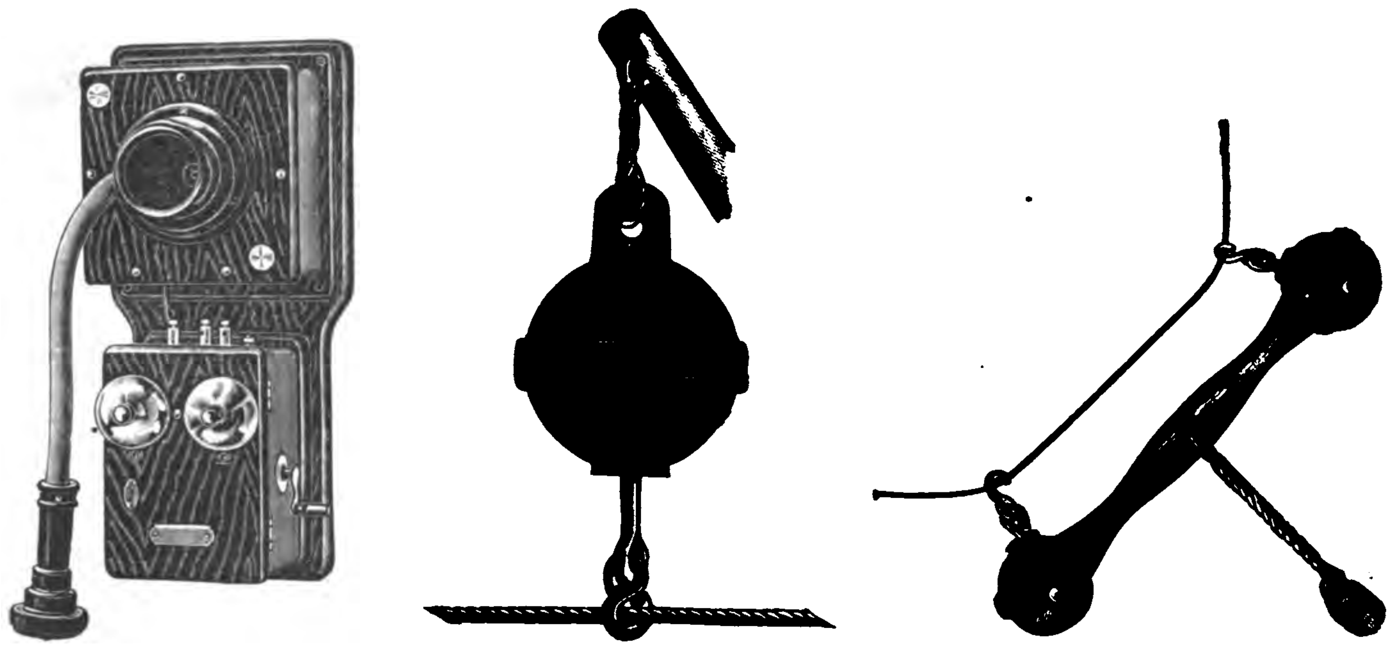
Among the orders booked the past week are: One 14 x 36 for a grain elevator in Chicago. One 18 x 36 for the Dubuque Electric Street Railway, Dubuque, Iowa. One 18 x 36 for Le Mars Water & Electric Light Co., Le Mars, Iowa. One 18 x 42 and one 12 x 36 Corliss with Stirling boilers for the new paper mill at Salina, Kansas. One 11 x 24 Corliss for a flouring mill at Sanbourn, Iowa. One 14 x 36 Corliss for the Illinois Chair Co., Rockford, Ill.

SIOUX CITY, IA., IRON WORKS.

Mr. C. M. Giddings, president and general manager of the Sioux City Iron Works, reports having sold in Dubuque, Ia., on a recent trip a 150 h. p. Corliss engine to run the generators of the Rhomberg electric street railway line. One of their erectors is at Moline putting up four large engines, and another is at Rockford putting in an engine there. Within the past 4 months they have placed 10 large engines along and east of the river, a fact that shows the estimation in which the Sioux City engines are held. They are now running their works night and day, and have several large contracts ahead for early execution. This make of engine bids fair to become well known in the electrical field, as it is being pushed, and finds marked appreciation.

THE STANDARD NON-ELECTRIC TELEPHONE.

In order to supply the prevalent demand for a practical short-distance telephone that could be sold outright, the Bostwick & Burgess Manufacturing Co., of Norwalk, O., have recently produced the instrument shown in the accompanying illustrations. Here Fig. 1 shows the telephone mounted and provided with magneto-bells. Extension bells may be placed in other parts of the building if desired. No battery is used in this system, and any one of ordinary intelligence can, it is claimed, put up the line.



FIGS. 1, 2 AND 3.—STANDARD NON-ELECTRIC TELEPHONE.

The insulators are of rubber incased in a metal shell, which protects them from the weather. From the rubber hangs a galvanized wire hook, through which passes the line wire, as shown in Fig. 2. These insulators are throughly practical and durable, and may be used as electric insulators also.

The difficulty experienced in working around sharp angles has been obviated by the use of the angle insulator, shown in Fig. 3, which consists of two single insulators pivoted to a malleable iron yoke. The engraving is one-half of the actual size.

RECENT SALES OF BALL ENGINES.

Below we give a list of recent shipments of the Ball Engine Co., Erie Pa.: Temple Bethel, New York City, two 80 h. p. engines; Johnson Co., Johnstown, Pa., three 150 h. p. engines, one 300 h. p. cross compound engine; Frishmuth Bros. & Co., Philadelphia, Pa., one 25 h. p. engine; Gambrinus Stock Co., Cincinnati, O., one 25 h. p. engine; Bennett, Sloan & Co., New York City, one 25 h. p. engine; Allentown Rapid Transit Co., Allentown, Pa., two 125 h. p. engines; Lebanon Street Railway Co., Lebanon, Pa., one 50 h. p. tandem compound engine; Edison General Electric Co., New York City, one 80 h. p. engine; E. T. Copeland & Co., New York City, three 80 h. p. engines, one 25 h. p. engine; Schuylkill Electric Railway Co., Pottsville, Pa., one 125 h. p. engine; Durham Electric Light Co., Durham, N. C., one 80 h. p. engine and boiler; Amsterdam and Rockton Street Railway Co., Amsterdam, N. Y., one 100 h. p. tandem compound engine; Corvallis Electric Railway Co., Corvallis, Wash., one 150 h. p. tandem compound engine; Olean Electric Light Co., Olean, N. Y., one 150 h. p. tandem compound engine; Boston and Great Falls Electric Light and Power Co., Great Falls, Mont., one 150 h. p. engine; Crook, Horner & Co., Baltimore, Md., one 25 h. p. engine; Northwestern Electrical Supply Co., Tacoma, Wash., one 25 h. p. engine; E. Meyer, New York City, one 80 h. p. engine: Reading and Southwestern Street Railway Co., Reading, Pa., two 125 h. p. engines; Key West Gas and Electric Light Co., Key West, Fla., one 150 h. p. tandem compound engine, one 100 h. p. tandem compound engine, one 60 h. p. tandem compound engine, two 150 h. p. boilers, 300 h. p. Wheeler condenser, 300 h. p. Davidson air and circulating pump, 300 h. p. Davidson boiler feed pump, 300 h. p. Korting injector, etc.; Trenton Lamp Co., Trenton, N. J., one 35 h. p. engine.

THE TICONDEROGA MACHINE CO.

The Ticonderoga Machine Company, of Ticonderoga, N. Y., has recently increased its capital to $125,000, and has purchased new property in the vicinity of its old works, including a large addition to its water-power. A shop 144 x 80 feet, and a five-foot iron trunk and turbine, are now about completed. This shop i a model in convenience and equipment, and no pains or money have been spared to make it equal to any similar plant in the country. The Ticonderoga Machine Company, in addition to its other business, consisting of mining machinery, paper mill, special machines, etc., will manufacture and sell the Woodbury, Merrill, Patten and Woodbury air engine, having perfected an agreement with the patentees by which the Tincoderga Company becomes the sole licensee for New England, New York and New Jersey.

The air engine will be made a specialty, and the results now being attained in the way of economy by this engine are said to promise a large field for it.

The company has opened an office for sale of its machinery at room B, 126 Liberty street, New York, where Mr. W. B. Hammond, manager of sales department, will be pleased to attend to the wants of patrons.

ELECTRIC LIGHT IN A WESTERN QUARRY.

The firm of Dolese & Shepard, contractors and stone-quarry owners in Illinois and Wisconsin, have recently installed an arc light plant of the Thomson-Houston system at their quarry at Hawthorne Station, Ill., for the purpose of facilitating the quarrying of stone at night. Twenty-five Thomson-Houston double-carbon standard arc lamps, are used for the purpose, and are suspended from poles mounted on movable standards, so that while blasting is in progress the lamps may be moved back from the edge of the quarry pit. The firm state that since putting the plant into operation they have not only largely increased the output of their quarry, but that the men working at night turn out more stone per man than those working during the day. This is probably due to the fact that the men working at night do not suffer from the heat to so great an extent as those employed during the hours when the sun shines.

THE "CHICAGO" TROLLEY CLAMP.

Mr. John S. Gustin, purchasing agent for the Electric Merchandise Company, Chicago, after long and earnest study, has devised the "Chicago" trolley clamp, shown in Figs. 1 and 2.

The clamp is formed in three distinct parts, two sections with opposing lips, one of which is provided with a threaded projection upon which the clamping nut is screwed; the other by a dog enclosed by the protruding lower rim of the nut. Through the

Fig. 1.—"Chicago" Trolley Clamp.

lower portion of these opposing sections a groove is formed to contain the trolley wire, the size of which does not call for a different construction of the clamp. The opposing lips are cut at such an angle that they still engage each other when the largest trolley wire is inserted in the groove. The screwing down of the nut upon the threaded projection and over the dog causes the lips to slide one within the other, thus forcing together the lower sections of the clamp upon the wire, preventing all possibility of falling. The movement of the wire from expansion and contraction is provided for in the hinge joint included in the nut. With this clamp an absolutely reliable support is provided for the trolley wire, while at the same time its simple mechanism makes its adjustment, at any place upon the wire, or entire removal

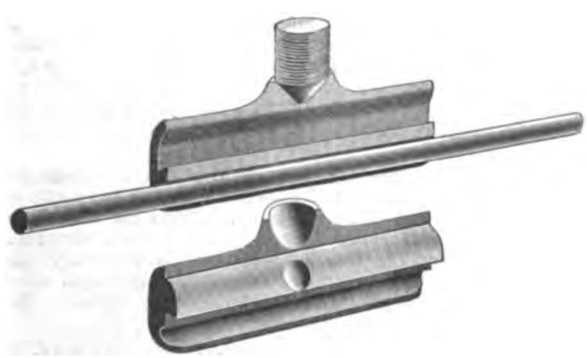


Fig. 2.—"Chicago" Trolley Clamp.

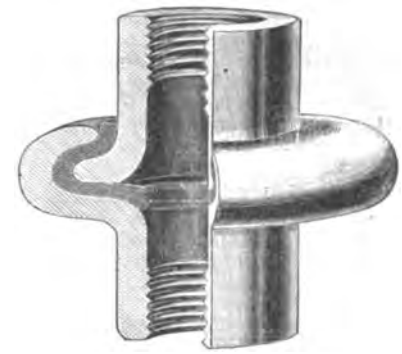
therefrom, an easy task of a minute's time. The clamp is equally efficient, whatever may be the style of insulator used in connection with it. While possessing all necessary strength, the clamp is light, and presents a neat appearance. The Electric Merchandise Company, Chicago, are sole agents for this device.

"Practical Electricity," of Boston, hitherto published as a semi-monthly has become a fortnightly, and more than ever justifies its title.

THE "PRIOR" INSULATING JOINT.

An improved insulating joint for chandeliers, where both gas and electricity are used, is illustrated in this issue, and is of special interest to those who make the wiring of stores and houses a specialty. This insulating joint was designed and is being put upon the market by Matthew Prior, of Watertown, Mass. It is made of bright brass in two castings insulated from each other by



"Prior" Insulating Joint.

the best insulating fibre, put in under a pressure of several tons and firmly held in place, thereby making the joint perfectly tight and secure from all action of gas or atmosphere. These joints are made in all the standard sizes, have no screws to twist, break off or cause short circuits, and are as strong as a solid casting. Mr. Prior is prepared to fill any and all orders from stock, and would be pleased to have our readers send to him at Box 2649, Boston, for sectional samples and all information. It has the approval of the Electrical Department of the Boston Fire Underwriters' Union.

THE "H., J. & C. CO." ELECTRICAL BLAST FURNACE.

We illustrate on this page a very simple, handy and efficient device made and sold by the Haines, Jones & Cadbury Co., of 1136 Ridge avenue, Philadelphia. The "H., J. & C. Co." electrical blast furnace is one of those things particularly useful to linemen. It is furnished, as shown, with an oblong shield attached, suitable

"H., J. & C. Co." Electrical Blast Furnace.

for their special purposes. The oblong solder pot allows the user to solder together perfectly the two ends of the wire by simply springing the wire into the pot, thereby saving much time and labor over the old way of pouring the melted solder on the joint. The apparatus is at once durable and cheap, and promises to find a wide field of popularity.

COBB VULCANITE CO.

It is understood that the party holding the mortgage on the property of the Cobb Vulcanite Co., of Wilmington, Del., has foreclosed, and that the real estate and personal property of the company will be sold at sheriff's sale on August 4.

ST. LOUIS TRADE NOTES.

THE ST. LOUIS CAR Co. are building for the Union Depot Railroad, of this city, 20 of the finest parlor street cars ever turned out in the United States. The cars are 35 feet over all in length with double trucks, a motor to each truck, and they are elegantly upholstered and fitted up. They are also engaged on an order of 130 cars for the St. Louis and Suburban Railroad, which is now being changed into an electric railway, A part of this order is being delivered. They have also just delivered a special long car to the Lindell Railway. The car is 42 feet over all, mounted on two trucks, each being supplied with a motor, and is a very handsome piece of street car work. This company has also delivered lately an order of 20 long cars for Indianapolis, also a large number of electric cars for Appleton, Wis.; Menominee, Wis.; Springfield, Ohio; Clinton, Iowa; Marquette, Mich.; Marionette, Wis.; and a lot of their well-known vestibule cars for Wichita, Kan.

THE MISSOURI ELECTRIC LIGHT AND POWER Co. are enlarging their building to twice its old size, and will put in two 5,000-light Westinghouse generators which will increase their output to 37,000 lights. The 5,000-light generator is the largest type of machine manufactured by the Westinghouse Co. The addition to the building will increase the total capacity of the station to 80,000 lights. The business of the company has increased steadily from the opening of the station some two years ago up to the the present time, the total output now being 27,000 lights. During the present summer months there has been an increased output of current due to the successful introduction of alternating current fan motors in St. Louis, and the motor business promises well for a continued output of current, owing to the fact that alternating current motors of larger power are about to be put on the market.

THE EMERSON ELECTRIC MANUFACTURING Co. have advertised for a new location East of Twentieth street. Although established only about ten months, their business has outgrown their present facilities. Their alternating current fan motor has proven a great success, and Mr. A. W. Meston, their electrical engineer, is engaged in working out plans for alternating motors of larger power for general industrial use. The Bagnall fuse switch, which has been adopted by the Lindell Railway Co., has proven successful beyond all expectations. The fuse wire always blows in the middle, leaving the clamps uninjured. This is due to the fact that the clamps do not compress or reduce the sectional area of the fuse wire. The fusing takes place quietly, leaving only a short gap between the ends of the fuse wire.

THE LACLEDE CAR COMPANY are building 10 electric cars for Duluth, Minn., and eight for Windsor, Ont. Th y have lately delivered 35 cars for electric roads in Cincinnati and Springfield, Ohio. The company is shortly to be reorganized and their capital stock increased, and they will then put on a full force of men to carry out their season's work.

THE BROWNELL CAR Co. are manufacturing the Low adjustable street car, the invention of a Californian. The car is a combination summer and winter car, which can be changed from one to the other in five minutes' time. The company are also building their well known cable and electric cars.

THE WAGNER ELECTRIC MFG. Co., 1822 and 1824 Olive street, are meeting with a very flattering demand for their alternating current motor, the sales running far ahead of their expectations. They are now engaged in perfecting motors of larger power for general use.

THE AMERICAN ELECTRIC MFG. Co. have got their incandescent lamp factory into successful operation and are turning out lamps for all purposes. They report a very flattering state of trade and inquiry for their lamps.

WESTERN TRADE NOTES.

THE POND ENGINEERING COMPANY report encouraging business from the Southwest. They are building the complete power plant for an Edison central station at El Paso, Texas; also a complete plant at Paris, Texas, for lighting and railway service. They are also furnishing Armington & Sims engines for Texarkana, Ark., and Austin, Tex.; the latter for the new Capitol building—the second engine of this make now in the Capitol.

THE ELECTRIC MERCHANDISE Co., of Chicago, the well-known dealers in street railway supplies and equipment exclusively, report business as excellent. In fact, street railway material is in very large demand all over the country, and a large number of new roads are being built, of which the Merchandise Co. with their energetic business, are obtaining a very large proportion.

MR. D. B. DEAN, traveling representative of the Electric Merchandise Co., has just returned from a trip to the Pacific coast. He has obtained numerous large orders for electric street railway supplies, and has had a highly pleasant and profitable trip.

NEW ENGLAND TRADE NOTES.

THE EASTERN ELECTRIC CABLE COMPANY, of Boston, well known as the manufacturers of the popular Clark wire, are extremely busy and do not complain at all of "dull times." This week they received one order for 50 miles of insulated wire, and they lately received the order for the whole of the cables and wire through their Western agents, the Electrical Engineering Company, of Chicago, for the incandescent wiring of the World's Fair Building in Chicago. The order calls for wires varying from the smallest single wire for incandescent purposes to cables of 500,000 circular mils. One lot has already been shipped. It may be interesting to note that the Eastern Company have built for themselves a comfortable office building, where Mr. Clark and Mr. Eustis will be pleased to see their patrons and friends. Possibly a number of our readers will remember the cosy old office with feelings of regret.

THE NATIONAL ELECTRIC COMPANY, of Boston, are enjoying a run of good business, especially with the telephone companies, in their well-known anti-induction and anti-abrasion line wires. They have now a number of lines in operation which are giving excellent anti-induction results, and the line at Revere, which is stretched on the poles of the local electric street railway company, is so perfect that whispered conversations can be distinctly heard over it. The National Company are shipping wire to New Haven, Philadelphia, Somerville, Boston and other cities for city fire-alarm and telephone purposes, and have now in contemplation a substantial increase to their factory, and will put in a number of new braiding machines.

THE RUSSELL ELECTRIC MANUFACTURING COMPANY, of Providence, has been reorganized, and has moved into its new quarters, at 212 Eddy street, of that city, with Mr. John Heathcote, treasurer, and Mr. Chas. W. Russell, manager. They are now busy manufacturing the well-known Russell mast-arm, and expect to fill contracts within the next month for about 15,000 feet. They are also bringing out a number of specialties for the electrical trade, notably a double pole arc light cut-out and an adjustable pole step, to be carried by trimmers instead of a step-ladder. The latter is made of aluminum, and weighs only three ounces, and has a spring catch which slips into the pole socket when applied.

THE WADDELL-ENTZ COMPANY have their new factory in Bridgeport all ready now for turning out work. They will go into the manufacture of dynamos and motors and storage batteries, paying special attention to electric railway work. The factory is a large and well-lighted building, and is now well equipped with machinery. Messrs. Waddell and Entz are both well known to the electrical profession, having been connected with it in varied capacities for many years, and are sure to build up a large and successful business in Bridgeport.

WARREN S. HILL, of Boston, has just brought out a neat line of single and double covered switches for incandescent work. The switches are made for branch circuits of from 1 to 25 lamps, are all mounted on porcelain bases, have the well-known Hill contact, and have plain brass or nickel covers. The price of the fifteen-ampere switch is but $2.00. With his large and varied assortment of other switches, Mr. Hill has now a very complete line of goods, and can supply a switch for almost any purpose or use in the electrical business.

A. AND J. M. ANDERSON, of Boston, well known as the manufacturers of the Anderson trolley, are placing on the market an excellent insulating material called "Ætna," which is being used extensively for bell insulators, trolley insulators, and strain insulators for electric railway work. The Buffalo street railway has a large number of them in successful use, and they are also used in Boston and Brooklyn. "Ætna" can be moulded into desired shape, is thoroughly waterproof, and will withstand an immense amount of heat.

ANNUAL CLAM BAKE.—Mr. Eugene F. Phillips, president of the American Electrical Works, of Providence, with his usual whole-souled hospitality, has sent out his invitations for the thirteenth annual Rhode Island clam dinner tendered to the electrical fraternity, to be held at the Vue de l'Eau Club, on Saturday, August 8. From past experience of these delightful meetings, we would advise every one to be present who can possibly attend. May the weather be propitious and the clams willing!

THE HART AND HEGEMANN MANUFACTURING COMPANY, manufacturers of the well-known Hart snap switch, who recently moved East from Kansas City, are now comfortably settled down in their new quarters on Pearl street, Hartford, where they have a convenient and well-equipped factory. They will continue to manufacture their regular line of goods, and are getting out a number of new specialties.

☞ ***Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Miscellaneous, etc., will be found in the advertising pages.***

ELECTRIC LIGHT.

Luling, Tex., is to have an electric light plant.

Tarkio, Mo., will enlarge its electric lighting plant.

Wauoo, Neb., is to have a municipal electric lighting system.

Butler, Mo., is receiving bids for a municipal electric light plant.

Chicago, Ill.—The Exposition is to be open at night, and every building will be supplied with electric lighting. Several miles of water in the lagoons and canals will also be illuminated by electric lamps sunk beneath the surface.

Union City, Pa.—A $20.000 electric light plant is to be put in by the Climax Electric Light Co., of Warren.

Beverly, Mass.—The Beverly Gas and Electric Co. has elected Hon. J. I. Baker, president; A. W. Rogers, clerk and treasurer, with a board of directors.

See further, page xii.

ELECTRIC RAILWAYS.

Lock Haven, Pa.—A company is to be organized to build an 8-mile electric railway to Mill Hall.

Lincoln, Neb.—The Lincoln Street Railway Co. now controls the street railway service of the city, which has a rapidly growing population of 70,000. Its electric plant represents a total investment of about $2,000,000, which is the capital stock of the company. The plant comprises 37½ miles of track, 100 miles of trolley wire and feeder, 80 motor cars, 40 trailers, 10 motor cars to arrive, and a fine power house with four Dick & Church compound engines of 150 h. p. each, driving four Thomson-Houston generators of 80,000 watts each. A new motor house is now being built. The rolling stock is of the Westinghouse and Short railway systems. The officers of the company are: F. W. Little, of Sioux City, president; C. J. Ernst, secretary; C. C. Upham, treasurer and general manager; E. L. Woolley, superintendent, and F. A. Webster, cashier.

Aurora, Ill., and Elgin are both ready to contribute to the proposed electric railway between the two towns.

Colorado Springs, Col.—The Rapid Transit Co. has been granted the right to lay a double track through West Colorado Springs.

See further, page xvi.

ELECTRIC LIGHT.

Shelbina, Mo.—The Royal Electric Lighting Co., of Peoria, Ill., has the contract to furnish an electric light plant for this place.

Beloit, Wis.—The Wiley-Warner Electric Lighting Co. is setting its poles. The lines will be mostly in alleys and will enter buildings at the rear.

Peru, Ind.—The electric light company has ordered a 650 light Thomson-Houston alternating current dynamo for incandescent lighting.

Waynesboro, Pa.—It is almost definitely settled that the Electric Light Co. will be granted a franchise providing the right to erect poles, etc., and with all the usual privileges.

Leavenworth, Kan.—The Merchants' Electric Light Co., recently incorporated, has elected C. M. Salinger, President; C. Hoffman, vice-president; J. H. E. Weigant, secretary, and H. Bruns, treasurer. Stock is sold in $10 shares.

Waterbury, Conn.—The Connecticut Electric Co. has elected the following officers: President, D. S. Plume; Treasurer, E. T. Turner; secretary, A. M. Young, with a full board of directors.

Chicago, Ill.—The contract for the electric light plant of the Masonic Temple has been awarded to the Western Isolated Lighting Department of the Thomson-Houston Electric Co. It will be one of the largest in the world, and will consist of six 80,000 watt generators. Between 7,000 and 8,000 lights will be wired.

TELEPHONE.

Lawrence, Mass.—The directors of the New England Telephone Co. have declared a dividend of 75 cents per share to stockholders of record at close of business July 21st.

Boston, Mass.—The decline of Bell Telephone stock to 186 is, in part, attributed to the selling of some New Bedford stockholders who were desirous of investing in Cleveland and Canton 5 per cent. gold bonds at 80, which carry a bonus of 50 per cent. in preferred stock.

TELEGRAPH.

Boston, Mass.—At the annual meeting of the Vermont and Boston Telegraph Co., Dr. Norvin Green was elected president, and R. H. Rochester, secretary and treasurer.

San Francisco, Cal.—The report of the Fire Alarm and Police Telegraph system shows that the department has now 170 miles of telegraph wire. The disbursements were $18,345, whilst the appropriation was only $18,000.

See further, page xx.

NEW BUILDINGS.

Roanoke, Va.—A residence for E. T. Burnett is to have electric work.

Boulder, Col.—An $8,000 house for Mr. Williams is to have electric lights.

Philadelphia, Pa.—St. Mary's church is to be altered and fitted with electricity.

Denver, Col.—A business house for E. W. Lowrey will be lighted by electricity. Cost, $80,000.

Pueblo, Col.—A business building for J. C. Wilson is to be lighted by electricity. Cost, $80,000.

Detroit, Mich.—An $8,000 carriage factory for Gray Bros. is to be fitted with electricity.

Philadelphia, Pa.—A club-house is to be erected on Ridge avenue and lighted by electricity.

Findlay, O.—A business house for L. D. Howes is to cost $12,000 and will have electric lighting.

Milwaukee, Wis.—A $40,000 bakery, to be erected for Johnston Bros., is to be lighted by electricity.

Windsor, Ont.—The Ever-Ready Dress Stay Co. will build a $10,000 factory and put in electric lights.

Detroit, Mich.—A warehouse for J. N. Bogley & Co. is to cost $22,000 and will be lighted by electricity.

Philadelphia, Pa.—The South Chester School Board will erect a school building and light it by electricity.

Detroit, Mich.—A building is to be erected for the Detroit Club at a cost of $50,000. It will have electric lights.

Owosso, Mich.—The First Congregational Church will erect a $25,000 building, which will have electric lighting.

Detroit, Mich.—A church is to be erected on Cass avenue. It will cost $25,000 and will be lighted by electricity.

New York, N. Y.—The wardens of St. Bartholomew will erect a $25,000 church, which will be lighted by electricity.

Madison, Wis.—The University of Wisconsin will build an armory and gymnasium, which will be lighted by electricity.

Philadelphia, Pa.—A residence for M. Gilbee and a dwelling on New street are both to be lighted by electricity.

Philadelphia, Pa.—A large mill for Clark, Thomas & Co. is to have electric lights; also a factory for Powell Bros.

New York, N. Y.—A church, to be built on 104th street and the Boulevard, will cost $50,000 and be lighted by electricity.

Wyandotte, Mich.—A trunk factory for the Beals & Selkirk Trunk Co. is to be erected at a cost of $15,000 and will have electric lighting.

ELECTRIC LIGHT.

Claremont, N. H., wants electric lights.

Toledo, O.—Plans are being drawn by N. B. Bacon for the new electric light station.

Cannelton, Ind.—Work has been commenced on the plant of the electric light and water works.

Birmingham, Conn.—One part of the electric lighting department of the Derby Gas Co. is running in perfect order.

Providence, R. I., wants to appoint a committee to investigate, with a view to establishing, a municipal electric lighting and gas plant.

Topeka, Kan.—This city has had its own lighting plant for two years, and a most exhaustive report alleges a saving as compared with Kansas City.

See further, page xxi.

TELEGRAPH.

Flint, Mich., will soon have a fire-alarm system.

Indianapolis, Ind.—The Fort Wayne District Telegraph Co. has been formed with $20,000 capital.

TELEPHONE.

Missoula, Mont.—The Telephone Exchange has made a most successful opening.

Carbondale, Pa.—It is probable that a company will be formed here to put in a Shaver telephone system.

MISCELLANEOUS.

The Equitable Electric Co. has been formed in Jersey City, with a capital stock of $250,000, to make electrical devices, etc.

The Eastern Electrical Supply Co. has been formed at Portland, Me., with a capital stock of $250,000, to make and deal in electrical supplies.

The New England Electric Brush Co. has been formed at Portland, Me., with a capital stock of $500,000, to make electric brushes under the patent of A. Stanton.

ELECTRIC RAILWAYS.

La Salle, Ill.—Through the efforts and energy of Mr. E. S. Enyart, the City Electric Railway Co. has acquired the Peru and La Salle electric railway, which connects the two cities over two separate routes. The new company has a capital stock of $125,000. The road is equipped with the Edison overhead system. W. G. Reeves, is president; F. X. Kilduff, secretary; L. B. Merrifield, treasurer and E. S. Enyart, superintendent. There are 6½ miles of track with 52 lb. Johnson rail, and 6¼ miles of No. 2 B & S. hard drawn copper trolley wire, with Simplex feeder. Guard wires will be used throughout. There are 8 cars, five double 15 h. p. motors and three open trailers, all from the St. Louis Car Co., with McGuire trucks. The power house is of brick, and is equipped with a Lane & Bodley engine of 150 h. p. and two 80 h. p. tubular boilers. Mr. Enyart writes us that they have just completed one mile of new track and are putting in a second 80 h. p. Edison generator. "The road cannot accommodate the people, and new equipments must be added." One and a half miles of extension will be added before January, 1892.

See further, page xxii.

ELECTRIC RAILWAYS.

Joliet, Ill.—Thomas Creevy and others have asked for right to build a street railroad to Lewistown. The storage-battery system is proposed.

Murphysboro, Ill.—A 120 h. p. Armington & Sims engine is to be supplied to furnish additional power for the electric street railway line.

Newtonville, Mass.—The Garden City Street Railway Co. will build an electric road between Newtonville and Newton Centre. The storage-battery system will be used.

Parsons, Kan.—The time allowed to the electric street railway has again been extended one year. As this is the third franchise allowed, the people are naturally becoming dissatisfied that nothing has yet been done.

Fort Wayne, Ind.—Workmen are employed grading the road for the railway tracks, notwithstanding the suit pending between the Land and Improvement and the Gravel Road Companies. Should it result favorably to the former, electric cars will be running before next winter.

New York City.—The Rapid-Transit Commission has taken another important step towards fulfilling its destiny by adopting resolutions concerning an East Side branch of the proposed underground railroad. The plan contemplates the piercing of a divergent tunnel from the main artery under Broadway at Fourteenth street, running thence with two double tracks, or one four-track way, to a point under Madison avenue near Ninety-sixth street, the rest of the road being carried overground to the Harlem river. This route has the double merit of directness and ease of construction. The greatest depth to the rock that underlies Manhattan Island is at Duane street, and at all other points south of Ninety-sixth street deep sewers and building foundations can be avoided without much difficulty. The preliminary work will be at once pushed.

NEW HOTELS.

West Chester, Pa.—A hotel is to be erected for J. Spence and lighted by electricity.

See further, page xxiv.

MISCELLANEOUS.

Electrical Exports.—The *American Exporter*, in its last issue, reports that the electrical exports from New York during the first six months of this year reached $369,926. The total of electrical goods for June shipped to Southern ports was 2,164 cases, valued at $80,017, or more than in any previous month. It includes a shipment of electric railway apparatus for Rio de Janeiro.

The Dr. Harm Electric Pocket Co. has been formed, to operate in Boston, New York and Chicago, with a capital stock of $200,000 to make pocket batteries.

ELECTRIC LIGHT.

Indianapolis, Ind.—Plans will soon take definite form as to the electric lighting of the city. One scheme is to buy a plant and sell it to the city on the instalment plan. The principal electric light companies will also be asked to submit figures.

Penacook, N. H.—Articles of incorporation of the Penacook Electric Lighting Co. have been filed. Capital, $10,000. The incorporators are: C. H. Sanders, E. H. Brown, G. W. Abbott, J. Whitaker, W. W. Allen, C. F. Foote, E. E. Graves, W. G. Buxton, J. C. Pearson, A. C. Alexander, I. Baty, F. A. Abbott.

Del Rio, Tex., has been lighted by electricity, and has one of the finest plants in the State.

Kansas City, Mo.—Bids are to be in by August 10 for city lighting for one year. The advertisement will call for bids for 100 or more arc lights of 2,000 c. p. each, to be located as designated by the board of public works and lighted every night of the year one-half hour after sunset and continued until one-half hour before sunrise, additional lights to be located as designated by the council upon thirty days' notice to the lighting companies.

New York City.—Residents of Thirty-second street, between Fifth and Madison avenues, have complained because the asphalt pavement in front of their homes is torn up. William H. Burke, the water purveyor, said that the Edison Company had received a permit to make some subsidiary connections in the street for the purpose of supplying houses therein, and that as soon as the work was completed the pavement would be restored by the contractor who put it down, at the expense of the Edison Company.

Missoula, Mont.—The Missoula Electric Light Co. is to install about 1,300 lights September 1, and a 150 h. p. engine. This additional plant has not yet been bought or contracted for. The existing plant is Thomson-Houston arc and alternating incandescent, and Edison direct incandescent, with 25 miles of P. & B. Candee and K. K. circuit. This plant is run by 4 Westinghouse engines and three 80 h. p. boilers. The capital stock is $50,000, fully paid in cash. Chas. Covill is president; W. A. Simons, secretary and treasurer, and H. M. Ogden, manager.

Corning, N. Y.—The Corning Gas Co. is putting in another 50-arc light dynamo. It has a capital stock of $100,000. L. C. Kingsbury is president; C. R. Cole, secretary; F. D. Kingsbury, treasurer; W. H. Christie, superintendent, and D. Gertin, assistant superintendent and engineer. The plant is combined gas and electric, the Thomson-Houston system being used. There are 18 miles of K. K. and Ansonia Brass and Copper Co. wire. The plant is run by two Rice engines of 118 and 162 h. p., with 150 h. p. boilers, built by D. M. Nichols, of New York City.

Princeton, Ill.—The Princeton Electric Light & Power Co., with a capital stock of $15,000, has recently put in a fine Thomson-Houston plant. It comprises an arc dynamo of 30 lights capacity and an incandescent machine of 650 lights. The plant is run by a 60 h. p. automatic high speed engine and a 70 h. p. boiler. Over five miles of circuit have been put up. The plant has been so arranged as to allow of an early increase. Mr. A. Sadler, of Kewanee, is the engineer, and Mr. C. C. Travis is the superintendent. The plant and the workmanship shown in its construction are highly spoken of by the *Bureau County Republican*.

See further, page xxv.

ELECTRIC LIGHT.

New Castle, O.—The New Castle Electric Light Co. has been ordered to put up more street lights or sell its plant to the town. It will probably be glad to supply street lights in any quantity for a fair consideration.

Syracuse, N. Y.—The Common Council has passed the franchise of the Onondaga Electrical Co. over the Mayor's veto.

Bristol, R. I.—About 20 25 c. p. incandescent lamps have been added by the Bristol Electric Light Co. on the Main Road, &c.

Paris, Tex., has received its electric light plant, which is being rapidly placed in position.

East St Louis, Ill.—The East St. Louis Electric Light Co. has added a new 150 h. p. engine and 2 dynamos to its plant, in order to meet demands for increased service.

Key West, Fla.—The work of planting poles and stringing wires is being rapidly pushed forward by the Key West Gas and Electric Light Co., and the plant will soon be running.

Woodland, Cal.—Improvement is the order of the day, and the Electric Light Company is in it, so says Superintendent Dunton. A new steel boiler of 65 h. p. has just been received from the California Boiler Works, of San Francisco. Fifty feet of 30-inch smokestack was also received. The new boiler will be put in position alongside the old one, which will undergo repairs. Other improvements will probably be made.

Rochester, N. Y.—The Brush Electric Light Company, through President Mumford, has sent a communication to the Executive Board, asking permission to place underground conduits in streets, to be designated by the board, preliminary to testing devices for operating underground circuits of high tension electric currents. The company said it would be to the interest of the city as well as the company to make the tests before any particular device is adopted. The matter has been referred to the board and Superintendent Barnes.

New York City.—About 10 p. m, on Saturday, the 18th ult., the Electric Light Commission, of the city of Wheeling, W. Va., arrived in this city, for the purpose of examining its electric lighting facilities. The visiting commission consist of P. F. Farrell, chairman; A. A. Franzheim, secretary; Members of Council, P. F. Farrell, J. A. Campbell, Albert Capps, C. W. Kreiter, Chas. Craig; Board of Gas Trustees, A. J. Schultze, William H. Shafer, all of Wheeling, W. Va., and electrical engineer for commission, John A. Seely, of New York. They had with them as guests S. W. Darrah, superintendent of Wheeling city gas works; John J. Farrell, of Wheeling city gas works; W. C. Beans, city editor of *Wheeling Register*; J. W. Phoebus, of the *Wheeling Intelligencer*, and D. W. Dunn, of Pittsburgh, Pa. After visiting the different electric plants the party left for home on the evening of the 20th.

THOMAS G. SMITH, JR.,

Consulting and Contracting Engineer,

11 Hammond Bldg., Cincinnati, Ohio.

Complete steam plants for electrical and power purposes contracted for and erected.

Sole Agent for the

Improved Ball Automatic Engine

For Southern Ohio, Southern Indiana and Kentucky.

Plans and estimates furnished on application, and first class work guaranteed.

ELECTRIC RAILWAYS.

Braddock, Pa.—The Braddock electric railway line has been opened successfully.

Norristown, Pa.—The Philadelphia and Reading Railroad Co. will light the new De Kalb street station with electricity.

Washington, Pa.—The new power-house is to be located at some distance from the residences, to avoid trouble from noise.

Ottawa, Ill.—Mr. A. L. Millard, of the Edison General Co., has been testing and starting a new generator for the Street Railway Co.

Hudson, N. Y.—President McGonigal, of the Hudson Electric Railway Co., states that the earnings of the railway since it has been in operation, about nine months, will exceed $11,000.

See further, page xxvii.

ELECTRIC LIGHT.

Hazelton, O., is thinking of electric lighting.

Chehalis, Wash., is now lighted by electricity.

Villisca, Ia., has voted for an electric light franchise.

Red Oak, Ia., has a franchise for an electric light plant.

Wardner, Idaho, is to have an electric light plant.

Taunton, Mass., is talking of an electric light plant.

Willamette Falls, Ore., has a 100 arc light dynamo.

Eagle Grove, Ia.—Electric lights are being talked of.

Loveland, Col., will probably have an electric light plant.

Wakefield, Mass., is thinking of having municipal electric lighting.

St. Augustine, Fla.—The Alcazar Hotel will put in a new electric light plant.

Bramwell, W. Va.—The Bramwell Electric Light Co. has put in some new machinery.

Ellicott City, Md.—An electric light plant is proposed. W. L. Nott can give information.

West Union, Ia.—An electric light plant is to be operated here by a private company.

Hastings, Mich.—The citizens have petitioned the council to erect a $13,000 electric light plant.

High Point, N. C.—A committee has been appointed to purchase an electric light plant.

Weedsport, N. Y.—The Thomson-Houston Company is putting in an electric lighting system.

Hyde Park, Mass.—J. R. Bullard has been elected a director of the Hyde Park Electric Light Co.

Winnipeg, Man.—The Royal Electric Co., of Montreal, will put in the Prince Albert electric light plant.

Niles, Mich.—The Niles Electric Co. is pushing work rapidly, and in a short time will furnish electric lights.

Wheeling, W. Va.—N. E. Whittaker and others will organize a company to operate an electric light plant.

Marion, O.—The Marion Electric Light & Power Co. has increased its capital stock from $25,000 to $40,000.

Niles, O.—The sale of $10,000 electric light bonds for building an electric light plant will take place September 1.

Waterville, Me.—The Fairfield & Waterville Electric Light & Power Co. will furnish power for the Electric Light Co.

Sioux City, Ia.—The Corn Palace is to be lighted by the Sioux City Electrical Supply Co. There will be over 3,000 lights.

Schuylkill Haven, Pa.—The Thomson-Houston company has the contract for furnishing an electric lighting plant for this place.

Pittsburgh, Pa.—The large Ferguson Building is to be wired by the Edison General Co. for 900 lights. The "interior conduit" system is to be used.

Elmira, N. Y.—The Elmira Illuminating Co has elected P. K. Kobbe, of New York, president; F. A. Cheney, of Elmira, secretary and treasurer.

Schenectady, N. Y.—Bids for lighting are to be put in, and it is expected that the struggle will be a lively one between the gas company and other interests.

Quincy, Ill.—The total cash value of the Thomson-Houston electric light plant is placed at $105,000. The city will probably pay $90 per light monthly, and put in a smaller plant.

Southbridge, Mass.—The Southbridge Gas & Electric Co. has elected H. C. Wells, president; C. W. Johnson, treasurer; E. P. Wells, clerk. A most gratifying report was made.

Sharpsville, O.—The Electric Light Co. has made a proposition to furnish 10 or more lights of 2,000 c. p. for $85 each a year. The lighting committee offer in return to take 12 lights at $75.

Old Town, Me.—A contract is to be made with the electric light company for 28 incandescent street lights for the villages of Old Town, Upper Stillwater and Greatworks, until April, 1892.

See further, page xxviii.

Kettle Falls, N. Y.—The capital stock of the Kettle Falls Light & Power Co., recently organised, is $100,000; all the incorporators are Rochester men: G. H. Smith, A. A. Davis, J. H. Richards and others.

Portland, Conn.—The electric light plant will probably be ready to begin operations by November. The river will probably furnish the water-power required, which will also serve to run street cars within a year.

St. Paul Minn.—Mr. T. Lowry has a plan for placing arc electric lights on every side of the block on which his arcade building is situated. The St. Paul Light, Heat & Power Co. asks permission to lay subways in the streets and alleys.

St. Cloud, Minn.—Bids for putting an electric light plant in the Minnesota State Reformatory have been received by D. E. Myers, the superintendent. The plant to be of 4,000 lights, with accessories of chandeliers, pulleys, &c.

Oakland, Cal.—A contract has been made between the board of trustees and Mr. Osborne whereby he is to receive a salary of $150 monthly for which he is to light the town, he having the privilege of supplying incandescent light to private customers.

Paxton, Ill.—The Electric Light Co. has entered into an agreement with the city to operate the water works for $60 per month, and will furnish 18 large street lamps at $7.25 each per month. The company earns a profit of 10 per cent. on its $24,000 capital.

Orange, N. J.—The Essex County Electric Co. will put in a large and improved plant to furnish light for Orange. It will erect a fine fireproof building, and will have two 300-h. p. Corliss engines, six 100-h. p. Ball engines and 32 dynamos. The capacity will be 1,440 arc, or 16,000 incandescent lights. The cost will be about $50,000.

San Francisco, Cal.—The California Electric Light Co. has been authorized to change some of its lights, and to place 25 arc lights of 2,000 h. p. on poles 40 feet high in certain places. A proposition to form a new company in conjunction with the Edison system was unanimously approved. P. B. Cornwall is president; G. Sutro, vice-president, G. R. Roe, secretary.

Ottawa, Can.—On July 28, J. R. Arnold, chief mechanical engineer of the Public Works Department, admitted, before the public accounts committee, receiving bribes from two Montreal firms doing a large Government business. The agent for the Edison Company, whose light is in use in the Government buildings, had sent him a present from New York, but he had not accepted it as a bribe. The agents of the United States Electric Light Company had, he said, tried to buy him, but had failed.

See further page xxx.

ELECTRIC RAILWAYS.

Tacoma, Wash.—Ten new electric cars have been ordered from the Pullman Company.

Baldwinsville, N. Y.—The people here are hoping for an electric line soon from Syracuse.

Haywards, Cal.—Subscriptions for the Haywards Electric Railroad bonus continue to come in. Already $3,225 have been subscribed.

Niles, O.—The ordinance granting the Trumbull Electric Railway Co. the right to construct and operate a railway is under discussion.

Marion, Ind.—There is a project to extend the Marion Electric Street Railway to Jonesboro, which gives great satisfaction to the latter place.

Pittsburgh, Pa.—The Pittsburgh and Birmingham electric road employees have recently had a raise in wages, but say they are willing to take less for shorter hours.

Spokane Falls, Wash.—Four more electric cars have arrived and the entire number will soon be here and in operation, after which horse cars will be a thing of the past.

Asheville, N. C.—The electric street car lines work admirably, and are regarded as a great institution. The 4-mile track to Sulphur Springs will soon be in operation.

Pittsburgh, Pa.—Sliding trolleys are being put on the cars of the Pittsburgh and Birmingham Traction Co. All the other lines in Pittsburgh use the underrunning wheel trolley.

Wilkesbarre, Pa.—The Wyoming Valley Traction Co. has adopted the Short gearless motors for its electric road, and its 18 new cars will be equipped with that type of motor.

Athens, Ga.—Manager Voss reports that in spite of the burning out of the generator armature, the road will get down to business again at once. Two new cars will also be put in operation, making 4 on the road.

Oakland, Cal.—J. W. Hearst is interested in a proposed long electric road for which a franchise has been petitioned. He is a nephew of the late Senator, whose widow is said to be back of the enterprise.

Kansas City, Kan.—A statement has been made by Colonel Edgerton that as soon as a franchise can be obtained the company will take its "L" trains off some part of its line and substitute electricity as a motive power.

Vincennes, Ind.—A Chicago firm has contracted to furnish the Vincennes Street Railway Co. with the Westinghouse trolley electric system. A power-house will be erected at once. The contract calls for four 20 h. p. single reduction motors.

Worcester, Mass.—A new street railway company has been organized by C. S. Turner, J. M. Drennan, G. A. Stevens, H. H. Bigelow, J. H. Clarke, I. E. & L. Bigelow. The name will be the Worcester & Shrewsbury Street Railway Co. The capital is $20,000, divided in 200 shares of $100 each.

See further, page xxxi.

ELECTRIC RAILWAYS.

Madison, Wis.—The Madison Elevated Electric Railway has been formed with $10,000,000 capital.

Whitinsville, Mass.—The proposed electric railway will connect this place with Manchaug, East Douglas, Douglas, Uxbridge, and probably Millville. A six-mile branch would connect it with Mendon and the Milford and Hopedale road.

Seattle, Wash.—An electric line is to be built from this place to Puyallup by F. E. Sander, L. H. Griffith, and others. The line will be 32 miles long, and will cost $400,000. It will connect with the Tacoma and Puyallup Electric Line, making a continuous line between Seattle and Tacoma.

Paterson, N. J.—The Paterson Railway Co. proposes to raise funds for improvements in the adoption of the electric overhead system, and will execute a mortgage for $1,250,000. The entire system will be reconstructed, and a contract for the work has already been awarded to the Field Engineering Co. of New York City.

New York City.—Judge Coxe, of the United States Circuit Court, having decided that the Brush Electric Company is entitled to the control in this county of the manufacture and sale of electric storage batteries, it is understood that the running of storage-battery cars will be resumed on the Fourth and Madison Avenue street-car lines.

Santa Cruz, Cal.—The Santa Cruz, Garfield Park and Capitola Electric Railway, capital stock, $100,000, has a Thomson-Houston plant of the overhead system. It has 8 miles of 40 lb. track, and contemplates building 8 miles. It has 6 miles of Roebling circuit. Guard wires will be used in part. There are 4 motor cars and 4 trailers, the cars being built by Holt Bros., of Stockton, Cal. More cars are to be added. The plant is run by a Fraser-Chalmers Corliss engine of 250 h. p., and a Taylor-Beck of 85 h. p. The power-house is of wood and insured. J. H. Logan is president; E. H. Robinson, vice-president; Bank of Santa Cruz Co., treasurer, and F. W. Swanton, secretary.

Windsor, Ont.—The Sandwich, Windsor and Amherstburg Electric Railway Co. are going in for a number of improvements. Their capital stock is $200,000, and they have $100,000 bonds not yet sold. J. M. Clark is president; C. E. Warner, treasurer, and W. C. Turner, general manager. The company has the Westinghouse overhead system with 6 miles of track, and 6 miles of No. 0 Roebling wire circuit. No guard wires are used. There are 10 cars equipped, built by the Laclede Car Co., with Brill trucks. The plant is run by a Brown engine of 200 h. p. capacity. The power-house, of stone and iron, cost $12,000. The company has a 14-mile extension in mind to Amherstburg, and has been thinking of operating it by steam direct. It also proposes to put in a plant of 1,000 incandescent lights. It is to add 10 new cars to its rolling stock.

See further, page xxxii.

ELECTRIC LIGHT.

Hammond, Ind., is thinking of electric lights.

Dixfield, Me.—Electric lights will soon be started again.

Centerville, Ia.—An incandescent electric light system is to be put in.

Cœur d'Alene, Wash.—The Edison General Electric Co. has contracted to put in a 700-light plant. W. L. Gleason is manager.

Madison, Me.—A system of electric lighting is to be put in the village and at the pulp mill, by the Thomson-Houston Electric Light Co.

Ellenville, N. Y.—Lyman Russell succeeds his father as bookkeeper for the tanning company, and will give his attention to the electric light business.

Milwaukee, Wis.—The Milwaukee Power & Lighting Company has been granted equal rights with the other lighting companies, despite strong opposition.

Pittsfield, Mass.—The local electric light company has elected Alex. Kennedy, president; W. A. Whittlesey, treasurer; W. L. Adams, clerk. The report for the last six months is most satisfactory.

Hoboken, N. J.—The D., L. & W. Railroad Co., through its electrician, P. H. Brangs, is putting in a large combination plant for generating electricity, gas and steam. The electric light room will be 40x40 feet; the boiler house will be 40x65 feet and will contain eight 100 h. p. boilers from the Stearns Mfg. Co., of Erie, Pa. Mr. Brangs, will install a plant first-class in engineering and in every item of construction.

Salt Lake City, Utah.—The Salt Lake Power, Light and Heating Co. is to put in two new Armington & Sims engines of 100 h. p. The plant is Thomson-Houston, Western Electric and Edison incandescent and arc. There are about 200 miles of circuit of various makes. The plant is run by 400 h. p. Buckeye engines, 600 h. p. Armington & Sims, and 65 h. p. Westinghouse. Frank H. Dyer is president and James Moffatt, secretary.

See further, page xxxiii.

MISCELLANEOUS.

Chicago, Ill.—The Electrical Reminder Co. has filed an increase of stock from $25,000 to $250,000.

Denver, Col.—A new ordinance provides that all electricians and those engaged in the business of wiring shall pay a yearly license and file a $2,000 bond.

Boston, Mass.—Everything is now ready for operating the Federal street drawbridge by electricity. The bridge will be run by a Thomson-Houston 22 h. p. motor.

The Baehr Electric Mfg. Co., of Newark, N. J., has been formed with a capital stock of $50,000 to make and handle electrical appliances.

The Welsh-Edison Suit.—E. Baker Welsh, who sued T. A. Edison for $250,000 for breach of contract, has been ordered by Judge Nelson of the United States Circuit Court to produce certain letters within thirty days and also file a bill of particulars setting forth in what patents, inventions, etc., he claims to have an interest.

VOL. XII. AUGUST 12 1891. No. 171.

THE MANCHESTER SQUARE, LONDON, ALTERNATING CURRENT STATION.

ALTHOUGH London had for a long time labored under the reproach of tardiness in the adoption of the electric light, the progress which has been made during the last year or two gives sufficient indication of the fact that before long the capacity of its stations will exceed considerably that of like plants in any other city in the world. Situated in the majority of cases right at the centre of densely populated districts, these stations have found a ready demand for current, and capital has now been easily found for the erection of large and excellently equipped plants.

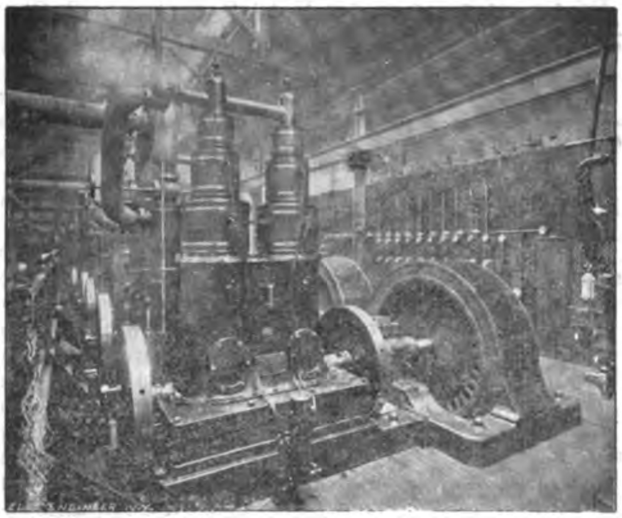

FIG. 1.—MAIN DYNAMO ROOM, MANCHESTER SQUARE STATION, LONDON.

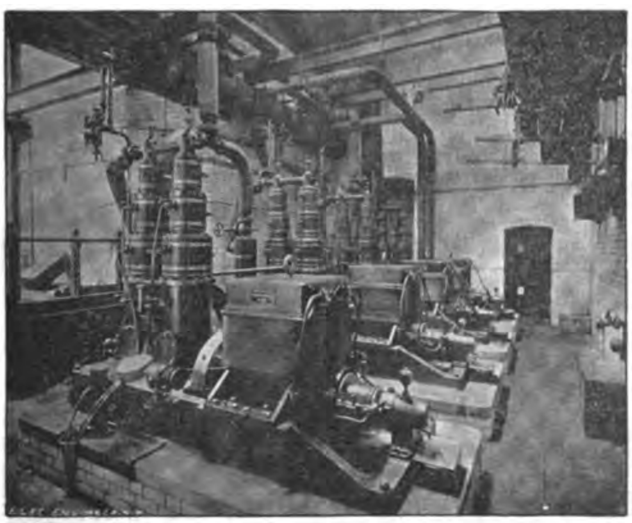

FIG. 2.—EXCITERS, MANCHESTER SQUARE STATION, LONDON.

The most recent addition to these is the alternating station of the Metropolitan Electrical Supply Co., situated at Manchester Square, which has been equipped throughout by the Electric Construction Corporation, Limited, of London, whose works are situated at Wolverhampton.

The plant consists of nine 160 h. p. Babcock & Wilcox boilers, with duplicate pumps and feed-water arrangements throughout; 10 Willans & Robinson double triple-expansion, central-valve, high-speed engines, each capable of indicating 200 h. p. at 350 revolutions per minute, each of these being coupled direct to an Elwell-Parker alternating-current machine mounted upon a common bed-plate with the engine, as shown in Fig. 1, and giving an output of 1,000 volts and 100 amperes. In addition there are four 50 h. p. engines, running at 450 revolutions, driving four Elwell-Parker shunt-wound dynamos as exciters, Fig. 2, any two being capable of exciting the whole number of alternators in the station. The steam pipes are arranged so that there is a duplicate feed to every engine.

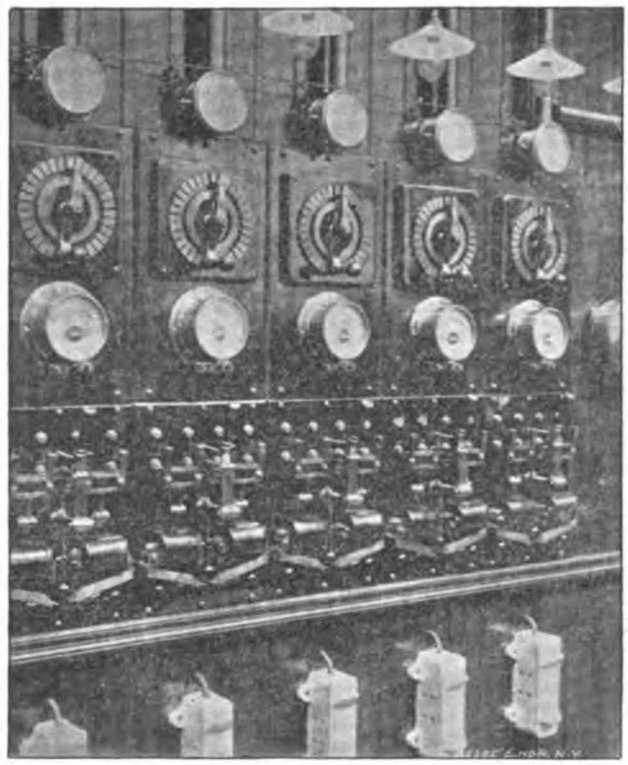

FIG. 3.—SECTION OF MAIN SWITCH BOARD, SHOWING DOUBLE-POLE AUTOMATIC CUT-OUTS, ETC., MANCHESTER SQUARE STATION, LONDON.

A new feature of the main switchboard consists in the employment of double-pole automatic magnetic cut-outs in place of fuses. These cut-outs, which are shown in Fig. 3, have given most satisfactory results; they can be set exactly to go off within one or two per cent. of the determined amount of current. One of these is fixed in each dynamo circuit.

There are 22 circuit switchboards, a section of one being shown in Fig. 4, arranged so that any dynamo can be connected on to one or all of the circuits. Trunk mains are also brought into the station from other stations of the

Metropolitan Company, so that when there is only a light load, and in case of necessity, the Manchester Square station may be stopped entirely, its load being taken by one of the other stations. This is found of great advantage in the summer months, when only light loads are required, one station supplying the whole of their system

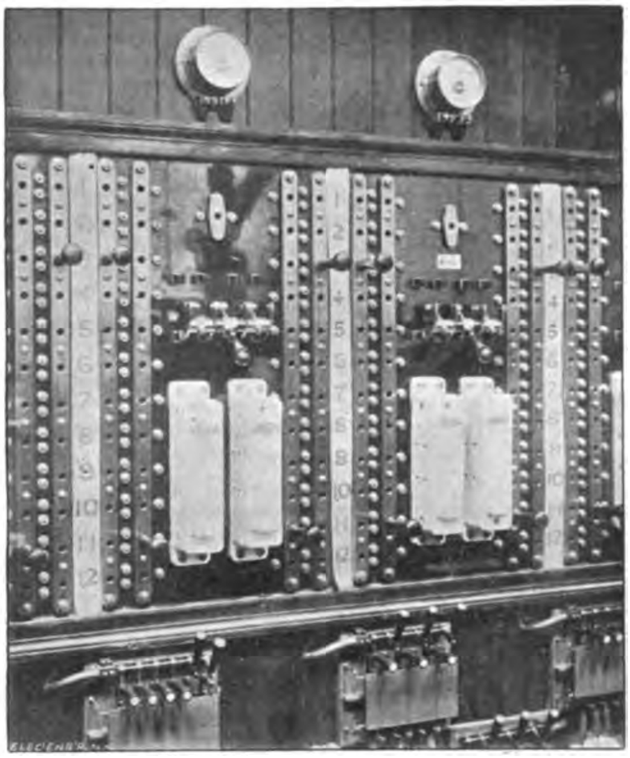

FIG. 4.—SECTION OF CIRCUIT SWITCH BOARD, MANCHESTER SQUARE STATION, LONDON.

excepting during a few hours in the day. The transformers used in conjunction with this station are of the ordinary Elwell-Parker pattern.

THE PHOTOGENIC EFFICIENCY OF VARIOUS SOURCES OF LIGHT.

In a recent communication to the Académie des Sciences, M. Witz gives the following figures relating to the comparative photogenic efficiency of the various sources of light.

Sources of Light.	Expenditure.	Calories transformed.	Intensity in carcels.	Calories per carcel-hour.
Stearine candl.	10.5 grammes per hour...	110	$\frac{1}{6.5}$	716
Ordinary gas-burner.....	105 litres per hour.	567	1	567
Regenerative lamp	35 litres per hour.........	189	1	189
Glow lamp.....	3.5 watts per candle.....	3.1	$\frac{1}{6.5}$	20
Arc lamp......	4.5 watts per carcel	4	1	4

If we take the arc lamp as our standard, the comparative efficiencies are as follows: Arc lamp, 100; glow lamp, 20; regenerative gas-burner, 2.1; ordinary gas-burner, .7; stearine candle, .56.

THE ELECTRO-DEPOSITION OF ZINC AND ALUMINUM.

The following recipe for an electrolytic bath is given by Kaselowsky, of Berlin:

Sulphate of zinc.................	10 kilogrammes.
Glucose.........................	5 "
Water...........................	100 litres.
Sulphate of aluminum...........	200 grammes.

Weak, but constant, currents must be employed, and the strength of the bath must be kept up by the addition of fresh quantities of the soluble salts of zinc and aluminum. Kaselowsky has also obtained good results from a bath composed as follows:—

Chloride of zinc.................	6 kilogrammes.
Glucose.........................	5 "
Water...................... ..	100 litres.
Chloride of aluminum............	350 grammes.

AN AERIAL WIRE VIEW IN ADELAIDE, S. A.

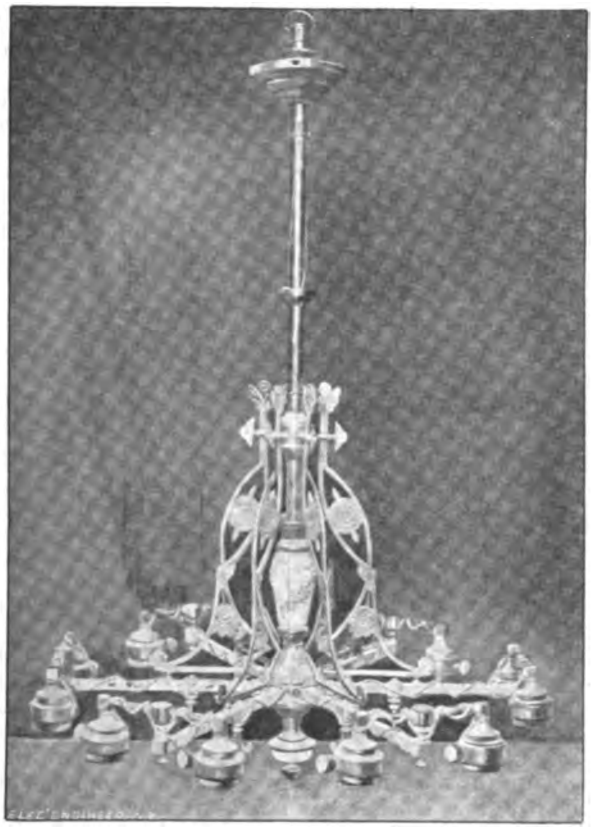
It is stated that the agitation for underground wires has spread to Australia, and that one of the first results is the proposition to give the city of Melbourne a complete underground system. Data are now being collected for the purpose, and a board of expert engineers is to give the matter immediate attention. As a general thing, however, street wiring in Australia has been above the average, and the view which we present here from King William street, Adelaide, South Australia, gives a fair idea of the manner in which work is done in that part of the world. The use of wood is avoided, one reason probably being the scarcity of big timber for the purpose, and another the fact that with such exposure to the climate the poles would not last long. The poles shown are of iron, in sections, and reach a height of about 40 feet. Those in the view are restricted to telegraph and telephone work, and carry about 150 wires. It will be observed that in some instances the cross-arms are, so to speak, made into simple brackets, and are carried on one side of the pole. This is due to the frequent occurrence of awnings and balconies across the sidewalk for shade, the arms being turned out so as to clear them. As will be seen, the

OVERHEAD WIRES IN ADELAIDE, S. A.

work is neat and trim throughout, and does little to detract from the beauty of the thoroughfare, adding rather to the air of life and bustle that one would expect in the leading business street of a new and growing city. We are indebted for the photograph to Mr. Lee L. Murray, electrical engineer, of Melbourne, Victoria.

THE FIRST INCANDESCENT CHANDELIER.

HE chandelier of which an illustration is shown on this page is one of the most interesting relics of the early days of incandescent electric lighting. It is, in a word, the first chandelier ever used for the specific purpose of carrying incandescent lamps. It was in use at the residence of Mr. Francis R. Upton, at Menlo Park, near the laboratory where all the experimental work in connection with the Edison lamp was done; and was put up during 1880. This fixture was purchased from Mitchell, Vance & Co. originally, and then wired on the spot in a manner that indicates more than anything else the crudeness and difficulties of pioneer practice. It will be noticed that the wire runs exteriorly around the stem of the chandelier and the branching arms. Moreover, great care was taken to distinguish the polarity of the two sides of the circuit, the positive wires being of red "flexible cord" and the negative of blue. Another observable point is that the lamps were burned in the inverted position now so familiar, but then so entirely new and novel. The initial letter of this article shows one of the arms with sockets attached. The lamps that were in the sockets when the chandelier was first used have been preserved also, and are of the early Edison make in which platinum clamps were employed for holding the carbon filaments.



THE FIRST INCANDESCENT LIGHTING CHANDELIER.

This chandelier is now in the possession of Mr. Luther Stieringer, of this city, to whom it was presented by Mr. Upton, and to whom we are indebted for the opportunity of making the present cuts of it. Mr. Stieringer, by the way, has made a large collection of such interesting and valuable mementoes and relics, and hopes the day is not far distant when the electrical community will have provided some fireproof place of deposit for them—a museum of the electrical arts and sciences. He and others of like tastes are in possession of enough material for a collection and exhibit second to none of its class for interest and importance.

ELECTRIC LIGHTING OF RAILROAD CARS.

BY

J. D. Dallas

PERHAPS it may not be generally known to what an extent the development of the electric light has been applied to the lighting of trains. With the idea that a short account might be of some interest, the writer will proceed to give a brief description.

The two principal methods of lighting trains are:

1. By storage batteries, the charging of the cells being performed at each terminus.

2. By storage batteries as auxiliary to a dynamo operated by steam on the train.

The second method is the one more generally adopted. Each car has a certain number of cells connected to a dynamo in such a manner that each set of cells is equidistant from the dynamo, and each, consequently, receives the same amount of charge. Every car is also a complete unit in itself, so that should any one car be detached at a way station, the continuity of the circuit is still complete; at the same time the car thus detached is provided with the power to operate the lamps.

The method of obtaining this end is shown in the accompanying diagram, Fig. 1, three cars alone being shown for convenience. From the dynamo D one main is run the whole length of the train and back again to one terminal of the battery nearest the charging dynamo, and from the other pole of the machine the return main is run the length of the train merely. Connection between successive cars is accomplished by couplers. These connections usually are placed under the roof of the car over the platform. At the end of the train furthest from the dynamo a jumper is employed, completing the circuits A_1 and A_2.

Supposing that each car be of the same length, the distance from the dynamo to each battery is the same, or, in other words, each battery is equidistant from the source of power. Given that each battery be of the same counter-electromotive force and resistance, each will receive an equal amount of charge. The lamp circuit is, of course, distinct from the charging circuit, so that should any one battery become charged sooner than the others the circuit may be opened and the charging stopped on this particular battery, and thus the circuit for charging the other batteries is not disturbed.

A detail of the connections is shown in the diagram, Fig. 2. By opening the switch the charging circuit is broken. A is a switch for regulating the discharge of a greater or lesser number of cells; the other connections can easily be traced.

Having thus described the circuits generally, it will be well to consider the method of operating the dynamo. The ideal source of power, of course, would be by the transmission of the power from the axle. However, as this has been so far, in this country, impracticable on account of mechanical reasons, steam taken from the locomotive is usually employed. The Pullman Palace Car Co. operate many trains in this way, such as those running from Jersey City to Chicago over the Pennsylvania road; the Florida special, running between Jacksonville, Fla., and Jersey City, in winter; the Montezuma special, the Golden Gate express, etc., all solid vestibuled trains. The dynamos are coupled directly to engines of the Brotherhood type, running at a speed of four hundred revolutions per minute. The dynamos are of the Eickemeyer ironclad type, suitable for slow speeds; they are shunt-wound machines. There is, of course, a suitable means of regulating the charging with an automatic switch in circuit to prevent the running of the dynamo as a motor, should any accident occur to the engine, or by reason of steam-supply becoming inoperative.

A solid train, for example, leaving Chicago at 5.30 p.m., during six months of the year would require all the lamps to be lit when the train started; this load would continue, with the exception of the lights on the dining car, till 11 p.m. At this hour all but two lamps and vestibule lights are extinguished. During this time the dynamo and battery have been running in conjunction, part of the load being taken by the dynamo and part by the batteries. By 11 o'clock they have become partly exhausted of their charge, which is replenished during the night, and when complete the engine is shut down. The batteries then run the lights in cupboards, etc., during the day and when going through tunnels; also for operating the fan motors for exhausting and replenishing the air in the cars; so that when the train arrives at Jersey City on the following evening the batteries are fully charged, ready to commence the return journey in the morning to Chicago, at which place the train again arrives on the third from the time of its departure.

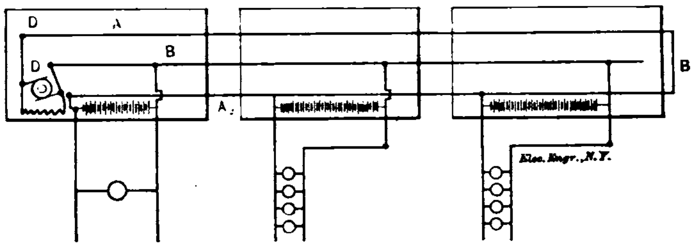


FIG. 1.—ELECTRIC TRAIN LIGHTING.

In conjunction with the operation of an electric plant on the cars the heating of the train is also accomplished. Connections are made so that this end may be obtained in three ways:

1. By heating the train from the exhaust steam. 2. By the heating of the train by a reducing valve on the steam-supply pipe and running the engine at the same time; or, 3. Should the engine not be in operation the heating by steam from the locomotive can still be carried out. The patent for this method is held by the Pullman Co. The method of lighting cars by batteries charged at each terminus is employed to a greater or less extent by the Burlington, Cedar Rapids and Northern R. R. and other roads. The Chicago, Milwaukee and St. Paul light two or more of their solid trains running between Chicago and St. Paul, and between Chicago and Omaha. In these cases a separate car is employed, with engine, boiler and dynamo, all complete, the water being stored in a tank beneath the floor. There are other roads employing electrical methods of illuminating their cars, such as the Intercolonial, of Canada. Many forms of storage batteries are, and have been, employed, such as the Julien, Brush, etc., the one adopted by the Pullman Co. being the type known as the Faure-Sellon-Volckmar, manufactured by the Accumulator Co.

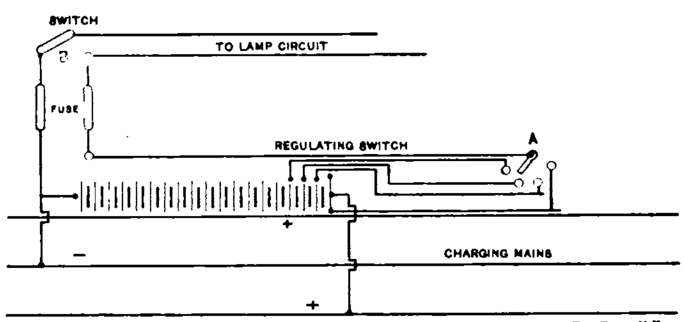

FIG. 2.—ELECTRIC TRAIN LIGHTING.

As to the cost, it may be briefly stated that for solid trains, running long distances, the electrical is a more economical than the old oil method of illumination.

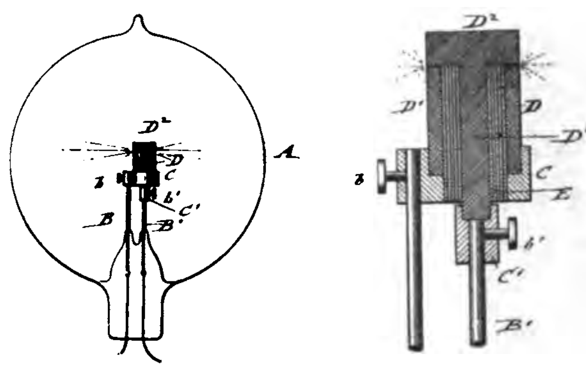
Considering that the deadly car stove has been superseded by steam-heaters, it is a source of wonder that the public do not insist on a better method of illumination than oil. Perhaps more human beings have met their deaths from fire in cars caused by lamps than by heaters.

Light in cars at night is an essential all the year round; on the other hand, for a considerable portion of the year heaters are unused. Nevertheless, in the height of summer every railroad wreck, when burnt, is attributed to the heater. The writer is, of course, aware that the locomotive is a source of many of the fires at wrecks, and would add that the oil in such cases yields an efficient aid to the kindling process.

THE WERTZ ARC LAMP.

THE operating mechanism for feeding the carbons, although more or less complicated, has always been considered a *sine qua non* of the arc lamp, and the efforts of inventors have hitherto been directed towards simplifying, rather than abolishing, it.

Recently, however, Mr. Xavier Wertz, of this city, has, by an ingenious combination of the principles of arc and incandescent lighting, invented a lamp in which the arc



WERTZ ARC LAMP.

is placed in a vacuum, the carbons being consumed so slowly that no feeding device is required.

In the accompanying illustrations, Fig. 1 shows the lamp itself, while Fig. 2 is an enlarged view of the carbons and leading-in wires. As will be seen, A represents a glass globe, the air being exhausted after the conducting-wires have been sealed into the neck. The conducting-wires B B′ pass through the neck into the interior of the lamp and are attached by the clamp-screws *b b′* to the cup-shaped sockets C C′, which serve to support the inner and outer carbon pencils D D′, by the contact of which the arc is obtained. The outer carbon D is cylindrical and is supported in the cup-shaped socket C. The inner carbon D′ is made with a cylindrical shank having an enlarged head, D², which rests on the upper edge of the outer cylindrical carbon. The space between the shank of the inner carbon D′ and the tubular outer carbon D is filled with an insulating layer, E, of asbestos, which prevents the current from passing from one carbon to the other, except at the contact faces. The shank of the inner carbon D′ is in contact with the conducting-wire B′ and supporting socket C. The sockets C C′ are made of metal, and serve to conduct the current to the outer and inner carbons.

At the point of contact of the upper edge of the outer carbon with the head of the inner carbon an arc is formed which is of sufficient size to produce a light of considerable power.

This lamp is intended for high-tension currents, and may be used in circuit with the ordinary arc lamps now in use.

A HANDY WIRING TABLE.

BY

N. R. Leyden

THIS table is arranged to show the size of wire for all the various low potentials and percentages of loss used in practical electric lighting and for 500-volt motor and electric railway circuits. It is calculated on the assumption that the conductivity of commercial copper wire is .97 of the conductivity of pure copper, according to the Matthiessen standard. It is also assumed that the cross-section of wire doubles with every three sizes of Brown & Sharpe gauge, which, though not absolutely correct, is sufficiently accurate for practical work. The safe-carrying capacity is taken as four-tenths of the current required to heat underwriter's insulated wire to 212° Fahrenheit in air, or seven-tenths of the current required to bring it to the same temperature when placed in moulding.

The manipulation of the table is very simple; for example, suppose we wish to carry 40 amperes 300 feet from the centre of distribution at 100 volts and 5 per cent. loss. From "40" in the column for "300 feet" cross laterally to the column headed "5 per cent. loss" at "100 volts," and we have the size of conductor as No. 3 B. & S. gauge.

The table is calculated for even percentages of loss at 100 volts. For 110 and 220 volts the percentages are fractional, but, by taking the nearest fractional percentage below the required one, the error is always on the safe side. For example, suppose we wish to carry 10 amperes 75 feet at 110 volts and 2 per cent. loss. From "10" in the column for "75 feet" cross to the column headed "1.8 per cent. loss" at "110 volts," and we have No. 11 B. & S.

FIGURES AT TOP OF COLUMN: DISTANCE IN FEET FROM CENTRE OF DISTRIBUTION. CURRENT IN AMPERES GIVEN BELOW.

FEET.

CURRENT IN AMPERES.

THE LEYDEN HANDY WIRING TABLE.

Or, suppose we wish to carry 60 amperes 100 feet at 220 volts and 2 per cent. loss. From "62" in the column for "100 feet" cross to the column headed "1.8 per cent." at "220 volts," and we have No. 5 B. & S.

For 500 volts the table does not indicate above 2 per cent. loss; but higher losses and greater distances can readily be estimated by rememberıng that the cross-section varies inversely with the loss, and directly with the distance. In taking the size of wire from the table, care should always be taken not to exceed the safe-carrying capacity of the conductor.

ELEMENTARY GEOMETRICAL THEORY OF THE ALTERNATE-CURRENT TRANSFORMER.—XI.

BY

Chas. Steinmetz.

VIII. Constant-current Transformers.

In chapter VI. we have seen that a properly designed transformer, when fed by constant primary E. M. F. compounds, that is, gives very nearly constant secondary

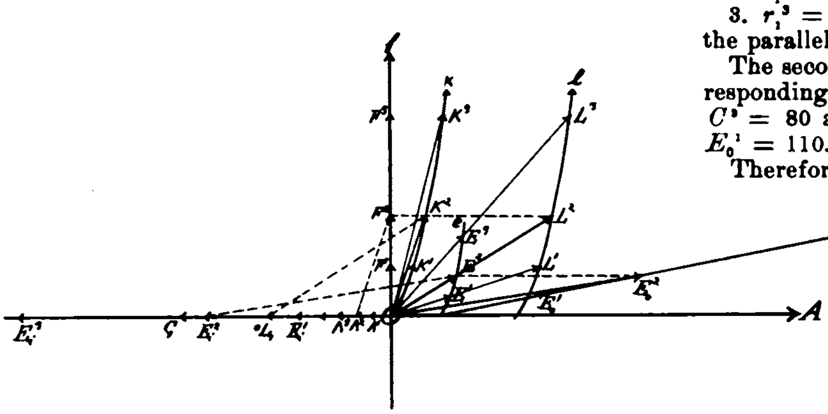

Fig. 23.

E. M. F., so that a slight regulation of the primary impressed E. M. F. would be sufficient to give absolutely constant potential at the secondary terminals; but that, even if it is not practicable to regulate the primary E. M. F. according to the load, the primary terminal pressure being kept constant by the dynamo-alternator, the secondary E. M. F. of a well-designed transformer will remain constant enough for all practical purposes. On the other hand, when fed by an alternate current of constant effective strength in the primary, the transformer gives about constant effective strength in the secondary circuit, within wide limits.

To consider this phenomenon, we first suppose, in the diagram, Fig. 23, that the *secondary current* is kept constant; $C_1 = \overline{\text{O C}_1}$. Then the *secondary* M. M. F., $L_1 = \overline{\text{O L}_1}$, is constant also. Therefore the *secondary* E. M. F. $E_1 = \overline{\text{O E}_1}$, must vary, from E_1^0, the value just sufficient to overcome the internal resistance, r_1^0 of the secondary coil at short-circuit, increasing proportionally to the increasing secondary resistance r_1. The *induced primary* E. M. F., E_1, also varies proportionally. Hence the *resulting* M. M. F., $F = \overline{\text{O F}}$, must vary from its minimum value, F^0 at short circuit, increasing proportionally to E_1, that is, E.

Thus the *impressed* M. M. F., K, travels on the curve of magnetic lag, the cubic parabola k, from K_0 at short-circuit, upwards.

The *primary* M. M. F., L moves along a parallel and congruent cubic parabola, l, which, because of the parallelogram of M. M. F.'s, O L_1 K L has the horizontal distance L_1 from the curve k. The *primary current*, C travels on a similar, or proportional, cubic parabola, and similarly the *primary resulting* or *heating* E. M. F., E, on the curve, e.

Because of the parallelogram of primary E. M. F.'s, O E, E E_0, the primary impressed E. M. F., E_0 travels along a curve, e_0, which intersects parabola e on line $\overline{\text{O A}}$, and is very nearly a straight line. Hence, for increasing secondary resistance, r_1, to keep the secondary current constant, the *primary current* $C = \overline{\text{O C}}$, and thus the *primary* M. M. F., $L = \overline{\text{O L}}$, have to increase, first very slowly, the slower, the smaller the coefficient of magnetic lag, γ, is; then faster, and at last, for high secondary resistance, almost proportionally to the secondary resistance.

The *impressed primary* E. M. F., $E_0 = \overline{\text{O E}_0}$ increases from a minimum value E_0^0 at short circuit, its increase being nearly proportional to the secondary resistance. The *difference of phase* between primary current and impressed E. M. F. increases with increasing secondary resistance.

In Fig. 23, the diagrams of the transformer are produced for the secondary resistances:

1. $r_1^1 = 1$ ohm.
2. $r_1^2 = 2$ ohms.
3. $r_1^3 = 3$ ohms.

the parallelograms being dotted in for $r_1^2 = 2$ ohms.

The secondary current being $C_1 = 50$ amperes, the corresponding primary currents are $C^1 = 45.8$. $C^2 = 56.6$. $C^3 = 80$ amperes, and the impressed primary E. M. F.'s, $E_0^1 = 110$. $E_0^2 = 183$. $E_0^3 = 323$ volts.

Therefore, below a certain critical value of secondary resistance, a transformer, when fed by constant primary current, will compound for constant secondary current beyond a certain value of secondary resistance; a transformer, fed by constant primary current, will compound for constant secondary E. M. F.

To consider this more particularly, produce, in Fig. 24, the diagram of a transformer, which is fed by *constant primary current.* But, to make the diagram simpler, we shall consider a constant current transformer, which has in its secondary coil the same number of turns as in the primary coil, $n_1 = n = 100$, so that the induced primary E. M. F. equals the secondary E. M. F., $E_1 = E_1$ and can be represented in the diagram by the same lines.

We need not remark, that this limitation is not essential, but that we can produce the diagram in the same manner for any other ratio of transformation. One ampere-turn being represented by .0003 inch, one ampere by .03 inch, in this diagram the curves of the current and of the M. M. F.

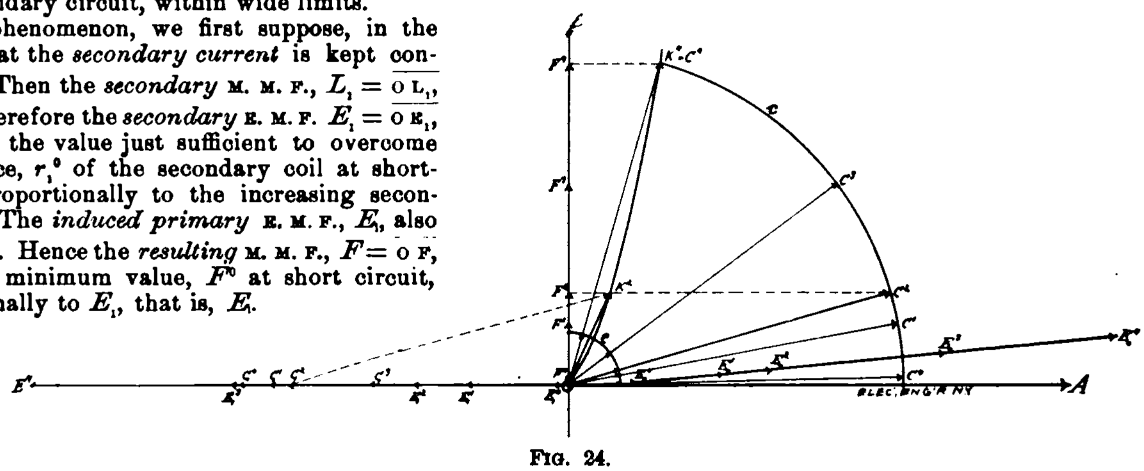

Fig. 24.

are the same, so that we only need to consider the curve of the current, and can apply the parallelogram of M. M. F.'s directly to the curves of the current.

The *magnetic resistance* of the transformer may be $P = .03$, hence the *resulting* M. M. F., F, will induce the E. M. F., $E_1 = \dfrac{2\,\pi\,N\,n\,F\,10^{-8}}{P} = .025\ F$ volts.

If now the *primary current* is kept constant, at 65 amperes, for instance, then the point C must lie upon a circle, or rather a quadrant, with $\overline{\text{O C}} = c = 65$ amperes as a radius, and O as centre.

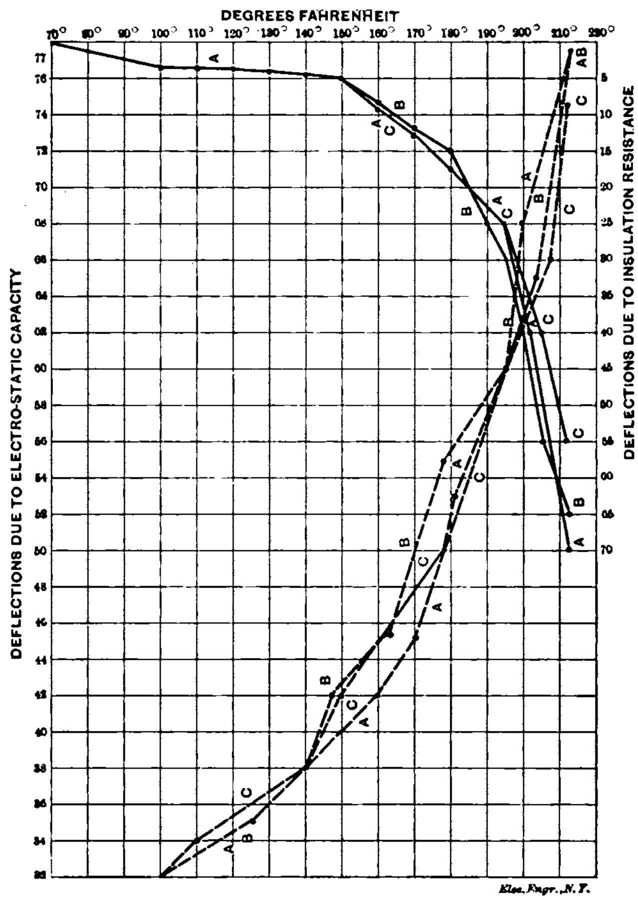
This quadrant is shown in Fig. 24 as c, and gives in this case also the curve of primary M. M. F., L.

EFFECTS OF HIGH TEMPERATURES UPON THE INSULATION RESISTANCE AND INDUCTIVE CAPACITY OF VULCANIZED INDIA-RUBBER.

BY

Wm. Maver, Jr.

In some of the streets of New York City an abnormally high temperature exists underground, caused by defective pipes of the New York Steam Company. In certain ducts and manholes of the electrical subways in the locality heated by the steam pipes, the temperature has been found to range at times from 110° F. to 200° F.



Effects of High Temperature on India-Rubber Cables.

It was early found in the case of certain forms of fibrous, lead-covered cables that the insulation resistance fell very rapidly above 125° or 150° F. It was already known that the low softening point of gutta-percha, 115° F., unfitted it for use in the presence of high temperatures. The hardening effect of prolonged heat upon vulcanized india-rubber was likewise known, so that no difficulty was anticipated from the softening, and consequent decentreing, of the conductors encased in that compound; but there was no ready data as to the effect of high temperatures upon the insulation resistance of india-rubber compounds, and it became, therefore, a matter of interest to ascertain the actual effect of such temperatures upon such compounds, a considerable amount of which was being used in the electric light service in various portions of the subways.

To ascertain this effect the writer undertook a series of tests, the results of which are shown in the accompanying diagram. Tests were also made at the same time to ascertain the effect of high temperatures upon the inductive capacity of vulcanized india-rubber, the results of which are also shown.

The cables tested were three in number, A, B, C, in the diagram, each 100 feet in length. The cables originally belonged to one piece. The conductor was .097 inch in diameter. The outside diameter of the insulating material was .350 inch, approximately $\frac{11}{32}$; hence the thickness of the insulating wall was .126 inch.

Cable A was unbraided and not lead covered.
Cable B was unbraided and lead covered.
Cable C was braided and lead covered.

This arrangement of the cables was chosen purposely to learn the effect, if any, of such coverings in diminishing the effects due to high temperatures.

A Thomson reflecting galvanometer was used, and for simplicity the results of the tests are plotted on the diagram from the deflections; the resistance and capacity being, as is well known, practically proportionate to the deflections. The readings for the capacity tests were, in each case, taken at "charge"; those for the insulation resistance after one minute's electrification, that is, one minute after the depression of the charging key. Preliminary tests of the cables had shown the insulation resistance to be 1,500 megohms per mile at 70° F.

In the diagram the insulation resistance readings are arranged to increase from top to bottom of the diagram, that the curve may properly indicate a fall in the resistance due to the increased degrees of temperature; while the capacity readings are arranged from bottom to top, so that the curve may graphically indicate the increased inductive capacity found to be due to increased temperatures. To further avoid confusion the capacity curves are shown dotted, the insulation curves, solid.

The working constant of the galvanometer at the time of tests was 35,000 megohms. Hence it will be seen, for example, that the total insulation resistance of cable A fell from 7,000 megohms at 150° F. to 500 megohms at 212° F.; that of cable B, from 7,000 megohms at 150° F. to 538 megohms at 212° F.; that of cable C, from 7,000 megohms at 150° F. to 636 megohms at 212° F.

Calculated per mile, the insulation resistance of A would be, at 150° F., 132.5 megohms; at 212° F., 9.5 megohms; that of B at 150° F., 132.5 megohms; at 212° F., 10.02 megohms; of that C at 150° F., 132.5 megohms; at 212° F., 12.4 megohms.

It is, however, unlikely that such high temperatures as these will ever be met with over a continuous extent of territory amounting to one mile. In practice such temperatures have not hitherto been found to extend continuously for more than 50 or 100 feet. Hence, assuming the normal insulation resistance of a cable practically similar to those tested to be as stated, 1,500 megohms per mile, it may be observed that even with a one hundred foot section of the cable exposed to a temperature of 212° F., the cable, as a whole, would show an insulation resistance of, approximately, 450 megohms per mile. From the results of the tests it may also be seen that any one foot of the cable would possess at 212° F. an insulation resistance of, approximately, 63,000 megohms, while any one inch of the same cable would possess an insulation resistance of 756,000 megohms at the same temperature.

Concerning the effect of ordinary changes of temperature on the electrostatic capacity of conductors, Kempe states: "The exact effect has not, it is believed, been yet determined or published." The capacity tests of the cables in question, as will be seen by reference to the "capacity" curve in the figure, indicate a marked increase in the inductive capacity of the insulating material between the temperatures of 100° F. and 212° F., namely, an increase of nearly 140 per cent.

The capacity of C at the boiling point was somewhat less than that of A and B; which result, it is assumed, indicates that the cotton braiding acted, measurably, as a non-conductor of heat. It may be noticed also that, in both the insulation and capacity tests, the curves for c indicate a more uniform effect due to the increasing temperature.

The foregoing tests, which extended over a period of six hours, were made while the cables were immersed in water in a vat. The temperature of the water was gradually raised to the boiling point. The final tests were made after the cables had been subjected to the boiling temperature for over one hour. Immediately after the final tests the temperature of the water was reduced to the normal, when it was found that the insulation resistance and capacity of the cables were again practically normal.

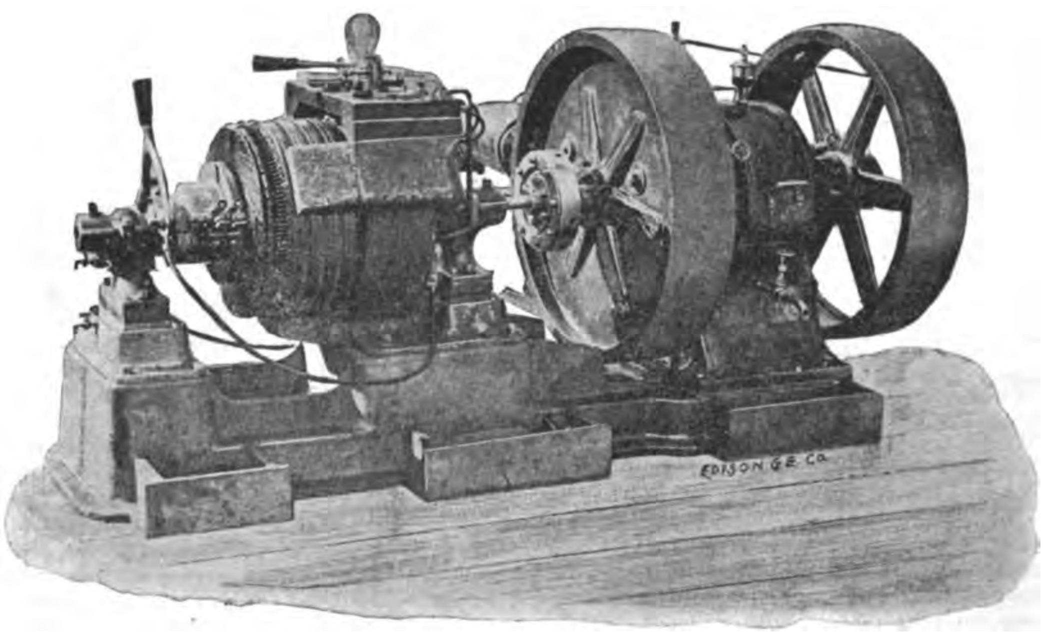
It may be of interest to note that for over one year "high" potential electric light circuits have been successfully operated through ducts in the "heated districts" of New York City, and without any perceptible deterioration in the insulation resistance of the cables.

EDISON COMBINED DYNAMO AND ENGINE FOR ISOLATED PLANTS.

The limited space usually available for installing electric light plants in buildings makes it desirable to combine the dynamo and engine on a single bed-plate, and recognizing this, the Edison General Electric Co., has recently brought out the combination shown in the accompanying engraving. This consists of an "Ideal" engine with a 6x6 inch cylinder, designed to work with a steam pressure of from 80 to 100 pounds. This engine is coupled directly to an Edison marine dynamo, wound for 65 volts and 50 amperes, running at 500 revolutions per minute.

The over-all dimensions are as follows: Height 30 inches, length 50 inches, width 81½ inches.

The dynamo has been so designed that it will give its rated output with an increase in temperature of only 20° Cent. after 4 hours' continuous run.



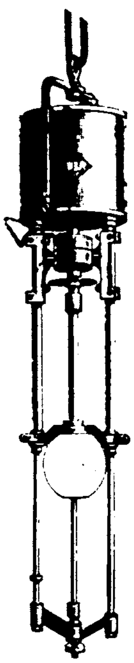
Edison Combined Dynamo and Engine for Isolated Plants.

Where, as stated above, space is confined and the temperature of the dynamo-room is high, as it usually is in buildings, such a combination plant ought to find many applications.

Mr. A. S. Temple, manager of the Salem, Mass., Electric Light Co., has resigned to accept the position of general manager for the U. S. of the Lamson store service system, with headquarters in Boston.

THE MIDGET ARC LAMP.

The great economy of arc, as compared with incandescent, lighting renders interesting any attempt to popularize the use of small arc lamps. For large shops or small lecture theatres something between the usual large arc and the ordinary incandescent lamp has long been wanted. It is absolutely necessary not only that these small lamps should possess perfect steadiness, but also that they should be so simple in construction that they may be relied on for keeping in working order without constant skilled attention.



"Midget" Arc Lamp.

A lamp fulfilling these conditions has just been brought out by Woodhouse & Rawson, United, Limited, of London. It is called the "Midget" from its small size, and is made to give 250 candle-power, using 5 amperes at an electromotive force of 45 volts, so that even with this small size of lamp one candle-power of light is obtained for the expenditure of every watt of electrical energy used. The illustration shows the general appearance of the lamp. The smallness of the globe prevents any depth of shadow, and minimizes any complaint which may be urged against the inequality of the distribution of the light. The principle upon which the lamp works is very simple. The upper part of the rods forming the frame of the lamp are hollow, and in these the lower portions slide quite easily. The bottom carbon is attached to the lower part of the frame, which is fastened to the upper portions of the lamp by a chain passing up the hollow pillar forming the upper portion of the lamp, round a pulley wheel, whose motion is controlled by clockwork, and then to the upper carbon holder, which acts as a counterpoise, and slides freely between the hollow pillars forming the frame of the lamp. The motion of the pulley is controlled by clockwork, which is started and stopped by a pivoted bar, on whose under surface a number of teeth are situated, which engage a pointer attached to the pendulum of the clock. This bar is pivoted in the centre and attached at each end to iron plungers, which move inside the cores of electromagnets actuated respectively by the main and shunt circuits.

When, owing to the distance between the carbon points, the resistance of the main circuit, and consequently the current through the shunt, increases, the plunger is drawn further into the core round which the shunt circuit passes and the pendulum is released, the clockwork moves the carbons nearer together until the main circuit increases so much as to draw the other plunger into the core round which it passes, and so overpowers the effect of the shunt circuit. The bar is drawn down, the teeth engage the pendulum of the clockwork, and the carbons are maintained apart until, owing to the burning away, the same action is repeated. This action is so delicate that no inconvenience at all is caused by the intermittent feed; indeed it is scarcely noticed. When the current is stopped the pendulum is released, owing to the action of a spring upon the bar, and the clockwork causes the carbons to come together.

In the small box over the upper carbon holder, the current, before passing to the carbon, magnetizes an iron core, and lifts the upper carbon a small distance above the lower one, thus forming the arc when the current is first put on the lamp. The carbon is held up in this manner all the time the current is passing through the lamp.

The lamp is wound in three different ways, one suitable for parallel working, one for series, and one for use with alternating currents.

THE WADDELL-ENTZ STORAGE CAR AT CHESTER, PA.

Our readers will remember the description[1] of the Waddell-Entz storage car "Direct," which was for some time in successful operation on the Lehigh Avenue Railway in Philadelphia. The heavy Sunday traffic on this road, however, necessitated the withdrawal of the car, which, on the invitation of the Union Passenger Railway Co., of Chester, Pa., was removed to that place and will soon be placed on the lines in regular service. Messrs. Wright & Starr, the agents for the Waddell-Entz system in that district, have already made a number of successful trial runs with the same equipment employed on the Lehigh Avenue Railroad.

The condition at Chester, are very different from those obtaining at Philadelphia, inasmuch that there are very few grades of over ½ to 1 per cent., with one exception, and this is a 7 per cent. grade. The severest grade on the Lehigh Avenue road was 5 per cent. and shorter than the Chester 7 per cent. grade.

The first three trips were made, not taking into consideration the number of people on the car, but merely to note the action of the car over the grades and the curves. On the subsequent trips from 50 to 65 passengers were carried. The president of the road, Col. Samuel A. Dyer, together with the superintendent, Mr. John Macfayden, expressed a strong desire to issue invitations to the Chester and South Chester councils, the directors of the road and the prominent citizens of Chester. Messrs. Wright & Starr agreed to have the car in readiness on the day which they had named, the 21st of July, on which day the invited guests were on hand at the car-stables to witness the method of loading the batteries. It was discovered about this time that the number of guests would be excessive for one car. They had anticipated this event and had prepared a drawbar four feet long to connect a summer car to be taken as a trailer on which the gentlemen who had been unable to get on the motor car "Direct" now took their seats in the open car. The total number of passengers was 66.

There is a considerable curve just outside the car-stables and they were a trifle anxious for the result, taking into consideration the fact of the trailer being coupled on; however, the signal for the start being given, Mr. Wright, who was operating the switch, threw the handle to the first position and quickly followed to the second. When the curve was reached all on board were gratified to find the cars go round with apparent ease.

The run was with one exception thoroughly successful, and this exception proved to be of use, inasmuch as it showed the remarkable working rate and strength of the Waddell-Entz battery. When the route was about one-half covered, and in ascending a 1½ per cent. grade, one of the terminals became unsoldered; this left only the first and second positions on the switch operative, which, however, were quite sufficient to bring the car home, though at a reduced speed. Upon reaching the station the unsoldered cell was cut out with a short piece of cable, the battery loaded on the car again, and with the president and superintendent of the road ran out again.

Subsequent to this two other runs were made for the purpose of getting an ampere current record. The first of these runs was with the whole equipment and with between 40 and 50 people on the car. The last run was made after having removed one of the motors and with 62 people on the car.

On one of the short curves of the road the car was stopped to ascertain the ability of the motor to start the car and carry it off. It was found that by first reversing and quickly throwing the handle around again the car moved off with considerable ease. The gentlemen interested feel that the experiments and tests have been severe and that the batteries and motors have shown themselves to be highly efficient.

Messrs. Wright & Starr, whose experience dates back to the beginning of the storage batteries, firmly believe that the Waddell-Entz battery exceeds in vital features anything which the lead storage battery can hope to do.

1. See The Electrical Engineer, May 13, 1891.

BALATA.

An exhaustive report on balata, or chicle gum, has recently been drawn up by Mr. G. S. Jenman, Government Botanist and Superintendent of the Botanic Gardens in British Guiana. The bullet-tree, from the bark of which balata is obtained, is a large forest tree ranging from Jamaica and Trinidad to Venezuela and Guiana. The tree grows to a height of 120 ft., and has a large, spreading head. The trunk is nearly cylindrical. The bark is about ½in. thick, with deep parallel fissures, an inch or so apart. The hard, reddish-colored wood is one of the densest in the colony, and is used for all sorts of purposes where great strength and durability are required. Dr. Hugo Müller, in a report on the substance, says: "It seems that balata is by no means neglected, and, in fact, it would find ready purchasers if more of it came to the market. It commands a higher price than gutta-percha. It is used in almost all cases in which gutta-percha is used, but, on account of its higher price, only for superior purposes. It seems that balata is treated by the manufacturers simply as a superior kind of gutta-percha, and therefore its name disappears when manufactured. Nevertheless, balata is distinctly different from gutta-percha, and this is especially manifested in some of its physical characteristics. For instance, it is somewhat softer at ordinary temperatures, and not so rigid in the cold. In one respect balata shows a very marked and important difference from gutta-percha, and that is its behavior under the influence of the atmosphere; while gutta-percha, when exposed to light and air, soon becomes altered on the surface, and changed into a brittle, resinous substance, into which the whole of the mass is gradually converted in the course of time, balata, on the other hand, is but slowly acted upon under these circumstances. The electrical insulating quality of balata is said to be quite equal to that of gutta-percha." The price for pure milk is 4s. per gallon, or occasionally a dollar, and for clean, well-dried balata, 1s. per pound. The yield of a tree varies according to circumstances. If favorable, a tree 15 in. to 20 in. in diameter, bled 8 ft. high, will yield three pints of milk.

"THE DUTY AND REWARD OF LOYALTY."

Mr. Allen R. Foote, himself an old Union soldier, and a badly wounded one at that, has issued a striking pamphlet entitled "The Duty and Reward of Loyalty." It is directed against the present pension system, and is written in a spirit of lofty and disinterested patriotism. It has received special notice and approval at the hands of the New York *Herald* and the New York *Evening Post*.

THE EDISON CONVENTION.

IN view of the fact that the Association of Edison Illuminating Companies meets in this city during the current week, we have seized the opportunity for presenting, in the shape of a special Supplement, an illustrated survey of the Edison light and power industries as existing to-day and as compared with their humble beginnings of ten years ago. It is the first time, we believe, that such a sketch has been made of any of the great industries created by electricity and inventive genius in this country, and the reader will no doubt find in it many points of interest. Probably the fact it brings out more forcibly than any other is the rapidity with which electrical inventions have become part and parcel of modern civilization and comfort, and the varied manner in which these new developments affect every condition of social intercourse.

In fact, one of the most pertinent lessons to be drawn from our Supplement lies in its very emphasis upon this largeness and comprehensiveness of electricity as applied to light and power. There was a time, and not so long ago, when each of the local companies entering the field stood merely as the advocate or exploiter of one peculiar and particular method of furnishing electrical service. The process still continues. It had, and has still, many advantages, but it is a feudal method at best, and falls infinitely short of the favorable conditions and generous opportunities of the hour. It cannot make for the profit of a station, or for the welfare of the public, when a local company so restricts itself that it can do business in only one way. It surely cannot promote professional spirit for any one to be only known as an "Edison man," or a "Thomson-Houston man," or a "Brush man" rather than as an electrical engineer, pure and simple, aiming at the best that can be done. There has in a word been too much of the bitter partisanship of the schools of theology, and too general an acceptance of the erroneous belief that salvation, electrically considered, was to be found in only one doctrine. Out of this conflict and narrowness, and the denial of the truth that there is "good in all," have come many of the evils that all deplore in electrical work.

But the times change, and we expect that the Edison convention this week, equally with the National Electric Light Convention in Montreal a month hence, will broaden the lines of its discussion and work. It cannot be otherwise. A great many companies that bear the name of Edison and were established simply to supply the Edison incandescent light are to-day operating apparatus also for arc and alternating circuits and are generating current for electric roads. Some of them are indeed as much arc lighting or electric railway companies as they are anything else. On the other hand, not a few companies actively represented in the National Association run Edison plants of one kind or another, and the tendency is to increase the number. Now if these conventions are to be of any practical benefit they must handle the topics in which delegates are interested and have traveled hundreds of miles to talk about. It seems to us that more and more the conventions should consist of the men who are actually, as presidents, managers, and superintendents, operating these plants; and the way to reach that end is to deal exclusively with the questions that concern the efficiency and prosperity of central stations or large isolated plants. Other questions are not proper for the floor of a large convention, but belong to the class of matters that concern in their private offices the individual parties, as licensor and licensee, manufacturer and purchaser. An Association that spreads itself all over creation as did the National at Providence last February, will quickly go to pieces; an Association that narrows itself down to a handfull of ultra-jealous and suspicious licensees, as did the Telephone, soon peters out.

The view of the situation that we have been suggesting may be got from another standpoint, or may be briefly stated in the dictum that the successful station of the future will be a composite station. The stockholders and managers of such stations, of which the number is already far larger than is generally supposed to be the case, are in the field to render service in the most efficient and most profitable manner. If they want to reach a populous suburb, they will not be deterred from putting in an alternating machine because the bulk of their incandescent lighting is done on direct current. If they have the chance, they will not hesitate to load their direct incandescent circuits with arc lamps made for that purpose. If it will pay, they will run special day circuits for motors. If they started with an incandescent plant, they will be ready to do regular arc street lighting should occasion arise. If they find it worth while, they will absorb the local horse railway, make it electric, furnish the current, and then throw motors by day and arc lamps by night on the railway mains. When winter comes they will take off the fan motors and put on electric heaters. We say they "will" do it, but these things are actualities of the present, and the companies, large or small, that are thus shaping their policy know that their example is daily more and more imitated, with the result that the whole industry throughout the country, whether as to ownership or as to the make-up of the various plants, is undergoing a change that places it in the front rank of desirable and stable investments.

In view of what has been said above, the general accuracy of which no one, we believe, will question, it is certainly desirable that the Edison and National Associations should draw more closely together. More and more they are doing the same work, and the lines of distinction daily become less well defined. Sooner or later either of them may find itself superfluous, but before that happens they will, we trust, have become one. United they can do a great work, greater than either of them has been able to do singly, good and useful as that work has been.

THE LONDON ELECTRIC LIGHT STATIONS.

The recognition which was accorded to the merits of the electric light and its commercial development in America will always stand as a monument to American genius and enterprise. And it is safe to say that no art or industry of any time or character was ever so quickly and so thoroughly developed as that of electric lighting in America. In contrast to the rapidity of development here, the slow exploitation of the electric light in Europe for some time stood out in marked contrast. Conservative capitalists as well as conservative engineers long hesitated to give electric lighting the trial and opportunity which the results here might have warranted. But gradually European capitalists have awakened to the fact that the business of furnishing electric current for all purposes offers a most promising field for investment, and especially on English capitalists has this idea now been thoroughly impressed, and this is evidenced by the numerous and excellently equipped stations now in operation, or in course of construction, in London. Although the general arrangement of some of these stations has been the subject of criticism in some quarters, there is probably no question as to the fact that they are all equipped in the most substantial manner and provided with the most improved apparatus for the economical generation of the electric current. Our article this week on the Manchester Square alternating station in London will give a good idea of the methods adopted in this particular case. While the installing of such a large number of comparatively small power units may be criticised, the designers of this station have probably thoroughly weighed the question of the most economical arrangement of power units and adapted them to the existing conditions. It is also worthy of note that this station is at times completely shut down and its load taken by another station of the same company so that the highest economy in operation may be secured. We believe that this practice will shortly be followed in this country in stations belonging to the same company, and separated some distance, and now all operated during the light-load period with probably doubtful economy.

THE GREATHEAD ELECTRIC UNDERGROUND ROAD.

Some of the New York newspapers would have us believe that the underground electric road in London is not liked by the public and consequently languishes for want of traffic. There has, however, been a steady accumulation of evidence to the contrary, and now come various independent statistics, which go to show that the road is greatly preferred over the old methods of travel, even though they give "fresh air and bright sunlight." The New York *Times*, in its London dispatch of August 8, has the following: "Although it has been opened to the public for some eight months only, the little experiment of the underground railway, constructed on the Greathead tunneling system and operated by electricity from the city of London to Southwark, on the south side of the Thames, has already begun seriously to affect the short-traffic receipts of the other railway companies. At the half-yearly meeting of the London, Chatham and Dover Company, Mr. Forbes, the chairman, attributed the notable falling off of passengers on the short trips entirely to the competition of the City and South London Railway Company. He said his company had lost from this cause 38,482 first-class, 57,000 second-class, and 160,000 third-class passengers. These figures, unwillingly extorted from the chairman of the directorate of the company, speak well for the hold which the new system has already obtained over the public mind. It must be noted that the distance covered by the City and South London line is as yet only three and a half miles. With an extension of the system a much heavier blow to the existing companies must be expected."

These figures are more than ordinarily significant. It will be seen that the loss is not in any one class of travel, but is made up of all the three classes into which English passenger traffic still, as a general thing, divides itself. It also shows that Londoners have taken kindly to underground traction, the use of electric motors, and the charge of but one rate of fare. As to the stories of discomfort and inconvenience that have been circulated here, it can only be said that these figures do not reveal any hindrance to patronage on that account. Not long since, Mr. G. H. Guy had an admirable letter in the papers in which he cited the testimony and experience of Americans who had tried the road and were delighted with it.

There is a difference, however, between the conditions in London and New York—at least to this extent: there the roads are not overloaded with passengers as they are here. What is in London a preferable means of travel is here a vital and absolute necessity. There is no way out of the difficulties in New York but by going underground, and once underground, electric traction is essential. It is not necessary in support of this statement of the facts to prove that the innovation in London works perfectly or is free from every possible objection. It would be strange indeed if our American inventive geniuses did not hit upon a number of improvements, and already the system has attracted to its support and advocacy some of the men who have been foremost in introducing the electric street railway. The arguments against the system must be rare, indeed, when one of its newspaper opponents has to give editorial page prominence to the report of an accident to a hasty passenger in one of the elevators. Such reasoning, if it is good for anything. is not pertinent against underground electric traction, though it might be against the distinctive and pernicious American habit of using elevators rather than stairs.

ELECTRIC DISCHARGES IN VACUUM TUBES.

As was to be expected, the lecture delivered by Mr. Tesla in which he describes the illuminating effects observed in vacuum tubes, has called forth a number of communications from other experimenters who had, it appears, been working in the same direction. Mr. Tesla, it will be remembered, has succeeded in obtaining the effects observed by the employment of very high potential combined with a very high period of alternations, and ascribes the results as due almost, if not entirely, to electro-static action. Prof. J. J. Thomson, in his study of these phenomena, is led to the conclusion that luminosity in tubes without electrodes can be produced by electro-dynamic as well as by electro-static action. In proof of this he cites an experiment in which the electro-static action was ostensibly screened by covering the tube with wet blotting paper. It would seem doubtful, however, whether the precautions taken were sufficiently complete to avoid any electro-static action whatever, and for lack of further proof on this point final judgment may well be suspended. However, Prof. Thomson's experiments certainly show that the effects apparently produced by electro-dynamic action are greatly inferior to those due to electro-static action, and in this he bears out the point insisted upon by Mr. Tesla, that it is to the latter that we must look for the most efficient light production.

HIGH TEMPERATURES AND RUBBER INSULATION.

The placing of electrical conductors underground in New York City has labored under disadvantages probably not paralleled in any other city in the world. The innumerable pipes and conduits of all sorts already existing would in themselves have made the task one of no small magnitude, but the existence, also, of pipes carrying steam under high pressure, close to the electrical conduits, introduced a factor into the problem, the successful solution of which at one time indeed seemed problematic. But the attempt was made and we believe that the results accomplished will act as a stimulus for further work in this direction. The fears which had been entertained as to the destructive action of the heat on the cables appear not to have been altogether well founded and to still further investigate this subject, Mr. William Maver, Jr., the able electrical engineer for the underground construction company, made a series of tests, the results of which are detailed on another page. These experiments show that, as was to be expected, the insulation resistance fell with rise in temperature, while the electro-static capacity rose, but that even at the high temperature of 212° F. the rubber cable still possessed a good working insulation resistance, which would not unfit it for practical work. The result of actual experience with the cables in the conduits of the steam-heated districts of New York corroborates this result, it having been shown that a year's use with high-tension currents left the cables practically unchanged. It may be argued that it is still too early to form any definite conclusion as to the life of such cables, but sufficient time has, we think, elapsed to give at least some indication of the fact that the fears at one time expressed as to the absolute uselessness of the attempt to run cables in such heated places were groundless. As bearing on the question of the life of rubber at high temperatures while in contact with copper, some recent investigations of Sir William Thomson seem to show that metallic copper when heated to the temperature of boiling water in contact with rubber, exerts upon it a destructive effect, oxidizing it and thus rendering it brittle. These experiments also showed that platinum had only very slight effect under these conditions, while zinc and silver had no injurious influence whatever. As copper wires are as a rule tinned when covered with rubber insulation, the effect above noted would probably not take place, but it is to be regretted that the experiments above referred to did not include tin, so as to settle this point definitely.

Care of Electric Railway Apparatus.

One hears occasionally of queer things done with electrical apparatus, but the most extraordinary in the electric railway line is that reported from Lynn. There two of the electric cars met on a single track. Each conductor claimed the right of way and would not budge. The quarrel intensified and at last the motormen turned on full current and the cars were at once jammed together like angry bulls, each trying to push the other out of the way. The scene was a lively one for some time, and we need not wonder that the passengers became frightened while the cars butted. At last the superintendent appeared on the spot and suspended one of the motormen. It does seem that this treatment was altogether too mild. When men handle expensive machinery in this way and endanger passengers, leniency is a mistake. The fact that electrical apparatus is not built to be abused but to be taken care of like any other machinery is not yet as fully grasped as it can be. We know of instances where electric cars have been left outdoors for months, in all weathers, without attention after long daily runs, and then expected to be in first-class condition every morning. This is simply encouraging men to be criminally careless, whereas a little appeal to their personal pride will easily lead them to be as vigilant as the management in keeping apparatus in order.

A Handy Wiring Table.

The variety of wiring charts and tables now available would seem to make an additional one almost superfluous, but we believe that the table by Mr. H. R. Leyden, which we give in this issue, allows of a wider range of applicability and occupies a smaller compass than any table thus far seen. Its range includes all practical percentages of loss at the voltages most generally employed and its range of distances is also large. While a wiring diagram is an aid to many, there are not a few who are better able to work with a table such as the one we publish, which has been found to give good results in practice.

EXPERIMENTS ON THE ELECTRIC DISCHARGE IN VACUUM TUBES.

OUR readers will recall the communication of Mr. Nikola Tesla, in our issue of July 1, in regard to Prof. J. J. Thomson's experiments on the "Electric Discharge in Vacuum Tubes."[1] Mr. Tesla's communication, which was reproduced in the London *Electrician*, has elicited a reply from Prof. J. J. Thomson, published in that journal under the date of July 24, in which he says:

"Mr Tesla seems to ascribe the effects he observed to electrostatic action, and I have no doubt, from the description he gives of his method of conducting his experiments, that in them electrostatic action plays a very important part. He seems, however, to have misunderstood my position with respect to the cause of these discharges, which is not, as he implies, that luminosity in tubes without electrodes cannot be produced by electrostatic action, but that it can also be produced when this action is excluded. As a matter of fact, it is very much easier to get the luminosity when these electrostatic effects are operative than when they are not. As an illustration of this I may mention that the first experiment I tried with the discharge of a Leyden jar produced luminosity in the tube, but it was not until after six weeks' continuous experimenting that I was able to get a discharge in the exhausted tube which I was satisfied was due to what is ordinarily called electro-dynamic action. It is advisable to have a clear idea of what we mean by electrostatic action. If, previous to the discharge of the jar, the primary coil is raised to a high potential, it will induce over the glass of the tube a distribution of electricity. When the potential of the primary suddenly falls, this electrification will re-distribute itself, and may pass through the rarefied gas and produce luminosity in doing so. Whilst the discharge of the jar is going on it is difficult, and, from a theoretical point of view, undesirable, to separate the effect into parts, one of which is called electrostatic, the other electromagnetic; what we can prove is that in this case the discharge is not such as would be produced by electromotive forces derived from a potential function. In my experiments the primary coil was connected to earth, and, as a further precaution, the primary was separated from the discharge tube by a screen of blotting paper, moistened with dilute sulphuric acid, and connected to earth. Wet blotting paper is a sufficiently good conductor to screen off a stationary electrostatic effect, though it is not a good enough one to stop waves of alternating electromotive intensity. When showing the experiments to the Physical Society I could not, of course, keep the tubes covered up, but, unless my memory deceives me, I stated the precautions which had been taken against the electrostatic effect. To correct misapprehension I may say that I did not read a formal paper to the Society, my object being to exhibit a few of the most typical experiments. The account of the experiments in *The Electrician* was from a reporter's note, and was not written, or even read, by me. I have now almost finished writing out, and hope very shortly to publish, an account of these and a large number of allied experiments, including some analogous to those mentioned by Mr. Tesla on the effect of conductors placed near the discharge tube, which I find, in some cases, to produce a diminution, in others an increase, in the brightness of the discharge, as well as some on the effect of the presence of substances of large specific inductive capacity. These seem to me to admit of a satisfactory explanation, for which, however, I must refer to my paper."

MORDEY ALTERNATORS RUNNING IN PARALLEL.[2]

EXPERIMENTS were recently made at the engine works at Thames Ditton with two A. 9 Mordey alternators, each capable of an output of 50 h. p. at 666 revolutions per minute, the one being the machine commonly used for testing at the Lambeth Works; and the other a similar machine of an early pattern, used for occasional work. Two Willans engines, of their two-crank E size, were taken from stock, and were coupled direct to the dynamos. The governors were of the ordinary kind, simply taken from the stores, and used without any special adjustment. Neither the engines nor the dynamos were arranged specially for the work, nor were they suited for each other as regards output and speed. A pair of transformers were arranged in the usual way as a synchronizer, and a pair of lamps were placed in series with the secondary coils. The engines were started, and ran at about 472 revolutions per minute. Before attempting to switch them together, the great regularity of speed of the two engines, as shown by the synchronizing lamps, was very remarkable. The lamps glowed and faded at first rapidly, and as soon as both stop valves were opened, and the full speed attained, it was possible, by adjusting the governor of one to slow down the synchronisms to less than four a minute, and one long glow taken at random timed 28 seconds. It was very easy to select the best moment for switching on, and this being done both at light load, half, and full load, the fact was proved, which, though perhaps a foregone conclusion, had not actually been proved before, that a flexible driving, by belt or other elastic connection, is not only not necessary, but does not appear to offer any appreciable advantage, except in cases where the speed of the engine is very irregular during each revolution, owing to irregular turning moment. A load of about 36 kilowatts was put on, and the steam was shut off from one engine, leaving only about 5 lbs. to keep the connecting rod from lifting. The one machine took the load and drove the other as a motor, taking with it the engine, which requires about 25 lbs. of steam to move it. Some further experiments were carried out afterwards, to try the effect of a considerable resistance in the circuit connecting the two machines, and during these tests the switch was more than once intentionally pulled over a little before the moment when the lamps showed that the two machines were exactly in step, but the two armatures adjusted themselves instantly without any perceptible shock or noise.

These experiments remove one uncertainty in a most satisfactory and conclusive manner, and show that the difficulty is of a purely electrical nature, and depends probably on the presence of iron in the armature and the frequency of the alternations, because at high frequencies there is not time for the iron to respond to the pull.

STATISTICS OF THE ASSOCIATED PRESS SYSTEM.[1]

BY W. H. SMITH.

THE records of the Western Union Telegraph Company may be consulted to show the extent of the expenditures by the individual newspapers and the Associated Press, for telegraphic tolls alone, on this largest telegraph system.

During the year ending June 30, 1890, the Western Union Telegraph Company delivered at all stations 322,088,438 words of "regular" or Associated Press report. This was delivered to an average of two newspapers in each place, at an average cost of 15 cents per 100 words for each place. This is rendered possible only by the great number of places served on a circuit—from 30 to 40 being supplied in some cases at the same time. During the same period the company handled 206,025,094 words of specials, at an average cost of 51 cents per 100 words.

These figures do not include reports transmitted by the Associated Press over its leased wires or special correspondence sent on individual newspapers' leased wires. Estimating these two classes and the reports of the outside press, there was delivered to the newspapers during that year an aggregate amount of 1,500,000,000 words of telegraph news. On the regular service a little more than 22 per cent. is handled by the telegraph company in the day-time, while on the special service only about five per cent. of the volume is handled in the day-time.

The day rate is twice the night rate. On the Associated Press leased wires the proportions are 34 per cent. of day report to 66 per cent. of night, and the difference in cost the same as by Western Union lines. The total press receipts by the telegraph company for the year ending June 30, 1890, including regular, special, and leased wires, were $1,848,247.23.

It should be borne in mind that these figures do not include tolls on other lines, or cable tolls, or the wages of correspondents and operators, or miscellaneous expenses, or the sums paid for news by both individual newspapers and the Associated Press, which would aggregate a very large sum.

One very interesting feature of the news service, of which the public has no knowledge, is telegraphing in cases of storms and interruptions. It is on such occasions that the utility of a vast system is made manifest. During the blizzard of March, 1888, for instance, the Washington report was sent to Philadelphia via New Orleans, Memphis, St. Louis, Chicago and Pittsburgh; while New York City received it from Albany, it having reached Albany via New Orleans, St. Louis, Chicago, Cleveland and Buffalo.

A more extraordinary case is that of Boston, which received a condensed report from New York via London, it being sent by one cable from New York to London, and thence back by another cable which lands in New Hampshire. Boston is frequently served with New York news via Montreal, and Albany via Pittsburgh and Buffalo, the route being via the Pennsylvania railroad to Pittsburgh, thence across via Cleveland to Buffalo, and thence down the New York Central to Albany.

"ITS LATEST PIECE OF ENTERPRISE."

THE following appreciative paragraph is from the *Boston Transcript* of July 25: "THE ELECTRICAL ENGINEER, of New York, is nominally a weekly magazine, but when anything of more than ordinary interest in the electrical world occurs, it does not hesitate to issue an extra edition in order that the public may get immediately reliable data on the subject. Its latest piece of enterprise was the publishing of an Extra giving the full opinion in the incandescent lamp suit."

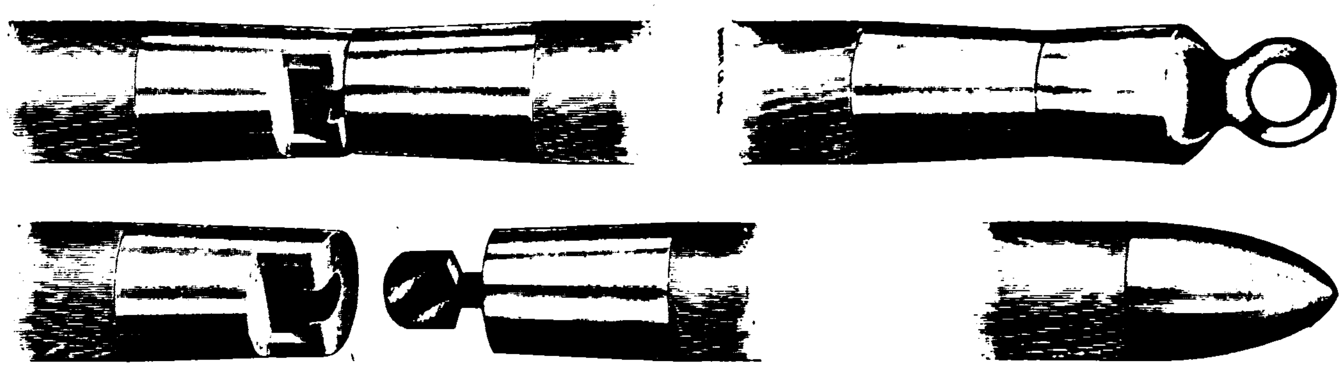
1. From article in August *Century*.

RAPID TRANSIT IN NEW YORK.

Some recent episodes in the movement to secure rapid transit for New York are of more than ordinary interest. The chairman of the Rapid Transit Commission, Mr. W. Steinway, was understood to declare himself as, after all, being in favor of getting very near the surface with an underground road, and as considering the Greathead system to be too expensive. Mr. F. J. Sprague, who has now allied himself with the Greathead interests in this country, took forcible and pithy exception to these views, as did some of the city papers. Mr. Steinway now comes forward to explain that he neither meant nor said anything of the kind; and thus everything gets back into the "as you were" attitude. But the episode has been of value in eliciting many expressions of opinion and not a few facts in favor of the underground electric methods of rapid transit. Certainly no one familiar with the state of the immediate sub-surface of Broadway and other main thoroughfares, believes that it is possible to have an underground road that does not dive down below all such obstructions and pierce its own way freely from one end of the city to the other. The motive power of such a road must of necessity be electricity, but the argument for electricity does not merely depend on the depth of the subway. The day has gone by when even in the shallowest sub-surface road anything else would be proposed.

ANDRAE'S CONDUIT WIRE DRAWER.

THE great difficulty experienced heretofore by electrical companies operating underground conduits has been in passing the first or dummy wire by which the cable itself is drawn in through the conduit. Gas-pipe rods with right and left hand threads have generally been used. These require two men in each manhole, one holding the coupling while the other man screwed on the second rod. This is a very long and expensive mode. With the new patent rods just brought out by Julius Andrae, of Milwaukee, Wis., one man can thread a section of 450 feet in about 15 minutes and this with the greatest ease. These rods are made of the best hickory in two-foot lengths, and the joints are made of the best malleable iron. They are durable, light and cheap, and will last a lifetime. The first rod inserted from the manhole into the conduit is bayonet-shaped to overcome any roughness which it might encounter in the conduit, while the last or end rod has a swivel connection which will move around no matter how irregular the drawing-in wire may be. The apparatus is so effective, and meets the difficulties of the work so admirably, that it seems destined to very general use in the large underground installations now being made. The details are shown in the accompanying illustrations.



ANDRAE'S CONDUIT WIRE DRAWER.

THE GOOLDEN-ATKINSON SEPARATOR.

AMONG the machines shown at the recent meeting of the Royal Agricultural Society, at Doncaster, was a magnetic separator, intended to remove bolts, nuts, nails, horseshoes, etc., from bones, oilcake, or minerals, before they are passed into disintegrating machines, by the use of a hollow truncated cone with 10 internal magnets of alternately opposite polarity. The cone revolves on outside runners, driven by friction only, which is found ample for the purpose. The bones are fed into the back end by a shoot, and, falling to the bottom, are rolled over and over again, so that, as they gradually travel forward—in about 10 or 15 complete revolutions—to the front, they pass 100 to 150 times over the magnets. In the upper part of the barrel is a fixed tray, into which the iron is carried and collected. Each magnet in turn, as it comes to the bottom, is magnetized, and remains so till it reaches the top, where it becomes demagnetized, and the iron is detached. This process is carried out by a commutating ring on the back of the machine, and the arrangement is such that each coil has one end permanently connected to one pole of the dynamo, and the other ends are in turn connected during one-half a revolution to the other pole. Thus the magnets receive current in parallel. The power required to excite the magnets is about 600 watts for the largest size, capable of dealing with four tons of bones per hour. The machine was exhibited by the Hardy Patent Pick Company, of Sheffield, and was manufactured by Messrs. W. T. Goolden & Co., under the joint patent of Messrs. L. and C. Atkinson and G. W. Elliott.

SOUNDINGS FOR THE PACIFIC CABLE.

REAR-ADMIRAL BELKNAP'S survey of parts of the Pacific, preparatory to the laying of the proposed trans-Pacific telegraph cable, indicates that extraordinary difficulties will be encountered. His soundings show the existence of a trough or basin of extraordinary depth and extent along the east coast of Japan and the Kurile Islands, and under the Kuro Siwo, or Japan or Black Stream. The basin exceeds any similar depression yet found in any other regions of the great oceans. In a run of 30 miles after leaving the coast of Japan the waters deepened more than 1,800 fathoms, and upon the next cast of the lead the wire broke after 4,643 fathoms had been run out, without bottom having been reached. Thermometers specially constructed for deep-sea sounding were wrecked by the unprecedented pressures. The depth of the deepest cast—five miles and a quarter, the deepest water yet found—is sufficient to hold two mountains as high as Japan's great Fusiyama, one on top of the other, and then the summit of the highest would be nearly two-thirds of a mile under water.

ELECTRICITY AS A FRIEND OF GAS.

THE president of one of the leading gas companies of New York stated at the last meeting of the company that no greater benefactor to the interests of gas companies had ever been known than the electric light. In stating that the gas output of New York was doubling itself now in a period of six and one-half years instead of ten years, as before, he gave it as his belief that this phenomenal increase was due to the fact that the electric light had educated the human eye to demand more light, and that people are not satisfied with the volume of light that formerly satisfied them.

APPRECIATIVE OF POLE LINES.

THE following from the Ogden, Utah, *Commercial* is so contrary to the usual run of remarks about pole lines, that we cannot refrain from quoting it: "The poles for the electric wires are all set from the river bridge north to Five Points, and a *beautiful appearance* is added to this part of the city through this grand enterprise."

OTTAWA, CAN., ELECTRIC RAILWAY.

Thanks to the energy of Ahern & Soper, the city of Ottawa has been given a first-class electric railway, the system adopted being the Westinghouse. The opening of the road was recently celebrated by a public luncheon at which a number of the most distinguished men in the Dominion were present. It is expected that the road will materially assist in the development of the quarter of the city through which it runs.

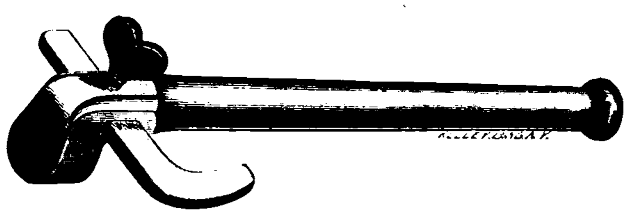
UNDERGROUND WORK IN WASHINGTON.

THE Electrical Board of the District of Columbia, Andrew Rosewater, C. E., chairman, have about concluded their labors, having made a very thorough and practical investigation of the whole subject. The report and estimates are now being prepared by Mr. Rosewater, at his Omaha office. They will be formally signed and presented by the members of the Board at their final meeting in Washington, in the early part of October.

THE VAN DYCKE WIRE SPLICER.

In putting up electric light, telegraph, and telephone wires, in the construction of wire fences, and, in short, wherever and for whatever purpose great lengths of wire are used, the splicing of the different pieces is a matter of inconvenience and difficulty. In order to facilitate this operation, Mr. J. D. Van Dycke, of Oneonta, N. Y., has devised the exceedingly simple and efficient tool shown in the accompanying illustration.

Its use will be readily understood. The wires to be spliced are held so that the ends lap over each other several inches. Midway between the ends the wires are held by a clamp, and each end is then bent out at a right angle to its original direction. One end is then passed through the hole in the end of the splicing tool until the hook engages the main portion of the wire, when, by rotating the free end of the tool about the main wire as a centre, the end is drawn around it helically to any desired extent. When the other end has been treated in the same manner the splice is complete. As may be imagined, the work is done quickly and with very little trouble.



Van Dycke Wire Splicer.

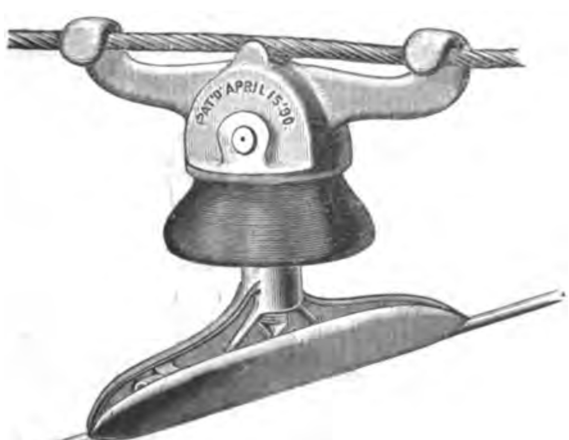
The hook is adjustable for the purpose of taking wires of any thickness.

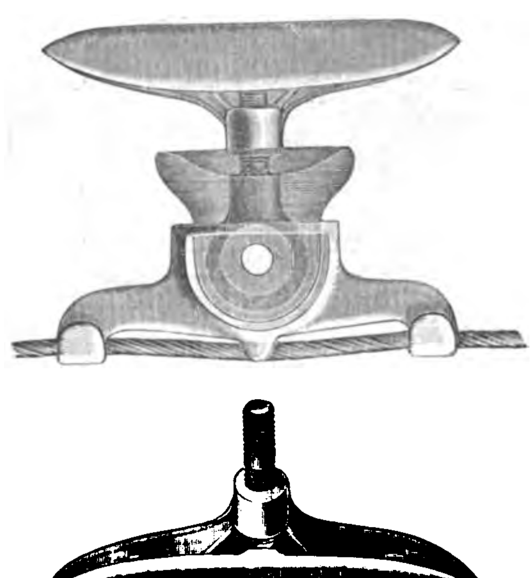
For the purpose of making spiral springs the wire is held in exactly the same way, and wound about a mandrel.

This instrument is made in three sizes, and is controlled by Messrs. Stevens & Hills, of 113 Main street, Oneonta, N. Y., who are now placing it on the market at a moderate price, and who have already found it to give great satisfaction wherever tried.

THE "UNIVERSAL" TROLLEY WIRE CLIP.

Among the electric railway specialties manufactured by the Lieb Machine Works, of this city, which have met with considerable favor, is the Universal trolley wire clip, illustrated in the accompanying engravings. It will be noted that the construction is such that the clip can take in any size of trolley wire and grips it firmly. In order to provide for expansion and contraction of the line, the clips are suspended by a link imbedded in a fireproof asbestos insulating material moulded around it. The construction is such that should the insulation break or be destroyed in any manner the line still remains suspended.





The "Universal" Trolley Wire Clip.

PLANT FOR THE MASONIC TEMPLE, CHICAGO.

The contract for the electric light plant for the Masonic Temple, in Chicago, which will be one of the largest isolated plants in the world, has been awarded to the Western isolated lighting department of the Thomson-Houston Electric Co. The generating plant will consist of six 80,000-watt generators and between 7,000 and 8,000 lights wired.

This plant rivals in capacity either of the plants installed by the Edison Co. in the Auditorium Building, at Chicago, although the two plants together possess a somewhat larger capacity.

Competition for this contract was unusually keen, nearly every company in the field having made proposals, and the isolated department of the Thomson-Houston Co. naturally felt elated at their success, particularly as, in addition to the generating plant and wiring, an order was secured for 3,750 Thomson-Houston incandescent lamps and the necessary sockets.

SPEED OF ELECTRIC SIGNALS THROUGH AN OCEAN CABLE.

Recent experiments at McGill College, Montreal, under the auspices of the British and Canadian governments, to ascertain the longitude of Montreal by direct observations from Greenwich, have led to the determination of the length of time it takes a telegraphic signal to cross the Atlantic. The land line was worked into the cable by a repeater, and a circuit was arranged so that the signal sent from Montreal would go over the land lines to Canso, N. S.; thence over the cable to Waterville, Ireland, and return to Montreal again. Attached to the sending and receiving apparatus was a chronograph, which measured the time. Out of 200 signals sent it was found that the average time taken to cross the Atlantic and back again—about 7,000 miles—was a trifle over one second.

H. WARD LEONARD & CO.

Under the above title there has just been formed a new corporation whose principal office will be in New York City, and whose business will be that of electrical engineering generally, and special attention will be devoted to electric motor appliances, the transmission of power, the installation of central station lighting and power plants, the concealed wiring of large office buildings, hotels, etc., and plants in which advantages can be obtained by a combination of apparatus of various companies, such as alternating current systems, storage batteries, arc lights, etc.

A feature of the business of this concern, which is entirely novel, will be the supplying of expert information regarding engineering matters, the operation of different plants and upon the best methods and system of accounts in connection with the operation of electrical plants. Such information will be supplied by correspondence at a very moderate charge per annum.

Mr. H. Ward Leonard, who has just resigned as manager of the Lighting and Power Department of the Edison General Electric Co., brings with him an experience second to that of no other electrical engineer in the country, and the many new ideas which he proposes to carry out will probably lead to a distinct and valuable departure in the application of electric power. He will be ably seconded by his former assistants in the Edison Co., Messrs. A. S. Vance and E. H. Harrison, and we have no doubt that their united efforts will result in a most successful and lucrative business.

The company will be actively in business before September 1st. Their offices will probably be in the Columbia Building, No. 29 Broadway, New York City.

NEW DEVICES OF THE INTERIOR CONDUIT AND INSULATION CO.

THE handsome new catalogue of the Interior Conduit and Insulation Co., of this city, besides containing excellent descrip-

FIG. 1.—CEILING PENDANT CUT-OUT FOR CONDUIT TUBES.

tions of the well-known products of this company, brings out also the latest devices made by them, and which deserve more than passing mention on account of their exceedingly practical character. Thus we note the ceiling pendant cut-out for conduit tubes, illustrated in Fig. 1, and designed especially where the tubes are run on the surfaces. It is made entirely of porcelain,

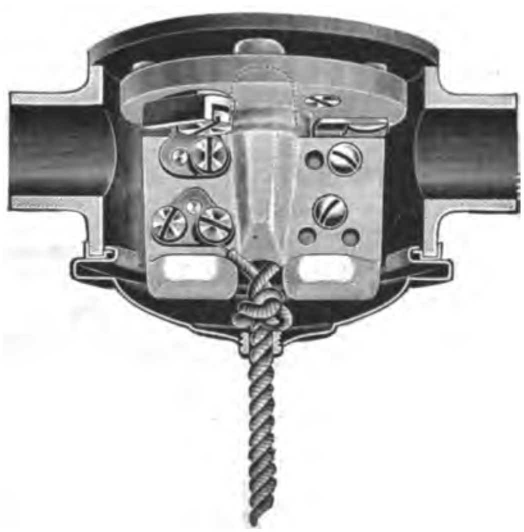


FIG. 2.—CEILING PENDANT BLOCKS FOR BRANCH CONDUIT BOXES.

the base portion being provided with side holes for receiving the tubes. These holes are curved so that the wires may be drawn in or out, and, therefore, the usual branch box is unnecessary. The terminals for connecting the wires are cast into the block itself, and, as will be seen from the illustration, the connection between the upper and lower pieces is made with a screw thread, so that no tools are needed to make the connection.

In Fig. 2 there is illustrated an improved form of porcelain ceiling pendant cut-out, designed with special reference to utilizing the space and protection afforded by the conduit branch boxes. By using this cut-out the necessity of making an outlet base at the branch boxes for the reception of the ordinary forms of cut-outs is done away with, and besides the advantage of having the cut-out concealed from view, it is at the same time well protected from any outside source of injury; and if the safety fuse is melted the fused metal is safely confined within the branch box. It can be easily applied, connected and readily handled.

Fig. 3 shows a pendant fixture made with conduit tube and suspended from the cover of the conduit branch box just described, making a flexible pendant, which is stronger and safer than ordinary flexible cord pendants.

The new spring snap-lever switches on slate bases, made by the company, are shown in Fig. 4, which illustrates the double-pole type. These switches are constructed on a novel principle, the merit of which will be at once recognized. The contact plates, which receive the bridges in the handle that close the circuit, are mounted on springs, which move with, and in the same direction as, the handle, and when sufficient power is stored up in the same break away instantaneously with a snap action. A simple screw adjustment provides for exact division of the small arc or spark. The contact plates are of the best phosphor bronze, and the action of the switch keeps the same always clean and bright, insuring the carrying capacity at all times. One important advantage possessed by the switch consists in the fact that the handle cannot fall on the contact plates and close the circuit

FIG. 3.—PENDANT FIXTURE SUSPENDED FROM CONDUIT BRANCH BOX.

imperfectly; and the design of the switch requires the exertion of force to close the circuit, and, therefore, insures its being done properly.

In addition to the apparatus described, we also note a variety of novel devices, among them an automatic switch operated at any distance by push buttons, and necessitating only a small wire between the switch and push button; various porcelain cut-outs designed for use in connection with the interior conduits, lever-switches, combined insulating joints, and cut-outs,

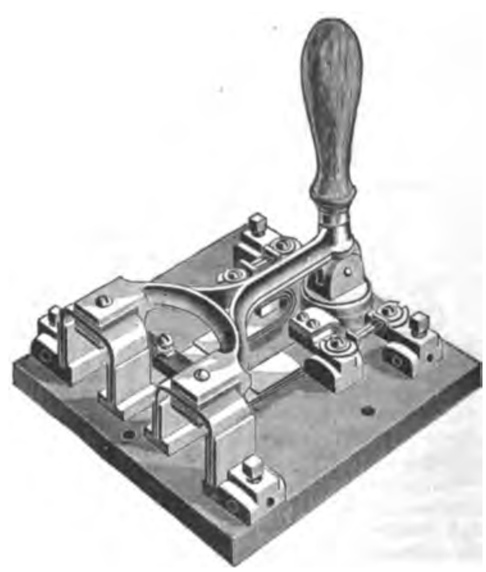

FIG. 4.—NEW SPRING SNAP LEVER DOUBLE-POLE SWITCH.

fixture cut-outs and safety catches, and a variety of fixtures for conduit branch boxes, etc. The catalogue, which is excellently illustrated, ought to be in the hands of every one interested in electric light installations.

Literature.

Telephones: Their Construction and Fitting. A practical treatise on the fitting up and maintenance of telephones and auxiliary apparatus. By F. C. Allsop. E. & F. N. Spon. London and New York, 1891. Price, $2.

WHILE many in this country are patiently awaiting the expiration of the patents which will throw open the telephone to free use, our English cousins are already on the threshold of this, in the opinion of many, glorious event. The Bell patent on the receiver did indeed expire in December of last year, in England, and before that time what was known as the "English Mechanic" receiver, with membrane diaphragm and electromagnets, was largely used by outsiders. On the 30th of July the Edison transmitter patent expired in England, throwing open to public use the battery transmitter, and it is interesting to know that on this patent, and not on that of the Blake transmitter, the United Telephone Company maintained their right to use a battery transmitter in England.

With this condition of affairs it is not strange that a volume describing in detail the construction of a variety of telephone apparatus should make its appearance. The author has, we think, succeeded admirably in the description of the various types of receivers and transmitters as well as the auxiliary apparatus necessary for the erection and maintenance of telephone lines, and we believe that any intelligent mechanic, or amateur, will be able to construct much of the apparatus described, owing to the clearness of the illustrations. For those who are clamoring for the most improved transmitters, such as those used on long-distance telephone lines in this country, it may be comforting to note that, although the National Telephone Company, of England, are the owners of the patent rights of most of the forms of microphones, including those of the Hunnings and Crossley type, they, nevertheless, adhere to the use of the Blake transmitter, and that, even, in the form illustrated in the original patent specification. The reason for this is evidently that the Blake transmitter is easy of regulation, and probably the best all-round instrument for holding up to its work.

Electric Transmission Handbook. By F. B. Badt. *Electrician Publishing Co.*, Chicago, Ill., 1891. 4 x 6 in., 97 pages. Price, $1.

ELECTRIC transmission of power has formed the subject of quite a number of valuable papers read before various scientific societies during the last few years, and much useful information has in this way unfortunately been scattered in various journals and transactions of such societies. The author has therefore done a good service in collecting the best of these papers and bringing them together in a form handy for reference. Thus the well-known papers on this subject by Kapp, Sprague, Mansfield, Spaulding, Leonard, and others have been brought together, and the tables and diagrams accompanying them will be found of use in the calculations involved in such work. It is to be regretted, however, that the author has not exercised greater care in coordinating the information contained in the material at hand, the work showing a lack in this direction. It is yet, we believe, too early to lay down comprehensive general laws for many cases involving transmission of power, and indeed it may appear later on that some of the laws at present enunciated and generally accepted may prove to have been based on false premises. Though not without considerable value, even at the present time, they may, however, in the future receive such modifications as practice and experience may dictate, so that a work of this kind must be used guardedly in order to avoid possible serious errors.

FOSTER'S "CENTRAL STATION MANAGEMENT AND FINANCE."

THE series of articles recently published in THE ELECTRICAL ENGINEER by Mr. H. A. Foster on "Central Station Management and Finance" have proved a great success. There has been a continuous demand for them, to meet which Mr. C. C. Shelley, Jr., of 10 and 12 College Place, N. Y., is now about to reprint them in book form. The book will be of handy size, and will contain not only the text, but all the forms, blanks, schedules, etc., employed by Mr. Foster as practical examples or to elucidate his suggestions. It would be difficult to find a more useful work for those engaged in central station work. The book will be ready in about a couple of weeks, and orders will now be received for it, either by THE ELECTRICAL ENGINEER or by Mr. Shelley. The price, in paper covers, is $1. Mr. Shelley has also made an exclusive arrangement with Mr. Foster to handle his copyrighted blanks, and will furnish samples and prices upon application.

College Notes.

ELECTRICAL COURSE AT TULANE UNIVERSITY, LA.

ANOTHER evidence of the advanced ideas of the New South seen in the fact that the Tulane University of Louisiana, of New Orleans, has a special course in electrical engineering. The University has a good faculty and is well equipped with apparatus The special course in practical electricity and related subjects is offered to such students as are unable to devote four years to the regular engineering course. This course extends over two years and includes instruction in mathematics, manual training, drawing, physics, chemistry, practical electricity, and French. On the successful completion of this course, a certificate will be awarded indicating the character and amount of the work done. Applicants must be not less than fifteen years of age and must be prepared to stand the regular entrance examination in mathematics, including arithmetic entire, algebra through quadratic equations, and six books of geometry. We should imagine that many students in the South desirous of following up electrical branches would be glad to avail themselves of this opportunity, especially as the fees are moderate. New Orleans is in many ways a central city and has a good many electrical establishments on a large scale as examples for study and test.

Society and Club Notes.

AMERICAN INSTITUTE EXPOSITION.

THE American Institute of New York City has issued announcements with regard to its sixtieth grand national industrial exposition, to begin September 30 and to close November 28. Applications for space, rules, information, etc., by intending exhibitors should be made at once to Mr. C. W. Hull, the general superintendent, at the offices, 113 West 38th street, this city.

Obituary.

WILLOUGHBY SMITH.

THE death of Mr. Willoughby Smith took place on Friday, July 17, at Eastbourne, England, where he had gone in the hope of gaining strength. He leaves six children, three sons and three daughters.

Mr. Smith was born in Yarmouth, Norfolk, on April 16th, 1828, where he remained until he took a position in the service of the Gutta-Percha Company, in 1848. His connection with submarine cables formed the theme of the two reviews on "The Rise and Extension of Submarine Telegraphy." This recent volume, which worthily closes the list of Mr. Smith's published works, really gives the history of the author's life-long labors until he retired, owing to failing health, from the Telegraph Construction and Maintenance Company in 1887.

In addition to his numerous papers presented to the Institution of Electrical Engineers, with which he was intimately connected from the beginning, he had also published lectures on "Induction," "Volta and Magneto-Electric Induction," "Induction and Conduction," and "Magnetism."

The death of Mr. Willoughby Smith snaps another of the few links in the chain which connects the men who in the old days were simply termed electricians, with the more modern electrical engineers, and only those who were associated with the early work of telegraphy can truly appreciate the great loss which the electrical world sustained by his death. At the funeral, which took place at Highgate Cemetery, the Institution of Electrical Engineers, of which the deceased was a Past-President, was represented by Profs. W. Crookes, F.R.S., President, G. Carey Foster, F.R.S,, Past-President, and the Secretary, Mr. F. H. Webb.

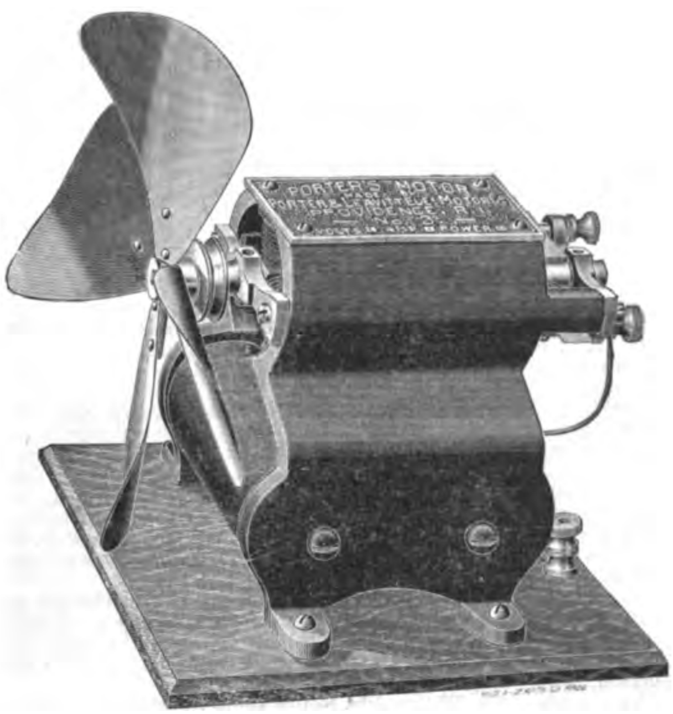
Appointments, Etc.

MR. F. SMITH, for ten years manager of the Salem, Mass., telephone exchange, has been elected manager of the Salem Electric Light Co., and will enter upon his new duties August 15.

MR. EDWARD R. GRIER and Mr. John J. Berger, formerly experts for the North American Construction Company, of Pittsburgh, Pa., are with the Thomson-Houston Co., at Lynn, Mass. Both these gentlemen have been prominently connected with the installation of the Westinghouse electric light plant in the Hoosac tunnel. Mr. Berger had charge of the rewiring of the tunnel during the past winter.

THE PORTER AND LEAVITT BATTERY MOTOR.

FOR some time back there has been an active demand for a good, reliable *small* motor, capable of being worked on a few cells of battery, and yet of such design that it would do good work and be at the same time cheap. There are a number of small motors on the market, but many of them, owing to their construction, are expensive, or have too much of the toy element. It is with pleasure, therefore, that we present to our readers the Porter & Leavitt motor, illustrated in the accompanying engraving, which seems to fill all demands, and which has met with remarkable success. These motors are patented, embodying many new principles, and are suitable for fan work or for driving small dental or jewelers' lathes, sewing machines, etc., etc. They are at present made in three sizes, No. 1, 2 and 3, but we will content ourselves with describing the No. 3, which is the largest, the most complete and the most efficient. The armature consists of two sections, on a single steel shaft. The sections are composed of three segments, each segment resembling a simple Siemens armature, made of cast iron and carefully annealed. There is no dead centre. They are insulated with varnish and paper and wound with No. 21, B & S covered wire. The commutator is made of a brass tube, mounted on a vulcanized fibre bushing, and is cut diagonally into three segments, which are fastened to the bushing by brass screws. The brushes are of solid, flat copper. The field magnets, of which there are two, lie horizontally at the bottom of the motor, and have vertical pole-pieces extending from them, curved at the upper end to fit the shape of the armature. Each field magnet is cast solid with one pole piece, and the two are then fastened together by screws entering the field magnets, one



THE PORTER AND LEAVITT BATTERY MOTOR.

at each side of the motor. The fields are wound with No. 14 B & S wire and are in series with each other, both giving the same polarity at the adjacent ends. The bearings are of brass, provided with a small oil recess. For fan purposes the No. 1 motor is fitted with a 5-inch fan, the No. 2 with a 6-inch fan and the No. 3 with a 7-inch fan, and they cost respectively $3, $5 and $7. The motors are thoroughly well made, and though small, have first-class workmanship, and everything is guaranteed by the manufacturers, who are at present also experimenting with motors to run on 110 volt circuits. They have been carefully tested by reliable electricians for their capacity, and the following data may be found interesting: The No. 1 weighs 1½ pounds, will run on one acid cell, taking 35 to 40 watts, and has a capacity of about $\frac{1}{25}$ h. p. The No. 2 weighs 3 pounds, takes from 60 to 120 watts, and has a capacity of about $\frac{1}{8}$ h. p. The No. 3 weighs six pounds, is 5½-inches long, 4¼ inches high and 4⅓ inches wide, and with 6 to 10 volts, and 20 amperes, has, while running at 2,205 revolutions per minute, a capacity of about $\frac{1}{5}$ h. p. The motors are manufactured by the Porter & Leavitt Electric Manufacturing Company, of Providence, R. I., and the Electric Gas Lighting Company, of Boston, are the exclusive agents for the New England States.

Reports of Companies.

ERIE TELEGRAPH AND TELEPHONE CO.

THE Erie Telegraph and Telephone directors met in New York, August 7, to declare the regular quarterly dividend of 1 per cent. as recommended by the executive committee. The dividend will be paid August 17 to stockholders of record August 8. The Erie's statement of operations for the first quarter of the fiscal year, ended June 30, makes the following comparison :

Quarter ended June 30—	1891	1890.	Increase.
Gross income	$208,782	$189,393	$19,389
Expenses and dividends	198,000	179,550	18,450
Surplus	$10,782	$9,843	$949
Proportion divs. rec'd by Erie Co	$52,287	$51,601	$686
Div. No. 31 (Aug., '91)	48,000	48,000	....
Surplus	$4,287	$3,601	$686

During the quarter 163 subscribers were added, making the total number connected July 1, 13,539, against 12,662 a year ago, and 11,564 July 1, 1889.

THOMSON EUROPEAN ELECTRIC WELDING CO.

THE Thomson European Electric Welding Company has granted the purchasers of the patents for Great Britain until Sept. 1 to pay the balance of £30,000 cash due upon the contract. The company has already received some $320,000. It has also extended the option of the German parties until Sept. 1. Trial machines have been sent to the South of Europe, on which a royalty is received, and there is a prospect of selling the rights for Italy, Spain and France. Beside this, the company has given a license for the use of the projectile patents all over Europe for a royalty on the welds made. It is thought by some that the projectile business will be the best of all the electric welding business in Europe.

THE APPLEGATE ELECTRICAL FLOOR MAT MANUFACTURING CO., of Camden, N. J., has been seized by the Sheriff on executions amounting to $2,000.

THE UNITED ELECTRIC SECURITIES COMPANY, of Boston, announces that it has bought for sinking fund under third call $50,000 of its first series collateral trust sinking fund 5 per cent. bonds.

THE DOMINION ELECTRIC MFG. CO., composed of Henry L. Shippey, John B. Wallace, C. E. Saunderson and Jas. Leggat, has been dissolved.

DIVIDENDS.

THE GREAT WESTERN ELECTRIC SUPPLY CO., at a meeting of its directors recently, declared a quarterly dividend of 2 per cent. on $350,000. of preferred stock. It is said they will soon pay 6 per cent. on the common.

HARTFORD, CONN.—The Hartford Electric Light Co. has declared the usual half-yearly dividend of 8 per cent., payable on demand.

A WESTINGHOUSE ROAD FOR WORCESTER, MASS.

MR. R. S. BROWN, representing the railway department of the Westinghouse Electric Mfg. Co., in New England, reports that the Consolidated Street Railway Co., of Worcester, Mass., is putting in an equipment of Westinghouse apparatus for its new line to Lake Quinsigamond. The single-reduction motor is to be used. Mr. Brown reports excellent prospects for New England business.

THE U. S. PATENT GUARANTY CO.

THE United States Patent Guaranty Company, of which ex-Senator John J. Ingalls is president, has been formed in Washington. It proposes to treat property in patents in much the way that the title-insurance companies treat property in real estate. Incidentally it will undertake the capitalization and exploitation of valuable patents, in regard to which it will occupy the relation of trustee. As a patent trustee, the Guaranty Company will be in a position to protect minority interests. Patentees with the certificate of the United States Patent Guaranty Company will more readily secure a hearing from capitalists, while inventors will find backing to protect them from the interests opposed to their possible competition. The names of several well-known capitalists and business men appear in the list of founders and directors.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED AUGUST 4, 1891.

Clocks:—

Clocks, W. K. Menns & W. J. Dudley, 457,090. Filed Mar. 8, 1890.
Relates to clocks in which the vibration of the pendulum controls the circuit of an electromagnet which actuates the impelling devices.

Dynamos and Motors:—

Armature for Dynamos or Motors and Method of Winding the Same, F. A. Wessel, 457,065. Filed Nov. 15, 1889.
Relates to drum armatures and is especially applicable to the winding of those of the Siemens type.

Brush Holder for Dynamo Electric Machines, Sidney H. Short, 457,226. Filed Dec. 18, 1889.
Relates to improvements in carbon brush holders for dynamos or motor.

Commutator or Contact Brush, L. Paget, 457,327. Filed Sept. 25, 1889.
Brush is composed of one or more layers of wire gauze cut bias.

Automatic Brush-Shifter for Dynamo-Electrical Machines, T. E. Adams, 457,330. Filed Sept. 16, 1887.

Galvanic and Thermo-Electric Batteries:—

Galvanic Battery, J. R. Hard, 457,116. Filed Feb. 6, 1891.
A closed cell has a gas outlet in its stopper and a self-closing valve opening outwardly.

Lamps and Appurtenances:—

Coupling for Electric-Light Shades, P. Levison, 456,997. Filed Mar. 23, 1891.

Incandescent-Lamp Socket, W. C. Bryant, 457,072. Filed Mar. 9, 1891.

Socket for Incandescent Electric Lamps, J. Criggal, 457,109. Filed Jan. 3, 1891.

Socket for Incandescent Electric Lamps, J. Criggal, 457,109. Filed Jan. 3, 1891.

Electric-Arc Lamp, X. Wertz, 457,141. Filed Dec. 5, 1889.
The carbons are enclosed in an exhausted glass globe; a layer of insulating material is interposed between the carbons.

Coupling for Electric Incandescent Lamps, I. J. Flagg, 457,151. Filed March 12, 1891.

Miscellaneous:—

Electro-Magnetic Cut-out, S. H. Cobb, 456,940. Filed Nov. 29, 1890.
A protective device.

Rheostat, J. A. Mosher, 457,090. Filed Nov. 5, 1890.

Mechanical Switch for Electric Systems, C. Dauffenbach, 457,110. Filed March 3, 1891.
A quick-acting switch.

Electric Hand-Fan, W. B. Luce, 457,127. Filed May 19, 1890.
A revolving fan and electric motor of small size with a handle and flexible conductors.

Electric Smoothing-Iron, W. Mitchell, 457,164. Filed Nov. 21, 1890.
Relates to tailor's irons and laundry irons heated by a removable coil.

Electric-Fence-Station Device, D. H. Wilson, 457,296 Filed Aug. 25, 1890.
Employs a battery and induction coils for the benefit or detriment of fleeing cattle.

Electric Switch, W. C. Bryant, 457,300. Filed April 8, 1891.

Electric Switch, L. D. Castor, 457,301. Filed May 20, 1891.

Electric Elevator, F. B. Perkins. Reissue 11,185. Filed June 24, 1891.
Original No. 439,180, Dated Oct. 28, 1890.
Relates especially to starting, stopping and braking devices.

Railways and Appliances:—

Car Propelled by Electricity, S. H. Short, 456,970. Filed Dec. 15, 1890.
Relates to a direct-acting system, the armature being axially placed with reference to the driving axle; the field magnets are mounted on side-bars connecting the pedestals and journal boxes of the car and are upheld by the journal boxes.

System for Conducting Electric Currents, E. Britt, 456,979. Filed Oct. 11, 1889.
Employs a series of distinct sectional conductors, which by means of pressure are brought into electrical connection with a continuous conductor.

Trolley for Electric Railways, S. H. Short, 457,015. Filed Mar. 29, 1890.
Employs a dash pot in connection with the trolley-arm for checking and limiting its upward movement when escaping from the trolley wire.

Electric Car-Brake, E. Verstraete, 457,016. Filed July 26, 1890.

Electric Motor for Street Cars, E. Thomson, 457,036. Filed Jan. 19, 1891.
Combines slow speed and maximum efficient torque, with compactness, in order to accommodate itself to the limited space beneath the body of a street car.

Electric Track-Signal, M. W. Parrish, 457,058. Filed Aug. 8, 1890.
Has for its object improvements in track signals, by means of which the incoming train gives an alarm while the outgoing train does not.

Electric Car-Brake, C. R. Arnold, 457,067. Filed Aug. 21, 1890.
An electromagnetic brake in which the circuit consists of two car wheels and the section of track between them.

Electric-Railway Motor, N. C. Bassett, 457,102. Filed Mar. 20, 1891.
Improvement consists of a water-tight case, and means for protecting the field-coil from injury.

Electric-Conductor Support, E. M. Boynton, 457,105 Filed Oct. 17, 1880.
Relates to an overhead conductor support and guide rail for the Boynton bicycle railway system.

Electric Conductor, E. M. Boynton, 457,106. Filed Dec. 15, 1890.
Similar in its object to No. 457,105.

Railway-Signal, W. C. Serrell, 457,135. Filed May 18, 1891.
An alarm to give warning of the too close proximity of two trains or locomotives.

Electric Railway, S. E. Wheatley & J. W. Schlosser. 457,240. Filed Apr. 2, 1891.
Provides for controlling the switch connecting the working conductor with the main line, by means of the main current and mechanical appliances on the car.

Telegraphs:—

Printing-Telegraph, H. Van Hoevenbergh, 457,239. Filed April 16, 1885.
Claim 1 follows:
In a printing telegraph, type wheel controlling device consisting of the combination of a scape wheel, an anchor applied thereto, an armature for controlling the movements of said anchor, a permanent magnet polarizing said armature, and two single coil electromagnets for controlling the movements of said armature.

ARC LAMPS ON RAILWAY CIRCUITS.

THE Universal Arc Lamp Co. have lately been introducing large number of their arc lamps on railway circuits with excellent results. Mr. L. S. Dumoulin, superintendent of the electrical department of the West End Street Railway Co., of Boston, in a recent letter to the company, says: "In reply to your inquiry respecting the arc lamps supplied by you, I am pleased to say that they are giving us good satisfaction every way. Our normal current is 500 volts, and we arrange the lamps in series of 10; and although subject to extensive variations of potential the light is both steady and constant. The twin carbons are a great success, and give 14 hours' light without causing any trouble." Similar results have been reached at Reading, Pa., and Amsterdam, N. Y.; and there is no question that this method of running arc lamps is destined to be very generally resorted to by street railway companies. Meanwhile the Universal Company is experiencing a large demand for lamps to go on regular incandescent circuits, where a great many are now in daily use.

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

THE 1891 meeting of this Association will be held in Washington next week, from the 19th to the 25th. The headquarters will be at the Arlington, and reduced rates will also be obtainable at the Arno, Ebbitt, Randall and Fredonia. The meetings will be held at the Columbian University.

MR. F. ROBINSON, of Fair Haven, Vt., reports that there is a growing demand for slate for electrical purposes, with a decided appreciation of its many good qualities. The special sphere for slate is to be found in places liable to a burn-out, and hence it is particularly in demand for cut-outs, switchboards, etc. There is also a demand for new work in odd and original sizes and shapes. The chief drawback has been that much of the slate heretofore furnished has been poor in quality and of low-grade finish.

Financial Market.

QUOTATIONS ON ELECTRICAL STOCKS.

The following are the last reported quotations up to August 8, 1891, from New York, Boston and Washington:

Westinghouse El. & Mfg. Co. ¾

THIRTEENTH ANNUAL CLAMBAKE OF THE AMERICAN ELECTRICAL WORKS.

A CLOUDLESS sky, warm, fair weather, a refreshing breeze, and about 210 guests, made the occasion of the thirteenth annual clambake at the Vue de l'Eau Club, Providence, on Saturday last, probably the most auspicious and enjoyable of any for a number of years. In past years these clambakes have always been held immediately after the electric light convention, and Mr. Phillips looks to the members attending the convention for a large number of his guests. This year, however, as the convention is somewhat later than usual in the season, the clambake had to depend altogether for its success upon its own attractions, and the result was most satisfactory and flattering to the American Electrical Works, as it was the most largely attended of any ever held. Everyone who could possibly attend was there, and Messrs. Philips' and Sawyer's hospitality was enjoyed to the full. Many anxious looks were pointed toward the weather quarter in the morning, as a violent thunder and rain storm had passed over sections of New England the preceding night, but in the morning all signs of rain had passed away and the event came off in as perfect weather as one could wish for. Guests came from all parts of the country and entered into the sports with that entire abandonment which characterizes the members of the electrical fraternity and which has made them known as "good fellows" all over the United States.

When your correspondent arrived on the scene a hotly-contested game of baseball was in full swing between the New York and Boston teams, resulting in a complete victory for Boston of 16 runs to 4, while New York claims to have completely demolished the Boston team by nine runs to nothing. Mr. W. A. Hathaway, of Providence, well known for his undoubted veracity, acted as captain for the New York team and efficiently steered them to success, while Mr. Charles B. Burleigh, one of Boston's brightest athletes, both in the field and in the arena of electricity, covered himself with glory as a batsman of renown. The actual result of the match probably will never be known to history, the proneness to ingenious prevarication of both captains on such occasion being beyond dispute. A *recherché* lunch was served to all the guests about noon, while a full and flowing bowl of punch of real Rhode Island merit served as a stimulus to drooping spirits, and got in some very subtle work. The usual photograph of the group arranged on the piazza of the club house was taken, after Mr. Day, of Providence, by sundry persuasions in the shape of brimming cups of punch, offered to the photographer, had prevailed upon Old Sol to kindly hide his shining face behind a convenient cloud. At three o'clock promptly dinner was served under a spreading awning and was enjoyed by all, especially the clams, which appeared to be as good as, if not better than, usual. After dinner, Mr. T. D. Lockwood made a very efficient croupier, and introduced the various speakers with a few bright and well-chosen remarks. The first toast in order was the American Electrical Works, which was very modestly responded to by Mr. Eugene Phillips, who simply took the opportunity of welcoming all his guests. The State of Rhode Island was then toasted and responded to by his Excellency the Governor, the Hon. H. W. Ladd. Mr. Lockwood then gave out the toast of the city of Providence, and Mayor Sidney Smith responded. Electricity, as represented by electric light and power, was duly responded to by Mr. A. J. De Camp, while Mr. G. M. Phelps, of THE ELECTRICAL ENGINEER, attended to that branch of electricity represented by the telegraph and telephone. Mr. Ralph W. Pope ably responded for the electrical press, and Mr. Martin Day, of Providence, kept the audience in a roar of laughter while apologizing for his existence as a member of the local daily press.

Most of the guests departed by the 5:45 boat for Providence, whence they separated for their various destinations, all agreeing that a most perfectly harmonious and pleasant day had been spent, and looking forward with pleasure to many more such outings, which undoubtedly go to produce good feeling and good fellowship.

Yes! Mr. Fred Gilbert's battered and time-stained hat still adorns the top of the telegraph pole, where it was carefully and laboriously placed some three years ago.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

You put in the ad.; we do the rest.

THE MASON READING LAMP OUTFIT.

THE hot summer evenings make reading by gas or oil lamp intolerable and a small incandescent lamp fully meets all the demands of comfort and convenience. A neat electric lamp outfit has therefore been brought out by Mr. James H. Mason, 87 World Building, this city. It is illustrated in the accompanying engraving.

The zinc and carbon elements are attached to a board so that they can be lifted clear of the solution when the battery is not in use, and by opening out the hinged board in front, the cells can be easily got at. The box is made of solid walnut, beautifully polished, and is fitted with lock and key. A polished brass handle is screwed to the top lid so that the whole battery can be easily carried with one hand. The lamp-stand is attached to the two

THE MASON READING LAMP OUTFIT.

binding-posts on the side of the box, as shown, by means of 10 feet of silk-covered flexible incandescent lamp cord.

The lamp is of six candle power, but owing to concentration and the rays being thrown directly where desired, it said to be superior to many lamps claimed to be of sixteen candle power. The light supplied by the battery is a beautiful soft white, and comforting to the eyes, and can be turned on or off by means of the key over the shade.

One charge of solution, costing 10 cents, will run the lamp at a bright light for three consecutive hours, and the same can be used alternately for a long period of time

THE SUN ARC LAMP CO., 203 S. Canal St., Chicago, have a large demand for their Sun Arc lamps. This lamp is adapted to either arc or incandescent circuit. Several large Dry Goods houses with plants of their own are installing this lamp in place of the incandescent.

MR. J. W. MASON, the well-known dealer in electrical supplies, of Kansas City, was in Chicago last week.

THE "ISOLATINE" INSULATING AND PROTECTING PAINT.

OWING to the success "Isolatine" has met with in the market as insulation for wires, cables and underground work, as also to its well-known quality of not affecting, but permanently protecting, metals, wood, etc., the manufacturers have decided to put on the market a paint having all the qualities of Isolatine, and combining, it is claimed, as no other covering does, all that is necessary to lastingly protect and insulate, chiefly owing to the fact that it never either cracks or peels. For all parts subjected to vibration, jars, etc., it is specially recommended, and since "all the world is continually a-jarring," it follows that it should be in use for every conceivable purpose.

"Isolatine Paint" is very cheap, and only asks for a thorough trial to prove its superiority. The manufacturers, the Roessler & Hasslacher Chemical Co., No. 73 Pine street, N. Y., will be glad to answer all inquiries.

R. D. NUTTALL CO.

THE above-named concern, of Allegheny, Pa., has taken steps to increase its capital stock to $500,000, for the purpose of enlarging its plant and extending its business. It succeeds to the business of R. D. Nuttall & Co. and of the Electric Railway Specialty Co. Mr. J. F. Porter, the manager of the Specialty Co., will remove to Allegheny, where his time will be spent in looking after the affairs of the company. The Eastern office, at 29 Broadway, will be under the immediate supervision of Mr. J. G. White, electrical engineer. Messrs. Carey and Mayer will travel for the company.

BABCOCK & WILCOX BOILERS.

MR. L. M. MOYES, formerly agent of the Babcock & Wilcox Company, at No. 32 North Fifth street, Philadelphia, has surrendered the charge of the office and business at that point to their new agents, Messrs. W. C. Temple and Henry F. DePuy. Any business transacted with the Philadelphia office should be done through either of these gentlemen, who will always be ready to attend to it at that place.

PRATT'S PORTABLE REGISTER.

As another evidence of the enterprise shown by the Electric Merchandise Co., of Chicago, it may be mentioned that they have lately secured the sole agency for Pratt's portable register for street car use. They claim that this device has advantages of a special nature, and as a consequence they have been flooded with inquiries and orders during the last few weeks.

A NEW DEPARTURE.

MR. W. S. CHESLEY, of the Electrical Exchange Building, No. 136 Liberty street, this city, has established a purchasing agency for new apparatus and supplies, and proposes to give customers the benefit of low prices. He also makes a specialty of apparatus that is thrown on the market, and job lots of supplies that must be disposed of quickly.

JOHN P. CUSHING & COMPANY, of Boston, have just completed a very handsome stage switchboard for the new Empire Theatre, now in course of construction in Philadelphia, which is well worth examining, as being a perfect piece of work in all its details. The board is made of quartered oak 6 feet 6 inches high by 8 feet 3 inches wide, and sits on a cabinet 17 inches high by 8 feet 6 inches wide, containing the cut outs and bus bars. The whole board is protected by a roll top cover. Moulded mica, manufactured by the Gould & Watson Company of Boston, is used for mounting the heads, of which there are eight, which are connected to eight circuits furnished with resistance boxes for raising and lowering the lights. By means of a special shunt switch one of the heads can be used for three different circuits of red, white and blue lights. The board comprises 200 lights for the four borders, 120 footlights, 480 bunch lights, and 1,578 lights for the auditorium, which is controlled by fourteen different circuits. Ten circuits are on gang snap switches, which can be worked one at a time or altogether by means of a lever. The whole is controlled by one main breakdown, reciprocal-acting switch. The board was built under the supervision of Dr. W. A. Drysdale, consulting electrical engineer, of Philadelphia. Messrs. Cushing & Co. are building a switchboard for the new Columbia Theatre and for the remodelled Park Theatre, of Boston, and have already attained quite a reputation for this class of work.

MR. GEO. F. CARD, of the Fort Wayne Electric Co., was a welcome visitor to Chicago last week. He is investigating various matters electrical here.

TAYLOR & WALSH.

The above firm have started in business at 100 South Fifth avenue, New York City, for the manufacture of the Fibrous Battery in its dry and liquid forms, and of Leclanche fibrous cups. The firm comprises C. G. Taylor and Louis Walsh, with J. Hart Robertson as electrician. Mr. Walsh is well known through his active connection with the battery business, and his associates have also been identified with the industry. They bid fair to enjoy a large share of the trade in their line of specialties.

THE STRATTON SEPARATOR AT PURDUE UNIVERSITY.

MANUFACTURERS and steam users generally will be interested in the following communication:

"PURDUE UNIVERSITY,
La Fayette, Ind.

THE STRATTON SEPARATOR CO.,
32 Cortlandt street, New York.

GENTLEMEN: We have been using for about a year one of your 4-inch separators in connection with the compound engine in our engineering laboratory.

Steam for this engine is supplied by boilers located 580 feet away, and notwithstanding the long length of pipe through which it is thus required to pass, it was never found, by repeated calorimeter tests, to contain as much as 3 per cent. of moisture when it passes out of the separator, regardless of the amount of water previously held by the steam.

Very truly yours,
WM. F. M. GOSS,
Professor Experimental Engineering.

UNDERWOOD COTTON-LEATHER BELTING.

THE attention of readers is called to the illustration in our advertising pages of the four large Underwood Cotton Leather Belts. An agreement entered into last month by the Engineering Equipment Company, 143 Liberty street, New York, and the Underwood Manufacturing Co., of Tolland, Conn., constitutes the former company the sole Eastern selling agent for the Underwood Co. By this new move the Engineering Equipment Company assumes charge of the offices and salesrooms of the Underwood Manufacturing Co., at 126 Pearl street, Boston, in addition to the similar agency acquired at New York last February. Mr. W. D. Warner had been previously retired from the management of the Boston office, and the sale of Underwood Cotton-Leather Belting, Dodge Pulleys, and Rope Transmission is now in control of the Equipment Company, with Mr. F. A. Magee as their manager at the Boston offices.

"KIND WORDS."

UNDER the above title, Mr. W. J. Morrison, general agent of the Fort Wayne Electric Co. for New York State and Canada, has just published a most interesting pamphlet that contains a number of testimonials to the value and merits of the company's system of Wood arc lighting. What adds very greatly to the importance of the collection is that it was not made by the company itself. The letters, all of which are given in fac-simile, were received by the Board of Public Works of Jamestown, N. Y., whose secretary wrote inquiring as to the results that had been obtained with the Wood system, and as to experience with any other system. Hence they are characterized by a fullness and frankness that contributes very much to their weight, and Mr. Morrison is to be congratulated on his shrewdness in making the collection public.

THE AMERICAN LIGHTNING PROTECTOR CO.

Articles of incorporation of the American Lightning Protector Company have been filed at Sioux City, Ia. The company will have $100,000 capital. The incorporators are: Geo. W. Felt, Thomas F. Byron, A. H. Ward, H. R. Hopkins, W. F. Weyburn, H. S. Hubbard and L. S. Pearson. The provincial board of directors includes N. D. C. Hodges, the inventor of the device which the company will handle; W. H. Beck, Geo. W. Felt, A. H. Ward, Thomas F. Byron, Jennie E. Rogers, W. F. Weyburn, F. M. Ferris and H. S. Hubbard. The Hodges "dissipating conductor" has already been very fully described and discussed in our columns.

PUTTING TELEPHONE WIRES UNDERGROUND.

The telephone line from the summit of Pike's Peak to Manitou has just been completed and put in operation. It is said to be the highest telephone line in the world.

THE THOMSON WELDING PLANT AT JOHNSTOWN, PA.

The Thomson Welding Co., of Boston, are putting in a very fine welding plant for the Johnson Co. at Johnstown, Pa. A large brick building has been erected, 101x52 feet. There are five alternating current machines of the following capacity: Four of 80 kilowatts, and one of 40 kilowatts. These machines are run direct from the engines, Schieren belting being used. The engines are two 275 h. p., from W. A Greene, of Altoona; one 90 h. p. Ball engine; three 150 h. p. Ball engines and one 300 h. p. cross-compound Ball. This plant runs a Thomson metallic tie welder, a Thomson rail welder and two chair welders. Clark wire is used throughout the installation. The work, though the plant is not yet in full running order, is giving entire satisfaction.

THE OLD TIMERS' MEETING IN WASHINGTON.

The eleventh reunion of the Society of the U. S. Military Telegraph Corps and the Old Timers' Association will be held at the Ebbitt House, Washington, D. C., on August 19th and 20th. Mr. M. Marean is the secretary of the local committee on arrangements, with Mr. G. C. Maynard as his right hand man. The attendance promises to be very large, as Washington is a place of peculiar interest to those who were early associated with telegraphic work or were engaged in it actively as military telegraphers. Particulars can be had of Mr. W. J. Dealy, at "195." It is proposed to have a loan exhibit of relics, and to visit various places of interest.

INFECTIOUS TELEPHONES.

SOME officials at Danzig, Germany, are reported to have discovered that bacillary infection can be communicated by the membranes of telephones.

MR. FREDERICK DUGGAN, formerly general manager of the electrical department of the Trenton China Co., has purchased from them their entire plant for the manufacture of porcelain for electrical purposes, and has established himself as the Imperial China Works, at Trenton, N. J.

GEORGE CUTTER has just been granted another patent on his lamp-supporting pulleys, against which the rope-cutting demons are said to have a strong grudge, and perhaps the marking of the new date on the next batch of pulleys will give the little imps some satisfaction.

NEW YORK NOTES.

THE ONGLEY ELECTRIC COMPANY'S SYSTEM is meeting with success; the public have recognized the value of their reliable Watchman's Register, which faithfully records the movements of a night or day watchman, and its many adjuncts, viz., engine-stopping device, fire-alarm signals, automatic sprinkler protector, etc. Among the latest establishments which have been equipped with this system we may mention the Pennsylvania Railroad yards both at Jersey City and Hoboken; Eble & Herter's Brewery, Philadelphia, Penn., and the Appleton Manufacturing Company, of Brooklyn; and we learn that many other large and important concerns have just closed contracts with the Ongley Electric Company. The system is pronounced by all most reliable and thorough in all its workings. Particulars or any information may be had by applying to the company's office, at No. 1 Broadway, New York City.

MESSRS. MILLIKEN BROS., New York and Chicago, have lately gone to a great deal of expense and trouble to get complete tests made at Cornell University of their patent poles, showing ultimate strength, elastic limit and corresponding deflection in connection with standard pipe and wooden poles. This firm has shown great enterprise in trying to give to the public an improved and trustworthy pole. A complete report of the tests is promised.

THE MANITOU BEACH ROAD.—The new electric road to Manitou Beach, connecting at the lake with the Rochester and Ontario Beach line, is making a great success and will undoubtedly return good dividends.

MR. T. J. MURPHY, slate dealer, has removed from 96 Columbus avenue to the Electrical Exchange Building, 136 Liberty street. This is rendered necessary not only because of his increase in business, but also for the reason that he is making a specialty of slate for electrical purposes. Mr. Murphy furnishes a material entirely free from any conducting substance, and it can be had either plain, in black or marbleized. We can testify to the beauty of the latter style from a specimen which has reached this office in the shape of a checker-board. Small samples of the above may be had on application.

ROCHESTER, N. Y. NOTES.

TWO NEW THEATRES, with full equipment of electric lighting apparatus, will be opened in September. The Lyceum is making extensive changes and will have a good part of its large auditorium rewired.

THE WHITCOMB HOUSE.—The new six-story fireproof addition to the Whitcomb House is being wired in interior conduit for electric lighting by Putnam, Gay & Co.

PUTNAM, GAY & CO. are wiring the Rochester Free Academy building for electric lights in the insulating tubes of the Interior Conduit Co. for about 100 lights.

THE AMERICAN BREWING CO. are installing a 200-light plant in their six-story fireproof building. Contract taken by the Western Electric Co.

THE UNITED STATES COMPANY is adding a new alternator to its plant here.

THE STATE INDUSTRIAL SCHOOL.—The proposed plant fails to materialize. Bids were advertised for to be in by June 24th, but on that date it was decided to throw out all proposals and have specifications drawn up showing precisely what contractors would be expected to furnish. The first plan required contractors to furnish their own specifications, and it is supposed that the wide variations between bids caused the managers' course. It is unlikely that any decisive action will be taken in time to secure the plant this season.

NEW ENGLAND TRADE NOTES.

J. E. WILSON AND COMPANY, with headquarters at No. 8 Oliver street, Boston, are becoming quite well and favorably known as agents for the Rollins Engine Company, of Nashua, N. H., and of the Lawrence Machine Company, of Lawrence, Mass. The two engines do not compete with each other at all, the Rollins engine being made in sizes from 50 to 600 h. p., and the Lawrence engine from 4 to 30 h. p. Mr. Wilson, of the above firm, recently closed a contract with the Boston *Journal* to furnish them with a Rollins engine of 100 h. p. The *Journal* is increasing in size from its present form to a 16-page paper, and the order was secured in the face of severe competition, fully sustaining Mr. Wilson's reputation as a "hustler." The Rollins engine is of the automatic cut-off type, and has a Corliss exhaust valve and slide valve for the admission. At present there are two 250 h. p. Rollins in the Nashua Electric Light Station, one 250 h. p. engine in the station of the Concord Street Railway Company, two 100 h. p. engines in Newburyport Electric Light Station, and one 100 and one 125 h. p. engine in the station of the Amesbury Electric Light Company, at Amesbury, Mass.

THE WAINWRIGHT MANUFACTURING COMPANY, OF MASSACHUSETTS, have just furnished a 300 h. p. heater to the Reading and South Western Railway Company, of Reading, Pa., and two 600 h. p. compound engine heaters to the East River Electric Light Company, of New York. They have also furnished two 600 h. p. compound engine heaters for an electric railway plant in Denver, and a 100 h. p. heater for the electric light plant of the Toledo *Bee*, Toledo, O. They have just completed for the West End Street Railway Company, of Boston, 20 large corrugated copper expansion joints, two being 20", sixteen 16", and two 12" in diameter. These latter are for the new power station now being built in Boston.

THE ELECTRIC GAS LIGHTING COMPANY, of Boston, has just been loaded down with orders for the never-failing "Samson," as many as 10,000 having been ordered within the last two weeks, so Colonel Burnham says. Six men are employed in the basement packing these giants for shipment to all parts of the United States, while the Colonel sits fanning himself with a Porter & Leavitt motor in his comfortable office above, concocting more such stories. The Porter & Leavitt motor has recently been added to the number of specialties controlled by the Electric Gas Lighting Company for the New England States. This motor is well worthy of special attention by all, and has been designed for use in battery circuits.

THE GOULD AND WATSON COMPANY, of Boston, are having continued success with their moulded mica insulators for railroad work, as evinced by the large demand for their goods. Notwithstanding the fact of there being many other materials in the market, they have supplied the Thomson-Houston Electric Company alone with as many as 23,000 insulators in the past six months, and their last order recently received—in August—was for 2,000 pieces. The West End Street Railway Company of Boston, has just placed a large order with the Gould & Watson Co. for span insulators known as the Brooklyn strain insulator, recently illustrated in the columns of THE ELECTRICAL ENGINEER.

MR. J. F. WHITNEY, 189 Asylum street, Hartford, has been appointed agent for the Germania Electric Company for the State of Connecticut, and is proving himself a good one, having sent in in one month orders for about 10,000 lamps.

MR. W. M. MORDEY, the electrician of the Brush Electric Company, Limited, of London, who is well known by reputation in this country for his valuable work, was a visitor to Boston this week, and favored the Boston office of THE ELECTRICAL ENGINEER with a call. Mr. Mordey reports that his company is beginning to do considerable electric railway work, and he is spending most of his time here in looking up the overhead details of construction. Mr. Mordey, doubtless, would be glad to receive on his return to England, about the 20th of this month, any samples or descriptions of railway details which any of our railway supply houses choose to forward.

MR. F. A. MAGEE, of the Boston branch office of the Engineering Equipment Company, of New York, is becoming quite a familiar figure now in Boston streets, and in resorts of the electrical fraternity. Mr. Magee has been well known to the electrical trade in general for many years, and is working up a good business in the East in general supplies for the electrical trade. Mr. Magee is always glad to see visitors at his office, 126 Pearl street, Boston.

MR. HENRY J. HADAWAY has gone West to join Mr. George Cutter, of Chicago, in the interests of the Germania Electric Company, where he will push the sale of the improved Schaefer lamps. The word "improved" is used advisably, as the Germania Company have recently carefully revised the whole manufacture of their lamps, and are turning out now a lamp superior to all those of their previous manufacture.

THE CONNECTICUT MOTOR COMPANY recently received their third order from the Government for a combination of Connecticut motor and Sturtevant blowers, for use on board the cruiser "Philadelphia." They have already supplied similar installations on board the "Concord" and "Bennington," which have been entirely satisfactory.

PHILADELPHIA NOTES.

MR. C. K. WESTBROOK, manager of the Isolated Department of the Thomson-Houston Electric Co., has recently made the following installations: One 30,000-watt generator to the Pencoyd Iron Works; a 250-light plant for A. B. Farquhar & Co., of York, Pa.; a 250-light plant for Croft & Allen Co.; a 300-light plant for the Omnibus Co.; six small motors for C. F. Langston & Co.; two small motors for the Union League Club; besides numerous smaller installations. Mr. Westbrook has added to his force Mr. Arthur I. Plaisted, who for the past six years has been engaged in the Engineering Department of the Thomson-Houston Electric Co., at Boston.

E. T. ORNE, 112 Randolph St., Chicago, will place his electric speaking tubes in the new *Daily Herald* building of that city, and will use as a part of his system, 100 or more of Partrick & Carter Co.'s new King Annunciators, which he has decided as best adapted to his plans. These annunciators need only to be seen to be appreciated.

MR. THOMAS YEARSLEY, of 123 North Third street, has finished the installation of a 30-arc light plant for the Neshaming Falls Co. There are two miles of wire construction and the plant will light the entire grounds of the pleasure park owned by the above company.

MR. A. H. CHADBOURNE, who for some time past has represented the Westinghouse system of electric railways, recently resigned his position to accept a similar one with the Thomson-Houston Electric Co., with headquarters at 509 Arch street.

MESSRS. CLAY, PEPPER & REGISTER are installing a 500-light plant at the New Century Club on 12th street. It is to be wired with the three-wire system and interior conduits will be used through the building.

ST. LOUIS TRADE NOTES.

THE INTERSTATE COMPLETE ELECTRIC CONSTRUCTION CO. have been incorporated with a capital stock of $10,000; Wm. Wurdock, president, and Chas. P. Lampel, secretary and treasurer. The new company have taken quarters at 809-817 South Seventh street, the buildings formerly occupied by the Heisler Electric Light Co. The company will manufacture and repair all kinds of electrical apparatus and also undertake the complete installation of electric light and power plants, wiring, etc. Their shops are already quite busy with general electrical work, of which they are doing a good deal for the Columbia Incandescent Lamp Co. They are also developing an alternating current motor for light industrial uses. The company has just been appointed general Western agent for the Heisler Electric Light Co., of Philadelphia.

W. L. ARNOLD, the St. Louis agent for the Thomson-Houston Electric Co. has just sold to the Texarkana Gas & Electric Railway Co. a complete installation for 50 double-arc lamps. A 150 h. p. Armington & Sims engine will be put in. Mr. Arnold reports that the new lighting plant of the Arkadelphia Water & Light Co. is finished and n successful operation.

THE POND ENGINEERING COMPANY report increased activity in the territory tributary to their Chicago and St. Louis offices. In addition to the two 400 h. p. Armington & Sims engines now being furnished the Edison station in Chicago, they have just started a 250 horse power Armington & Sims engine in the station of the Cicero and Proviso Electric Railway. This is the second electric railway now in Chicago, both of which are using Armington & Sims engines, furnished by the Pond Engineering Co. They are also furnishing the Murphysboro Water Works and Electric Light Co. with an Armington & Sims engine of 120 h. p; also a complete steam plant for the Grand Ridge, Illinois, Electric Light Company, also one automatic engine, vertical pattern to the Chicago office of the Edison General Electric Company.

THE WESTERN ELECTRICAL SUPPLY CO. are now well settled down to business again and report that they have just closed a contract for the complete installation of the Interior Conduit system for the new *Globe-Democrat* Building. The conduit system will accommodate the wiring for 1,000 lights and also a complete messenger call system and telegraph and telephone wires. Mr. T. J. Wilson, manager of the company, is in the East and on his return will organize a construction company for the purpose of carrying out their contracts.

THE HEINE SAFETY BOILER CO. report the sale of four 200 h. p. boilers to the Denver Consolidated Electric Light Co.; two 250 h. p. boilers to the University of Michigan, Ann Arbor, Mich.; three 375 h. p. boilers to the Chicago Edison Co.; one 150 h. p. boiler to the Thomson-Houston Electric Light Co., Ann Arbor, Mich.; one 300 h. p. boiler to the Dubuque, (Iowa,) Electric Light & Power Co.; and three 250 h. p. boilers to the City Electric Street Railway Co., Little Rock, Ark.

WASHINGTON NOTES.

NATIONAL THEATRE.—The wiring of the National Theatre has just been completed by the contractors, Messrs. Kingsbury & Mustard, of Baltimore, Md. The work has been done in a very thorough manner throughout. The switchboard is a model one in every respect. Pilot lamps, connecting with every circuit in the house, are so arranged over the switch and regulator of the respective circuits that the operator need have no trouble in adjusting his candle-power. The local Electric Lighting Co. supply the current through Thomson recording meters.

CONSTRUCTION BUSINESS BRISK.—The large number of new buildings now being erected have made business for the construction companies very brisk.

WESTERN TRADE NOTES.

THE SUN ARC LAMP CO., 203 S. Canal St., Chicago, Ill., have greatly enlarged their manufacturing facilities, and are now prepared to fill all orders for the Sun Arc Lamp promptly, either for incandescent or arc circuits. The Great Western Electric Supply Co. have secured the general agency for the West; this lamp has been upon the market but a short time, and it has achieved a phenomenal success, especially among the isolated plants and central stations that have the direct incandescent system. It is simple in design, and gives a bright, steady, white light. The company will also engage extensively in the manufacture and introduction of several new articles, upon which they have secured patents. The company is incorporated with a capital of $300,000.

THE WESTERN ISOLATED LIGHTING DEPARTMENT of the Thomson-Houston Electric Co. report the following sales: Drenberg, Glick & Horner, of the Leader, corner Adams and State streets, Chicago, for a 14,000 watt incandescent dynamo, a one horse power motor and a fan motor; E. Rothchilds & Bros., one 17,500 watt 10 ampere arc light dynamo, to be installed at their place, 203 Monroe street, Chicago; Wakefield Rattan Co., corner Robey street and Blue Island Ave., Chicago, one 400-light incandescent dynamo; The University of Illinois, Champaign, Ill., one 18,000 watt alternating current dynamo and appurtenances for use in electrical laboratory.

CHICAGO ELECTRIC MOTOR CO.—Owing to the large number of requests to repair dynamos and motors, this company, of 205 and 207 South Canal street, have decided to equip a general repair department in connection with their manufacturing business, and will make a specialty of repairing and rewinding armatures of all makes of railway motors, stationary motors and dynamos. They have spared no expense in securing the most experienced men for this department. Having had 12 years' practical experience winding armatures of all systems, they guarantee first-class work and prompt service, at reasonable charges.

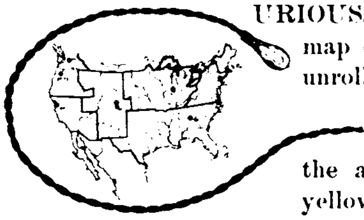
EDISON BUILDING, BROAD ST., NEW YORK CITY, HEADQUARTERS OF THE EDISON GENERAL ELECTRIC CO.

EDISONIA.



CURIOUS, indeed, and striking is the map of the United States that unrolls before us on the wall. The distinguishing colors that occupy and partition the area are red and blue and yellow as usual, but the divisions are far from conventional. They show little respect for State Rights as embodied in border lines, still less for limitations made by mountain range or river course. At first glance it looks as though the various commonwealths of the Union had merged themselves in a series of huge federations so that instead of forty or fifty States, there were only half a dozen, much to the mental relief of the juvenile student of geography. But the truth is simply, as we discover on closer inspection, that creative and constructive genius has been at its old work once more. Some day, perhaps, it might be a profitable study to investigate the exact nature of the connection between great men and the prosperity of the map-making industry, for it is evident that to the cartographer the achievements of such persons as Napoleon, or Bismarck, or Henry M. Stanley must open up dazzling possibilities of unlimited wealth. Here, at any rate, we have a proof particular of the essential fact, in the map before us, it being that which the Edison General Electric Company has published, to show the eight great districts into which the magnitude of its operations has made it necessary to divide the country, so that its business may be conducted efficiently and successfully.

Nor is it merely in a big map that the vast interests which have grown up around the inventions of Mr. Edison, in electric light and power, find their expression. The fine Edison Building in Broad Street, New York; the sumptuous show rooms and art rooms on Fifth Avenue; the branch offices in Chicago, Toronto, Boston, San Francisco, Portland, Denver and Atlanta; the huge factories in New York, Harrison, N. J., Schenectady, N. Y., and Peterboro, Ont., all tell the story of a growth and development that is unsurpassed in these days of invention and industrial triumph. Out of the trials and vicissitudes and humble beginnings of a bare decade, has come the organization of a business with a capital stock of \$15,000,000 and a gross annual business of nearly the same amount. Even if this were not census year, and, coincidentally, the beginning of the second decade of commercial incandescent lighting, it would repay us to glance a moment at the record of advance and achievement that these figures embrace. Hardly yet can it be said that the unification of the Edison light and power industries which was effected in 1889 has revealed its full measure of benefit and usefulness; but an idea of what it means and of the forces that it controls and has set in motion may perhaps be formed from these pages, exhibiting as they do in detail of pen and pencil the methods and products of the latest electrical arts.

The formation of the Edison General Electric Company not only brought a variety of corporations under one comprehensive management, but massed together a number of offices that had been scattered all over New York City. To-day, within the stately Edison Building on Broad Street, a view of which is shown in the frontispiece, one may accomplish in ten minutes business for which, under the old conditions, a whole day of traveling uptown and down-town was not sufficient. Each of the old concerns, moreover, was conducted as a distinctly separate institution, leading very often to confusion, friction and costly delay; and this state of affairs was not improved by the existence of at least a score of territorial sub-companies and agencies, each in its own way selling Edison apparatus, making contracts for plants and supplies, and carrying on the work of construction. Of course these conditions had sprung up and developed chiefly through the inevitable resort to rough but ready methods of meeting the sudden needs, first here and then there, of a great new industry. But, as in other departments of life and work, the very success of these crude, pioneer plans soon led to a higher evolution of system, and to a broader plane of administration. Without some such unification of interests, it would have become impossible to exercise satisfactory supervision of detail, while those who were entrusted with executive functions would have found their energies frittered away in the mere effort to keep the complicated machinery going. The extent of the change that has been made, and the degree to which the economical simplification of control has been pushed under the present regime will be understood when we state that the entire business of manufacturing, selling and installing is now conducted by the Edison General Company in its own name and through its own employees. One cannot therefore visit the Edison Building without being impressed with the sense of irresistible power that a large, well-knit body in swift, onward motion always arouses. The halls and elevators are thronged, and at every floor one encounters the same bustle and hum of activity. At first, one is inclined to wonder how even a moderate stint of employment can be found for so many hundreds of clerks, but with only ordinary powers of

observation it is easy to see that the difficulty is to get the day's work done within the day. The industry of which these are the headquarters has over 6,000 names on its pay-rolls, and has a monthly income and outgo of a million of dollars. The transactions of its last fiscal year showed an aggregate business of $10,000,000 and the increase is steady. The Company has between 4,000 and 5,000 customers on its books. Its raw material on hand and work in progress often represent a sum of $4,000,000. The aggregate capacity of the large and small Edison stations reaches 1,371,000 lamps, and if to these we add the thousands of isolated plants, we can readily imagine how enormous is the demand for lamps and supplies simply inside what may be called the Edison fold. Then there is the electric railway department with sales of 27,679 horse power of motors and 22,836 horse power of generators in a single year. Then come the newer demands for mining outfits, mill plants, stationary motors large and small, apparatus for electro-deposition of metals, dynamos for supplying telegraph current, electric elevators, etc. All the thousand and one uses to which electricity is now put in this Age of Wire have to be dealt with, and every want is met as promptly as the telegraph and long-distance telephone, reinforcing the efforts of this army of intelligent workers, will permit.

ONE of the features of the growth of New York City has been the invasion of the fashionable Fifth Avenue by trade and commerce. That thoroughfare from Fourteenth Street up to Forty-second is now lined with handsome stores and office buildings, with an occasional hotel or apartment house, and it will not be long before the last of the private residences this side of Central Park will have been given up. In one of the stateliest of the old-time mansions in this new stronghold of business has been established the Fixture and Decorative Bronze Department of the Edison General Co. The show-rooms at 275 are in a sense the lineal successors to those at the historic "Sixty-Five," but unless they are seen it is difficult to realize how novel a departure has been made.* Our sketches will, however, furnish some idea of the attempt to deal with light as an æsthetic element. In this house, whose modernized front has quite a charm of its own, each room has its characteristic or distinctive style of decoration in carpets, tapestry, woodwork, ceilings, fire-places, chairs and other equipments, and then the final touch has been given by showing electric light fixtures in harmonious correspondence. Thanks to this arrangement, he who is building a house or refurnishing one, may come here and see for himself exactly how the lustres or candelabra or chandeliers will look when installed. It is needless to point out the manner in which this facilitates choice or the elaboration of effect. In this room, for example, we may study out the best plan of illuminating a room that the decorator is to treat in the style of the Renaissance. Here we have a Louis Quinze salon, whose brilliancy and delicacy can only be done justice to by the deftest disposition of the light. Or perhaps it is a dining-room that is to be lit up, and here is one we can admire and imitate, noting how skillfully the effects are obtained, and how felicitous Charlotte Bronte's phrase about "festal breadths of light" seems when it is here embodied in a radiance that at once adds to and borrows from the beauty of gleaming plate, sparkling crystal and snow-white damask napery.

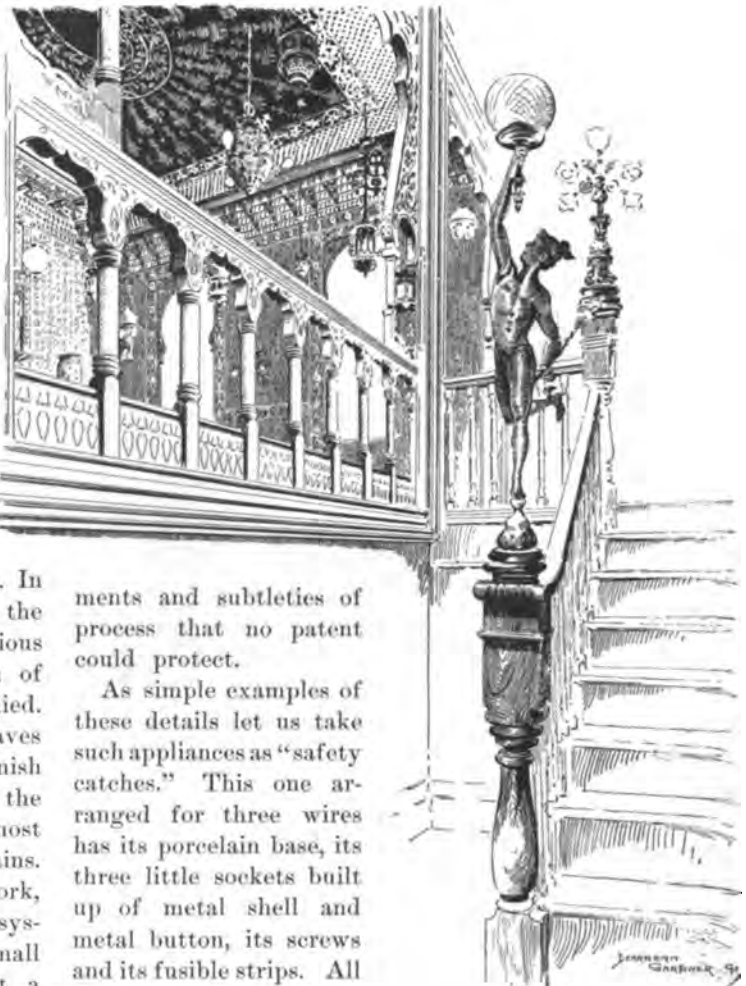
The Edison General Electric Co. long since recognized what we may call the artistic possibilities of electric lighting, and while, as a matter of course, it went into the manufacture of all the ordinary lines of electroliers and fixtures, it made the production of the very highest art work in this branch a matter of deliberate policy. It reasoned that while on the one hand the wealth and culture of the country would now be satisfied only with the most refined and delicate examples of metal work, the taste and ability of the American workman, if given classic and beautiful designs to embody, would be quite equal to the exactions of the most critical connoisseur. How far the Company has succeeded in its aims may be determined not only from the views we have shown of the house it has expressly fitted up at 275 Fifth Avenue, but from the various designs scattered through this text, of electroliers, lustres, trophies, standards, brackets and other special art products. These pieces are first worked out by the Company's own artists, either from the suggestions of patrons or, more often, from their own ideas, and while one may condemn the straining after novel effects that is often seen in such art work in America, there is little here that calls for anything but hearty praise. It has been truly said that one of the charms of the work done by even the humblest Japanese artist is its endless variety and freshness. And so here. Every new production is new, and not a mere stereotype of that which has already wearied us to death by its familiarity or, more likely, by its ugliness. Of course it is difficult in these sketches to give any conception of the glow and sparkle and color of these fixtures and electroliers, but an indication is at least furnished of their grace of outline and delicacy of finish. Here, for instance, is one in which every

line in metal flows in curves as airy and spiral as those of a tender vine, tendril springing above tendril so spontaneously that the whole is a creation of nature rather than of art. In this lamp, with its mellow tint and fine tracery, "the slumbrous light is rich and warm," while in this orbed pendant, the light, as

> "in a globe of film all vaporish
> Swims full-faced like a silly silver fish."

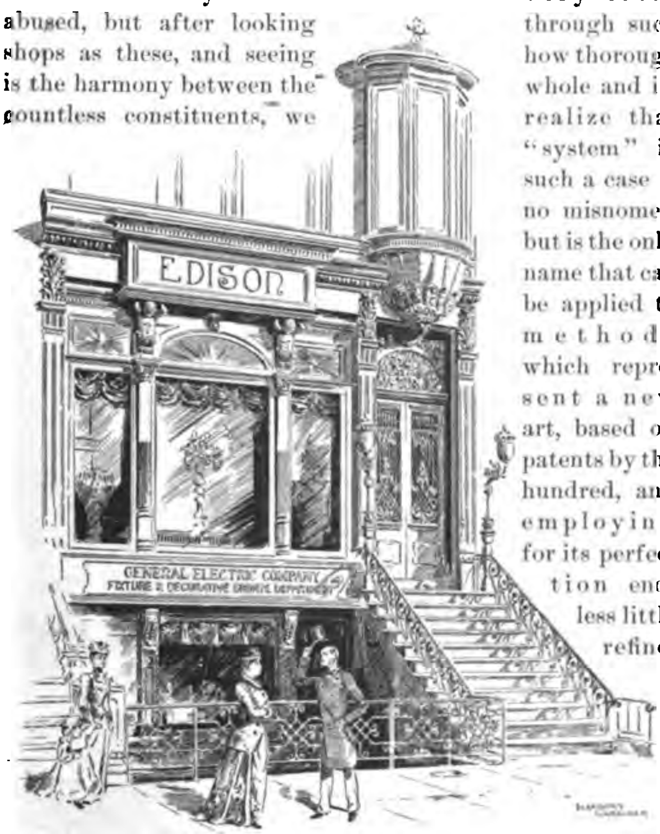
Or in another, a dragon or other fabled monster writhes up a standard and shoots out at us his tongue of fire.

Needless to say, such products demand not only taste in the designer, but skill in the artisan, and it may be doubted whether finer workmanship of the kind is done anywhere in America than at the shops of the Company on East Seventeenth Street and Avenue B, and at Twenty-seventh St. and First Ave.



Stairway, 275 Fifth Avenue, N. Y.

These two shops now employ close upon 1,000 hands. In the larger and older one at East Seventeenth Street, the bulk of the artistic work is done, and there the various interesting processes connected with the production of hammered and oxidized metal pieces may be fully studied. We soon learn that, simple as one of these little oak leaves may look on a very ordinary bracket or fixture, its finish has been reached only after hundreds of blows with the craftsman's hammer, and that in this work, as in most others, the best results are reached with infinite pains. But these two establishments are not limited to art work, for they turn out the detail apparatus of the Edison systems of light and power, as well as the hundreds of small metal parts that go to make up a lamp, or a socket, a switch, or a cut-out. Sometimes one is inclined to think that the word "system" is very much abused, but after looking through such shops as these, and seeing how thorough is the harmony between the whole and its countless constituents, we realize that "system" in such a case is no misnomer, but is the only name that can be applied to methods which represent a new art, based on patents by the hundred, and employing for its perfection endless little refinements and subtleties of process that no patent could protect.



Fixture and Decorative Bronze Department, 275 Fifth Ave., N. Y.

As simple examples of these details let us take such appliances as "safety catches." This one arranged for three wires has its porcelain base, its three little sockets built up of metal shell and metal button, its screws and its fusible strips. All these parts have a definite relation to each other; all have had their conditions determined, and now all are being turned out literally by the million. How easy it seems, as these swarms of boys and men do it. Or, again, take this little switch with its base, its cap, its handle, spring and contact pieces. One could sit here all day and watch the clipping and stamping out and spinning of the various pieces, which pass from stage to stage by the gross. And yet, back of it all, how much of dreary calculation and weary experimenting lies. Simple as these little details are, the essence of the art is in them, and each of them is a necessary consequence of the wonderful step that was made when the incandescent lamp became a success, and yielded its jealous secret to the irresistible attack of Mr. Edison's genius and industry. As when Tennyson apostrophized the "flowers in the crannied wall" and exclaimed that if he could understand them he could know the meaning of all things; so might we, had we but the insight, take these modest, humble appliances and build up the incandescent art again from them in its every adjustment of means to ends.

The manner in which the great modern central stations have affected our notions with regard to interior illumination and decoration is a thing that is by no means clearly understood. And yet, after all, it is only natural that with the improvement in processes of artificial illumination should go hand in hand, a higher perfection in the lamps or the devices employed to hold and display the light. We are here at an immeasurable distance from the lamps made by burning animal fat in the skull of some wild beast slain in the chase, or by palm oil placed in a calabash or a broken cocoanut shell. The primitive lamps in clay or stone or metal were of the simplest construction, but they were steadily improved. It is, indeed, to the lamp that we must look for some of the finest specimens of fictile art, and the graceful productions of the potter's wheel have their match among those furnished also for light-bearing by the skill of the cunning worker in metal. So, too, with candlesticks, candelabra and chandeliers, to which the transition from lamps was easy. To many of these articles historical importance attaches equally with beauty of design, while the forms linger with us in many a fine modification or new application. The introduction of gas seventy or eighty years ago gave a fresh impetus to work in this field, for everybody saw that the beauty of the new illuminant demanded for it a more resplendent setting than had previously sufficed. The manufacture of gas fixtures became very rapidly a great and prosperous industry, giving employment to thousands of skilled workers in metal, and the fact that the gas was one of the chief instrumentalities in the destruction of the fixtures and chandeliers that bore it did not hinder from the production of most gorgeous and ornate works of art. It may be said that we are still within the bounds of the period of gas, for when electricity came upon the scene as an illuminant for interiors its introducers were glad to use such designs in chandeliers and gasoliers as were available, without troubling themselves much about form or comeliness. It is, however, a significant fact, that in the very first fixture wired up for incandescent lighting, the little lamps were reversed so that for the very first time since human beings had used artificial light at all, the lamps were burned "upside down." This was, in its way, as notable and revolutionary a departure as the incandescent lamp itself, for it at once cleared the path for the modern practice of treating light as something fluent and plastic in a decorative way—as something which for artistic purposes in the House Beautiful may be molded and elabor-

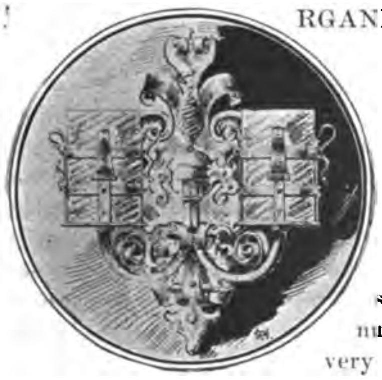
ated just as freely as though it were drapery or furniture. A lamp no longer has to stand stiffly upright, but, in the words of Dryden, our eyes are gladdened by its "descending excellence," while as becomes that which deserves Shelley's epithet as being "the radiant sister of the day," its very position may be changed with every hour.



RGANIZED in November, 1880, the Edison Lamp Co. began with a force of 55 men. To-day its successor, the Lamp Works of the Edison General Electric Co., at Harrison, N. J., of which an illustration is given herewith, employ some 750 hands, and the number required increases very rapidly, keeping pace with the extension of the incandescent lighting field, which has already become so large that the demand for "renewals" alone is an element in consumption that very few people have any idea of. In fact, the recent great reductions in price by the Edison Company have acted as such changes almost always do, in the way of stimulating and developing the market; and they who operate isolated plants or central stations have learned that true economy lies, not in burning up a big coal pile to render an old, dim lamp partially efficient, but in using only a minimum of current to keep new lamps up to their maximum of brightness. So great has been the growth that the increase in sales of 64 per cent. in 1890 over 1889 bids fair to be far exceeded during 1891, and the consequence is that this huge factory, whose capacity has been brought from 11,000 up to 25,000 lamps per day, is in full swing the year around.

Few more interesting arts can be found than that of the manufacture of incandescent lamps. The painful stages of experiment for fifty years along paths that led nowhither, and the thousands of theories and materials and methods tried by Mr. Edison before he opened the way into a grand new field of electrical utility and made the vital, momentous step from failure to success—all this has become matter of record, and furnishes one of the most fascinating and exciting chapters of modern industrial history. With the recital of that wonderful triumph of insight and perseverance, we need not now concern ourselves, but in our survey of the Edison light and power industries we shall find none more important than this carried on with such vigilant supervision at Harrison. The broad features of the process of manufacture it is easy to describe; into the esoteric details, which are of the kind that every manufacturer keeps strictly to himself, it would be impertinent to enter. The lamp, we note as we go through the factory, is formed from a longish, pear-shaped bulb, narrowing at one end to meet a hollow glass stem. These, on being melted together and filled up at the junction with plaster of paris, become the base of the lamp. The other end of the bulb serves for the connection to an air pump, and after the air has been exhausted by the pump that end is hermetically sealed by melting the glass there so that it forms a little nipple or knob. The chamber of glass has thus become a vacuum in which the "high resistance" horse-shoe or filament of carbon can be brought to the required illuminating point by the passage of the current for hundreds and even thousands of hours without any change in the structure of the filament and without any appreciable deterioration of the lamp from the light-giving standpoint. This filament of carbon is held at its two ends by little conducting wires of platinum which run out through the plaster to similar fine wires of copper. The glass bulb holds on tightly by means of horns or spurs to the plaster base, and this base in turn is capped with a thin metal shell, grooved like a screw, and to which

Putting Tubes on Bulbs for Exhausting.

Unpacking Department.

one end of the tiny copper wires from the filament is brought. The other little copper wire goes to a flat copper button insulated from the screw cap by the plaster. The lamp is now ready to go into a socket, upon turning whose key the circuit can be closed or opened, so as to bring current into the lamp or to shut it off.

This, in a few words and in popular language, gives the general construction of the Edison incandescent lamp, as we see it made, and it will be readily understood that back of such brief, bald statements lie a multitude of intricate details and delicate operations. The mere handling of the bamboo as it arrives in dainty bundles from Japan, tied up in flowery wrappers, and then passes from stage to stage of treatment, becoming small by degrees and beautifully less, until at last it is ready for the carbonizing retorts, involves the employment of many sensitive mechanisms and many lissom fingers; and at each advance towards the production of the finished lamp we encounter a like attention to the minutiæ of the art, of which our casual thumbnail drawings give a noteworthy glimpse or two. We come upon surprises all the time. One's interest is challenged at the very threshold by a gang of boys who spend their time in doing nothing else but unpack the bulbs as received from the glass works and smooth out for use in repacking the countless sheets of tissue paper in which the finished lamps go out. Such a scene would be accepted as quite natural in an orange or lemon grove, but here it strikes upon the fancy with a humorous touch of oddity. Another of our views shows the spacious glass-room where the tubes are put upon the bulbs to be exhausted. The next is the socketing-room, where bases are added to the lamps, making them look like so many transparent egg-shells with julep straws stuck into them. Then we see a bevy of keen-eyed, quick-fingered girls inspecting the lamps after the bases have been put on.

Putting Bases on Lamps.

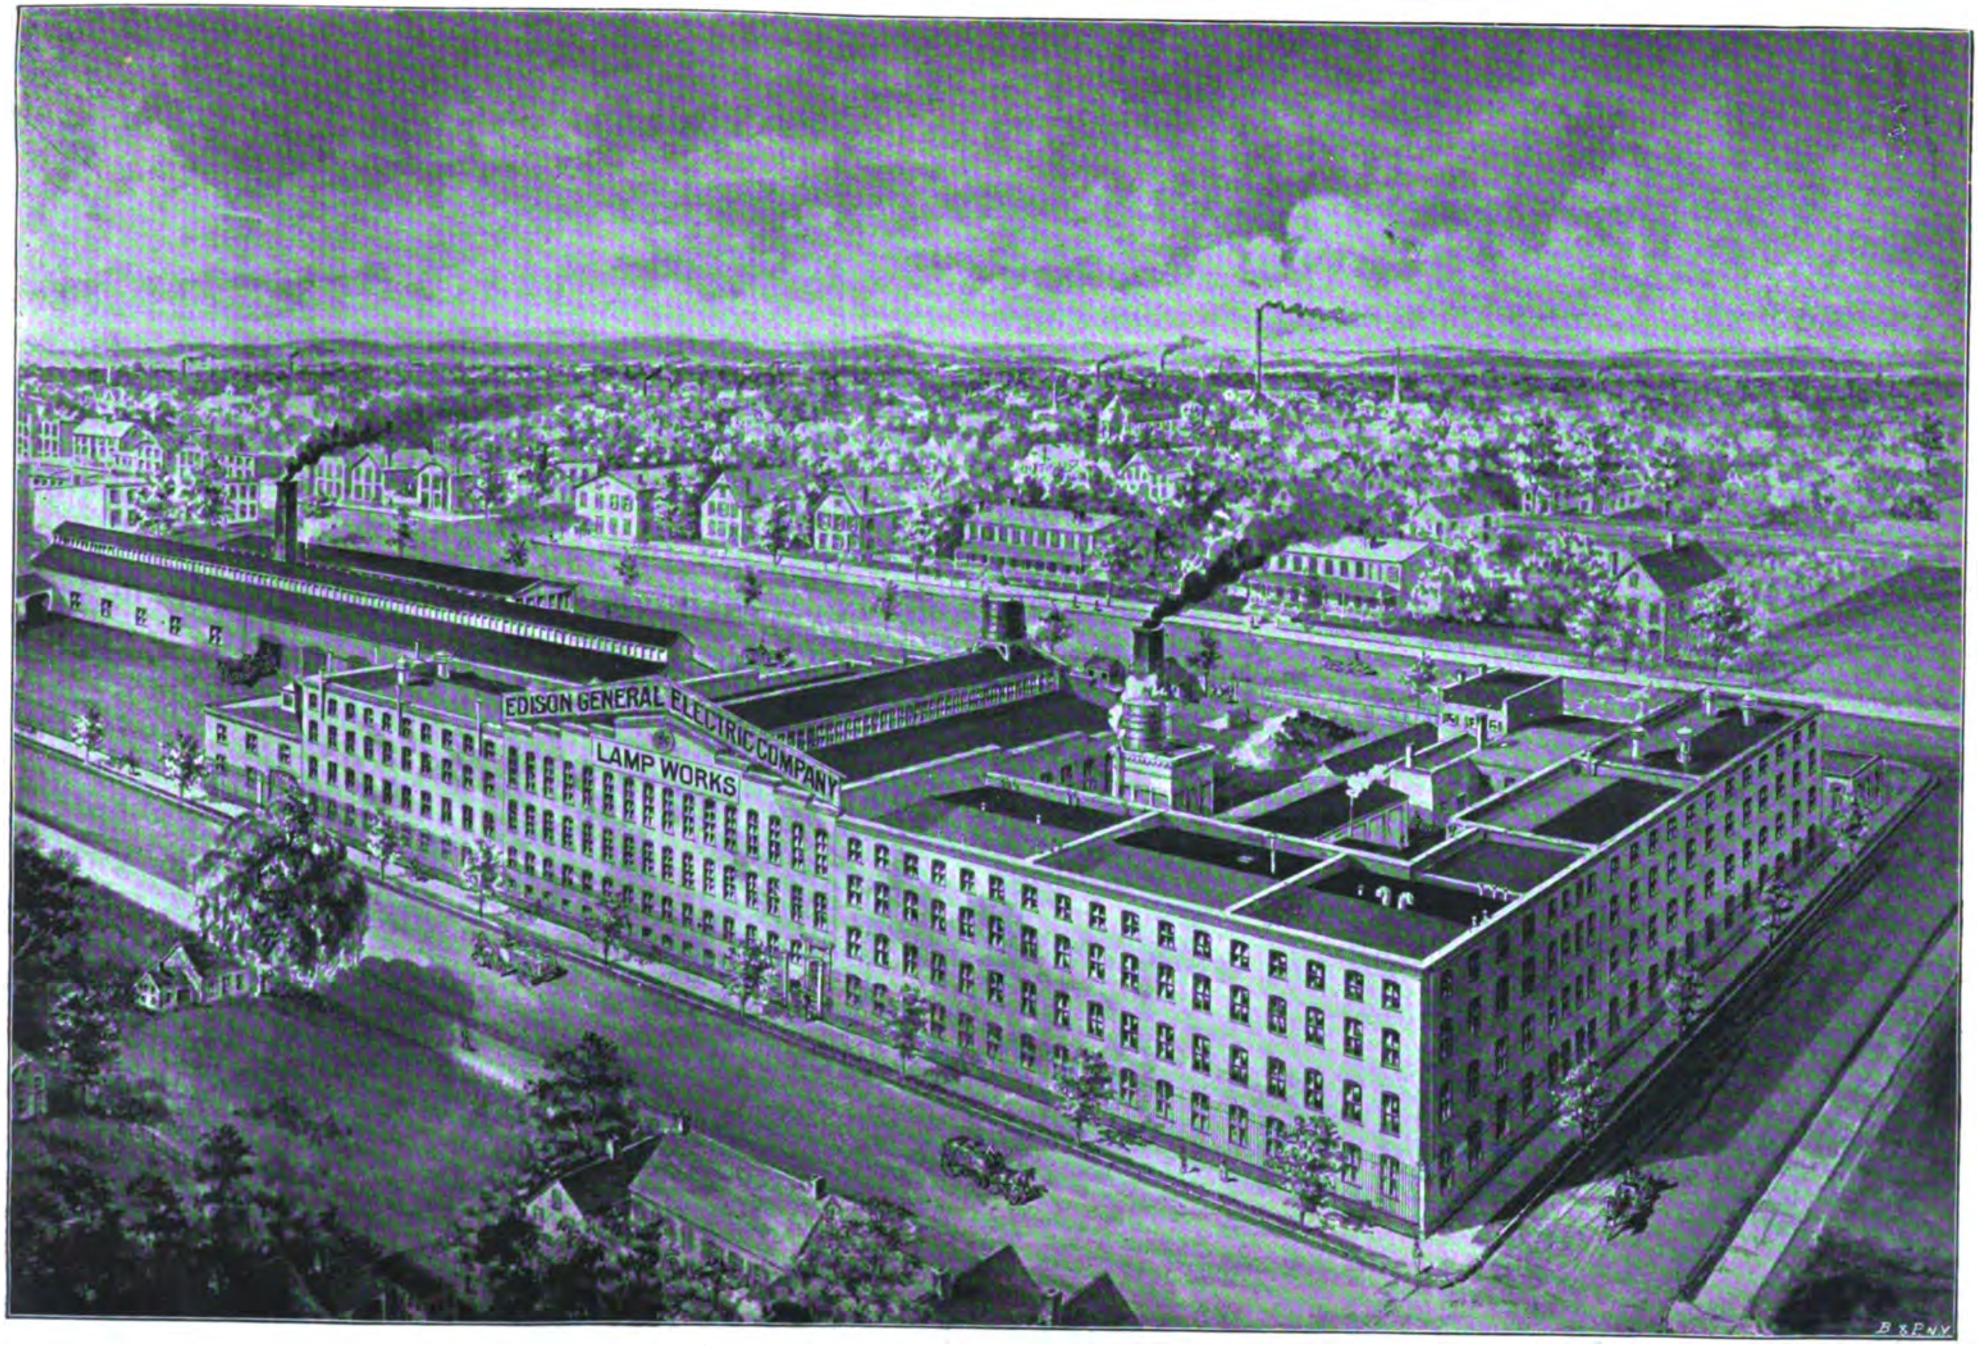
Lamps Ready for Shipment.

Next we come to the spacious packing-room, where the finished lamps are cleaned and inspected. And this inspection, by the way, is no simple routine, or nominal passing muster. Check against check, and a rigid accounting of every defective part, give to the thousands of lamps made daily an individuality of career from start to finish that seems well nigh incredible and impossible. At last, with the lamps, we reach the packing-room, where in huge racks like egg boxes, or in big barrels, they await labeling for the nearest city or for the far ends of the earth.

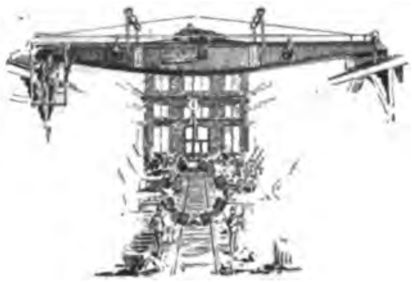
In passing through the lamp works we get a further idea as to the flexibility of methods of incandescent lighting. It is not to be supposed for a moment that the only lamps made are those of 10 or 16 candle power. The remark is still common among unobserving or ignorant people that one of the defects of the incandescent lamp is that its light is always of the same size, whereas larger or smaller lights are wanted. Such critics would be not a little surprised to see what an enormous variety of "railway," "pea," "surgical" and "dental" lamps are here in course of manufacture. The Company has even found it necessary to issue a pamphlet giving full instructions as to the use of small lamps with current from batteries or from a central station. Many of these lamps are also called for to be used on special occasions, and to ornament a dinner table, a ballroom or a wedding bower. Not a few are being used in the construction of signs and words. The lamps are made, too, in a great variety of colors, thus introducing another feature of importance in decoration. Perhaps the most vivid exemplification of what can be done in this way was afforded last year in this city at the Lenox Lyceum, where thousands of lamps in a lofty and graceful Tower of Light were made to glow in time with the pulses of the music, and where long streamers of small colored lamps canopied the whole auditorium, like gay ribbons spanning out from a maypole.

Inspecting Lamps that have been Socketed.

Cleaning and Inspecting Finished Lamps.



INCANDESCENT LAMP WORKS, HARRISON, N. J.



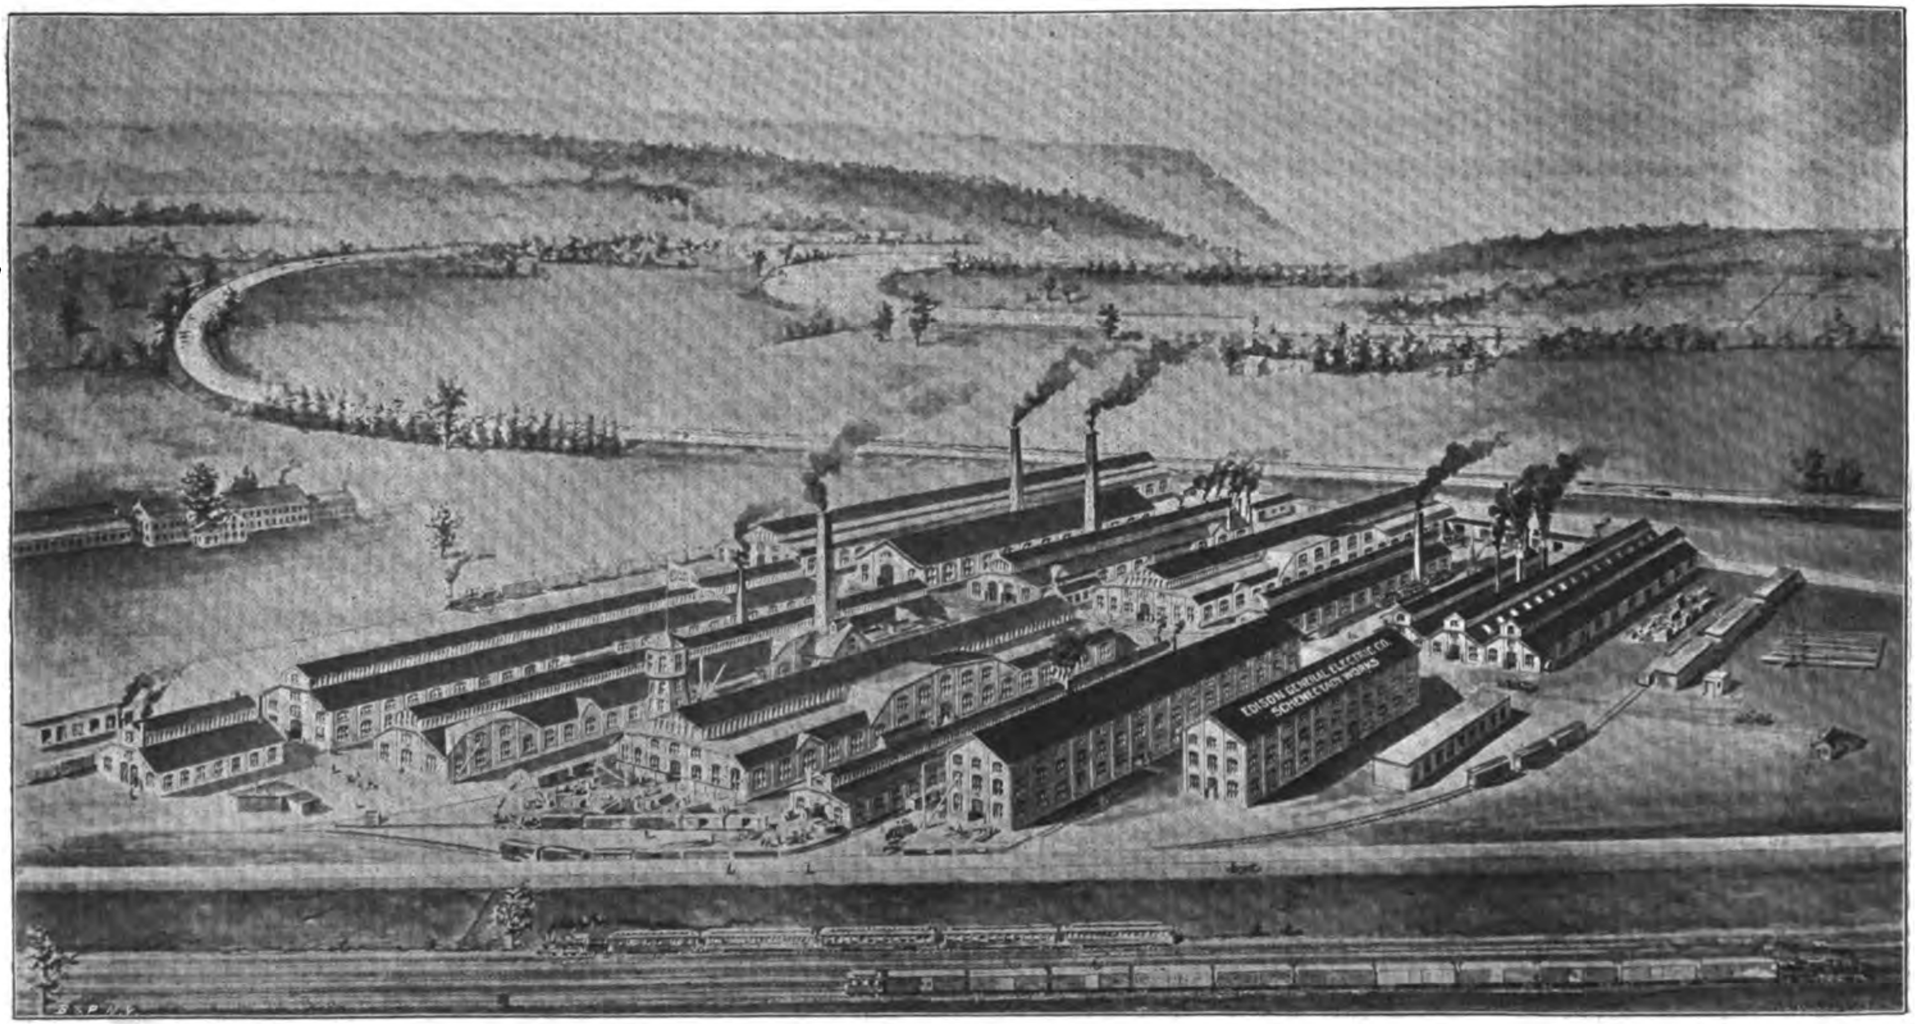
THIS quaint old city of Schenectady, settled so long ago by the easy-going Dutch founders of New York State, might well be renamed Edison, and there would not be in the act other than a graceful compliment to the industries that have brought so much activity, wealth and new life to this quondam Sleepy Hollow of the Mohawk Valley. The Edison Works there went into operation in December, 1886, after their removal from Goerck street, in New York City, with a total pay-roll of 300 men. To-day, only a little more than four years later, there are 3,200 names on the pay-roll—or ten times as many—with the probability that at least 1,000 more Edison employees will have become citizens of the place in a few months. These Works grow with the rapidity of a Western town, for even since the drawing that is here given of them was made—but a month or two ago—they have spread out in every direction, and have lifted up three or four new smokestacks to the sky. This growth is the more extraordinary in view of the fact that several subsidiary but profitable branches of the business that gave work to a large number of hands have been restricted of late to production simply for immediate use on the spot, in order that room might be made for other departments of essential importance.

Assembling a Standard Edison Dynamo.

Though it would doubtless be extremely interesting and instructive to deal with each department of the Works in detail, such an attempt is not our purpose, for only a volume of many hundred pages would suffice for the task. These huge cathedral shops, swarming every one of them with hundreds of busy artisans and filled to overflowing with machines and tools and labor-saving appliances, epitomize the progress to date both in mechanics and in the arts of dynamo and motor construction. If you would find the monument to American skill and genius in such fields, look around you. And as you look, the very first thing that catches the eye is this big traveling crane, which is swinging one of the armatures of Mr. Edison's new multipolar generators. This crane, sliding along so smoothly and so noiselessly is, like all the others, fitted with an Edison motor, and is evidently handled with far greater ease and precision than an ordinary power crane. The current is supplied by means of an overhead wire running the length of the building just above the rail. The operator, as we note, can reverse the direction of the crane or regulate its speed whether for travel or haulage, just as he chooses, by the simple movement of two hand levers on either side of him. Not far away we see another of these cranes assisting in the work of assemblage. A couple of the men are putting together an Edison dynamo of the familiar type, and one of the massive field-magnet cores is being lowered into position on top of the pole-pieces, without the least exertion on the part of the fitters. They merely give a guiding touch or two and the thing is done. All parts of the standard machines, being made to gauge, are interchangeable, and hence the assembly of the machine, though apparently a very difficult feat, becomes in this way, by the resort to such methods, one of the easiest in the world.

We walk into another shop and find a large number of men winding armatures. Some of these armatures are of the Gramme ring type, such as those used in the Edison Company's arc light dynamos; and here is one being wound for a 50-lighter. The ring is about two feet in diameter, and before these men have covered it they will have wound more than 100 sections of wire on it, each section having 50 turns of wire. When it is completed this ring will have on it about 700 wires lying side by side, counting around the periphery, and the weight of that wire will be more than 100 pounds. We ask if the work could not be done by one man. "Oh, yes," is the ready answer, "only one man is needed, but there is a great saving in time and labor in having two men, the one passing the wire over or through the ring to the other, who is waiting for the spool." Elsewhere in one of the other departments we enjoy the pleasure of watching a girl wind a drum armature single-handed, for we see that she is doing good work. Drum winding is certainly easier than ring winding, but the same care and watchfulness is needed throughout. The girl has just about finished the layer of wire on the body, having wound on 28 complete coils. After the first layer is on, the body will be carefully insulated, and the other 28 coils will be wound on. It is easy to see how the wire is built up at the ends around the shaft, all the wires here being carefully separated from one another by shellacked linen. The shellac pot and the linen strips are in front of her, and in her hand the girl holds the fibre rod by the gentle, firm pressure of which she straightens out the wire and coaxes it to lie snugly along the side of the armature. If we wander along into another shop we shall see the workmen assembling street car motors and slipping one of the larger armatures into its place within the fields.

Now we drift into the wire-insulating department, and are face to face with the intricacies and details of yet another great branch of the Edison industries. The Works make insulated wire of all kinds, not only for Edison plants but for a large number of outside customers, and here are rows upon rows of covering and braiding machines in vistas so long that they become dim, and the girls' heads seen against the wheels in the background of the distance look as if surrounded by a close-fitting halo. Some of these spindles



SCHENECTADY WORKS OF THE EDISON GENERAL ELECTRIC CO.

are reeling it off gaily at the rate of 7,000 revolutions a minute, and these thousands of bobbins are dodging around in the giddiest kind of a way, until we wonder that they don't get bewildered and stagger up against each other.

Now and again one of the machines loses the thread of his noisy discourse, but the watchful attendant quietly mends the break, and he chatters on once more vociferously, as if glad to have a womanly ear to tell it to. These machines are marvels of ingenuity, and in some of them the wire goes through pretty well a dozen operations, so that really all it needs when it comes to a rest is a good salesman to dispose of it.

Chatter, chatter, chatter go these busy machines, just like long lines of caged monkeys, and we are fain to escape into the comparative calm of the vulcanizing-room, in which other processes of insulation are going on. Here we see the wire that has been freshly coated with rubber subjected to vulcanization. Steam at the temperature of several Turkish baths is passed into the chamber into which the pans are presently inserted, and each pan contains wire that has been coiled into it for treatment. Near by we get a glimpse of the method of that treatment. Masticators or die boxes are fed with small, flat pieces of prepared rubber, which they chew up with the assiduity of a "boarding-school miss." Within the die box are cylinders fitted with worm thread, which revolves in such a way as to force the rubber compound up to the end at which the die is placed. Wire and rubber pass out together, the adjustment to the wire of the die being such that the rubber lies evenly all around it. The die box is kept at a certain heat all the time, and as the hot wire comes out it is drawn through a trough of cold water, so that the rubber is at once cooled and hardened sufficiently to prevent the wire from sinking out of concentricity by its own weight. The little sketch shows the man coiling the wire at this stage into one of the pans to go into the vulcanizing chamber.

But not even here is there an end of the insulating work done by the Edison General Electric Co. Our guide directs us into another large building where huge caldrons simmer and where huge piles of black iron pipe rise to the roof, for all the world like bundles of exaggerated lead pencils. This is the department in which the Edison electric "tubes" are made. In these tubes is embodied Mr. Edison's method of burying the conductors underground. The tubes consist of long sections of iron pipe, into which are pulled the copper conductors that constitute part of the circuit. Around these conductors or rods manila rope is loosely served, so that when tied up together they make a neat bundle, but in no wise touch.

This bundle is slipped into the pipe, and then when several sections are ready the whole lot is plunged into the insulating compound, which is of a semi-fluid, bituminous nature, and is forced into every interstice under great pressure. With mains and feeders nearly the same methods are followed. When the tubes have been thus treated, rubber plugs are fitted into each end, and the copper conductors stick out four inches beyond the 20-foot section of pipe. The tube is now practically ready for use and abuse. It gets about as much of one as the other, and suffers chiefly from the abuse, owing to the state of the soil in which it is laid in towns and cities where horse cars and gas have had sway, and to the frequency with which modern thoroughfares are dug up or blown up. But it has wonderful powers of resistance, and hundreds of miles in New York, Boston, Chicago, Philadelphia and other cities testify to its success as a solution of what the newspapers call "the underground problem."

Well, what shall we look at next? Here is a vast, airy, well-appointed shop in which has just been begun the manufacture of the famous Siemens cables for all classes of work. Or we will stop awhile in the fine, new power house, about the size of a city central station, furnishing current all day long for the motors that drive every bit of machinery in the Works, as well as for many hundreds of arc and incandescent lamps. In this station there will ultimately be two 130 horse power, two 260 horse power, and two 520 horse power combinations of the Edison direct connected triple-expansion engine and multipolar generator, such as evokes our admiration here. The units for central station lighting and power work are growing bigger and bigger,

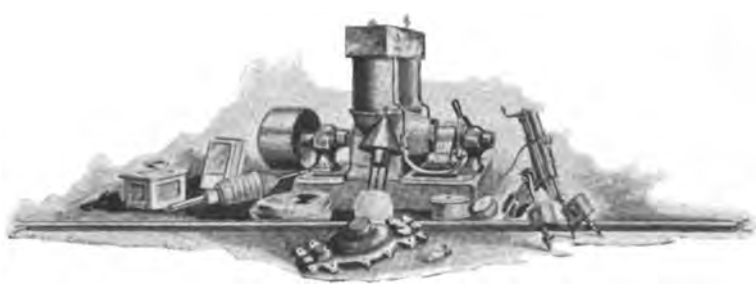
and the tendency is remarkably illustrated in this combination, already in active process of manufacture, both the engines and the generators being built at these Works, for central stations, over a wide range of sizes.

One might thus spend days and weeks observing and studying with curious eye all these details and developments. The most casual glance reveals some new process, and affords some new excuse for lingering. In one corner we chance upon a busy crowd of youngsters fixing up sample cards of wire. By and by we happen into a long gallery and there we see some very demure young ladies splitting mica, although at first glance it looked as though they were amusing themselves with newspaper scraps. Interesting, isn't it? This mica is largely from Canadian mines, and arrives in slabs about an inch thick of various sizes. These slabs are slivered into eight or ten pieces, and then laminated by the young ladies aforesaid. Laminæ one-thousandth of an inch can be obtained, for the girls are very expert and slice it up to the desired thinness with the utmost ease and certainty. They also take the little pieces, such as scraps from commutators, and paste them together with shellac or other varnish, forming sheets of any desired size. In fact, for many purposes these sheets are considered superior to the natural mica laminæ. As will be readily understood, the quality of the mica varies greatly, and hence each consignment is tested to determine that it is up to the standard. After trying a good many things, the Edison Company is quite in love with mica as an insulating material, and in many instances uses it entirely, to the exclusion of other materials, as, for instance, in making up armature bodies. In the commutators, too, mica is used, particularly the pasted sheets, which bend freely; and so securely is the whole pressed together and screwed up, it is very seldom indeed that the commutators suffer from loose or high bars.

In the Tubing Department.

A Corner of the Mica Gallery.

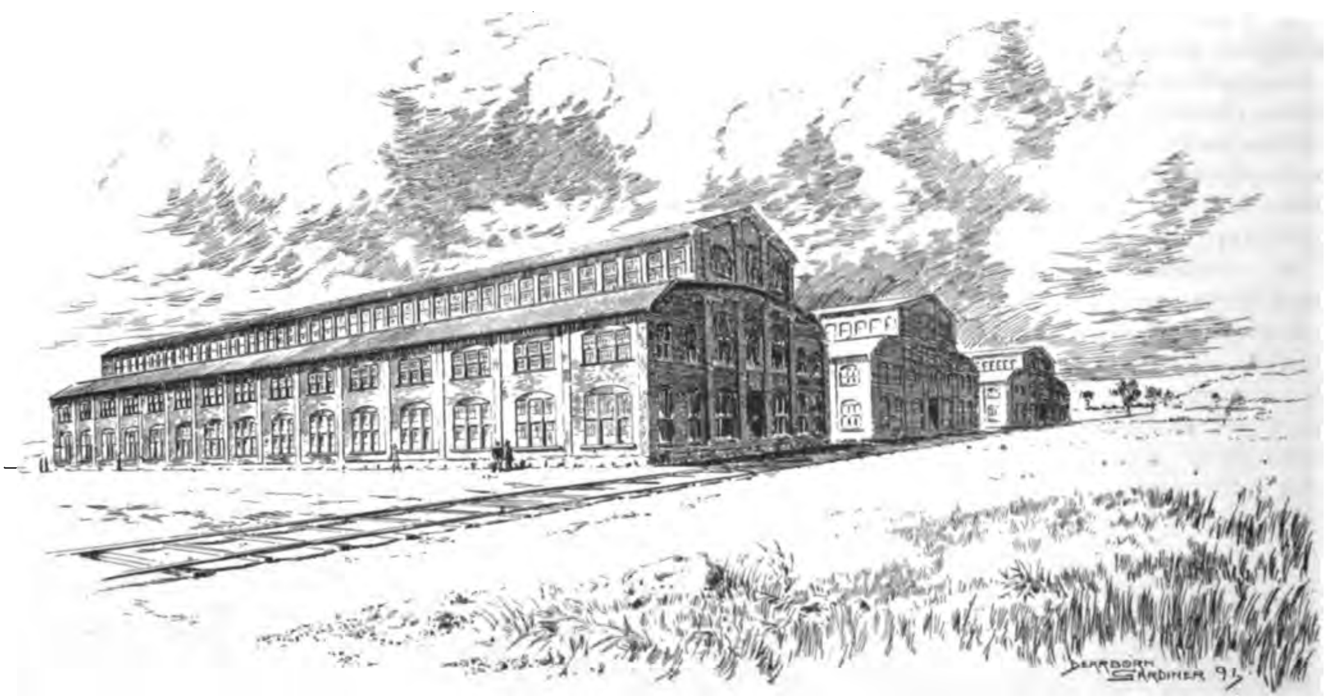
And so we lag and lag, and every time we stop the patient guide gives us notes enough to hang a dozen tales by. For here are testing-rooms for dynamos and motors; tracks for putting street cars through their paces; sections of dirigible electric torpedoes; an electric drill pounding away in a perfectly ferocious manner at the heart of a block of granite that once was proud and obdurate; wood-working shops as large as a furniture factory; suites of managerial offices as solid and imposing as those of a bank; drafting-rooms as big as a billiard hall; a fire-engine station; a locomotive hauling trains of cars all day long to and from the main railroad tracks near by; stabling, store buildings, and minor departments by the score—until at last one begs off on the plea of not being in training for the next six-day walking match, and is smilingly excused from further pedestrianism. There are many things left to be seen, and many well worthy of description, but it is not amiss to break off at a point where the physical fatigue of sightseeing comes in to deepen the impression of magnitude and power already made on the mind. Perhaps only by thus going through such enormous factories can one realize how vast has become the electric light and motor industry. "The greater lies before," no doubt, and yet as one looks back over the past decade, it does seem hardly possible that humble beginnings should have blossomed and fructified so soon in these establishments whose fame has spread through the whole world, and whose products are to be found girdling the earth with ceaseless illumination. When these Works were first projected, the incandescent lamp was treated with suspicion and scorn; but to-day electric light and electric power are alike universal in their triumph and popularity.



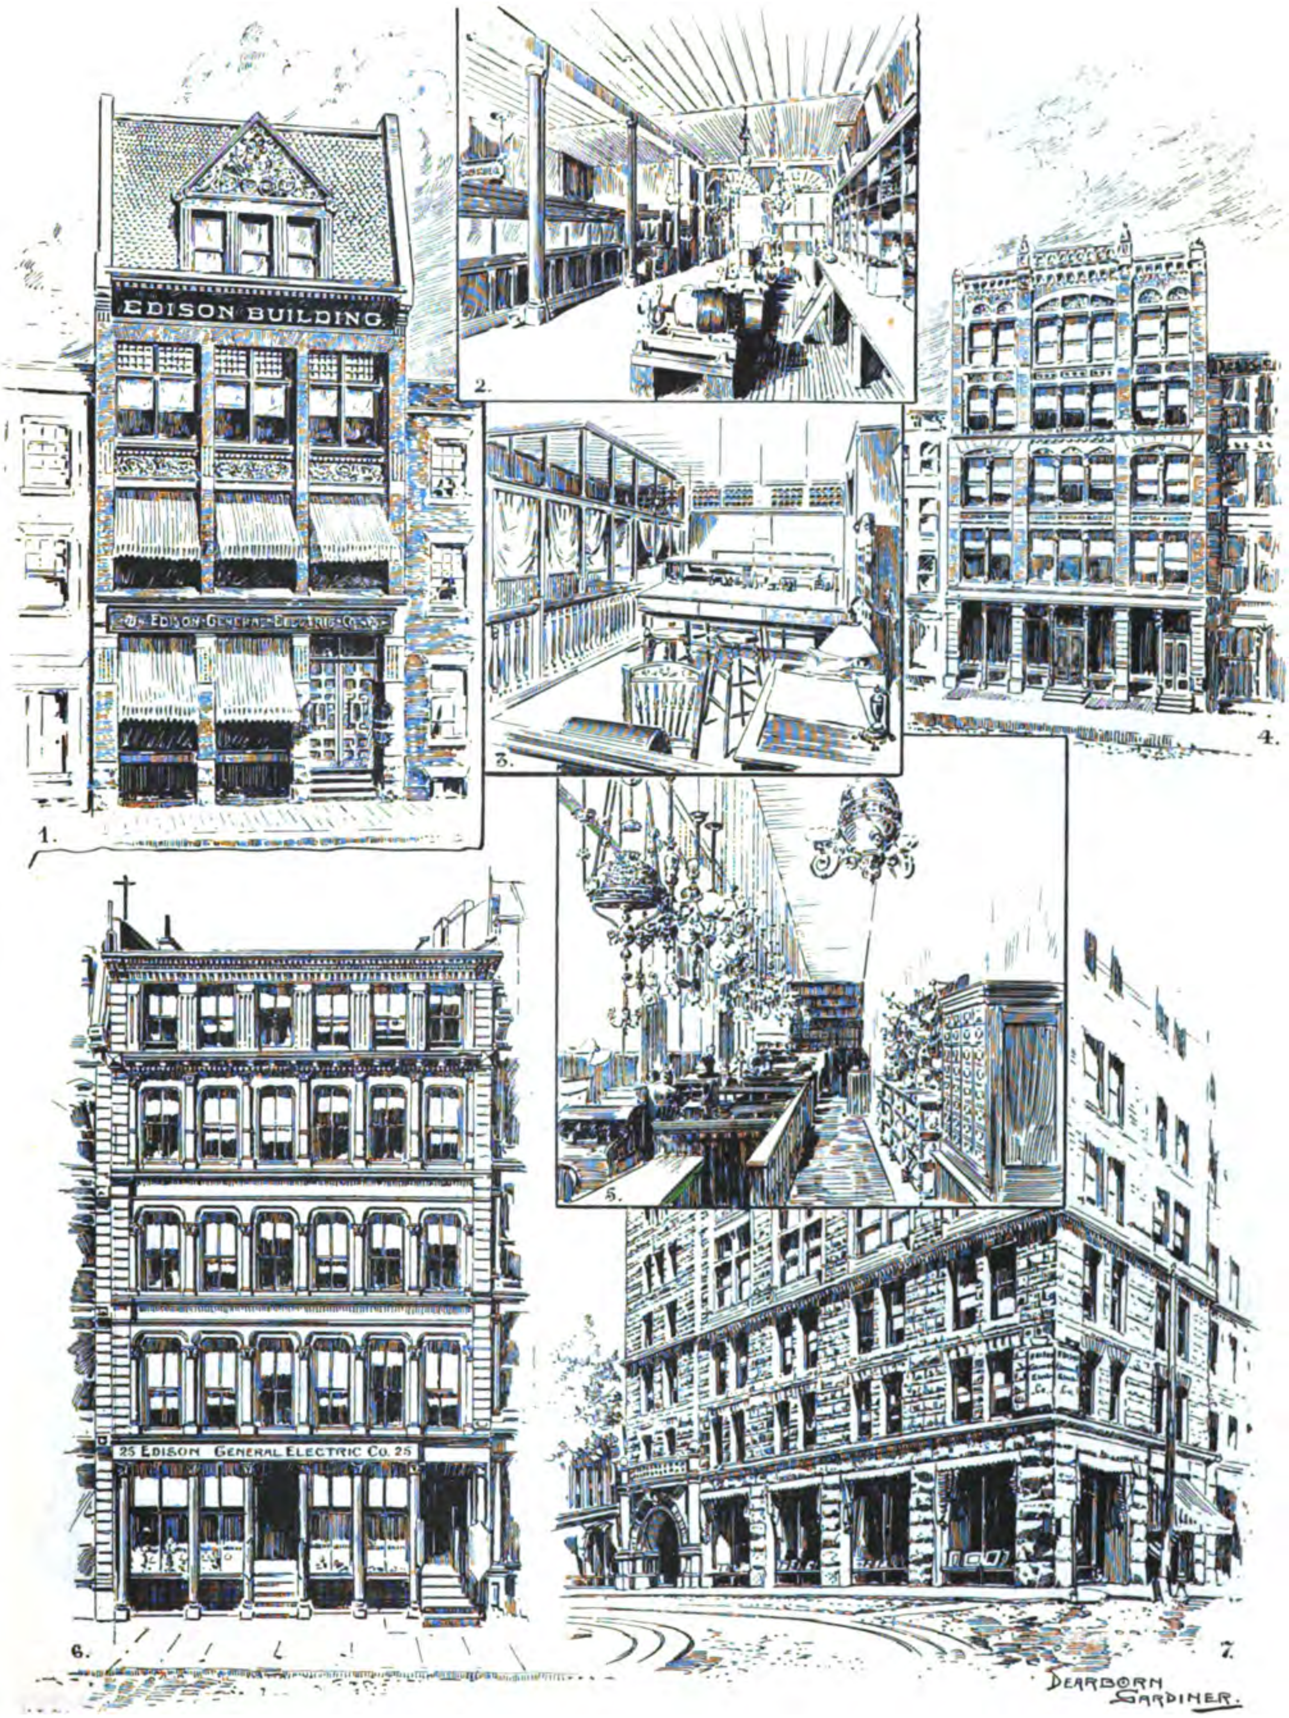
IT IS a well-known fact that Edison lamps and other electrical apparatus are now being made and used all over the world by various corporations, as the result of the exploitation of the patents secured. But in the growing Dominion of Canada, whose relationships with us are already so numerous, the Edison General Electric Co. is carrying on the business itself. From a very small beginning, with only a dozen men in February, 1888, the Company has already come to employ hundreds of skilled mechanics and is now concentrating its productive energies in a huge new factory at Peterboro, Ont. These Canadian Works are in many ways a replica of the vast shops at Schenectady. The property consists of about thirty acres of level ground, and the main building is without a doubt the finest machine-shop in the Provinces. It is 110 feet wide, 272 feet long, with a gallery of 25 feet on each side, and a central height of 60 feet. In it are employed about 400 hands engaged in the manufacture of dynamos; motors for stationary power and electric railway purposes; mining locomotives; underground conductors; various small electrical instruments and appliances; electric cables and insulated wire. When the other buildings are finished, this will be used exclusively as a machine-shop at once, and with that end in view it has already been equipped with a 10-ton traveling crane. Two other buildings, one 50 feet by 272, two stories high; and the other, 50 by 272, one story, are in course of erection, and when finished will be occupied by the wire insulating and cable department. A power station is also in process of construction, with an ultimate engine and dynamo capacity of 1,000 h. p. In the distribution of power the same methods are followed at Peterboro as at Schenectady; namely, all the power is transmitted electrically by means of underground conductors, and each shop is provided with an Edison motor to drive each main line of shafting. This mode of distributing power is at once a great convenience and a great economy, since the motors are entirely automatic and require no attention.

Main Floor, Machine-Shop, Peterboro, Ont.

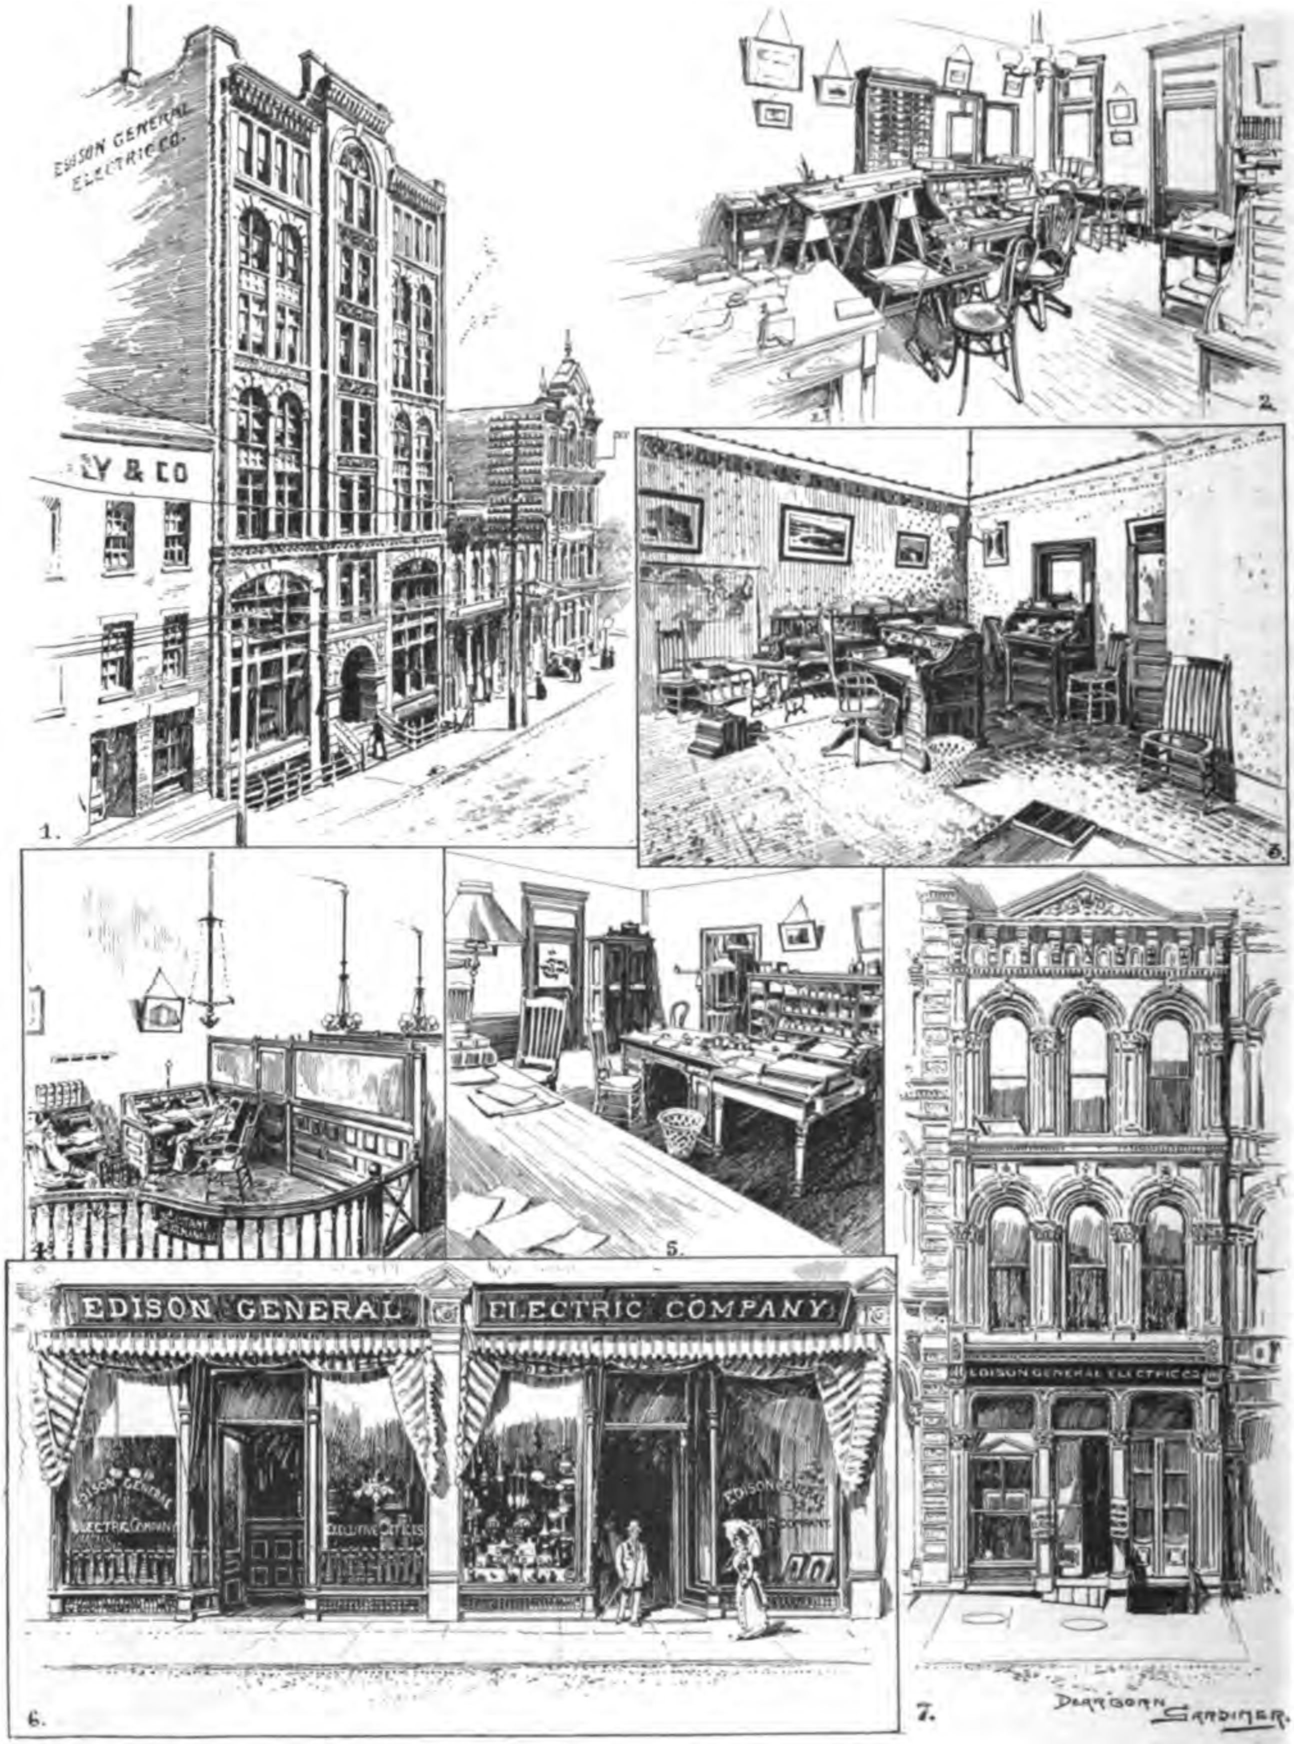
But this does not exhaust the plans. Two new buildings for the lamp factory, two for the carpenter and pattern shops, two for underground conductors, a second machine-shop, iron foundry, brass foundry, office and storehouse are already laid out, and will soon constitute an imposing suburb, with the others, to the prosperous little city of Peterboro. The Works have, moreover, direct railway connections with the Canadian Pacific and Grand Trunk Railroads. These connections are for the exclusive use of the company and unite with four tracks running parallel between the two rows of buildings throughout the entire length of the property—1,800 feet. Besides these steam railway connections there are railroad tracks connecting all the buildings, over which loaded hand-cars may be run to any portion of the establishment. The Dominion may well be proud of this addition to its manufacturing industries.



CANADIAN WORKS, PETERBORO, ONT.

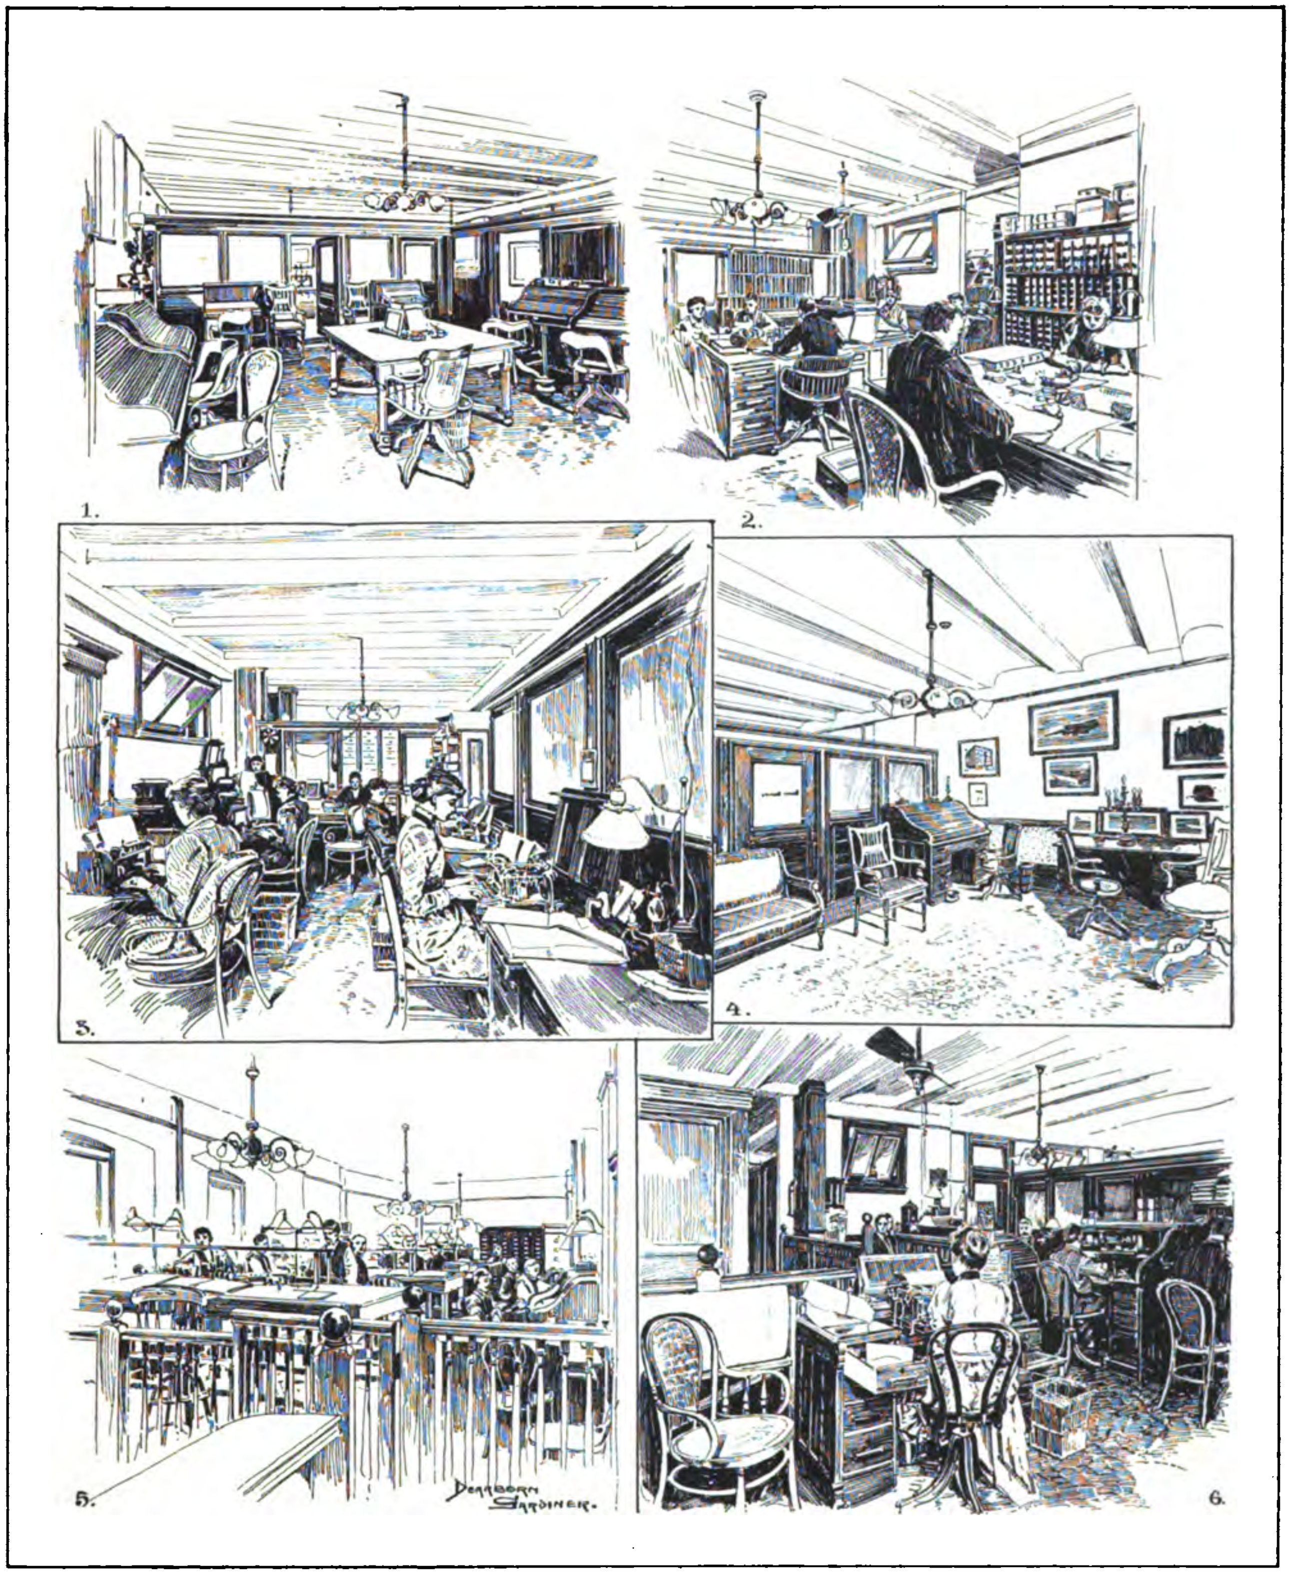


DISTRICT OFFICES: 1 & 3. TORONTO; 2 & 6. BOSTON; 4. CHICAGO; 5 & 7. DENVER



DISTRICT OFFICES: 1, 2, 3 & 5. ATLANTA; 4 & 6 PORTLAND; 7. SAN FRANCISCO

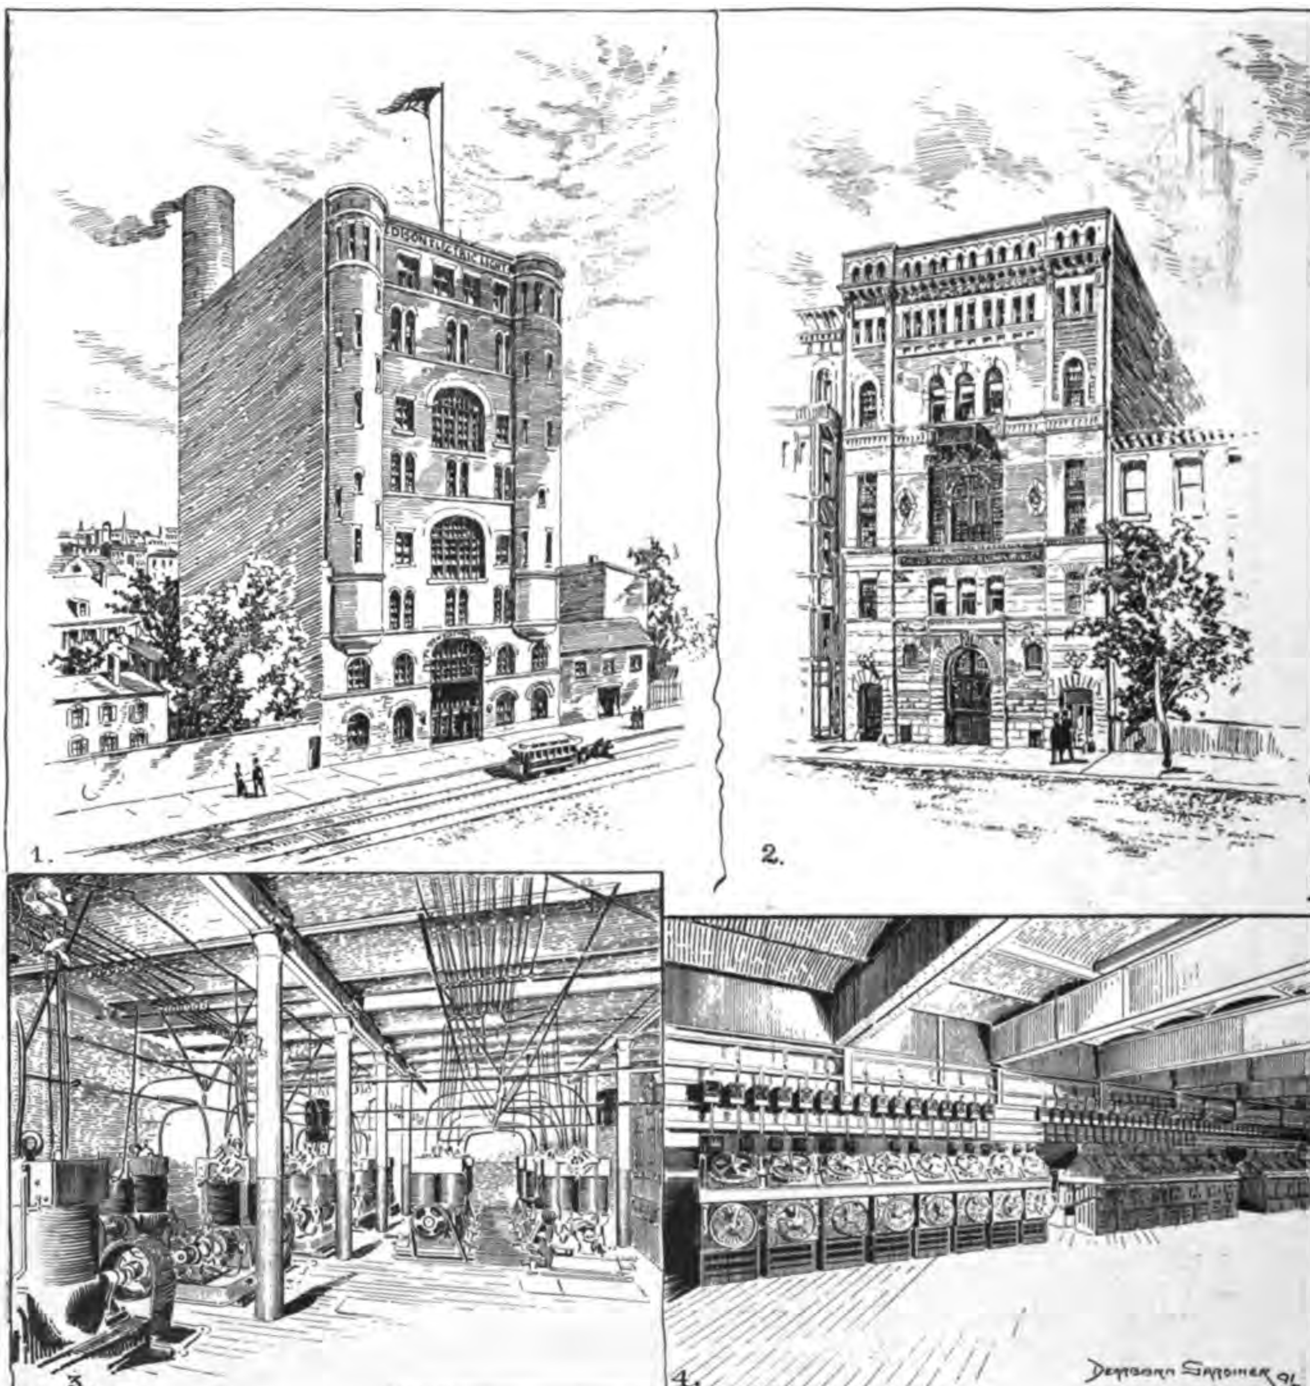
ON an earlier page of this "Survey," reference was made to the fact that the Edison light and power industries had been concentrated, and that the country had been divided up into Districts for greater convenience in handling the



GLIMPSES OF THE EASTERN DISTRICT OFFICE, EDISON BUILDING, BROAD STREET, NEW YORK.

vast business as it comes up. Of these Districts there are eight. Each District is taken care of by a District Manager who has full charge of all routine business within his territory. He has one principal office in his District, where there is an Engineering Department, an Accounting Department, Sales Department, Supply Department and Repair Shop. Depending upon the size of the District, there are a number of local agents, who carry on branch offices in various cities, but who report to the District Manager within whose territory they operate. All dealings with customers are attended to from the District headquarters; all bills are sent therefrom, and all collections are made through the District accounting offices to be forwarded to the New York central headquarters on Broad Street. The Engineering Department of each District has charge of the foremen in that District engaged in construction work, and makes up all estimates, &c. The Supply Department takes care of all renewal orders and miscellaneous supplies of all kinds. The Repair Shop takes care of all small repairs for customers within the District. concerned. Thus all work is despatched with the least possible friction or delay, and the responsibility in every case is easily determined. The District Manager is in direct touch with all the sources from which he derives instructions or supplies of any kind, and knows where to report in any case of emergency or when proposing any new line of campaign.

As will have been inferred, the District Managerships



TYPICAL EDISON CENTRAL STATIONS:—1. PHILADELPHIA; 2. NEW YORK CITY; 3. BOSTON; 4. CHICAGO.

Between the Districts and the executive offices in New York exists a close interdependence. The central authority is exercised through the Executive, Railway, General Supply, Light and Power, Accounting, Treasurer's, Fixture, Wire, Engineering, and Intelligence Departments, all of which have general control over the District Managers, in so far as the business of each department is carry with them no small burden of care. The Managers are like divisional generals actively engaged in the field, and have all the opportunities for the display of the varied ability that such positions imply. And, in fact, the amount of business to be attended to in even the smallest District is very considerable. What it is in the Eastern District can be seen by a glance at the offices of that District, occupying a whole floor in the Edison Building on Broad street. Our sketches of the other offices also show that the Company is very much *en evidence* throughout the country by means of these branches. Some of the District offices are in reality very large electrical depots, carrying in stock vast quantities of material of all descriptions. It may be added here, also, that the Company has an enormous foreign business, handled on the District plan. Part of it is disposed of at the New York headquarters, and part at the large London offices in Victoria street, Westminster.

Pioneer Edison Station.

NEXT to the District Offices as representing the great interests we have been contemplating, and, as a matter of course, far more directly known to and touching the public, come the Edison central stations. Ramified and various as the work is that we have been glancing over, it all dates back for beginning to the demonstration by Mr. Edison of the possibility and practicability of "sub-dividing" the electric light, and is primarily based upon the two new great elements, the incandescent lamp and the central station. Established at first simply to supply a certain number of lights, the central station now generates current in a wholesale way not only for illumination but for heat and power; and the same plant bids fair at no distant day to be as universal a source of supply for the modern citizen as are the great water reservoirs which pour their inexhaustible streams through countless conduits for his benefit.

Of Edison isolated plants there are several thousand, many of them reaching considerable magnitude, with a capacity of from 5,000 to 10,000 lamps, but naturally it is only in the central stations that the merits and beauties of electrical methods of furnishing current for light, heat and power become fully visible. There are to-day in America no fewer than 325 Edison central stations, prototyped in the dingy little shed at Appleton, Wis., and now exemplified by the magnificent buildings in New York, Boston, Philadelphia and Chicago, here illustrated. Such plants show to what a degree of perfection the new art has been carried, and yet are in no sense final, for even now designs are being carried out of others that will far exceed them in splendor of proportions and in refinement of engineering. Not less is this true of many of the new Edison stations for electric railway work, known more specifically by the name of "power house," and requiring many thousands of horse power for car service alone.

Nor is it simply with regard to lighting that these stations have introduced new ideas. Their supply of current for motive power brings us face to face with a new social economy. Electric motors operated from these stations, upon the self-same circuits as the lamps, are now being harnessed to every conceivable kind of work and mechanism; and the end is not yet. In due course the public will become familiar with the fact that it now has power on tap for every purpose, in the largest or the smallest quantities, at every point where it may be wanted, whether for domestic uses, for the machinery of a whole factory, or to lighten the toil of the artisan working single-handed; and the "day load" of a station will be as large as that which now represents the output of a busy night.

WIDE as the range of our survey has been, it takes in only the salient features of a great industry. We have referred but incidentally to the Edison electric railway work, whose totals of investment, mileage, cars and passengers are enormous, and whose success has already led the way in more than one city to the supercession of steam for purposes of urban travel. Then there is the important new department of mill work, as the result of which all the large factories of the near future will depend on electric power. Beyond that again awaits the vast field of electric mining, already broken into so promisingly; while back of these again are electro-deposition, electro-metallurgy and a score of other arts. But be these opportunities what they may, the record of the past and the survey we have thus cursorily made, alike tell us that they will be exploited to the full. It does not need much of the prophetic vision to see that the greatest triumphs of the Edison General Electric Company are those which still await it.

THE

Electrical Engineer.

VOL. XII. AUGUST 19, 1891. No. 172.

THE FIRST TELEGRAPH MESSAGE AND ITS AUTHOR.

THE fact that the Old Timers meet this week in Washington, with the United States Military Telegraph Corps, gives renewed and special interest to the occurrences associated with the sending of the first telegraph message from that city to Baltimore, in 1844. The story is a familiar one in its main incidents, but deserves to be retold in connection with the present interesting reunion. As early as 1838, Prof. Morse endeavored to secure the aid of Congress in the construction of a telegraph line between Washington and Baltimore, and in spite of rebuff and failure he persisted in his application, until, in 1843, it was proposed by John P. Kennedy, of Maryland, to appropriate $30,000 for a series of experiments to test the merits of the telegraph. Even then the scheme met with sarcasm from some and ridicule from others. One Congressman wanted half the sum for experiments in mesmerism. Mr. Houston suggested that Millerism was equally entitled to pecuniary aid from Congress; and Mr. John White, of Kentucky, in the chair, remarked, amid much laughter, that it would require a scientific analysis to determine how far the magnetism of mesmerism was analogous to that to be employed in telegraphs. But at last the bill passed the House and went to the Senate. There it did not encounter persiflage, but the procrastination of the slow-moving upper chamber was perhaps even more dangerous to it. The last evening of the session found it a rank outsider, with 119 bills ahead of it. Morse was a sanguine man, but the situation seemed to him hopeless. With a heart much heavier than his modest gripsack he prepared to return to New York. Meantime his old college friend, Henry L. Ellsworth, then Commissioner of Patents, was doggedly working for the bill in the small hours of the night, and at last he got it through five minutes before the adjournment, only one other measure passing after it. Next morning, March 4, Miss Annie G. Ellsworth, daughter of the Commissioner, hurried to Prof. Morse's hotel to give him the news and bear him away in triumph to breakfast with her father and mother. We can readily imagine the delight with which the despondent, incredulous inventor heard the news, and the pleasure with which he then promised the bright and winning young school-girl that she should send the first message over the wires.

S. F. B. MORSE.

(From a very rare photograph.)

A year later this promise was carried out. The line between Washington and Baltimore had been finished, and Morse had set up his instrument in the Supreme Court, in Washington, while Alfred Vail had the other at Mount Clare depot, in Baltimore. Miss Ellsworth now gave Morse the message suggested to her by her mother, "What hath God wrought," and that wonderfully apt sentence—a genuine inspiration—was sent in triplicate to Baltimore. *It was the first message ever transmitted by a recording telegraph.* The message with Prof. Morse's endorsement is here shown in full, in fac-simile, from the original as preserved by Miss Ellsworth, now Mrs. Roswell Smith, wife of the president of the Century Co. A duplicate of it is in the possession of the State Historical Society at Hartford, Conn.

Through the courtesy and assistance of Mr. W. W. Ellsworth, the secretary of the Century Co., we are enabled to accompany this brief account of two very dramatic and memorable incidents by portraits of the participators in them. The engraving of Mrs. Smith has been made from an admirable miniature on ivory, painted at the time of these occurrences in Washington. In view of her early association with the telegraphic art and her ardent interest in Morse's success, it seems to us that the Old Timers could not do a more graceful thing during their present meeting in Washington than to toast Mrs. Smith and elect her an honorary member of their organization.

ANNIE G. ELLSWORTH, NOW MRS. ROSWELL SMITH.

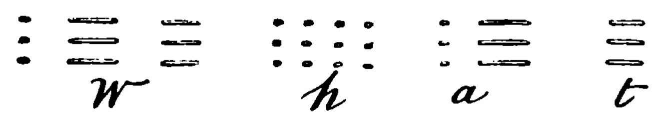
(From an ivory miniature painted about 1844, by Freeman).

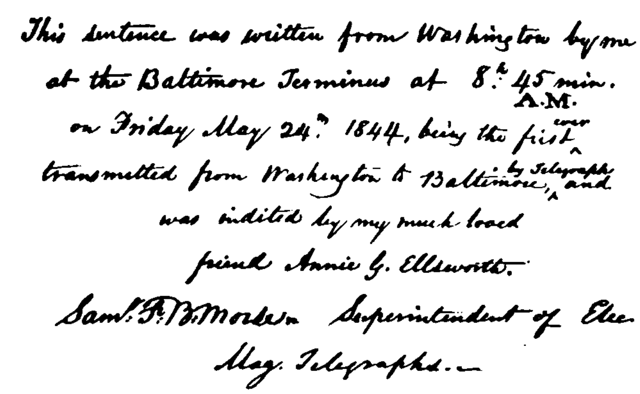
A word or two about Mrs. Smith's father, the Hon. Henry L. Ellsworth, will not be out of place. He was of New England birth, twin brother of the Hon. W. W. Ellsworth, at one time chief justice of Connecticut, and son of Oliver Ellsworth, third Chief Justice of the United States. He graduated from Yale College as a member of the class of 1810, and it was there that he made the acquaintance and friendship of Morse, who was his classmate. After farming at Windsor, Conn., and practicing law at Hartford, he was appointed a commissioner to the Indian tribes of the Far West by President Jackson, who later made him the first Commissioner of the U. S. Patent Office. This office was created in 1836, and he was its incumbent until 1845, when he resigned. Prof. Morse was extremely fortunate in having such a man as a personal friend, for Mr. Ellsworth was not only distinguished by birth and culture, but by great energy and executive ability. While to-day it might seem a little singular to have the head of the Patent Office actively lobbying on the floor of the Senate for a struggling inventor, there can be no doubt that his action at that time was considered entirely free from impropriety, and that but for his zealous work during the crowded closing hours of the session the introduction of the telegraph might have been deferred many years and Morse might have suffered the fate of many other deserving inventors.

HENRY L. ELLSWORTH, AS A CLASS MATE OF MORSE, AT YALE.
(From a miniature on ivory).

HENRY L. ELLSWORTH, FIRST U. S. COMMISSIONER OF PATENTS.
(From an old daguerreotype).

This act of friendship to Morse was not the only public service of this talented man. As already mentioned, he dealt with the difficult questions connected with the relationship between the Government and the Indian tribes, and his attitude toward "Poor Lo" may be gathered from the fact that Washington Irving accompanied him on one of his tours of investigation. As the first head of the Patent Office he did magnificent work in organizing the new Agricultural Bureau, that has since developed into a great department, represented in the President's Cabinet. He was one of the earliest to recognize the value of, and to invest in, the prairie lands of the West; and it is believed he used the first mowing machine introduced there. But while, as has been said, "the patience, enthusiasm and industry of Mr. Ellsworth in this work entitle his name to the grateful remembrance of the American farmers," it is not less true that his disinterested support of the great inventor in the hour of trial must ever secure for him, with his daughter, a warm place in the affection of the telegraphers of America. It is with no small pleasure that the editors of THE ELECTRICAL ENGINEER present in this issue these portraits, now published for the first time, and tell again, though briefly and inadequately, the ever memorable story of the first message.

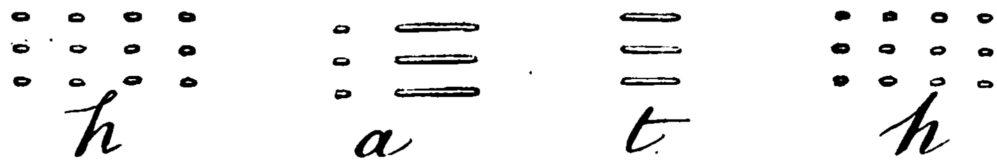




This sentence was written from Washington by me at the Baltimore Terminus at 8h. 45 min. A.M. on Friday May 24th 1844, being the first ever transmitted from Washington to Baltimore by Telegraph, and was indited by my much loved friend Annie G. Ellsworth.
Saml. F. B. Morse Superintendent of Elec. Mag. Telegraphs.

FAC SIMILE OF FIRST MESSAGE, NOW IN POSSESSION OF MRS. ROSWELL SMITH.

With regard to the portrait of Morse, it may be stated that it is taken from a very rare photograph in the possession of F. W. Jones, Esq., of the Postal Telegraph Co. The familiar portraits of Morse show him much later in life, with a full, flowing beard.



THE WORK OF THE U. S. MILITARY TELEGRAPH CORPS.

BY

Madison Buell

I.

TO what and to whom can the greatest credit be given for the favorable termination of the civil war?

Setting aside the military skill of the commanders of our armies and the bravery of the men who composed them, a close observer of the events of the war can only come to one conclusion—that steam and electricity, and the men who manipulated them, were the greatest factors, and that without them the destruction of the Union would have ensued.

At the time of the attack on Fort Sumter, in 1861, the entire military force of the Government was some 16,000 regulars, principally employed in the West to hold in check marauding Indians. The first call for troops by the President was for 75,000 men; the second call, in May, 1861, resulted in bringing into the field, by July 1st, over 230,000 men, and on the 1st of December, 1861, the entire strength of the army, both volunteers and regulars, was 660,970 men. Steam and electricity were the great agents utilized for the gathering, concentration and distribution of this army of unparalleled magnitude, and the enormous supplies necessary for its subsistence, and in no other way could it have been done in so short a time.

It was the telegraph that bound the loyal States together and stimulated civil and military authorities to greater exertion by the almost limitless contributions of men and money. It was in truth an electric nerve that united them, consolidated their power, inspired them with courage and hope and *and finally led them to victory.*

As an illustration of the marvelous facilities of steam and electricity as the great saving factors in the war, let us take the battles of South Mountain and Antietam. During the battle of Antietam the following message was sent to Halleck, at Washington:

Please take military possession of the Chambersburg and Hagerstown railroad that our ammunition and supplies may be hurried up without delay. We are in the midst of the most terrible battle of the war—perhaps of history. Thus far it looks well, but I have great odds against me. Hurry up all troops possible. Our loss has been terrible, but we have gained much ground. I have thrown the mass of the army on the left bank. Burnside is now attacking the right. I hold my small reserve, consisting of Porter's Fifth Corps, ready to attack the centre as soon as the flank movements are developed. I hope that God will give us a glorious victory. GEO. B. MCCLELLAN,
Maj.-Gen.

A mental photograph of this incident, taken at the time, would reveal in the telegraph office of the War Department at Washington the faithful military telegrapher at his instrument; and standing within hearing of the "click, click" of its armature, Lincoln, Stanton, Halleck, Eckert and others with their hearts beating rapidly. We can see them even now, men of wisdom, men of action, men pale with care, and men weary with the burden and responsibilities of a nation's welfare. All is hushed—the silence is like nightfall, broken only by the mournful beats of the instrument's armature, as if in sympathetic realization of the dreadful import of its magical sound waves. "We are in the midst of the most terrible battle of the war—perhaps of history." The head and advisers of a great nation endowed with such a range of vision as to enable them by the aid of the strange and "fierce electric fire," drawn as it were from the edge of a midnight storm, almost to see the battle's progress and hear the cannon spit out their iron wrath!

The evening's gray twilight descended upon the battlefield with its twenty thousand ghastly dead and wounded, and the telegrams were deluged with the tears of the mothers and wives of the slain and wounded. You could almost hear the heart's anguish ooze out of the words as they were recorded. Instead of the peaceful orders for daily wants as now, they were like the following telegram sent the night after the battle of Antietam.

To the Chief of Ordnance,
Washington:

If you can possibly do it, force some twenty-pound Parrot ammunition through to-night, via Hagerstown and Chambersburg, to use near Sharpsburg, Md. GEO. B. MCCLELLAN,
Maj.-Gen.

Let the mind grasp the incident for a moment—a general, after a day of bloody battle, surrounded by his killed

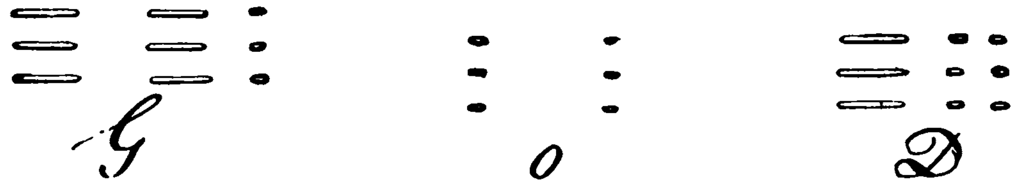
WITH GEN. MCDOWELL.

(From an Old Engraving).

and wounded, writes his telegram and orders his deadly supplies for the morrow's battle with as much assurance as we now order our daily marketing by the same means. Do not the two telegrams of McClellan furnish a wonderful amount of mental food for digestion and reflection in the way of illustrating the fact that steam and electricity were the saving factors of the Union?

II.

But what of the men—the bone and sinew of the whole military telegraph system? Twenty-five years or more ago they presented a long line of rippling glory for deeds



of bravery and faithfulness. To-day few are living—the rest—

> "On Fame's eternal camping-ground
> Their silent tents are spread;
> And Glory guards with solemn round
> The bivouac of the dead."

Some one has said that the world knows nothing of its greatest men; and that there are forms of greatness, or at least excellence, which "die and make no sign;" heroes without the laurel, and conquerors without the triumph. This is strictly applicable to the men who composed the U. S. Military Telegraph Corps from the date of its origin up to the present time.

The formation of the United States Military Telegraph Corps, in 1861, might readily be termed a meteoric electrical aggregation of men, beginning as it did under such men as the late E. S. Sanford, of the American Telegraph Company, and the late Col. Thomas A. Scott, of the Pennsylvania road, and Andrew Carnegie at its head, with young David Strouse as its first superintendent.

This aggregation, starting with those named, and D. Homer Bates, W. J. Dealy, James R. Gilmore, Madison Buell, Richard O'Brien, Jesse H. Bunnell, C. A. Jacques, H. W. Benton, Wm. Tinney, W. B. Wilson, Jesse Crouse and others as telegraphers, gradually increased at Washington, the West, and Southwest, until, at the close of the war, there was gathered a body of men unsurpassed for skill, and bravery, and faithfulness, who to this date have not received from the Government any official recognition of the invaluable services rendered as great and undisputed factors in the preservation of the Union. The remnant of the brave corps are still besieging the doors of Congress with olden-time vigor for the just recognition of a military status at the time of their service. So far it has been denied, and yet Congress could manage in ten years to increase the pension appropriations from $50,000,000 to $124,000,000. For military telegraphers of the civil war "republics are ungrateful."

The first superintendent of this corps was young David Strouse, who went to Washington with Col. Scott and Andrew Carnegie.

Young Strouse (peace to his ashes) so taxed his energies during the first part of the war that at the end of six months his life's work was done. David Strouse entered upon the scenes of the war impelled by the highest sense of duty to his country; he was found equal to its weight, and did it worthily. "Command was service; humblest service done by willing and discerning souls was glory," and David Strouse obtained it.

Of Andrew Carnegie, the messenger boy of the early days of telegraphy, and now the great iron king and millionaire, what can be said of him that has not already been published in a thousand and one forms?

Those who were so fortunate as to meet him in the early days of the war can now walk "along the pebbled shore of memory" and build up, at pleasure, their recollections of the events and his association with them.

III.

It is impossible to give in a short description even a faint conception of the character of the men who first organized the Military Telegraph system. Col. E. S. Sanford, president of the then American Telegraph Co., supplied money and material nearly a year for its support and maintenance. For its more perfect organization, however, the credit belongs solely to two men, the late Gen. Anson Stager and General Thomas T. Eckert, now General Manager of the Western Union Telegraph Co. Gen. Stager was appointed Captain and A. Q. M. of Vols. 11th of Nov. 1861, and Thomas T. Eckert received an appointment as Major and A. Q. M. July, 1862. Gen. Stager's headquarters were at Cleveland, Ohio, and Major Eckert was assigned to the Department of the Potomac. The value of the Military Telegraph was in a way recognized by Secretary Stanton in his official report to Congress Dec., 1863, as follows: "The Military Telegraph, under the general direction of Col. Stager and Major Eckert, has been of inestimable value to the service, and no corps has surpassed, few have equaled, the telegraph operators in diligence and devotion to their duties."

At the fall of Richmond, April 3, 1865, after announcing the fact, from the office window of the War Department, to the assembled multitude beneath, Secretary of War Stanton turned to the operators in the room and said: "Boys, I consider the telegraph my right arm, and if ever I can do anything for you, don't hesitate to ask it."

It is now August, 1891; the "boys" are still besieging Congress for a recognition. They have followed Stanton's advice, "don't hesitate to ask." The "boys" are still asking, and are sadly realizing "With what a heavy and retarding weight does expectation load the wing of time."

In June, 1864, Eckert's field telegraph was a marvelous success. Superintendent Doren built and took down an average of twenty five miles a day. All corps headquarters and many brigades were kept in constant communication with Grant's and Meade's headquarters during every engagement. Every reconnoissance made in force had telegraphic connection with headquarters, and yet notwithstanding the acknowledged vital importance of the Military Telegraph on every occasion, the "boys" are still following Stanton's advice, and are knock, knock, knocking at the Uncle Sam's bronze doors of the Capitol.

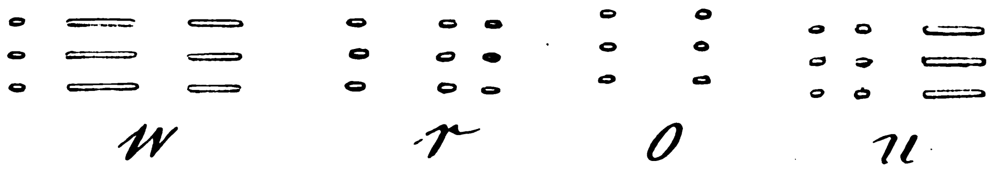
The Comte de Paris in his history of the Civil War says:

> "A single example will show the importance of the Military Telegraph. Without counting the lines in existence of which possession was taken, the employees of the Government constructed five thousand kilometres during a single year of the war, and they forwarded nearly one million eight hundred thousand despatches; and sufferings and dangers were not spared those whose merit was the greater in that it was less conspicuous. More than one among them, shivering with fever in an unhealthy station, lay down with his ear against the instrument to write with a trembling hand under dictation some important despatches, whose secret he would confide to no one. Many paid with their lives for their boldness in setting up their instruments under the very fire of the enemy, and one fact, almost incredible, bears testimony to the dangers to which they were exposed. During the siege of Charleston the wire which connected the besieging batteries ran so close to the rifle pits of the Confederate skir mishers that it was frequently cut by their balls."

IV.

It has been described how McClellan relied upon the military telegraph at the battle of Antietam, and perhaps another illustration of its immense value will prove interesting as well as instructive, bringing in as it does President Lincoln and Gen. Hooker, in conversation over a wire at a critical time in the affairs of the nation.

Lee's victories on the Rappahannock in 1863 produced in his army a spirit bordering on enthusiasm, and it was in better discipline than ever. Their commissary department was, however, in such a deplorable state that supplies were



an absolute necessity, and Lee determined to strike Pennsylvania. In less than two weeks he drew Hooker's army away from the Rappahannock to the upper Potomac. On his way Lee cut all the telegraph lines which connected Washington with Winchester and Martinsburg, and their loss was a serious one.

D. H. Bates.
(*From a War Time Photograph*).

The Washington authorities, as usual, were anxious about the safety of Baltimore and the capital. In the conversation that took place over the wire between Lincoln and Hooker, the former remarked: "If the head of Lee's army is at Martinsburg and the tail of it on the plank road between Fredericksburg and Chancellorsville, the animal must be very slim somewhere. Could you not break him?" Hooker replied, "that to proceed to Winchester and have him make his appearance elsewhere would subject me to ridicule."

Honest Lincoln! How shall we ever separate the fine silken threads of feeling and loyalty that were woven in your character from the fabric of quaintness and jest, or even know where one ended and the other began? I shall never forget the time in the War Department office when little Tad Lincoln stuck his fingers in the ink and walked down alongside the row of marble tables upon which our instruments were, and rubbed ink all over their tops as he went along. The writer seized him by the seat of his little pants with one hand, and with the other his collar, and walked him Spanish fashion back to the door. It suddenly opened and we were confronted by his father. It was a regular surprise party and no mistake. Mr. Lincoln looked at the writer, and the latter held up little Tad's bedaubed fingers and pointed to the marble-top tables. Lincoln burst out laughing, and taking the little youngster up in his great, long arms and hugging him closely to his breast, left the room with a jolly laugh and on a run down the hallway of the Department.

All offices of the Military Telegraph, however, did not have marble-top tables—quite the contrary, as Manager Dealy, of the W. U. Tel. Co., New York office, can testify. No doubt he often contrasts his present quarters with those he occupied near Darnestown, Md., in 1861—a pigsty—gorgeous in all its slime and filth, roofed in by blankets for protection against rain and cold.

V.

Every man in the Military Telegraph Corps from the Department of the Potomac of the extreme Southwest had within him that "independent spark from Heaven's bright throne"—courage—which enabled him to do his duty under the most trying circumstances. Some one has said that the brave man is not he who feels no fear, which would be stupid and irrational; but he whose noble soul its fear subdues, and bravely dares the danger nature shrinks from—and in confirmation of it, let me give one or two illustrations:

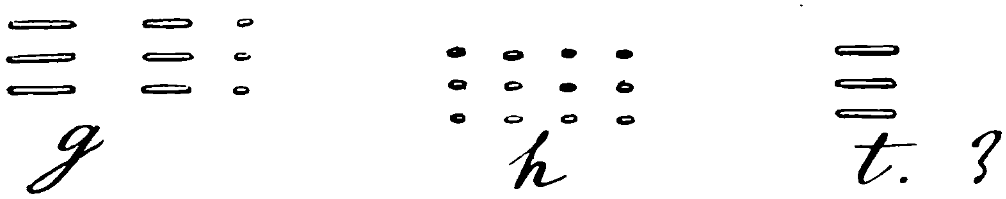
The battle of Mechanicsville was fought June 26, and that of Gaines' Mills, June 27, '62 Jesse H. Bunnell was the military telegrapher with Gen. Porter, and during the retreat lost his way. Porter falling back, formed in line of battle near a telegraph line, which vital fact Bunnell discovered in trying to get back to the right road.

Bunnell cut the wire, connected his instrument, sat down by a tree, called up McClellan's headquarters, and the ever-faithful telegrapher Caldwell answered.

It is well known that to be a great man it is necessary to turn to account all opportunities, and McClellan did so. Bunnell was furnished with mounted orderlies, and for hours he sent and received messages as to the progress of the battle. Plum in his admirable history of the Military Telegraph tells of this heroic incident and also of that of young Nichols; and let me say here that this invaluable book should be in the hands of every telegrapher in the country. They would then know the kind of material early telegraphers were made of.

A. B. Chandler.
(*From a War Time Photograph*).

Bunnell sat behind the tree, and "the roar of contiguous cannon, the crack of musketry, the Federal cheers and Confederate yells, added to the bursting of unnumbered



over-shot shells, and the zip-zip of bullets and the solid shot crashing through the trees," were not favorable to telegraphing by ear, but Bunnell was one of the best telegraphers in the country, although in his teens.

Several times Porter telegraphed for reinforcements. Longtreet and Hill were not easily shaken off. At 2 P. M. Porter telegraphed for aid, and Slocum's forces came across the river. An hour later other troops were crossed to the rescue; though Porter now had 35,000 men, he was hard pressed. At four o'clock Jackson had come to help Hill and Longstreet. Then Ewell fell upon Porter. The carnage was awful. It seemed as if nothing human could withstand it. Bunnell's orderlies were brave fellows. Several of the messages he handled were spattered with their blood, and he was obliged to forward his telegrams to Porter by two or three couriers, as several were shot on their way.

More troops were required and more answered the telegraphic call. McClellan was fighting the battle by telegraph.

Bunnell's action is no bright and illustrious illusion. It was an occasion which called forth the utmost power, vigor, and activity of the nature of a beardless youth. It was an act of heroism which showed a noble soul, subduing fear and bravely daring the danger which nature shrank from.

Is it a marvel that McClellan appreciated the Military Telegraph? Is it a wonder that Stanton considered the telegraph his right arm.

It is a great pity that some of Bunnell's telegrams, bespattered with the blood of his messengers, could not be placed upon the desks of the members of Congress as souvenirs—a sort of bloody reminder of the claims of telegraphers.

VI.

The other incident is also told by Plum:

Telegrapher Nichols, with Gen. Sumner during the retreat from Seven Pines to Harrison's Landing, opened an office at the top of a telegraph pole, which Gen. Wilson and himself constructed out of hardtack boxes piled one on top of the other. Cutting in on the wire, Nichols maintained communication with McClellan for hours after dark. To see to write he had a lantern, which made an excellent mark for the enemy, notwithstanding which he kept the office open till ordered closed by Sumner.

It was a critical and dangerous position, and Nichols was only another illustration of a soul that "bravely dares the danger nature shrinks from."

VII.

If the telegraphers showed courage and bravery in the field, others who were not there during the whole period of service performed their service—their duty—to the Government just as faithfully as though they had stood in the front rank of battle. Eckert, Bates, Chandler, Tinker, and others were shining examples of the men who were at Washington, struggling with difficulties that those in the field little knew the anguish required to surmount.

"In a fair gale every fool may sail, but wise behavior in a storm commends the wisdom of a pilot," and Major Thomas T. Eckert, who was at that time manager of the Military Telegraph for the Department of the Potomac, could be said to be the pilot who gave out his energy in proportion to the resistance it met. He took control at a time when everything had a gloomy and terrifying representation. His position was delicate and difficult. He introduced new ideas and greatly enlarged the scope of the system. Aware of the toil and hardship to be endured and the blood likely to be shed, he gave words of hope, confidence and commendation to his men. His great ability, ardent zeal and patriotic devotion seemed to cover and penetrate the system of every man within the department, and one might figuratively say, with truth, that the mountains, hills, rocks and glens of difficulties were swept away by that spirit of "enthusiasm which, like the leaping lightning, is not to be measured by the horse-power of the understanding.'" These are not sycophantic words, but impressions of memory "that dance without wages or compulsion."

GEN. T. T. ECKERT.
(From a War Time Photograph).

Naturally, Major Eckert relied upon the skill, judgment and fidelity of his men both in the field and at his own headquarters for the carrying out of his own ideas and the execution of his plans. At the end of the war their devotion, fidelity and courage proved to him that they had made for him and themselves "a name and place among the nations of the earth," with this exception, however, the name shines so brightly as to make the shadow so deep that the Congressional eye in America has not been able as yet to penetrate beyond the shadow. D. Homer Bates, A. B. Chandler, Chas. A. Tinker, Dennis Doren and others were men who were possessed of an energy and a perseverance that were as remarkable as great. There was but one sentiment prevalent among them, a stern and unrelenting determination to do all in their capacity to secure such success. They did their work well and without a thought of fame.

VIII.

What has been said applies equally to the men comprising the whole Corps, for those spoken of fitly represent the body. After four years of arduous service, through the East, South and Southwest, a period marked by courage and fortitude, unsurpassed even by the soldiers in the field, the noble band of men returned to their homes without a single word of official recognition, save in one instance. Gen. Eckert, as Assistant Secretary of War, presented to Messrs. Bates, Tucker, Chandler, Caldwell, Doren, Baldwin, Stewart, O'Brien, Sheldon and Buell, as souvenirs from the War Department, silver watches that had been purchased and used to establish uniform time in the Army of the Potomac, marked "United States Military Telegraph."

This recognition was given to these few of the most prominent men in the Department of the Potomac.

Outside of this and some words of appreciation and commendation, no other recognition has ever been given.

All that remains to the surviving members of the Corps, they who linger yet awhile for "Death—the black camel which kneels at the gates of all"—is the sweet satisfaction that comes from the consciousness of duty faithfully performed.

ELECTRICAL ENGINEERS.

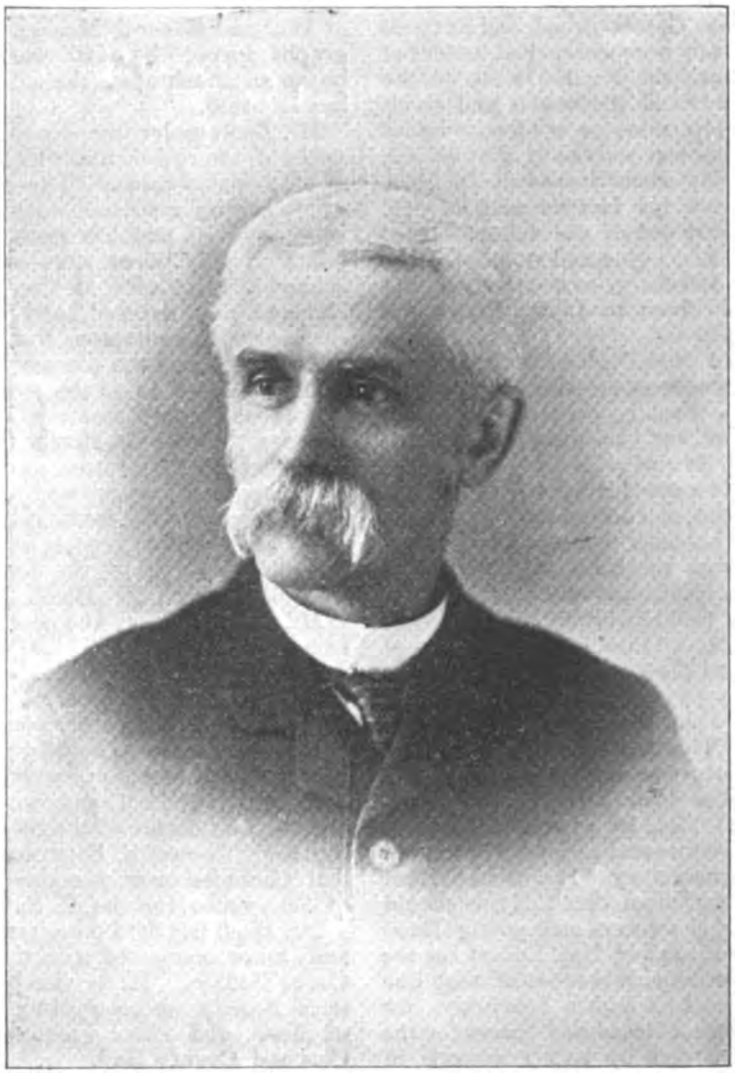
MADISON BUELL.

Madison Buell, one of the oldest telegraphers and electricians in the world, in point of years of service, was born at Lebanon, Conn., July 31, 1834. His experience as a telegrapher is almost as old as the invention itself, for it was only seven years after Morse patented his invention that Mr. Buell entered as a messenger boy the Buffalo, N. Y., office of the New York, Albany and Buffalo Telegraph Company, the first business telegraph company established.

The Buffalo office was opened in the basement of the Mansion House July 3, 1846, and Mr. Buell entered the office in February, 1847. After serving a few months as messenger, he learned the art of telegraphy upon the cumbersome machinery in use at that time. The lever of the register had three steel points for embossing the Morse characters upon the paper. A bell was attached to the side of the register which would ring whenever the clock-work of the register revolved, the latter being set in motion by the movement of the armature of the magnet in response to distant signals.

The relay magnets in use at that time were enormous affairs; one was composed of eight coils four inches in diameter and about ten inches long, of about No. 18 cotton-covered wire saturated with gum shellac. It weighed nearly one hundred pounds. During lightning storms the armature frequently stuck to the iron core of the magnets, and the office ruler was generally used to pry the armature off the cores of the magnets.

Mr. Buell's progress in telegraphy was so rapid that in the month of November, 1847, he was the operator at Niagara, C. W., now Niagara-on-the-Lake; and in 1849 was operator at Niagara Falls, N. Y.



MADISON BUELL.

As a pleasing incident in his early telegraphic life, he remembers enjoying there the almost constant companionship of Henry Clay, the great Whig statesman, who, after seeing him transmit his telegrams for Lexington, Ky., would take him by the hand and they would go over to Goat Island together. The eminent statesman would, after reaching the rapids between the first Sister Island and Goat Island, change his clothing, the young telegrapher doing the same. Ropes were then tied around their bodies and the ends attached to the trees on Goat Island, and hand in hand the two would wade across the rapids between the two islands. The water was remarkably low, about six or ten inches in depth. After returning to Goat Island, Mr. Buell distinctly remembers following Mr. Clay under the beautiful cascade that falls between these two islands, both reaching by this novel passage the first Sister Island.

From 1849 to 1857–58 Mr. Buell was connected with the New York, Albany and Buffalo Telegraph Company, and was chief operator at Buffalo for the Western Union Telegraph Company on the Eastern division.

At the breaking out of the war, in 1861, Gen. E. S. Sanford, president of the then American Telegraph Co., at New York, wired him to come on and go with him to Washington in connection with telegraphic service for the Government. Baltimore being in the hands of the rebel mob, the two men were compelled to take the steamer "Maryland" at Perryville, Md, and go to Washington via Annapolis. At Washington he found Andrew Carnegie in charge of the railroads and telegraphs, under the direction of Thomas A. Scott, of the Pennsylvania Railroad Co. Mr. Buell remained on duty in the War Department office until just previous to the movement of the army across the Potomac into Virginia, when he was assigned for duty with Capt. Carlisle, of the regular army, whose headquarters were at the important post of Long Bridge.

After the army moved across the bridge into Virginia, in May, 1861, he was assigned for duty with Gen. Irwin McDowell at Arlington Heights, and again with Wilcox and Heintzelman at Alexandria, Va.

The day before the battle of Bull Run, July 21, 1861, he was ordered to Fairfax Court House as telegrapher for Gen. McDowell, opening communication with McDowell's army by a line of mounted couriers from Fairfax Court House. After McDowell's futile efforts to stay the defeat of his army, and the major portion of his army had retreated by way of Fairfax Court House, the General and his staff, escorted by a company of cavalry, halted in front of the military outpost about 3 o'clock Monday morning, July 22.

McDowell seated himself alongside of young Buell and began writing messages to the Secretary of War and Lieut. Gen. Winfield Scott, while his Adjutant General, Capt. J. B. Fry, sank on the floor, and resting his head on the General's knee, fell asleep. They had been in the saddle over forty-eight hours and both men were thoroughly exhausted. As fast as McDowell wrote his messages, young Buell transmitted, word by word, following every movement of the pencil. McDowell was so worn out mentally and physically that he fell asleep with pencil in hand, so that Buell was compelled frequently to nudge and arouse him with "What next, General, they are waiting for you?"

The scene at this early hour in the morning was an impressive one; the straggling army in full retreat, Capt. Fry and the rest of the staff stretched upon the office floor, and Gen. McDowell, with a bullet hole through the crown of his cap, resting his head upon the office table, and only arousing when spoken to or when the click of the telegraphic instrument had ceased.

This was the scene at Fairfax Court House, but what occurred in the office at the War Department can be learned from the vivid description of the thrilling scene in Plum's History of the Military Telegraph.

In May, 1862, young Buell was ordered by Col. Stager to Strasburg, Va., with a locomotive and telegraphic supplies for the military line in the Shenandoah Valley. The trip was made on the Manassas Gap Railroad, and at times the engineer, fireman, and Buell were compelled to crawl on their hands and knees into the tender to escape the bullets of the guerillas who infested the woods and stealthily fired upon passing troop-trains or wildcat engines passing over the road. He had just arrived at Fort Royal, intending to remain over night, when Stonewall Jackson, the Confederate General, made his famous raid on Gen. Banks, driving the latter's army out of the valley. Buell succeeded in escaping with his engine and supplies. His brother Henry, stationed at Strasburg, was captured and carried to Richmond and confined in Libby Prison for months.

After McClellan commenced the "Peninsular Campaign" telegraphic communication was kept up with his army by the lines running north from Washington to Wilmington, Del., and thence over the military telegraph line which was built in February, 1862, down the Delaware railroad to Salisbury, Md., and on the turnpike by way of Drummondtown to Cherrystone Inlet, and across the Chesapeake Bay via a 28-mile submarine cable, which was at that time the longest in America. From the time that McClellan began his operations upon the peninsula until the time that the hearts of the American people were filled with gratitude by the great message that "the Confederate capital was repossessed and connected telegraphically with Washington," it was the main artery of communication between the commanding generals and the War Department.

After the battle of Seven Pines McClellan fortified himself with great care, and his future movements were awaited with feverish anxiety by the War Department. Telegraphic communication with him, by reason of frequent interruptions of the Delaware line and the want of proper railroad facilities, was not satisfactory. It was important to the Government and to McClellan that this line should be of the most trustworthy character, and young Buell was selected by Secretary Stanton and Maj. Eckert for the post of honor and assigned as superintendent of that line June 25, 1862. He was furnished with a locomotive for private use upon the Delaware railroad and horses for the turnpike. The line was guarded by two regiments of soldiers.

Before leaving Washington Mr. Buell asked Secretary Stanton the question, "How long will I probably be required on the Fortress Monroe line?" The Secretary of War replied, "Until Richmond is taken." The answer not being quite definite enough, Buell ventured once more with the remark, "Have you any idea, Mr. Secretary, how long that will take?" The Secretary of War raised his eyebrows, looked at Buell for a moment, and then answered, "In about six weeks, I hope." Mr. Buell, in relating this incident, says it was the longest six weeks he ever experienced, and that often the "gleaming taper's light" of hope shed its increase of brightness, only to be followed by what more than once bid fair to be the last flicker of a dying flame. He was in charge of this line nearly four years!

How well Mr. Buell performed the duty assigned to him during the time he was in charge of this, the most important of all the Government telegraphs, the official letters he holds will fully testify, and they are documents of which any man may well be proud.

After the close of the war Mr. Buell was assistant superintendent of the Western Union Telegraph Co., Philadelphia, under Mr. Bates, and afterwards called to New York by Gen. Eckert, who was general superintendent of the Eastern division.

In 1868, Cromwell Fleetwood Varley, the celebrated English electrician, made an exhaustive and comprehensive test of the condition of the Western Union Telegraph Co.'s lines from New York in every direction. Varley's report was a startling revelation of the miserable condition of the company's wires. Gen. Eckert recognized the immense value of this revelation, and with the same characteristics that made him the invaluable Assistant Secretary of War and General Manager of the U. S. Military Telegraphs during the civil war, grasped the situation and began an attack upon the evils under which the company was laboring.

Mr. Buell under the direction of Gen. Eckert began a series of improvements, which in a few months bore fruit of incalculable value. The relay magnets in the various offices having resistance varying from 500 to 2,500 ohms were removed, and low resistance coils introduced. Old joints in line wires were cut out, new ones made and soldered. Batteries at the principal main offices were changed and reduced, and the whole service bounded forward with an impetus that seemed miraculous.

Mr. Buell was the pioneer in this work, and caused reports to be sent in to the general superintendent's office, stating the exact working of all lines previous to the changes. After the changes were made the various managers and chief operators were constantly forwarding the most congratulatory messages. They were at first skeptical in regard to the contemplated improvements, and were chary of favorable reports until fully convinced that the splendid working of the lines were really due to the changes made by Mr. Buell.

Mr. Buell made all the changes, embracing the territory from New Orleans, to Plaister Cove, N. S. It was during this period that he invented and introduced the universal switchboard now in general use throughout the United States and probably other countries.

No patent was ever applied for, the two-year limit for the application of a patent having expired.

In 1876 Mr. Buell was recommended by the Governor and the Legislature of the State of Delaware, and also by the Hon. Thomas F. Bayard and the three U. S. Centennial Commissioners, for the position of Superintendent of Telegraphs for the U. S. Centennial.

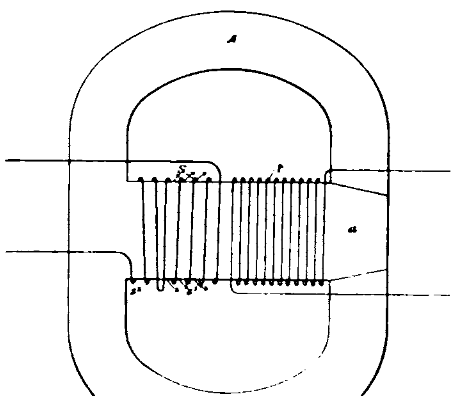
Mr. Buell has held important telegraphic trusts for years and is now connected with the Western Union Telegraph Co. at Buffalo. He is vice-president of the Buffalo Electrical Society and consulting electrician for the Academy of Music and other prominent buildings, including the City and County Hall.

He is and has been a frequent contributor for years to the daily press on electrical matters. A short time ago the Buffalo *Sunday Courier* published for some months a series of war articles written by him, which attracted general attention and were widely quoted.

His papers read before the Buffalo Electrical Society are numerous, the "Geni Electron," "Aerial Navigation by Electricity," "A Trip to the Moon," being the prominent ones, and copied more or less by the press of the country. His last paper, "The Electrical Utilization of Water-Powers," received general recognition here and abroad, and many applications are being received for copies. He is in frequent receipt of requests from publishers of leading magazines for articles from his pen, and it is evident that his whole electrical career furnishes material of a most valuable and interesting nature, not merely for occasional articles, but for a volume.

SPENCER'S SELF-REGULATING CONVERTER.

In certain forms of converters the primary and secondary coils are placed side by side upon a soft-iron core. When currents traverse the primary coil, lines of force are generated which thread the secondary coils and develop therein an electromotive force, which in turn establishes current in the secondary coil, if its circuit be closed. The lines of force developed by the flow of primary currents for the most part complete their circuit through the iron core;



Spencer's Self-Regulating Converter.

but in practice some of them escape through the air and thus do not thread all the convolutions of the secondary coil. In practice the number of lines thus escaping is greater as the current flowing in the secondary is greater, so that at full load the number of lines of force actually threading the secondary, and consequently the effective, electromotive force developed therein is less than at small load.

It is this effect which is utilized by Mr. Thomas Spencer, of Pittsburgh, Pa., for governing the converter and causing it to maintain a constant, or even increased, potential at full load. He carries this out in practice by placing upon the core s, in the accompanying illustration, a few convolutions of secondary wire, s^2, wound in the reverse direction from the main portion s^1, and in locating these convolutions so that the escaping lines of force do not thread them. From this construction it results that when but little current is flowing in the secondary, and consequently but little opposition is offered to the flow of the lines of force through the core, practically all these lines of force thread both the main and the reversed secondary convolutions. The effect of the reversed convolutions is therefore to neutralize an equivalent number of the main convolutions. The consequent effective secondary electromotive force developed is the resultant of the two opposing electromotive forces in the two sets of convolutions. If now the resistance of the secondary circuit be diminished and more current be permitted to flow, then more of the lines of force will complete their circuit outside of the iron core, and thus fail to traverse the reversed secondary convolutions. The reversed convolutions will no longer neutralize the same number of main convolutions, and the resultant secondary electromotive force will therefore be correspondingly increased.

The relative proportions of the two sections s^1 and s^2 may be varied to obtain different degrees of compensation or amounts of regulation. Thus it may be desired to compensate merely for the drop in the converter due to the resistance of the conductor, or it may be desired also to compensate for the loss in the conductors comprising the work-circuit, so that the amount of reverse winding must be made to suit the requirements of different cases.

THE KEYSTONE REVERSIBLE ELECTRIC ELEVATOR MOTOR.

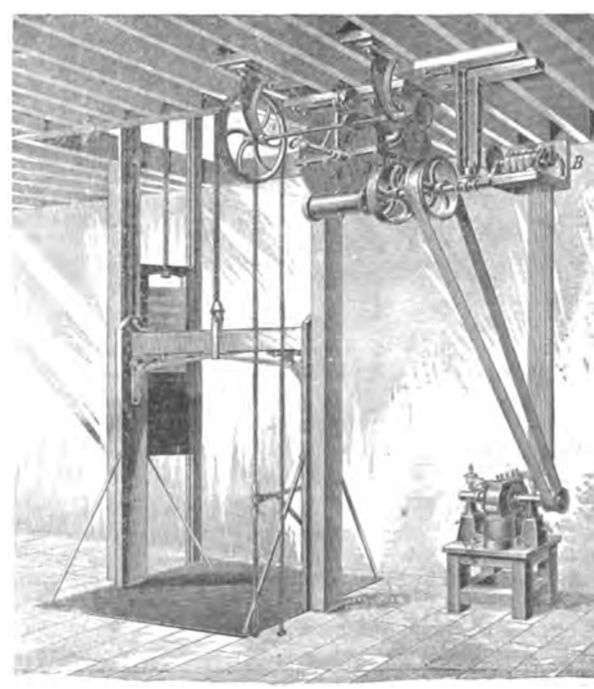
There is perhaps no more severe task to which an electric motor can be put than elevator service. In such situations the full load is constantly being thrown on or off instantly, and the motor is subjected to the most severe strains. To so design a machine, therefore, that will operate without external regulating mechanism of any kind, and which is capable of being started, stopped and reversed instantly, will be conceded to be an achievement of no small merit.

This, however, has been successfully accomplished in the electric elevator equipment now being built by the Keystone Electric Co., of Erie, Pa., and the manner in which it has been carried out is illustrated in the accompanying engraving.

Here, it will be seen, a constant potential motor drives a counter-shaft connected by worm gear to the winding drum A. The motor is controlled entirely by means of the switch B, which is attached by a sprocket-wheel and chain to the brake shaft C, which is controlled by a rope manipulated by the attendant on the elevator.

The motor is so wound that no external resistances whatever are required, the control being effected entirely by means of the switch B. Another important advantage of the arrangement consists in the fact that the motor stops with the elevator, so that when the elevator is not running no current whatever is consumed.

To accomplish the quick starting and stopping of the elevator without detriment to the motor the brake D is employed, which bears upon a brake wheel mounted on the driving shaft. It will also be noted that the brake shaft carries a cam, E, which is so arranged that when the attendant starts the elevator the cam lifts the weight W



The Keystone Electric Elevator.

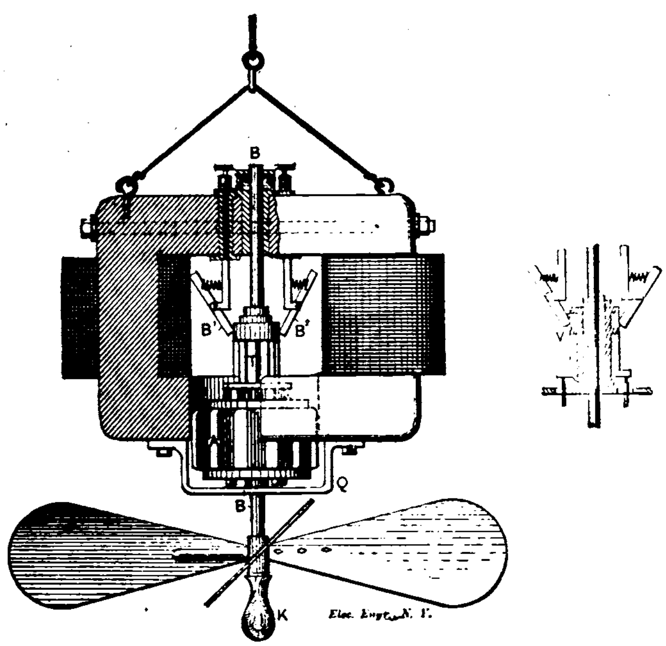
attached to the brake shoe, and allows the motor to start the elevator. When it is desired to stop the elevator, the cam is turned a quarter revolution in the opposite direction, which allows the weight W at the end of the brake arm to fall and apply the brake, bringing the elevator to a short stop. It will thus be seen that while the elevator can be stopped in the shortest possible space, the motor can never be started while the brake is on, since the starting switch is directly connected to the brake shaft. It is, therefore, evident that no matter how carelessly the elevator is handled, the motor cannot be burned out by starting the current while the brake is on, as has frequently been the case where the switch and brake act independently of each other. This excellent elevator arrangement has been designed by Mr. C. J. Sturgeon, electrician of the company, and is already in operation, in sixteen different installations, at Pittsburgh and Erie, Pa.

A NEW TYPE OF FAN MOTOR.

BY

C. J. Kintner

THE enormous demand for electric fan motors within the past two or three years has caused inventors to exercise no small amount of ingenuity in the adaptation of electric motors to this use; but although there are many types in existence, the writer believes that the motor designed by him and illustrated in the accompanying engraving embodies a number of advantages not obtainable in the ordinary type of fan motor.



FIGS. 1 AND 2.—KINTNER'S VERTICALLY-SUSPENDED FAN MOTOR.

It is a well-known fact that in a small motor the friction of the bearings absorbs an appreciable proportion of the electrical energy which should be utilized in driving the fan itself. It was with a view, primarily, of reducing the friction to a minimum that this motor was devised. The motor, which is illustrated in Fig. 1, is of the two-pole type, the field magnets being joined at their neutral point by a pair of bolts. An oblong journal box of non-magnetic material provided with an oil box at its upper end is secured between the two field magnets, the armature A being carried by a vertically arranged spindle, B, and supported, when out of action, by a non-magnetic yoke, Q, bolted to the lower ends of the field magnet poles.

The free ends of the commutator brushes rest normally on a ring of insulating material just out of contact with the ends of the commutator strips T. The field magnets and the armature are usually connected in series. The fan is secured to the shaft, and a ferrule or handle, K, is provided for lifting the shaft, the fan and the armature bodily until the commutator strips T come into electrical contact with the brushes.

The operation of the apparatus is as follows:

The attendant lifts the fan and armature by the handle K until the brushes B¹ B² make electrical contact with the strips T. As soon as the circuit is established the armature is drawn up and retained in its position by the magnetic influence of the field upon its iron core, and it rotates and is held continuously in this suspended position, the reactive influence of air upon the fan aiding to thus hold it up. When it is desired to stop the motor, the attendant simply grasps the handle and pulls the armature down into the position shown in the engraving, breaking the circuit between the brushes and the commutator strips.

Owing to the lifting effect of the fan and the magnetic action between the field and the armature when running at normal speed, the motor is self-regulating, for the reason that any tendency to run away causes the fan to tend to lift the armature out of the field, while the magnetism in the field tends to hold it back.

Among the advantages which the motor possesses may be mentioned its slight bearing friction, so that it may be provided with ball or gravity journal bearings, and hence requires no oil.

Besides, no additional switches are required, the commutator brushes acting as switches and breaking the circuit at two points at the same time, thereby reducing the spark.

Any number of these motors may be stopped at the same time by breaking the circuit for an instant, thus allowing the armatures to drop by their own weight upon the yokes, after which the circuit may be re-established for any lamps which may be in use upon the same circuit, the circuit through the motors being then permanently broken between the commutator brushes and the insulating ring on which they rest. This arrangement, therefore, affords a simple and efficient means for cutting out a motor from the central station after the user has left his place of business, if he has failed to disconnect it before leaving. In the engraving, Fig. 2, there is shown a modified arrangement for use in connection with series lamps or motors, the brushes in this instance resting upon the conducting ring V when the armature is in its lower position, so that the current travels from one brush through the ring to the other brush and on to the next lamp or motor.

ATMOSPHERIC ELECTRICITY.

METEOROLOGICAL observatories are generally ill adapted, by reason of dust and smoke, for observations on atmospheric electricity; and, with the view of inciting private individuals to such work, Herren Elster and Geitel, of Wolfenbüttel, have lately issued a *brochure*, in which they indicate the ends to be sought and the instrumental means. Three things demand attention: First, systematic observation and measurement of electricity in the open air at different times in the day, humidity and air temperature being determined at the same time; second, measurement of the fall of potential with a clear sky; and third, measurement of the fall of potential and its change of sign during rain, etc. The instruments and methods recommended are such as present little difficulty for private persons.

ELECTRIC TRACTION AT BREMEN.

THE Bremen Strassenbahn Gesellschaft has contracted with the Thomson-Houston International Electric Company for the electrical equipment of two-thirds of its Bremen system. The line that was in operation last summer at the Exhibition is to be retained, and a further line of four miles is to be equipped with six motor cars and as many tow-cars as may be required. The Bremen Company proposes to work its system by electricity as soon as the first portion is ready. The Bremen Strassenbahn Gesellschaft is the first tramway company in Europe to purchase outright an electric tramway. It will be remembered that an electric line was run very successfully by the Bremen Tramway in connection with the Thomson-Houston International Electric Company last summer. From June 22d to October 15th, 1890, 586,518 passengers were carried.

THE HAVANA, CUBA, ELECTRIC LIGHT STATION.

THE city of Havana is moving with the times, and one of the latest of the many improvements that have taken

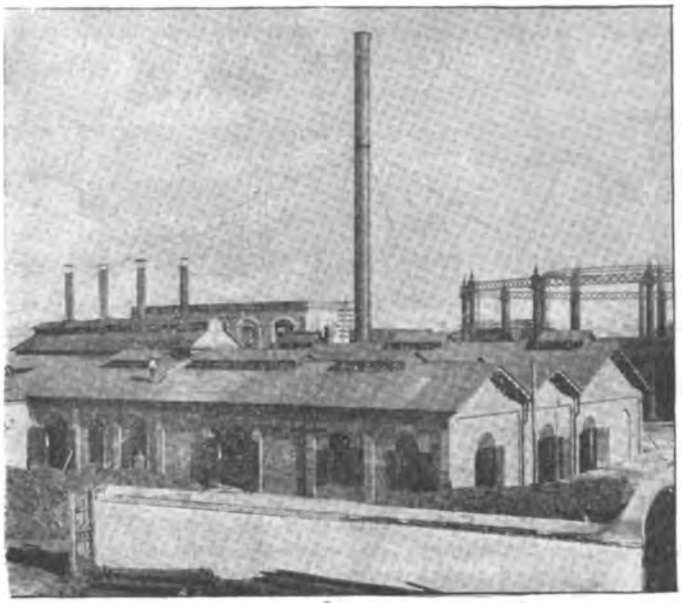


FIG. 1.—GENERAL VIEW OF THE HAVANA, CUBA, ELECTRIC LIGHT STATION.

place has been the establishment of a central lighting station.

The plant was erected by the Spanish-American Light

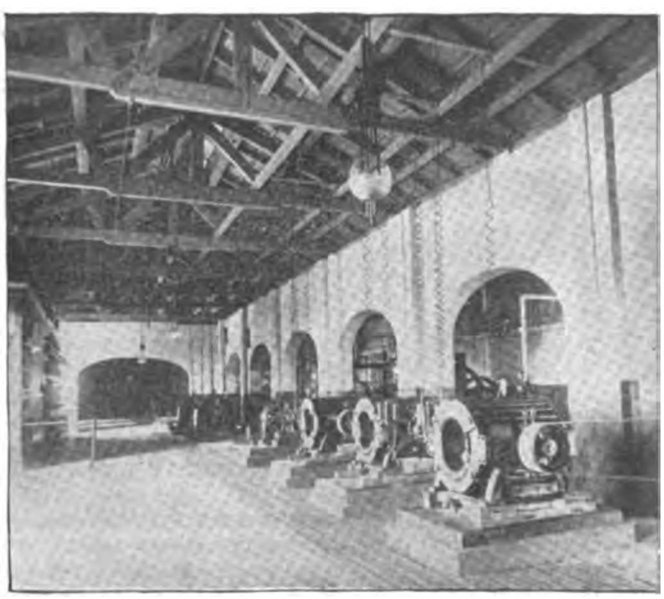

FIG. 2.—ARC LIGHT DEPARTMENT, HAVANA ELECTRIC LIGHT STATION.

& Power Company, who also own and control the gas works, and is situated on the same property, at a distance of about 1½ miles from the business portion of the city.

Three years ago a small plant was erected consisting of a 1,500 light Westinghouse A. C. dynamo, and 150 light Thomson-Houston arc machine with the necessary power for driving the same. The demand, however, for electric lighting soon exceeded the capacity of the dynamos installed, and it was determined by the directors of the company, after obtaining the necessary franchises and the assurance from the municipal government that it would pay for public lighting by electricity in place of gas, that the station be enlarged, capable of lighting 8,250 incandescent lamps and 500 arc lamps.

This plant, which was erected under the supervision of

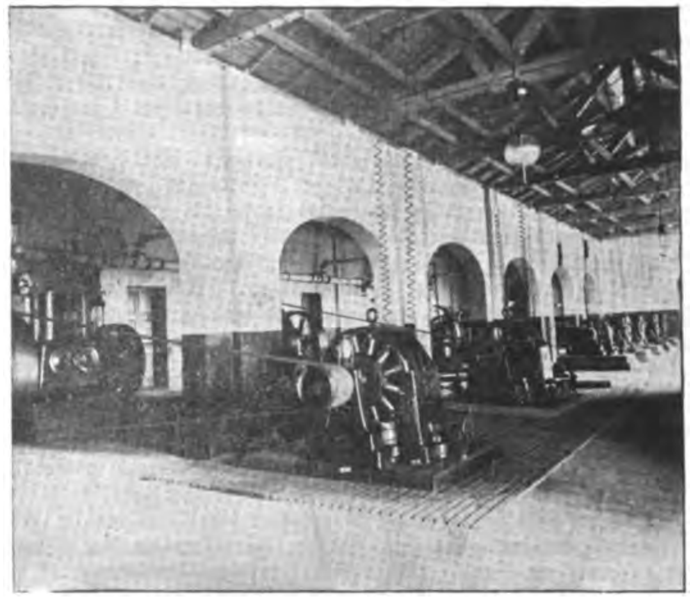

FIG. 3.—INCANDESCENT LIGHT DEPARTMENT, HAVANA ELECTRIC LIGHT STATION.

Mr. W. H. Fleming, is situated in a building, of which a view is shown in Fig. 1. It is of brick, 195 feet long by 90 feet wide, one story, covered with an iron roof. The building is divided into three parts running the entire length, with a width of 30 feet each.

The engine and dynamo rooms are joined by large

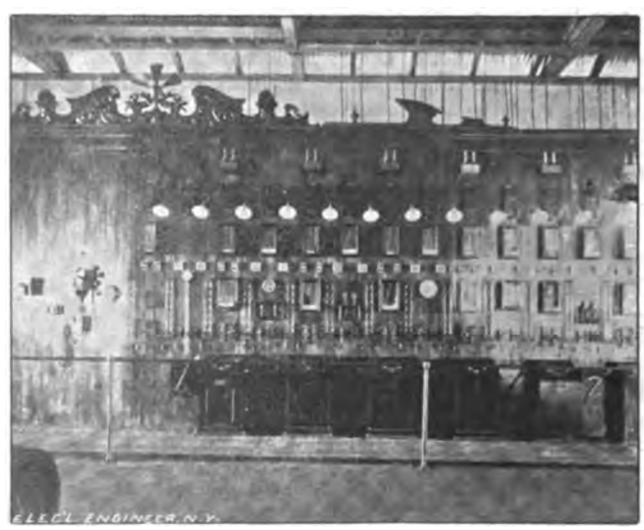

FIG. 4.—SWITCHBOARD, HAVANA ELECTRIC LIGHT STATION.

arches, so that at all times both engines and dynamos are in full view of the person in charge.

The boiler room is fitted with four Hazelton "Porcupine" boilers, of 150 h. p. each, and three 150 h. p. by Bartlett, Hayward & Co., of Baltimore, making a total of

1,050 h. p. The engine room has the following engines, all in line: four 150 h. p. Armington & Sims; one 150 h. p. Westinghouse; three 100 h. p. Armington & Sims; three 75 h. p. Armington & Sims; one 75 h. p. Westinghouse Company. Both the Westinghouse engines exhaust into separate Worthington independent condensers. The Armington & Sims engines exhaust into the feed-water heaters and then into an underground canal to a brick chimney 150 feet away from the station. In this way all the dirt and noise of exhaust is avoided and no trouble with backing up of condensed water in the exhaust is encountered.

In the dynamo room, Figs. 2 and 3, the dynamos are placed in one long room and are as follows: five 1,500 light A. C. Westinghouse, each self-excited; one 750 light 2,000 volt A. C. Westinghouse; ten 50-arc light 1,200 c. p. Thomson-Houston dynamos.

The incandescent switch board, shown in Fig. 4, is made of red cedar, 48 feet long, 15 feet high, with a raised platform in front carefully insulated from the ground. The board is supplied with all the most modern appliances. Each circuit has its own "Booster," ammeter, voltmeter, lightning arrester and compensator. Each circuit is brought to a central changing switch where it is connected to the ground detector. The arrangement of the changing devices is very convenient, the attendant being able to change from one dynamo to the other without moving from his position. The arc switch-board is very handily arranged for twelve circuits. The entire station is floored with Portland cement blocked off so as to represent paving. The pumps are supplied with fire outlets and hose.

The arc lighting is chiefly employed for illuminating the principal streets and public parks; the incandescent lighting for stores, dwelling houses and tobacco factores. By a recent order of the Government all theatres and places of amusement are to be lighted with incandescent lamps, otherwise their license is to be cancelled—a wise provision, and one which has a still greater tendency to increase the popularity of electric lighting.

It can be safely stated that there are few stations in this country that can compare with the Havana plant in the general completeness of the mechanical and electrical appliances that have been installed; it must be mentioned, however, that all the material, including poles of the line work, has been exported from this country.

The officers of the company are as follows: T. J. Hayward, president; R. A. C. Smith, vice-president and treasurer, in New York City; Ricardo Narganes, general manager; F. H. Thompson, electrical superintendent, in Havana.

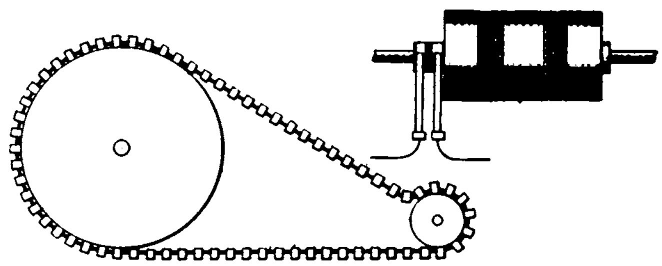
We are indebted to the *American Exporter*, of this city, for the the first three illustrations of this station.

EDISON'S MAGNETIC DRIVING BELT.

The method of increasing the adhesion of belts to pulleys by the aid of magnetic action so as to increase their driving power, though suggested some time ago, has not yet been carried out in practice on account of some of the mechnical difficulties involved. Recently, however, Mr. Edison has taken up the subject and has devised a method by which the efficiency, as well as the wearing qualities of such belts, is greatly increased

The belt which is shown in the engraving, Figs. 1 and 2, is composed of a number of steel wire ropes, upon which are strung cross-bars of soft iron. The wire ropes pass through holes in the bars, which holes, as shown in Fig. 3, are tapered from the centre of the bar outwardly in both directions, and the bar is secured to the wire rope by "setting" the centre of the bar upon the rope. This is accomplished by providing each bar over the horizontal hole through which each rope passes with one or more vertical holes or depressions extending from the top surface of the bar down to near the horizontal hole; by inserting a punch in the hole and driving it downwards the metal of the bar is "set" upon the rope, which is pinched and held so that the bar is fixed in its position with relation to the rope. The bar being set upon the rope at its centre and the hole flaring outwards from that point in both directions, the flexibility of the belt is thus assured.

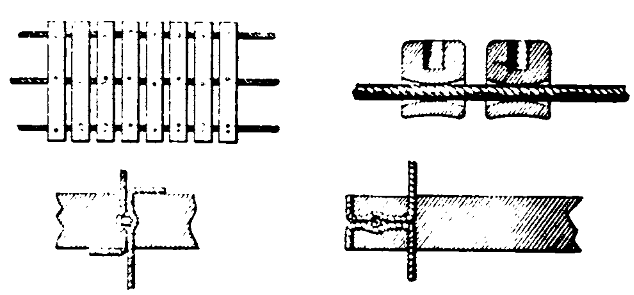
The ends of the wire ropes are secured, as illustrated in Fig. 4, by passing the meeting ends into a horizontal hole, which is large enough to receive them side by side, and is somewhat wider at the centre of the hole than at the ends. A screw-bolt or rivet is forced down between the adjoining ends of the rope, pressing them outwards into the enlarged centre of the hole and securely holding the rope ends; or



FIGS. 1 AND 6.—EDISON'S MAGNETIC BELTING.

if the rope is the one at either end of the bar, as shown in Fig. 5, the ends enter the bar from opposite sides and are then bent at right angles and pass out through a wider hole leading out through the end of the bar, and provided with an enlarged centre, a screw-bolt or rivet being used, as before, to spread the ends of the rope out into the enlarged centre of the hole.

The pulleys over which the endless belt runs are of iron, and are made strongly magnetic by means of magnet windings, which are placed in one or more circumferential grooves, as illustrated in Fig. 6, and are connected with insulated rings, upon which circuit springs rest, the springs connecting the magnetic windings with the source of electrical energy. Both pulleys are made strongly magnetic, and the iron bars of the belt bridge the magnetic windings and close the magnetic circuits about the windings, the bars being attracted to the face of the pulleys and adhering strongly thereto.



FIGS. 2, 3, 4 AND 5.—EDISON'S MAGNETIC BELTING.

In order to make the surface of contact with the smaller pulley as great as possible, the magnetic bars are curved on their inner surface to conform to the circumference of the smaller pulley.

Mr. Edison prefers to more strongly magnetize the small pulley than the larger one. The result of this is to make the belt "strip" more readily from the larger pulley than from the smaller pulley, to which latter the bars will cling, carrying the belt around over a greater surface of the pulley, as shown in Fig. 1, the belt being stripped tangentially from the larger pulley and radially from the smaller one.

ELECTRIC LIGHTING IN THE WESTINGHOUSE AIR BRAKE SHOPS, AT WILMERDING, PA.

BY

G. T. Evans.

IT is probable that no manufacturing establishment is better equipped with electric light than the shops of the Westinghouse Air Brake Co. at Wilmerding, Pa., about 14 miles east of Pittsburgh. The plant consists of carpenter shop, machine shop, iron foundry, brass foundry, blacksmith shop, boiler-house, and superintendent's office. The work of illuminating these buildings was begun about a year ago, by the North American Construction Co., Mr. John W. Rigby, well known in electrical circles for his thoroughness and ability, having direct supervision of all details. Arc lights of the Westinghouse alternating system are scattered about for general lighting, while 100 volt incandescent lamps are placed where precise and delicate work is to be done. The machine shop alone has upwards of 1,300 of these lights, each of the 1,000 lathes and other iron working machines having one or more. To the arrangement of the lights in the machine shop special attention should be drawn. It is most emphatically substantial. Simplex and Okonite wire, supported by porcelain insulators, is run on the ceilings below the machines. The lamp wires are carried from porcelain single-light cut-outs through the ten-inch thick floor in hard rubber tubes, and into substantial iron tubular stands, which are securely fastened to the floor. From these stands the wire is continued through universal jointed brackets to the lamps. This gives an excellent combination of solidity and flexibility. The stands will bear almost any shock, while the lamp may be adjusted to all the positions desired by the workman. At present the electric plant is in the boiler-house, but indications point to a separate power-house in the future. The equipment consists of one self-exciting 60-light arc machine of the Westinghouse alternating system, and two self-exciting incandescent alternaters of 1,500 and 500 lights capacity, also of the Westinghouse system. These are separately driven by Westinghouse compound engines, which are furnished with steam from Babcock & Wilcox boilers, natural gas being used as a fuel. These boilers give steam to a dozen Westinghouse engines throughout the works, the steam being carried underground through tunnels.

It would not be surprising if this plan of conveying power were to give way to an electrical method in time, for it is certainly less economical to carry power by steam for long distances than it is by electric currents.

The switchboard holds the usual Westinghouse apparatus used in controlling that system. The arc circuit is so laid out that the separate shops or the town streets may be lighted as required. The town of Wilmerding is lighted by several pole arc lights, but principally by four lights, set high in the park on Fort Wayne towers.

Wilmerding, outside of the shops, has already been wired for some 3,000 incandescent lights, several hundred of these being in the Westinghouse Club-house, a large building put up by the Air Brake Co. It contains the main offices, and also large rooms for library, billiard-room and natatorium, bowling alley, etc., etc., to be used by the employees. The lights are furnished per meter, the price being very low, viz., one-half cent per hour per 16 c. p. lamp.

The electrical departments of Wilmerding and the Air Brake Works are operated by the Turtle Creek Valley Electric Light Co., Mr. Rigby being general superintendent.

DEFENDING IQUIQUE, CHILI, WITH A 1,200 C. P. LIGHT.

THE political struggle now waging in Chili has had many interesting episodes and has furnished some noteworthy lessons with regard to the use of the tools of modern warfare. We have already heard of the activity of the torpedo launches, and now comes a very amusing story as to the effectiveness of the electric light. Mr. J. Acton Lomax, an electrical engineer, who has been associated with Mr. W. Hoffmann, the Thomson-Houston agent in Chili, has recently arrived in New York from the seat of hostilities. Being stationed at Iquique, the great nitrate port now in the possession of the Congressional party opposed to President Balmaceda, he was called upon by the former to furnish a light for an island about 1,000 yards from the shore in Iquique harbor, the idea being to place this light in a lighthouse standing there. The first plan of Messrs. Hoffmann and Lomax was to put eight arcs, of 1,200 c. p. each, inside a parabolic reflector, which they had made, six feet in diameter and eight feet in length. But although great efforts were made, the plant could not be got to work satisfactorily. They then borrowed from the engineer of the "Cochrane," one of the insurgent, ironclads, one of the old mirrors from her search light. This they rigged up with one of the 1,200 c. p. lights, put the combination in a box and tried it near the dynamo house, getting steam for the engine from the fire-brigade engine house, where steam was always kept up. It threw a ray beautifully. Then they improved it a little by putting a screw in the bottom, so as to raise it as the carbons burned down.

Now came the question of a circuit to the island. It was easy to get the lamp rigged up in the lighthouse, but it was not so easy to supply current to it. They had about 1,200 feet of copper wire in sizes from No. 0 to No. 10, but there was not enough of No. 0 to make an ordinary stretch. After rowing about all over the bay, Mr. Lomax found an old silted-up cylinder in a wrecked steamer. He knocked off the head and put in a big pole, which was steadied with rock, etc. This being about midway, gave him about 500 yards stretch on each side of the pole. Then he had an 80-foot pole both on the land end and the island end. But his wire was not equal to the task, and so Mr. Lomax went to the local telephone company and got from them a lot of No. 6 iron wire, which he used in the circuit. By the time it was finished the circuit was about 3,000 yards. Finally the whole thing was fixed up, but at that juncture the insurgent government did not want to pay, whereupon the plant was shut down. Then one night the saucy "Condell," one of the Presidential torpedo boats, ran into the bay, darted all round the shipping, sent off a torpedo at one of the Congressional ironclads, and "played the devil" generally. The Congressional party, in a great scare, paid for the plant, and it was set going, with the result of lighting up a couple of miles in any direction. It was arranged that any of the Congressional launches, cruising about all the time, should show certain lights, and they did so whenever the beam of light caught them. At last the search light picked up two craft coming in together, showing no light whatever. These suspicious craft made no responsive signal, so the ray was kept steadily on them. Very soon they got tired of this exposure, turned around and made for the open sea. They were evidently torpedo launches sent in by the "Condell" to smash up one or more of the ironclads. After this object lesson of its utility the light was kept going nightly, one of the sailors being instructed in its manipulation. The enemy probably took it at first for a man-of-war with search light, but whatever their opinion on the subject might be, they gave it a wide berth. The light was running when Mr. Lomax left Iquique for this country.

THE INCANDESCENT LAMP INDUSTRY.[1]

BY FRANK GÉRALDY.

THE Chamber of Deputies, during the sitting of July 6th, voted a duty of 500 francs per 100 kilogrammes on all incandescent lamps entering France.

The incandescent lamp market has altered enormously during the last four years. Lamps were then commonly quoted at 5 francs, 4 francs and 4 francs 50 centimes being considered as reduced prices. It was felt that a reduction was sure to come, but it was not foreseen that it would come so quickly, and that it would be so large. To-day incandescent lamps can be had for 2 francs 50 centimes, or 2 francs, and even less.

It is impossible to return to former prices; they are low and will remain so. The protection granted amounts to about .175fr. per lamp, and will not, I think, be sufficient to exclude foreign lamps. If it does succeed in doing so, French lamps will multiply, and home competition will bring down prices to the same level, because, after all is said and done, it is a possible price, and one which a large, well-organized industry should be contented with. The key to success will be the quality of the product. By quality I mean the general properties of a lamp, regular voltage, whiteness of light, long life, ease of fixing, strong construction, and other like essentials. Other more special qualities, such as satisfy the taste and requirements of the consumers, have to be aimed at. The public, indeed, has begun to have some taste in electric lighting matters. Only a little time ago it accepted all that was given it; great choice was not, indeed, then possible; to-day the public has seen, compared, and has its preferences. Certain styles of lamp, certain arrangements of filament, are in request. In Paris, at the present moment, fashion seems to favor looped filaments, and the look of the simple horseshoe shape is considered bare. Lamps, the filaments of which are closely coiled, emitting light from a more restricted centre, and appearing more brilliant, are preferred, and, generally speaking, small sized lamps are wanted.

Taste is also changing with regard to candle-power. Ten candle-power lamps were at first almost the only type asked for, because one such lamp naturally replaced a gas burner. Now people are beginning to take lamps of 16 c. p., and more, which is a good thing, because these lamps are in reality better and more efficient than the smaller units. The art of manufacture should be sufficiently flexible to be able to lend itself not only to meeting the present demands of the public, but probable developments.

1. Abstract from *La Lumière Électrique*.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers*

VOL. XII. NEW YORK, AUGUST 19, 1891. No. 172.

I do not think that the way to stop abuses of rights is to destroy the rights themselves.—J. J. Storrow.

THE OLD TIMERS AT WASHINGTON.

ELECTRICAL history is made at a rapid pace in these days, and the youngest of us in the profession or trade soon find ourselves looking back to the time when some new branch of electrical work was being established by our pioneer toil and perseverance. Only this year the first decade of commercial electric lighting was celebrated at Providence, and soon the electric railroad industry will signalise its great anniversaries in like manner. Yet the gathering this week in Washington reminds us that the jubilee of the telegraph will not arrive until after the Columbian Fair has come and gone, and that of the men who were Stanton's "right arm" during the Civil War twenty-five years ago, many are among the leaders in electrical development at this hour, strong, energetic and successful.

It has seemed to us appropriate to take special cognizance of this meeting in Washington of the Old Timers and the U. S. Military Telegraph Corps, and we are glad therefore to be able to present in this issue a few reminiscences, connected with events that have given Washington such prominence in electrical history. One of our articles recites briefly the circumstances that attended the sending of the first message by the Morse telegraph, in 1844, over the line from Washington to Baltimore, and gives the portraits of Miss Ellsworth, who sent that message, and of her father, but for whose friendship Morse, in all probability, would have abandoned his invention and ambitions. When Miss Ellsworth announced to Morse the fact that his appropriation bill for $30,000 had gone through Congress, the inventor had just 37½ cents in his pocket and a ticket for New York.

The article by Mr. Madison Buell tells in a most graphic and vivid manner how the telegraph repaid this investment during the crises of the Civil War, by placing at the disposal of Secretary of War Stanton that magnificent body of men, the United States Military Telegraph Corps, who through the long and weary years of struggle did their duty with noble courage, patience and fortitude, and whose work caused Stanton to say in the hour of the fall of Richmond: "Boys, I consider the telegraph my right arm, and if ever I can do any thing for you don't hesitate to ask for it.'" Strange to say, the only thing those faithful "boys" have ever asked for—mere recognition of their work—has been denied them. But no failure of the conscience of Congress can wipe out the memory of such gallant deeds as those of Bunnell and Nichols, as told by Mr. Buell, or of many another young hero, who, less fortunate, perhaps, went down to their graves the victims of sickness, imprisonment or the bullet.

The career of Mr. Buell himself is characteristic, and his work is part of that splendid record in which all of us take pride. As in so many other things, the Civil War constituted a great line of division between what had been and what is, and from that time dates, in effect, all the newer work in this country. The U. S. Military Telegraph Corps drew into its ranks the very flower of the Old Timers, and its members when released from war service threw themselves with unabated energies into quieter occupations. It is significant that immediately after the war we see Mr. Buell, under his old chief, Gen. Eckert, busy reconstructing the Western Union system, and doing his share of the task of carrying out the ideas and suggestions of Cromwell Fleetwood Varley. And what we have written of Mr. Buell, still active in the service to which he has been devoted these forty-five years, might be said of others who came out of that fierce ordeal of the war, to turn its lessons to account in the arts of peace.

ELECTRIC LIGHTING IN HAVANA.

OUR columns have recently contained a number of articles showing the popularity of electric lighting in tropical and sub-tropical regions. One of these articles dealt with Australia; one with the Sandwich Islands, and a third with Jamaica, West Indies. This week we publish a description of the plant at Havana, Cuba. The magnitude and growth of this station has hardly been suspected, but the electric light is pre-eminently *the* light for hot climates, and we need not wonder at its popularity in the largest city of the Caribbean. It is well worthy of note that in all the instances we have mentioned the alternating system enjoys great vogue. This is not to be wondered at. Buildings in hot climates are not high, but cover a great deal of ground with their piazzas and courtyards. Hence, the compactness of the American city, with its 15 story edifices, is missing, and the population spreads out over a great many square miles of territory in a manner that only those familiar with bungalows and patios can realize. Evidently in such cases the alternating system with its long arm reaches for patronage that would otherwise be impossible. The same tendency to expansion in tropical cities has made street railways necessary and successful, and it is more than likely that electricity will be resorted to as superior to the mule or steam dummy. This change of motive power has already begun.

THE INCANDESCENT LAMP INDUSTRY IN FRANCE.

THE voting of a duty of 500 francs per 100 kilogrammes on all incandescent lamps imported into France serves to draw attention to the state of the industry in that country, and brings out strongly the protective lines of policy, adopted by French manufacturers, paralleling those in this country. There also the price of lamps four or five years ago ranged between 80 cents and $1, while to-day lamps can be had for 40 or 50 cents. It has, however, been deemed necessary to grant French manufacturers protection from foreign competition, but we fail to see how the comparatively small duty of less than four cents per lamp will exclude those of foreign manufacture. Judging from the price at which lamps can be made in this country and the acknowledged cheapness of labor abroad, there is no reason why the present price of lamps manufactured in France should not be still more reduced from the figure given above, and it is to be expected that the levying of this duty will have this very effect, as foreign lamps will be brought in competition with the French in spite of the added duty. It is interesting to note also the expression of preference for certain styles and sizes of lamps, and even in the form of filament. Perhaps the most striking part of this is to be found in the more general adoption of small-sized lamps, which we believe will also find more recognition here than has been accorded them in the past.

THE MONTREAL CONVENTION.

GARDEN parties, conversaziones, promenade concerts, lacrosse matches, drives, banquets, excursions, Lachine Rapids, yacht trips—such are a few of the items in the welcome that awaits the National Electric Light Association at Montreal. Mr. Corriveau has more than fulfilled his promise that Canada would give the association as cordial a reception as it could meet with in any city of the Union, and it becomes the duty of everyone interested in the electric light and power industry to show that the kindness of these Canadian friends is appreciated.

There is every reason to believe that the convention will be signalized by good work as well as by generous entertainment. The programme that we print in another column is excellent, and embraces a brilliant list of names and subjects. The exhibition, too, is beginning to assume large proportions, and it will be without doubt one of the largest and best given under the auspices of the association. As an object lesson in the applications of electricity, the exhibition has great value, and the association has never yet visited a city in which a greater demand for electrical apparatus has not followed the display. It is certain that Montreal will prove no exception.

From what we hear, it seems likely that the attendance will be large, and we would heartily recommend our readers to seize this opportunity of visiting the Dominion. The chance is a rare one, and as the attractions are so many, it may be expected that the ladies will be out in force. Probably Montreal will see the last of the semi-annual meetings, as the sentiment in favor of one meeting a year is now so strong as to be practically irresistible. Under these circumstances, it behooves everybody to turn in and work with the object of making the Montreal convention the most memorable thus far held by the association.

The headquarters of the N. E. L. A. for the convention beginning September 7, will be at the Windsor Hotel. The rates there will be from $3.50 to $5 per day each. At the St. Lawrence Hotel the rates will range from $2.50 to $4. Special rates of railroad fare have been obtained from the various Traffic Associations on the certificate plan. Those attending the Convention will pay full fare going to Montreal and one-third returning, provided they return by the same route.

High-Tension Alternating Currents on Underground Cables.

THE increasing use of underground cable for high-tension work within cities has served to bring out a phenomenon, the importance of which cannot be overlooked, and which requires the attention of electrical engineers in order to leave such a system free from troubles and possible danger to those handling them. In the cables employed by Mr. Ferranti it has already been noticed that the potential at the far end of the line exceeds that at the generator, and the cause has been very satisfactorily traced to the influence of the static capacity of the cable. A communication this week by a correspondent describes another phenomenon analogous to that just referred to, which we hope will lead to a thorough investigation on this subject; and we will gladly open our columns to a discussion of the means for obviating the difficulty pointed out.

A Vertically-Suspended Fan Motor.

THE changes and modifications to which the ordinary type of electric motor has been subjected have probably not been paralleled in any other prime mover. In few of these changes, indeed, is any radical departure discernible, the majority consisting merely in modifications of detail rather than in the application of new principles of construction. This week, however, we describe a type of fan motor designed by Mr. C. J. Kintner, which exhibits several novel features. The operation of the shaft in a vertical position offers several advantages, which are pointed out by Mr. Kintner, the most interesting of which, probably, is its automatic regulating qualities.

Mechanical Storage Battery Filler.

THE introduction of machinery for work formerly done by hand is usually followed by a reduction in the price of the manufactured article, and the application of machinery to the manufacture of storage batteries, replacing the former process of pasting by hand, will probably be followed by a similar reduction. A machine employed for this purpose by the Consolidated Electric Storage Battery Company is described on another page, and, as will be noted, it applies the active material in the shape of dry powder, which is compressed into a solid mass within the grids, the plates being subsequently "formed" in the usual way.

THE ASSOCIATION OF EDISON ILLUMINATING COMPANIES.--SEVENTH ANNUAL CONVENTION, HELD AT NEW YORK.

THE Seventh Annual Convention of the Association of Edison Illuminating Companies met on Aug. 11. at the Murray Hill Hotel, with a very full attendance. The list of those in attendance, given below, comprises representatives from a large number of Edison Illuminating Companies from all over the country, in addition to the representatives sent by the Edison General Electric Co. and Mr. Edison.

The following delegates were present:

EDISON GENERAL ELECTRIC CO., New York:—J. Hobart Herrick, 1st vice-president; Samuel Insull, 2d vice-president: E. H. Johnson, director; J. P. Ord, comptroller; S. Dana Greene, assistant to 2d vice-president; Morris Slattery, agent Southern District; F. R. Upton, general manager, lamp manufacturing department; Sidney B. Paine, district manager, New England District; W. S. Kelley, engineering department; H. T. Edgar, engineering department; W. T. M. Mottram, assistant to district manager, Southern District; S. A. Douglas, New England District; L. Stieringer, guest.

Lamp Manufacturing Department:—Wilson S. Howell, inspector; Francis E. Jackson, inspector.

Light, Power and Intelligence Departments:—H. Ward Leonard, general manager.

Legal Department:—W. J. Jenks; B. W. Hammer; W. H. Lauman.

Eastern District:—Charles D. Shain, district manager.

Southern District:—A. H. Reece, district manager.

Official Stenographer:—M. J. Sullivan.

Edison Laboratory:—A. E. Kennelly.

EDISON ELECTRIC ILLUMINATING CO., of New York City:—R. R. Bowker, 1st vice-president; J. B. Skehan, treasurer: H. J. Smith, general operating superintendent; H. A. Campbell, assistant superintendent; J. Van Vleck; Arthur Williams; Henry Stephenson, superintendent underground construction; W. I. Donishea, assistant electrician; F. M. Tottingham, superintendent 2d district; Frank H. Briggs, acting superintendent 3d district; J. H. Tyler, superintendent meter department; J. E. Sayles, general agent.

GRAND RAPIDS EDISON LIGHT & FUEL GAS CO., Grand Rapids, Mich.:—A. F. Walker, superintendent; T. C. Harnish, constructor.

APPLETON EDISON LIGHT CO., Appleton, Wis.:—A. L. Smith, president.

CONSOLIDATED ELECTRIC LIGHT CO., Birmingham, Ala.:—Leigh Carroll, secretary and general manager.

DES MOINES EDISON LIGHT CO., Des Moines, Ia.:—J. A. Colby, director, secretary and manager.

COLUMBUS EDISON ELECTRIC LIGHT CO., Columbus, O.:—A. W. Field, secretary and manager.

EDISON ELECTRIC LIGHT & POWER CO., St. Paul, Minn.:—Geo. H. Finn, secretary and treasurer.

EDISON ELECTRIC ILLUMINATING CO., Lawrence, Mass.:—W. H. Wolvekamp, electrician.

EDISON ELECTRIC ILLUMINATING CO., Topeka, Kan.:—W. W. King, superintendent.

EDISON ELECTRIC ILLUMINATING CO., Westchester, Pa.:—Maurice Hooper, superintendent.

EDISON ELECTRIC LIGHT & POWER CO., Kansas City, Mo.:—W. Preston Hix, director.

EDISON ELECTRIC ILLUMINATING CO., Amsterdam, N. Y.:—J. H. McClement, vice-president; H. K. McCoy, general manager; T. D. Mosscrop, secretary and treasurer.

WINSTON-SALEM RAILWAY & ELECTRIC CO., Salem, N. C.:—J. H. McClement, president; H. S. Cooper, general manager.

EDISON ELECTRIC ILLUMINATING CO., Hazleton, Pa.:—J. Edwin Giles, manager.

EDISON ELECTRIC ILLUMINATING CO., New Orleans, La.:—Wm. Oswald, director.

EDISON ELECTRIC ILLUMINATING CO., Philadelphia:—Wm. D. Marks, supervising engineer and general manager.

EDISON ELECTRIC ILLUMINATING CO., Paterson, N. J.:—Wm. M. Brock, manager and secretary.

EDISON ELECTRIC ILLUMINATING CO., Pottsville, Pa.:—Geo. H. Barker, manager.

READING ELECTRIC LIGHT & POWER CO., Reading, Pa.:—T. P. Merritt, J. K. Righter, general manager.

EDISON ELECTRIC ILLUMINATING CO., of Brooklyn, N. Y.:—C. E. Chinnock, director; W. D. Barstow, general superintendent; R. Lindsay.

EDISON ELECTRIC ILLUMINATING CO., of Boston, Mass.:—Walter C. Baylies, vice-president; C. L. Edgar, general manager; W. A. Hill, cashier; Chas. E. Pattison.

HARRISBURG ELECTRIC LIGHT CO., Harrisburg, Pa.:—John I. Beggs, director; W. R. Fitzpatrick, superintendent and electrician.

EDISON ELECTRIC ILLUMINATING CO., of Detroit, Mich.:—C. P. Gilbert, secretary and manager; Hoyt Post, attorney; Barton L. Peck, motor inspector.

TIFFIN EDISON ELECTRIC ILLUMINATING CO., Tiffin, Ohio.:—A. Kaup, manager.

EDISON ELECTRIC LIGHT & POWER CO., Little Rock, Ark.:—G. H. Van Etten, president.

ELGIN CITY RAILWAY CO., Elgin, Ill.:—Chr. Wustenfeld, manager.

SCRANTON ILLUMINATING, HEAT & POWER CO., Scranton, Pa.: J. E. Parrish, superintendent.

WILMINGTON CITY ELECTRIC CO., Wilmington, Del.:—C. Reginald Van Trump, general superintendent and manager.

TORONTO INCANDESCENT ELECTRIC LIGHT CO., Toronto, Can.:—Frederic Nicholls, manager and secretary; J. K. Herr, director and attorney.

RENOVO ELECTRIC LIGHT, HEAT & POWER CO., Renovo, Pa.:—J. H. Sheddy, general manager.

FOREST CITY ELECTRIC LIGHT & POWER CO., Rockford, Ill.:—M. A. Beal, secretary, treasurer and manager.

MT. HOLLY ELECTRIC LIGHT & POWER CO., Mt. Holly, N. J.:—J. L. Jamison, superintendent and treasurer.

EDISON ELECTRIC ILLUMINATING CO., Rochester, N. Y.:—H. L. Brewster, secretary.

The morning session was occupied with the reception of credentials of delegates, an address by the President of the Association, and the reading by Mr. A. E. Kennelly, of Mr. Edison's laboratory, of reports of committees on "Grounding Neutral Wire on Three-Wire Systems," and "Lightning Protection;" and a report by Mr. C. P. Gilbert, of Detroit, Mich., chairman, read by Mr. H. Ward Leonard, manager of the Light and Power Department of the Edison General Electric Co., on "Dangers to Edison Circuits from Crosses with High Potential Conductors." The reports were followed by a free discussion on these topics.

The convention extended the privileges of a portion of its session to Mr. A. S. Hibbard, general superintendent of the American Telephone and Telegraph Co., and Mr. John J. Carty, electrician of the Metropolitan Telephone and Telegraph Co., during the discussion of the reports on Protection from Lightning and High Potential Circuits.

On reconvening, at 2:30 p. m., the delegates were invited by the officials of the Edison Illuminating Co., of New York, to visit in carriages their various operating stations and the new Elm street station, now in process of construction: also to accept the further hospitality of the company in a dinner at the Brighton Beach Hotel, returning in the evening.

SECOND DAY'S SESSIONS, AUG. 12.

The morning was taken up in the discussion of Mr. A. E. Kennelly's report on the "Grounding of the Neutral Wire in Three-Wire Systems," read the day before; the reading of a paper by Prof. Wm. D. Marks, supervising engineer and general manager of the Edison Electric Light Co., of Philadelphia, on "How to Get Paying Loads for Stations;" the reading of a paper by Mr. R. S. White on "The Edison Meter in the Brooklyn Station;" an address by Mr. Samuel Insull, second vice-president of the Edison General Electric Co., on the present business policy of the parent company, the outlook in the patent suits, the condition of the business, etc.

On Thursday the delegates were given an excursion to Schenectady by the Edison General Electric Co., a special train of Wagner parlor and dining cars being provided for the purpose. The party, numbering about 150, started at 6 A. M., and breakfast was served at 6.30. By ten o'clock the great works at Schenectady, described in THE ELECTRICAL ENGINEER last week, were reached, and the train was run into the work-yard. The party was greeted by Messrs. Kruesi and Gilmore, the managers, who, with Messrs. Herrick, Insull and Dana Greene, then escorted the party through the fifty and odd buildings that constitute the establishment. The perambulation, even at a four-mile gate, occupied over two hours, and some 3,000 people were seen employed in every variety of handicraft connected with the construction of electric power and lighting apparatus. Then lunch was served on the train, and the heat of the August midday was delightfully banished by a number of Edison fan motors placed in the cars, current for them being supplied over a special cable from the works power-house. After lunch the visitors were permitted to examine more closely and in detail any part of the work that had interested them during the morning; and as the train had left New York so early, the fact that one of the works offices had been converted into a full-fledged barber's saloon was hailed by not a few with the liveliest manifestations of delight and gratitude at such thoughtfulness.

In short, nothing that could contribute to the comfort of the large party was omitted. At about 2.30 the train was run out again on to the main railroad, and by 5 o'clock an admirable dinner was served, with the beautiful Hudson River scenery as a setting. New York was reached at 7.05, and it is safe to say that 300 miles of travel and 12 hours of continuous sightseeing were never spent with more genuine pleasure and satisfaction.

On Thursday evening the delegates, refreshed rather than tired, by their day's outing, were again the guests of the local Edison Illuminating Co., and in that capacity enjoyed the concert at Madison Square Garden, inspecting the plant, the stage lighting effects and the tower. Then "home well pleased they went."

THE STORAGE BATTERIES OF THE CONSOLIDATED ELECTRIC STORAGE CO.

THE decision of Judge Coxe, awarding to Mr. Brush the sole right to the mechanical application of active material to a storage battery plate, has served again to call attention, prominently, to this department of work, and has served to place on a more stable foundation an industry which has for a long time suffered from the retarding influence which surrounded it on account of the legal questions involved.

The Consolidated Electric Storage Company, as the manufacturers of the Julien storage battery, and the sole licensees under the Brush patent, have for some time past devoted special attention to the improvement of their batteries, and also to methods for cheapening their cost. Both these objects have been accomplished by the employment of a mechanical filler, by the use of which the active material is mechanically applied to the plate and which does away with the tedious pasting process.

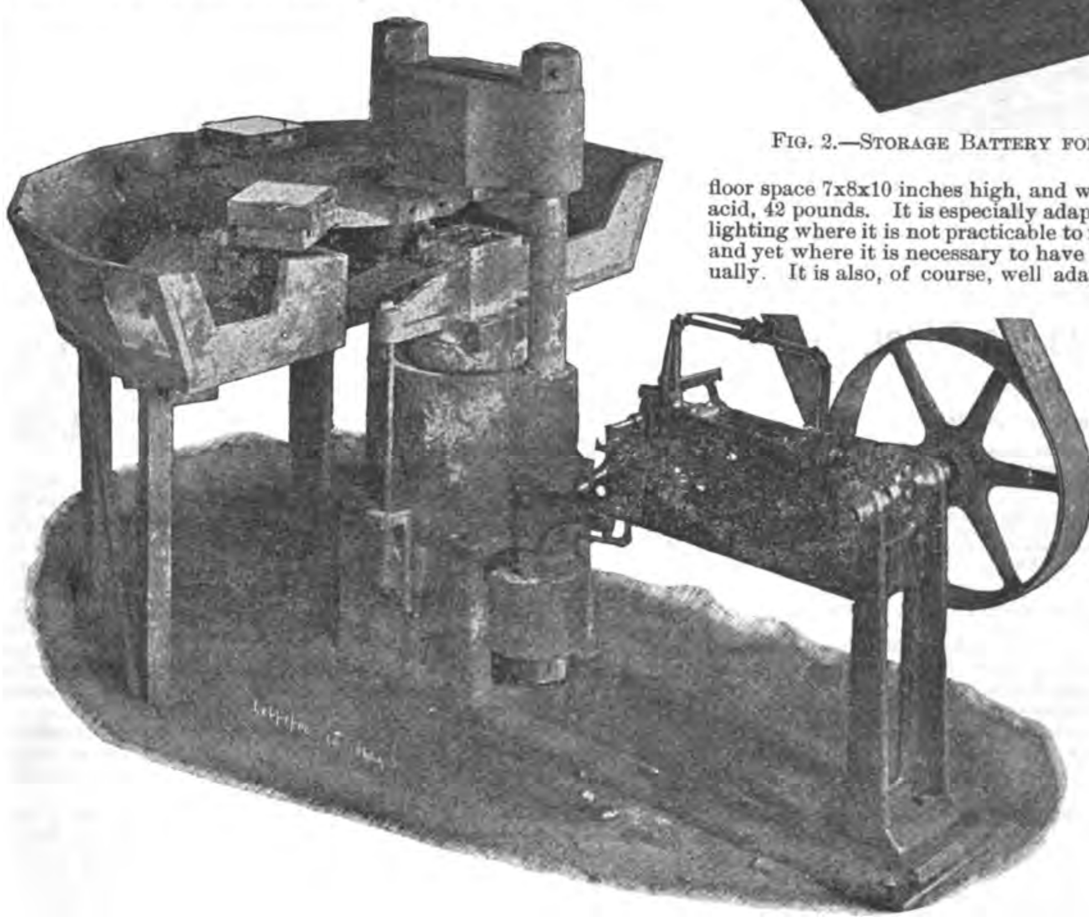

FIG. 1.—MECHANICAL FILLER FOR STORAGE BATTERY PLATES.

The apparatus by which this is accomplished is shown in the accompanying illustration, Fig. 1. As will be seen, it consists of a hydraulic press, obtaining its pressure from a pump driven by a belt and pulley. The plate to be filled with active material is placed in a die, which forms the top of the piston plunger of the hydraulic press. The active material, placed above and below the plate in the form of dry powder, is then brought up by the press against the opposite head, and the active material is then forced into the grid, so as to form a solid and compact mass. This operation requires less time than it does to describe it. Thus, one of these machines with two boys will fill 2,000 plates per day, and hence replaces the work of 80 skilled men, which would be required under the old method of pasting in the active material by hand.

The standard type of electric lighting and power cell, known as the S 17 accumulator, is shown in the accompanying illustration, Fig. 3. It has 180 ampere hours capacity, and its maximum charging rate is 15 amperes, and discharging 20 amperes. It occupies a

FIG. 2.—STORAGE BATTERY FOR MEDICAL PURPOSES.

floor space 7x8x10 inches high, and weighs, complete, set up with acid, 42 pounds. It is especially adapted for isolated incandescent lighting where it is not practicable to run an engine night and day, and yet where it is necessary to have lamps day and night continually. It is also, of course, well adapted to the running of arc lights on low potential circuits, and stationary motors in isolated installations.

The company have also devoted a large amount of their attention to special types of storage battery, among which their medical type deserves attention. This type, Fig. 2, has been designed for the medical and dental professions, and is specially adapted for conducting long and difficult operations where a constant current of considerable strength is required for a comparatively long period of time. It consists of four accumulators, each of which has a capacity of 50 ampere hours, each being capable of discharging at the rate of seven amperes. The plates are enclosed in rubber jars with sealed covers, and encased in a polished hard-wood box, which also contains resistance coils and a commutator, by which the operator is able to vary the voltage from 2 to 8 volts, and the current from 1 to 30 amperes. It can, therefore, be used equally well for small incandescent lights from 1 to 8 c. p., for galvano cautery, and for running small motors, circular saws, etc.

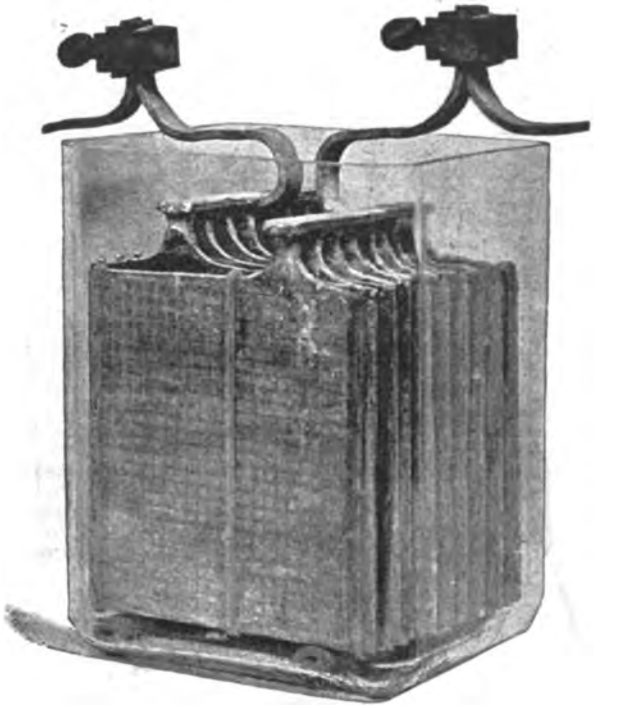

FIG. 3.—ELECTRIC LIGHT AND POWER STORAGE BATTERY.

Among the other special types of cell built by the company is the traction type, which weighs about 20 pounds with a rubber, and occupies a space 7½x5¾x9 inches high.

Letters to the Editor.

Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents.
Anonymous communications cannot be noticed.
The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.
In order to facilitate reference, correspondents, when referring to any letter previously inserted, will oblige by mentioning the page on which it appears.
Sketches and drawings for illustrations should be on separate pieces of paper.
All communications should be addressed EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

ELECTRICITY AND MINE VENTILATION.

THE above is the heading of a cutting from the *Coal Trade Journal* which appeared in your July 15 issue. I am not astonished at your publishing it, but it *did* surprise me to see the *Engineering News* endorse the views therein set forth. Now, to save any electrical man from putting up this idea when talking to mining men, I would like to state that there is nothing in it, from begining to end; it is simply "no good;" and for the following reasons:

Mr. Quackenboss "has made an investigation," advances a "novel theory that the prime cause of explosions in mines is due to the combination of *blower fans* and falling barometer." He then cites the explosion at Wilkesbarre to bear this out; but it does not bear out his theory, because, if he had investigated, he would have found that this mine is not ventilated with a *blower fan*, but with an exhaust fan. The July issue of the *Colliery Engineer* says on this subject: "There are no blower fans used in the region mentioned, all the collieries being ventilated by exhaust fans." It has been the practice for the past 30 years to use exhaust fans wherever it is possible, and this is so in the majority of cases.

Next comes the falling barometer. It has been thought that barometric changes did influence the quantity of gas given off in coal mines, and the English Government has been issuing warnings for the past 20 years of the possible approach of such changes; so there is nothing new in this discovery of Mr. Quackenboss'.

From a chemical point of view the theory may be all right, but the practice of mine ventilation for the past 30 years certainly does not uphold this theory. The only way to get rid of gas in the mines is to have considerably more than sufficient air and to use it. More than this, it is not the volume of gas given off on a fall of barometer that is the most dangerous, but the quantity of gas forced out into the gangways by larger or smaller falls of roof, and for this reason the falling pressure allows the gas to come out easily and slowly, and there is time to detect it. Probably the air current will blow it all away, but the sudden rush from the fall of the roof is dangerous because there is no warning, no time given at all; the danger is there all at once; it is like an earthquake, but worse, for it is in the dark; no sound, no smell, no trembling of the earth, until the one awful sheet of flame passes, tearing the timber out of its place and burning everything in its course.

Not once, or twice, is the battle fought underground; it is, in many mines, an incessant warfare between man, with fresh air for a gun, and the demon of the mine—gas—and when there is enough of it, the fresh air can win every time.

As to the electric motor underground, there are very few places where the mining engineer will ask for it that it will not be safe for it to be put. For coal cutting it can undoubtedly be made safer than the safest safety lamp; the machine may work as long as as the lamps can stay there and work the cutter, and that is one of the greatest uses for the electric motor underground; for pumping, where the motor is stationary, the machine can be made perfectly safe for a far longer time than the safety lamp. And for many other purposes the machine can be made perfectly safe. The greatest difficulty is not in the motor, but in the switch and rheostat, and there is no reason why these should not be as thoroughly protected.

Mining engineers are, as a rule, trained to overcome difficulties, and not to make them, and the mining engineers of this country are only just beginning to look to the electric motor as a means to do much work that has been most costly before; electricity is on trial and its work in the mine hardly begun. When the mining engineers see that it has come to stay, that it can do good work, that it is a machine and not a toy, then the development of electrical mining machinery will vastly exceed even the tremendous street railroad work which has been most astonishing, and the question will not be, Shall we use electricity or compressed air, but, Shall we use electricity or close the mine?

FRANCIS A. POCOCK,
Certified Mining Engineer.

SCRANTON, PA.

INFLUENCE OF ELECTROSTATIC CAPACITY ON ELECTRIC LIGHT CABLES.

IF it is not permissible, from considerations of safety to life, to operate high-tension continuous currents on grounded circuits, with, or without, static capacity, is it safe, for similar reasons, to operate high-tension alternating currents on circuits of large electrostatic capacity, even though their insulation be very perfect?

I recently laid two submarine cables, ⅛ mile in length, whose insulation resistance was 2,000 megohms, but whose static capacity was very large, due to the high specific inductive capacity of the compound used as insulation. The cables were connected to an alternating current dynamo giving a pressure of 1,100 volts and a frequency of 125 per second, supplying current for the lighting of a small village, which could only be conveniently reached by cable. In order to test the effect of the cable's capacity, I connected one end of the primary of a transformer to one wire leading from the dynamo and grounded the other end of the primary, when a lamp, attached to the secondaries, immediately lighted up nearly to full candle power.

I considered this due to the electrostatic capacity of the cables, and believe it would be very disastrous, indeed, to the one who would be unfortunate enough to get himself in a position similar to the primary of the converter.

Perhaps the matter may be of interest to the New York Board of Electrical Control, as so many lead-covered cables are being used in New York at present. R. B. O.

LIGHTING THE VERMONT INSANE ASYLUM.

A PLANT was recently started in the Vermont Insane Asylum by the Giant Electric Motor Co., of Portland, Me., the work being carried out by C. B. Story, superintendent of the company. The plant consists of 300 lights furnished by two 150 light automatic dynamos, run by two 8x10 Atlas new automatic engines. The plant is so arranged that the machines run independently or together, a special interlocking switch being used. This running together is done without the use of rheostat or equalizer, and irrespective of any large variation in the speed of the machines. The plant includes also two arc lamps. The work was in charge of Mr. J. E. E. Emmons, and is said to prove very satisfactory.

Society and Club Notes.

PROGRAMME FOR THE N. E. L. A. MEETING AT MONTREAL.

THE programme for the meeting of the National Electric Light Association, at Montreal, has now been arranged by Secretary Beane.

BUSINESS.

The sessions of the convention will be held from ten o'clock in the morning until two o'clock in the afternoon; final adjournment for the day being had at the latter hour.

On the 8th of September the reports of the following committees will be read and discussed: Committee on Relations of Manufacturing and Central Station Companies; on Data; on World's Columbian Fair; on Legislation; on Underground Conduits and Conductors; on Safe Wiring.

On the 9th of September the following papers will be read and discussed: Discussion of T. Carpenter Smith's paper read at the Providence Convention, on the "Distribution and Care of Alternating Currents;" W. C. Warner, "Various Forms of Carbons for use in Arc Lamps;" Capt. Eugene Griffin, "Three Years' Developments of Electric Railways;" H. Ward Leonard, "A Central Station Combining the Advantages of both Continuous and Alternating Current Systems."

On the 10th of September the reading and discussion of the following papers: J. I. Ayer, "Some Details of the Care and Management of an Arc-Lighting Station as Practiced in the Municipality of St. Louis;" C. J. Field, subject to be announced; George A. Redman, "Central Station Lighting by Water Power; J. J. Burleigh, "Uniformity of Method in Keeping Central Station Accounts."

An executive session will be held on the 10th of September to elect three new members of the executive committee and to name the place of next meeting.

ENTERTAINMENTS.

The following is the programme arranged for the entertainment of the National Electric Light Association of the United States by the Citizens' Executive Committee, Montreal:

Monday, Sept. 7th, 3 P. M.—Opening proceedings of the convention in the Windsor Hotel, address of welcome by His Worship the Mayor and other distinguished members of the Reception Committee. 8 P. M.—Formal opening of the exhibition by His Excellency the Governor General.

Tuesday, Sept. 9th, 2.30 P. M.—Drive through the city and around the mountain. 8 to 11.30 P. M.—Conversazione at Redpath Museum, Molson Hall, McGill College.

Wednesday, Sept. 9th, 2.30 P. M.—Fire department display on Champs de Mars. 5 to 7 P. M.—Garden parties. 8 P. M.—Banquet at the Windsor Hotel.

Thursday, Sept. 10th, 2.30 P. M.—Through the kindness of the Harbor Commissioners, trip by boat down the St. Lawrence and the Lachine Rapids, stopping on the way at Caughnawaga. 5 to 7 P. M.—Garden parties.

Friday, Sept. 11th, 3 P. M.—Lacrosse match. In the evening promenade concert at Sohmer Park, through the courtesy of Messrs. Lavigne and Lajoie.

Saturday, Sept. 12th, 7 P. M.—Excursion to Quebec at reduced rates.

In addition to the above, yachting parties are being arranged for the entertainment of the ladies.

Reception Committee under the patronage of His Excellency the Governor General: Premier Abbott, Premier Mercier, Lord Mount Stephen, Sir Francis Johnson, C. J.; Sir Donald A. Smith, Sir Joseph Hickson, Sir J. W. Dawson, Hon. Henry Starnes, Hon. Judge Wurtele, Hon. Judge Davidson, Hon. Judge Loranger, Hon. Judge Taschereau, Hon. Judge Baby, Hon. G. A. Drummond, Hon. Judge Jette, Hon. Judge de Lorimier, Hon. Louis Beaubien, Hon. Joseph Tasse, Hon. —— Lacoste, Hon. George Duhamel, Hon. J. K. Ward, Hon. Edward Murphy, Hon. A. W. Ogilvie, Abbé Laflamme, Hon. James McShane, Mayor of Montreal.

Messrs. R. B. Angus, W. C. McDonald, E. B. Greenshields, A. E. Gault, Aldermen Martineau, Clendenning, Farrell, Hurteau, McBride, Perrault, Prefontaine, J. B. R. Dufresne, Gauthier, P. Dubuc, Cunningham, Robert, Grenier, Conroy, Thompson, Hamelin, Savignac, Shorey, Boisseau, Lamarche, Griffin, Rainville, Tansey, Malone, Stevens, Stevenson, Rolland, Jeanotte, Germain and Villeneuve.

Messrs. W. M. Ramsay, H. Barbeau, James Gillespie, Hugh McLennen, Louis Perrault, W. W. Robertson, Q. C.; C. J. Fleet, Q. C.; H. M. Crombie, C. Geoffrion, Q. C.; D. McMaster, Q. C.; H. C. St. Pierre, Q. C.; E. N. St. Jean, Q. C.; G. S. Mantel, M. P. P.; P. E. Lablanc, M. P. P.; Dr. S. Lachappelle, J. Peck, Frank Paul, R. Hersey, J. A. Pillow, P. H. Roy, Q. C.; G. C. Dunlop, James Burnett, S. Carsley, G. Lessard, M. P. P.; H. Hogan, H. Boisseau, M. Allan, A. Allan, Henry Lyman, Geo. W. Eadie, A. McPherson, H. Graham, E. W. Bottrell, S. C. Dawson, C. E. Sanderson, W. C. Munderloh, A. Rhodes, Alphonse Desjardins, John H. Q. Molson, Dr. Johnson, Dr. Harrington, Robt. Archer, President of the Board of Trade; Walter Shanley, P. A. Paterson, E. P. Hanniford, C. A. Dansereau, Sam'l Finley, R. Reford, G. W. Swett, ex-Mayor Grenier, W. W. Ogilvie, Phelps Johnson, Hector McKensey, Alexander McDonald, C. P. Sclater, R. White, M. P.; J. S. Hall, M. P.; K. W. Blackwell, F. R. F. Brown, W. E. Gower, Lucien Huot, Louis Givernaud, J. B. Tressider, E. H. Parent, L. A. Lesage, H. Wallis, T. E. Normand, M. P. P.; S. Mohr, Dugald Graham, D. A. P. Watt, C. Gartle, Dr. T. C. Brainard, J. B. Dawes, W. Cassils, D. McIntyre, D. Parrizeau, President of the Chambre de Commerce; L. J. Sergeant, T. E. Shaughnessy, R. Esdale, D. Preston, D. McNicoll, W. C. Van Horne, H. Scott, C. Hosmer, H. Bulmer, J. Chabot, A. Grant, C. Gould, W. Wainwright, E. K. Greene, C. Drinkwater, J. Hodgson, Victor Hudon, J. Cassils, D. Morris, A. T. Taylor, F. L. Wanklyn, W. Edgar.

Citizens' Executive Committee.—Prof. Bovey, chairman; John Kennedy, vice-chairman; P. W. St. George, vice-chairman; M. R. Redpath, vice-chairman; Richard White, treasurer; F. Fairman, acting treasurer; Prof. John Cox, hon. secretary; John Carroll, joint secretary; Prof. Nicolson, C. F. Sise, Prof. McLeod, A. J. Corriveau, L. B. McFarlane, H. Beaugrand, W. L. Laurie, E. C. Arnoldi, W. E. Christie, Geo. W. Sadler, J. S. Shearer, M. Perrault, James Kent, L. W. Toms, H. M. Linnell, S. C. Stevenson, Phelps Johnson.

Sub-Committee of Exhibit Committee.—Frank R. Redpath, chairman; John Carroll, secretary; Prof. John Cox, Frederic Nicholls, Prof. Bovey, A. J. Corriveau, John Kennedy, S. C. Stevenson.

Sub-Committee on Finance.—F. Fairman, J. A. Beaudry, H. Beaugrand, John Carroll, J. Cooper, A. J. Corriveau, J. H. Burland, H. R. Ives, F. R. Redpath, J. S. Shearer, R. White, Dugald Graham.

Ladies' Entertainment Committee.—Prof. John Cox, John Carroll, S. C. Stevenson, A. J. Corriveau, E. C. Arnoldi, W. E. Christie.

Transportation:—Delegates and others who contemplate attending the convention can obtain full information on matters relating to transportation by addressing the following local committees on transportation: Geo. F. Porter, Girard Building, Philadelphia; R. D. McGonigle, Pittsburgh; W. A. Kreidler, *Western Electrician*, Chicago; E. R. Weeks, Kansas City; J. I. Ayer, St. Louis; A. C. Shaw, THE ELECTRICAL ENGINEER, Boston, and C. O. Baker, 136 Liberty street, New York. Special freight rates have been granted by the Canadian Railroads, by which exhibitors are obliged to pay freight only one way, provided the goods remain the property of the original owner.

Reports of Companies.

FIBRONE MANUFACTURING COMPANY.

DEPUTY Sheriff Heimberger has taken possession of the factory of the Fibrone Manufacturing Company, at No. 300 Monroe street, this city, on executions for $19,704, in favor of the following creditors: Thomas H. Wheeler, $15,525; Kasebier & Vigelius, $1,583; Elisha H. Allen, $1,298; Frederick H. Allen, $1,298. The company manufactured fibrone and plasticon in competition with celluloid and zylonite. The company was incorporated in January, 1890, with an authorized capital stock of $60,000, which was increased in March last to $100,000. The company succeeded Richle & Steinberger, who had commenced the business five months previously. Mr. Steinberger, the patentee, continued as president. A large amount of money was spent on the plant and in pushing the business, which was increased so as to manufacture electrical and telegraphic appliances. Thomas H. Wheeler, the largest judgment creditor, is a director of the company and is of Hyde, Wheeler & Co., of Boston. On July 25 the company gave Mr. Wheeler a chattel mortgage for $14,748 on machinery.

MAHANOY CITY, PA.—The Electric Light Co. has declared a dividend of 2 per cent.

Appointments, Etc.

MR. EDWIN ELLIS has been elected general manager and treasurer of the Kester Electric Co., Terre Haute, Ind., and is now busily engaged pushing the interests of that concern.

MR. J. R. HARDY, late superintendent of the Hannibal & St. Jo. Railroad, has been appointed general manager of the Augusta, Ga., Electric Railway Co. He will work with Col. Dyer, and will have full charge of the entire operating department. He is to assume his new duties the latter part of this month.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED AUGUST 11, 1891.

Accumulators:—

Electrode for Secondary Batteries, L. Paget, 457,555. Filed June 5, 1890.
First claim follows:
An electrode for a storage-battery having an active core in contact with the connecting-lug of the electrode and a perforating conducting-envelope surrounding the core and insulated from the connecting-lug, except through the working-faces of said active core.

Alarms and Signals:—

Annunciator, W. R. McCann and S. S. Creider, 457,454. Filed April 23, 1891.
For announcements in the alternative as, for instance, "in" or "out." Specially adapted for use in hallways of office buildings or the like.

Conductors, Conduits and Insulators:—

Connection for Electric Conductors, J. Dillon, 457,761. Filed Jan. 16, 1890.
Includes a locked box or cover; especially adapted for underground conductors.

Distribution:—

Self-Regulating Electric Converter, T. Spencer, 457,407. Filed Dec. 17, 1890.
Winds a few convolutions of the wire of secondary coil in the reverse direction to that of the main portion of secondary. (See page 209, this issue.)
Claim 3 follows:
The method of automatically governing the effective electromotive force developed in the secondary coil of an electric converter, which consists in generating in that coil two opposing electromotive forces and causing the value of the less of these electromotive forces to diminish as the current flowing in the secondary circuit is increased.

Dynamos and Motors:—

Electric Motor, W. S. Hill, 457,534. Filed June 23, 1890.
A construction relating mainly to the field-magnets which are of the laminated type.

Dynamo-Electric Machine or Motor, E. M. Waring, 457,754. Filed Mar. 23, 1891.
Design and construction employing field-magnets of star-shape form with coils on their arms.

Galvanic and Thermo-Electric Batteries:—

Electric Battery, F. Poudroux, 457,430. Filed Mar. 6, 1891.
Employs two porous cells, a carbon cylinder in the inner porous cup, a hollow cylinder of zinc between the two porous cups, and a hollow cylinder of carbon between the outer porous cup and the battery jar. The solution between the inner carbon and the zinc consists of azotate of potash, binoxide of manganese, bichromate of soda, and sulphuric acid in water; the solution between the outer carbon and zinc consists of chlorhydrate of ammonia and azotate of potash.

Lamps and Appurtenances:—

Means for Suspending and Controlling Electric Lamps, S. Bergmann, 457,-578. Filed Feb. 25, 1891.
For incandescent lamps.

Electric Light Hanger, F. A. Weimer, 457,687. Filed Mar. 28, 1891.
For incandescent lamps. Adjustable to any desired height.

Electric Light Carbon, W. P. Eltringham, 457,763. Filed Apr. 27, 1891.
Specially adapted for arc-lights. Employs a composition of coke, pitch and borax, in about the proportions of 72, 23 and 5 per cent. respectively.

Measurement:—

Electric Meter, E. Meylan & W. C. Recknlewski, 457,453. Filed Nov. 10, 1890.
Described in THE ELECTRICAL ENGINEER of Mar. 18, 1891, Volume xi, page 329.

Miscellaneous:

Electrical Switch, H. H. Blades, 457,338. Filed Nov. 3, 1890.
A rheostatic switch for use with motors.

Electric Switch, H. H. Blades, 457,339. Filed Nov. 10, 1890.
A rheostatic switch for use with motors.

Magnetic Belting, T. A. Edison, 457,343. Filed Sept. 10, 1890.
Employs strongly magnetized iron pulleys and an endless belt of magnetic material formed of one or more wire ropes passing through transverse iron bars.

Brush-Holder for Dynamo-Electric Machines or Motors, C. O. Mailloux, 457,358. Filed Mar. 18, 1891.
Includes guiding and following devices for carbon brushes, spiral springs employed for "following."

Electric Steam Generator and Heater, W. Mitchell, 457,362. Filed Nov. 29, 1890.
Combines, with a water-reservoir, a heating device consisting of a series of layers alternating with water-spaces, a wire forming part of an electric circuit and wound on the layers within the spaces.

Safety Device for Electric Wires, J. H. Sedlmeyer, 457,374. Filed Oct. 23, 1890.
For giving an alarm at the power-station of an electric railway when the line wire is broken or crossed with another wire.

Electric Oil-Well Heater, C. W. & S. D. Robinson, 457,457. Filed Feb. 18, 1891.
For removing accumulations of paraffine, etc., which clog the flow of oil.

Automatic Electric-Circuit Switch, W. L. Silvey, 457,483. Filed Apr. 19 1889.
For opening the circuit of a street railway whenever the conducting wires become crossed or short-circuited.

Apparatus for Heating by Electricity, R. Kennedy, 457,561. Filed Nov 20, 1890.
Utilizes alternating currents for heating by an apparatus including a core forming an open or discontinuous magnetic circuit, a magnetizing coil and a body wholly or in part of iron to be placed in the incomplete portion of the magnectic circuit and heated by secondary currents induced therein.

Switch, S. Bergmann, 457,572. Filed Jan. 26, 1891.
An electromagnetic switch.

Wind Apparatus for Generating Electricity and Charging Secondary Batteries, J. M. Mitchell, 457,657. Filed Mar. 23, 1891.
Employs a wind-mill and an automatic device closing the working circuit when the dynamo generates a current of predetermined strength and breaking that circuit and making a derived circuit when the current falls below a given point.

Electrically Heated Oven, W. Mitchell, 457,745. Filed Nov. 29, 1890.
Oven provided with successive layers of non-conducting material and a wire which forms part of an electric circuit and wound between the non-conducting layers.

Electrical Matrix-Making Machine, W. W. Street, 457,752. Filed Nov. 15, 1890.

Electric Air-Pump, A. A. Dittmar & H. Falkenhausen, 457,762. Filed Jan. 23, 1891.
Claim 1 follows:
In an electric air-pump, suction and discharge compartments communicating with the pump-cylinders by valve-openings, in combination with solenoids placed over openings in the top plates of the compartments and having movable cores which pass through the openings in the said top plates and act as valve-stems, so as to open and close the respective valve-openings by electric currents conducted alternately through the respective solenoids.

Railways and Appliances:—

Pole Trolley and Stand for Electric Street Railways, T. E. Adams, 457,334. Filed June 11, 1889.
In addition to the trolley contact proper employs a spark-catcher arranged to press against the under side of the line-conductor behind the trolley.

Trolley Pole for Electric Railways, C. A. Lieb, 457,356. Filed Mar. 28, 1891.
A tubular metallic conductor is enclosed within the trolley-pole which may thus be made of light weight and sufficient ragidity.

Electric-Car Motor, C. O. Mailloux, 457,357. Filed Mar. 18, 1891.
Relates to construction of motor and manner of mounting it upon car. Motor-frame is in two parts; one, the upper, supported upon the car axle or truck, and the other, supporting the armature, detachable from beneath.

Friction Gear for Electric Car Motors, C. O. Mailloux, 457,359. Filed Mar. 18, 1891.
Claim 1 follows:
The combination, with the driven shaft, of the motor sleeved on suitable shaft or bearing and having its armature-shaft parallel therewith, an interposed eccentric sleeve, and means for rotating the latter to adjust the relation of the gear between the armature-shaft and said driven shaft.

Trolley for Electric Railways, S. H. Short, 457,377. Filed Nov. 6, 1889.
Designed to ensure an extended contact surface with the conductor and to be self-adjustable to compensate for wear.

Trolley, S. H. Short, 457,378. Filed Mar. 26, 1890.
Designed to secure automatically a uniform pressure between the trolley-contact and the line conductor.

Electric Railway, M. H. Smith, 457,382. Filed Dec. 16, 1887.
Employs two parallel positive conductors in one horizontal plane, two parallel negative conductors in another horizontal plane, and collectors arranged to make contact with all four conductors simultaneously.

Signaling-Telegraph for Cable Railways, T. A. B. Putnam, 457,565. Filed Mar. 13, 1889.
To give an alarm instantly in the power-house whenever the grip of a car has got fast to the cable so that it cannot be released.

Truck for Electric Motors, G. M. Brill, 457,599. Filed June 19, 1890.
Car has side-beams carried by the axle boxes; motor pivotally supported at one end on one of the axles and at the other end supported from the side beams.

Hanger for Trolley-Wires, N. Newman, 457,660. Filed Sept. 23, 1890.

Electric Railway, R. M. Hunter, 457,736. Filed June 21, 1886.
Relates to a conduit system having two working conductors insulated from each other and from the conduit and exposing oblique contact faces.

Telephones and Apparatus:—

Automatic Telephone System, H. V. Hayes & H. Sears, 457,477. Filed Feb. 3, 1891.
Designed to dispense with an attendant for very small exchange service.

Legal Notes.

A NOVEL SUIT AGAINST THE MT. MORRIS ELECTRIC LIGHT CO.

AN odd suit has just been brought against the Mount Morris Electric Lighting Company, and an injunction will be asked for to compel the company to discontinue the use of a couple of arc lights placed under the windows of a flat in Harlem.

Howard H. Morse has for several years past been living on the first floor of the Eisleben apartment house, at Lenox avenue and 125th street. Directly beneath the flat is the store of Boynton & Co. On May 19 last the dealers in the store had two electric arc lights hung from the lower part of the windows of Mr. Morse's flat, over the show windows of the store. Iron bars and wire stays support the lamps, which shed a brilliant light upon the goods displayed in the show windows.

They also throw a brilliant light into Mr. Morse's rooms, and to this free illumination Mr. Morse decidedly objects. He prefers to pay for his light when he wants it. His servants are afraid to clean the windows lest the electric current might knock them out or set fire to the property.

A third and greater nuisance, however, consists in the myriad of moths, bugs and other insects which are attracted by the intense light. Mr. Morse claims to have suffered tortures during the hot weather. If the windows are left open to admit the evening breezes the rooms become brilliantly illuminated and hundreds of moths come in and fly about the room. If the windows are closed and the blinds are pulled down to keep out the light and moths the rooms become hot and almost uninhabitable in the warm weather.

Mr. Morse asked the electric company to remove the lights, but his request was not heeded, and so he decided to bring suit to compel the company to remove the objectionable lamps and to pay him $500 for damages.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

Josh Billings says you can't tell the extent of a man's business by the size of his letter head. His enterprise in advertising is a better test.

H. WARD LEONARD & CO.

In our last issue we gave a few details as to the important departure made by Mr. Leonard and his associates. The company has now secured fine offices on the fourth floor of the Electrical Exchange Building, in this city. The company is likewise making a very distinct innovation by the establishment of an Electrical Intelligence Department.

To any isolated plant the company offers at a very moderate subscription price ($25 a year) the privilege of corresponding upon any electrical subject of practical interest, and thus an isolated plant will be able to secure expert information as to its own plant and the best methods of operating it, and about any new electrical apparatus or methods and the principles underlying various devices and the prices thereof. For central station companies, whose queries would go further into steam engineering and methods of distribution, and would also cover business questions as to relations with consumers, systems of accounts, etc., the annual subscription charge for this electrical intelligence will be $50. This is an admirable idea, for any plant will get several times the value of the subscription price by placing before this company the matters upon which it desires information, data and statistics. As Mr. Leonard created and developed the Intelligence Department of the Edison General Electric Company, he has had the broadest possible experience in this line, since information of every character issued to those in the Edison Company has been issued by the Intelligence Department of that company. In case the expert judgment of the company be desired as to the comparative merit of various competing apparatus or methods, such expert judgment will be given by special arrangement, although the company prefers to merely supply full information under the subscription arrangement, and allows the purchaser to form his own conclusions.

H. Ward Leonard & Company will do no manufacturing and will do no supply business; neither will they, under any circumstances, act as the selling agents of any concern, directly or indirectly. They will, however, act for the purchaser, either as consulting engineers, supervising engineers, inspectors or purchasing agents. When acting in this way they will make the following charges, based upon the contract price:

For making preliminary plans, designs, determinations and estimates	1 per cent.
For making final plans and specifications	1 "
For drawing and executing contract on behalf of the purchaser	1 "
For supervising an installation made by another contractor	3 "
For inspecting and reporting on the work of another contractor	1 "
For acting on behalf of the purchaser in making the settlement with another contractor	1 "
For acting as the agent of the purchaser, from the beginning to the final settlement of a contract, including the making of estimate, plans, determinations, specifications, contract, supervising the installation, final inspection and report, and final settlement	5 "

It will be seen from the complete schedule given above that the purchaser will be able to obtain the services of this company for any portion of the work, and under terms which are so reasonable that there can be no question in the minds of those familiar with the subject that any purchaser contemplating the installation of electric plant would not only save a great deal of his own time and be spared a great deal of annoyance, but would actually effect a very material saving in retaining the services of a concern such as this to represent the interest of the purchaser.

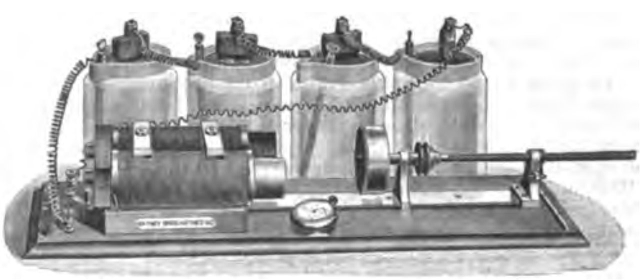
The various parent companies will also, no doubt, welcome the advent in the electrical field of an electrical engineering concern of this order, whose experience and ability is undoubted, and who are free from prejudice, and have no affiliations of any kind with any of the various electrical concerns. Any parent electrical company can refer a prospective purchaser to such a concern as this with confidence that any opinions given by it to the purchaser will be based on the honest judgment of those thoroughly competent to judge any practical electrical question.

The company will make a specialty of the transmission of power and the application of electric motors to such uses as necessitate the application of a wide experience in both mechanical and electrical engineering. Such applications of electric motors as are met with in elevators, pumps, hoists, mine tramways, printing presses, etc., are those which this company feels itself especially qualified to undertake under guarantee of perfectly satisfactory results. It may be added that, in addition to Messrs. Leonard, Vance and Harrison, already mentioned, the company will include Mr. C. H. Bloomer and Mr. A. Munning.

THE MATHEY WATCH DEMAGNETIZER.

The large variety of electrical apparatus embodying strong magnets in their construction which are now met with in daily life frequently affect watches not protected from such influence, and as a result many valuable timepieces are rendered practically useless. Fortunately, however, the cure for watches so magnetized is a very simple one and easily applied, involving principles which are thoroughly well known and understood. The simplest of these methods is the one which consists in revolving the magnetized watch within a magnetic field and gradually withdrawing it. By this method the magnetic polarity of the steel within the watch is constantly reversed and at the same time weakened, so that the watch finally is relieved of practically every trace of magnetism.

A simple apparatus for accomplishing this end has recently been brought out by Messrs. Mathey Bros., Mathez & Co., No. 16 Maiden Lane, this city. This, as will be seen in the accompanying illustration, consists of a plain horseshoe magnet which is energized by four Leclanché cells, which can be thrown in and out by means of a switch. The pole-pieces of the electromagnet are hollowed out so as to admit a cylindrical box within which the watch to be demagnetized is placed. This cylindrical box is placed at the end of a screw-threaded rod, which has a pulley mounted on it and which is supported at its rear end by a split nut, which can be opened by loosening the thumb-screw shown. The watch having been placed within the cylindrical box, the split nut is opened and the threaded rod run forward until the cylindrical box containing the watch is completely enclosed by the pole-pieces of the magnet. The split nut is then closed so that its thread gears with those of the rod. The little pulley is then worked by means of a bow, in a manner similar to that of the bow drill, and the revolution of the threaded shaft turns the watch quickly, while at the same time withdrawing it from the pole-pieces and hence out of the magnetic field. It is, of course, necessary to stop the balance wheel of the watch during the operation and to protect the watch by wrapping it in paper.



The Mathey Watch Demagnetizer.

One such operation, or, at the most, two, will deprive the watch completely of its magnetism and restore to it its original time-keeping qualities. The demagnetizer can be readily carried about and is placed in a fine mahogany case 2½ feet long by 6 inches high.

BALL ENGINES.

The Ball Engine Co., of Erie, Pa, has just shipped eight carloads of machinery to the Key West Gas & Electric Light Co., of Key West, Fla. The shipment comprised three large engines, two boilers, pumps, heaters, condensers, piping, etc. This local company propose to build one of the most complete plants in the South.

INTERIOR CONDUIT CO.'S AUTOMATIC SWITCH AND PROTECTOR.

IT has long been recognized that much inconvenience could be avoided and economy effected in the wiring of buildings if the circuit could be controlled from any number of points without the necessity of carrying the main current wires to the various points of control. A simple device by which this can be accomplished will therefore be welcomed by all electric light and motor con-

FIGS. 1, 3 AND 4.—NEW AUTOMATIC SWITCH AND PROTECTOR.

tractors to whom the problem just stated has often proved a vexatious one.

Such an apparatus has just been brought out by the Interior Conduit and Insulation Company, and is illustrated in the accompanying engravings. This consists of an automatic switch, Fig. 1, which is placed in the main circuit and which can be controlled from any distance by two push-buttons connected to it by ordinary bell or burglar-alarm wires. The method by which this is accomplished is very clearly shown in the diagram of connections, Fig. 2, the "on" button energizing a magnet which attracts the lever and closes the circuit, and the "off" button energizing a second magnet, which releases a trip and causes the switch lever to fall back and break contact Fig. 3 shows the push-button employed, which is of the ordinary kind.

In order to protect the circuit from any overload, the automatic cut-out, shown in Fig. 4, is inserted, being also indicated in Fig. 2. This cut-out or protecter can be set to open the circuit instantly at any fixed overload from one ampere upward. It is of special value, in view of the fact that the safety fuses ordinarily employed are usually made double the carrying capacity of the circuit in order to avoid their giving out and putting out the lights when there is really no danger. With the automatic cut-

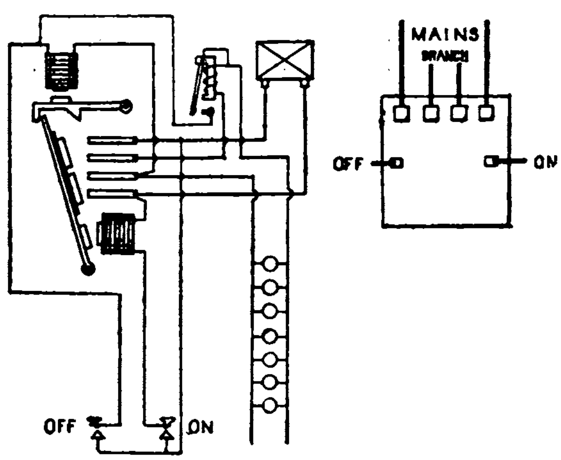


FIG. 2.—DIAGRAM OF AUTOMATIC SWITCH CONNECTIONS.

out, however, the circuit is ruptured at the proper time, but when the danger is over it can be at once restored to its original position without involving any delay or any cost for the renewal of fuses, which are rarely at hand when wanted.

MR. EUGENE DAVIS, formerly manager of the Brookline Exchange of the New England Telephone Co. has been appointed superintendent of Brookline fire alarms at a salary of $1,200. His new duties begin Sept. 1.

WESTERN ELECTRIC CO.

THE Western Electric Co. has just issued the July edition of its general catalogue. This handsome volume of over 300 pages is issued in an illuminated, stiff cover, and embraces within itself an enormous variety of electrical goods and apparatus. It is, in fact, an epitome of the electrical arts and applications, as is shown by the copious and careful index at the end. Among the leading specialties are the electric light dynamos and lamps, with other apparatus for that class of work, such as switches, fixtures, meters, shades, etc. Another large class of work is that of annunciators. Another is that of instruments for a large range of measurements. The section on wires is also large and important, and the same may be said about cables. A large number of tools and appliances are illustrated at the end.

THE ELECTRICAL SUPPLY CO., CHICAGO.

THE above company has recently removed to the corner of Michigan avenue and Randolph street, and with his wonted enterprise, Mr. F. S. Terry, the manager, has issued a dainty brochure showing the new quarters, which occupy the whole of a double five-story building, said to be the largest electrical supply house in the world. The illustrations show the building as seen from the street, and one of the busiest corners of its hustling, bustling interior. Noteworthy in this "busy corner" is a letter-box on which are the letters "F. S. T.," which represent the terse brief way in which Chicagoans, as well as New Yorkers, write and pronounce "first."

PHOSPHOR BRONZE SMELTING CO.

THE above company, of 512 Arch street, Philadelphia, whose Elephant brand trade-mark is so well-known and popular that it has lately been appropriated by the comic papers to represent the Republican party, has just issued a new and revised price list for a copy of which we are indebted to Mr. H. C. Lüders, the secretary. The list gives the fullest data as to roll and sheet, and particularly as to wire. A great variety of goods are included, and the different tables of weights, gauges, etc., are very useful.

HARRY ALEXANDER, ELECTRICAL ENGINEER AND CONTRACTOR.

IN order to obtain much-needed facilities for a rapidly increasing business, Mr. Harry Alexander has taken offices at No. 126 Liberty street, this city. Mr. Alexander devotes special attention to electric light and power installations and to wiring and construction work of all kinds. Mr. Alexander's experience, gained as inspector for the Thomson-Houston Electric Co., in Boston and the East, has made him fully acquainted with the requirements of first-class work. In his new quarters he will be enabled to undertake and carry out any work of this nature in the shortest possible time, and as all work is done under his personal supervision, the excellence of its quality is thus guaranteed.

RAPID TRANSIT PLANS FOR NEW YORK.

WITHIN the last two weeks some of the most important technical work required in a well-considered and comprehensive rapid transit scheme for New York City has been done by Chief Engineer William E. Worthen and William Barclay Parsons, his assistant.

One plan, that worked out by Mr. Parsons, makes provision for the pipe system under the pavement in Broadway by the construction of a subway in the middle of the street under the cable railway tracks and between the two railway tunnels. The pipe gallery or subway is made accessible from the railway stations, and not from the surface of the street through openings in the pavement, as has been heretofore reported. It is also designed to occupy the whole depth of the street to the foundations of the tunnel railroad.

The tunnels in this plan are designed to occupy the sides of the street next to the curb for a space of about ten or eleven feet; are to be "doubled-decked," or two stories in height, so as to accommodate two tracks, one above the other, and to be constructed of masonry walls and iron or steel roofs and cross-beams, with concrete foundations for the roadbeds. The motive force in both schemes is intended to be electricity, and the tunnels are to be made as light as possible with electric lights. In the plan referred to, the distinctive feature, however, is the provision of a permanent roadway for Broadway.

MR. J. S. CUMMINS, of Media, Pa., has become attorney for the Thomson-Houston Electric Co. in Chicago.

THE SIOUX CITY CORN PALACE.

THE electrical display and electric lighting were among the main attractions in the Corn Palace last year. This year both will be on a much more extensive scale. The buildings will be 380 feet long and 200 feet high, with daylight entirely shut out. About 3,000 incandescents and 50 arcs will be used for lighting and decorating.

The two leading attractions this year will be a South American exhibit in charge of representatives of each country, and the electrical display. For the latter alternating current of any potential up to 1,000 volts, direct constant potential up to 500 volts, and eight ampere constant current can be obtained in any quantity. Last year the model electric light plant and all goods displayed, except the ten horse motor, were sold. This year desirable exhibits from any manufacturer will be displayed and, unless sold, returned free of charge by the Sioux City, Ia., Electrical Supply Company, who have charge of all the electrical work.

The Palace opens October 1st, and the festival continues for seventeen days.

WESTERN TRADE NOTES.

THE HAY-HORN MANUFACTURING CO., of Chicago, report that they now have on hand orders for 6,000 bells, and that business is good. The Hay-Horn is a single magnet bell with an adjustable hammer.

THE SOUTHERN ELECTRICAL SUPPLY CO., of St. Louis, have just closed a contract for 235 miles of No. 10 insulated wire for fire-alarm telegraph service in St. Louis, also the necessary supplies, including 20,000 locust pins and all the equipment material. They have also received a large street railway order from Texas for No. 000 Okonite wire for feeder use.

MR. JOHN P. FRENZEL has just been elected president of the Citizens' Street Railway Co., of Indianapolis. He is also president of the Merchants' National Bank.

CHAS. T. LINDNER & CO., of San Francisco, consisting of Chas. T. Lindner formerly with the Edison General Electric Co., and J. H. Mathews, late superintending engineer of the Pacific Mail Steamship Company, have been appointed agents for the well-known Jenney lighting and power apparatus. The above-named gentlemen form a very strong combination, and will undoubtedly do well in handling this excellent apparatus, which is so well and favorably known.

THE WESTERN ELECTRICAL SUPPLY CO., of St. Louis, have closed the contract for the *Globe-Democrat* Building; the entire work is to be put in with interior conduits and about 1200 16 c. p. lamps will be installed, as well as telephone, telegraph and messenger wires and speaking tubes. R. V. Scudder is the secretary and treasurer

THC GREAT WESTERN ELECTRIC SUPPLY CO. are about settled in their new quarters, 201-207 S. Canal St. They report several large sales for K. K. weather-proof wire for which they are western agents. An agent for one of the large Electric Company's writes: "I recently had occasion to install a plant in a town where the trees and foliage were very thick; after testing all the leading brands of weather proof wire on the market, I decided that K. K. was best adapted for the work I had to do."

MR. W. W. GRISCOM, president of the Electro Dynamic Co., of Philadelphia, Pa., and also the vice-president of the Accumulator Co., was a visitor to Chicago last week. He spent several days here, during which time he was entertained by Mr. Wm. Hood, Western representative of both the above companies.

THE GREAT WESTERN ELECTRIC SUPPLY CO. are busily engaged in removing to their new headquarters in the Springer Building. They will carry on an extensive manufacturing business.

MR. W. H. MCKINLOCK, president of the Central Electric Company, is away on his well-earned vacation, and writes that he is finding both health and pleasure in the surf on the Jersey coast.

THE "PERFECT" INSULATOR, illustrated in these columns a few weeks since, sold by the Central Electric Company, is being received with very gratifying favor by construction men, and already a considerable number have been sold.

THE BALL CROSS COMPOUND ENGINE.

THE catalogue of the Ball Engine Co., of Erie, Pa., just to hand, contains excellent descriptions of the various types of engines manufactured by this firm. These engines, which have been specially designed for electric lighting, electric railways, and general manufacturing purposes, are built Simple, Tandem Compound, Cross-Compound and Triple Expansion, and each embodies features which give them special value. The cross-compound engine, which we illustrate in the accompanying engraving, was first designed about two years ago for the Edison station in Brooklyn, the company being convinced that a higher rotative engine could be successfully used when the work was distributed over two sets of crank pins and journals, than would be possible by the use of a single set of bearings of larger size, as is the case in the tandem compound; and this proved to be the case.

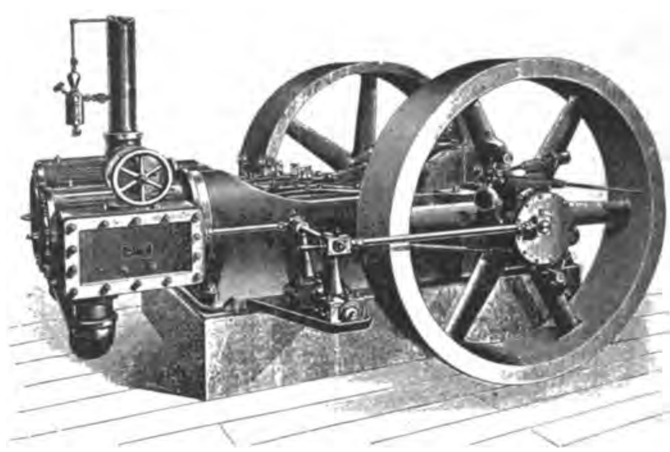
The crank-shaft is made of the best open-hearth steel, with the cranks opposite each other, one counteracting the effect of the other, so that the engine is perfectly balanced and capable of being run at a rapid speed with quietness and ease, and without heating.

The valves provide for quick admission of steam, and insure against all possible leakage. The pistons are as readily accessible as in the single-cylinder engine. The improved governor employed gives the closest regulation.

Instead of using an eccentric and strap on the low-pressure side, as is commonly done, an adjustable wrist-pin plate is bolted directly to the hub of the wheel. On this plate is the valve-driving crank-pin. This is found to be much preferable to the eccentric and strap arrangement, and on account of the smaller area of the crank-pin there is but little wear and but little oil required. The valve-operating mechanism is simple and reliable.

The Ball Company believe that the often-expressed desire of large central stations and other practice for an economical and reliable engine of medium power and occupying a comparatively small space, has been met by their cross-compound engine. Under the conditions of variable load generally encountered in service, they claim that their cross-compound will give more satisfactory results, and produce power at less cost, than any type of slow-speed Corliss engine, and considerably less than any single-cylinder high-speed engine.

As bearing out these claims, they point to the high economy



CROSS-COMPOUND ENGINE OF THE BALL ENGINE CO., ERIE, PA.

obtained with their engines in the Brooklyn Edison station, in which the consumption of coal is 2.75 pounds of coal per indicated horse-power, and three pounds per electrical horse-power.

The company also build a special cross-compound engine for electric railway work, and have a number of engines in successful operation in this service.

THE ADAMS ELECTRIC RAILWAY PATENTS.

THE Adams Electric Railway Co., of St. Louis, of whose claims and patents a full account was given some time since in THE ELECTRICAL ENGINEER, is sending notices to street railways of the various systems, warning them not to infringe Letters Patent No. 300,828, of June 24, 1884, granted to A. Wellington Adams for an electric motor for railway cars.

THE MINNEAPOLIS STREET RAILWAY COMPANY'S UNDERGROUND CONDUIT SYSTEM.

THE electric system of the Minneapolis Street Railway and the St. Paul City Railway Companies is, without doubt, the most complete, and one of the most extensive systems in the world. The underground conduit system employed by the Minneapolis Street Railway Company for carrying its mains and feeders has several times been mentioned in our columns. A series of tests having been recently obtained from the Street Railway Company, we take pleasure in bringing the matter before our readers again.

The novelty of the system employed throughout lies in the fact that there is not a wire in sight in the heart of the city except the overhead trolley wire. The feeders, mains, and track feeders are contained in a conduit underground, the trolley-wire connecting with the feeders by means of a sub-feeder through the hollow iron supporting poles. The conduit is located between the tracks and is built as follows: Two-inch plank, first treated by boiling in fernoline, is used for constructing a long trough of the desired size. This trough is so nailed together as to be continuous and without joints from manhole to manhole, a distance of 408 feet. The trough is placed below the surface at such a depth that the top is six inches below the paving blocks.

The conduit proper consists of a number of heavy paper tubes of the Interior Conduit and Insulation Company's make. The tubes, employed are one inch and one inch and a quarter, inside diameter, laid in the trough in ten-foot lengths and separated from each other and the sides and the bottom of the trough by rings or spaces. The tubes are made continuous from manhole to manhole by use of a telescopic joint. After the tubes have been properly put in place, pitch, liquefied by heat, is poured in, filling the interstices and leaving a series of highly insulated raceways with a solid insulating filling, impervious to moisture, around them.

The system is the first installation of underground conductors ever made in which bare copper wires were drawn into a conduit without other insulation than the conduit itself. There is, at the present time, about 60 miles of bare copper cable resting in the conduits, varying in size from 100,000 to 500,000 c.m. The insulation resistance on the entire amount of tubing, with overhead trolley and outlying feeders, as shown by actual test, is as high as 1,081,147 ohms.

A large amount of this conduit has been in service since September, 1890, and has not developed a single fault. The most emphatic and reliable tribute to the excellent results of this new method is found in the additional order for 200,000 feet of tube recently filled by the Interior Conduit and Insulation Co. The original order was for 400,000.

Some recent tests of the feeders in the conduits show an insulation resistance which is commendatory to the system and speaks for itself:

Feeder	A,	37,719,598 ohms,	Length,	3,122	feet.
"	B,	18,647,094 "	"	5,172	"
"	C,	2,251,122 "	"	8,048	"
"	D,	10,288,096 "	"	9,082	"
"	E,	1,790,898 "	"	7,219	"
"	F,	1,815,078 "	"	8,048	"
"	G,	1,488,031 "	"	5,172	"

The drop in the potential at the terminal of the feeders employed in the conduit is 5 per cent., while in the other systems, where the overhead feeders are used, 10 per cent., and over, is the result.

EXHIBITS AT THE EDISON CONVENTION.

Two exhibits at the Edison Convention last week attracted considerable attention. One was the Universal arc lamp burning in the room on the regular Edison circuit of the hotel. The light was pure, brilliant and steady. The other exhibit was the latest form of flatiron brought out by Mr. Carpenter, of the Carpenter-Nevins Electric Heating Co., of St. Paul. It was shown by Mr. G. H. Finn, the manager of the Edison St. Paul Station. A very thin wire is used imbedded in an under and upper coat of glaze, like that on certain domestic cooking utensils, and the wire brings the iron to a useful heat in about ten seconds, as soon as the circuit is closed. The same method of generating the heat is employed in a number of other appliances by Mr. Carpenter, and in every one of them with success. An extensive use of the apparatus is looked for, and the Edison men were most anxious to learn all about it.

THE ELEKTRON MANUFACTURING CO.

As we go to press, we are informed by this enterprising company that on account of the rapid growth of their business, due to the high reputation of their Perret motors and dynamos, they have found it necessary to increase their facilities. The first step has been to increase their capital stock from $100,000 to $200,000, and the new stock has been taken up for cash at par. The next step has been to move from Brooklyn to Springfield, Mass., into the Bullard Repeating Arms Works, the whole of which they have secured. The property consists of a brick building 52x40 feet, four stories high, with a three-story brick wing 125x40 feet. Another wing of the same size is to be added. The separate power-house contains 100 h. p., to which another 100 h. p. may be added.

The organization will remain as before, with W. D. Sargent as president; E. H. Cutler, general manager and treasurer, and F. A. Perret, chief electrician. Mr. W. E. Wright, of McIntosh & Co., Springfield, has been added to the board of directors. Mr. L. J. Harley, of the Smith & Wesson Works, becomes general mechanical superintendent. Mr. R. Watson will remain in charge of the business in New York, offices, store room and workshop being fitted up at 89 Liberty street.

NEW ENGLAND TRADE NOTES.

THE JENNEY STAR ELECTRIC COMPANY has recently been organized in Portland, under the Maine laws, with a capital of $50,000. The factory of the company is situated in New Bedford, Mass. Mr. J. A. Jenney is president; Mr. A W. Rounds, secretary and treasurer, and these two, with Mr. Bowker, of Messrs. Bowker and Tripp, are the directors. Mr. Jenney is well known as the originator of the Fort Wayne Jenney Electric Company, but has been actively engaged in New Bedford for the past year or two in perfecting the dynamos and motors which it is the purpose of this company to manufacture. Mr. Rounds is also president of the Russell Electric Company, of Boston, the manufacturers of the Russell disc carbon lamp, and the two companies will work to a certain extent in conjunction, though they will be entirely separate. The Jenney Star Company has no lamps, while the Russell Company has no dynamos, so that they can work well into one another's hands, in addition to other business. The purpose of the Jenney Company is to manufacture dynamos and motors from ⅛ h. p. upwards, and they already have large orders for numbers of the small motors. They are now equipping their factory at New Bedford with new machinery, engine and boilers, etc., and expect to be in running order in six or eight weeks. The dynamo will be entirely different from anything Mr. Jenney has yet brought out, and possesses many novel features, which makes it valuable.

THE RUSSELL ELECTRIC COMPANY, of Boston, are increasing their facilities for more rapid manufacture of the Russell arc lamp. The "Baby" lamp, built on the same principle as the large lamp, with disc carbon, is now ready to go on the market, and orders are being filled. The Russell Company are receiving the highest praises of their lamps from their customers, and orders are at present away ahead of production. The "Baby" lamp is designed for 45 volts and 6$\frac{3}{10}$ amperes, giving 1,200 candle power. It measures 27 inches over all, and only 23 inches from the hanger board to the bottom of the lamp. It will run from 10 to 12 hours, and can be used on any current from four to seven amperes, being provided with a regulating device to suit the current.

H. N. BATES & COMPANY, of Boston, general agents for the Hunter friction clutch, and general dealers in shafting, pulleys, hangers, etc., have decided, owing to the enormous increase in their business, to remove from their present quarter, at 1207 Pearl street, and will hereafter occupy the very handsome and capacious offices and store at the corner of Purchase and Congress streets, the exact location being 238 and 240 Congress street, and 182, 184 and 186 Purchase street. Here they will have a most commodious store on the first floor, measuring 80 feet long by 55 feet wide, one corner being partitioned off for offices and draughting room. They will also occupy the basement, which is the same size as the room above, and will altogether have one of the finest stores in Boston for their class of goods. The store is well lighted, dry and convenient, and is equipped with an extra large elevator. Altogether Mr. Bates is to be congratulated upon his change of quarters.

THE PORTER-LEAVITT ELECTRIC MOTOR COMPANY, of Providence, R. I., manufacturers of the small Porter-Leavitt battery motor, illustrated in our last issue, are being taxed very heavily to keep up with their orders. The business has grown upon them very rapidly, and abundantly proves that they are really filling a felt want. These little motors can be run with only two or three cells of battery, and are wonderfully efficient sources of energy for fans, small lathes, sewing machines, etc. The price varies from $8 to $10, according to size, which brings them within the reach of everybody. Fitted up as a fan, the Porter motor is invaluable in these dog-days, as it runs noiselessly and economically, and can be set down anywhere, on one'e desk, or at one's bedside, without inconvenience.

☞ ***Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Miscellaneous, etc., will be found in the advertising pages.***

THE

Electrical Engineer.

VOL. XII. AUGUST 26, 1891. No. 173.

THE FRANKFORT INTERNATIONAL ELECTRICAL EXHIBITION—V.

BY

Richard O. Heinrich.

MOST of the instruments contained in the collection of instruments of precision are well known. A number of improvements have been made, however, and it may be well to give a short description of the most important ones.

Fig. 1 shows a portable mirror galvanometer with lamp and scale. The light is thrown, by means of a prism, on a concave mirror within the coil, and from there on to the scale. On the mirror are fastened very light watch-spring magnets, in the well-known manner; a very short double-fibre suspension, and the lightness of the system of magnets make the instrument very quick acting and dead-beat. The respective positions of lamp and scale are a

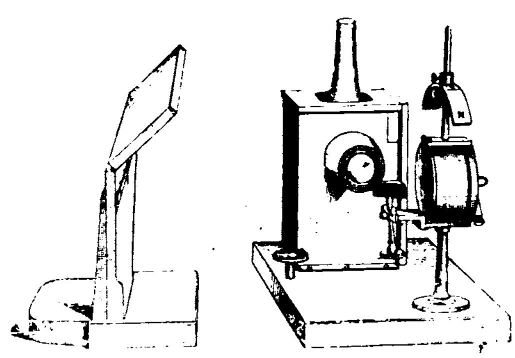


FIG. 1.—PORTABLE MIRROR GALVANOMETER WITH LAMP.

decided advantage for the observer. The whole combination is placed in a case of moderate size for transportation. Figs. 2 and 3 represent astatic mirror galvanometers of high sensibility. The galvanometer, Fig. 2, is intended for very accurate work in the laboratory. The coils are fastened on hinges, so that the astatic system of bell magnets may be easily reached. The mirror and the circular glass case may be turned in any direction, making the position of the reading device independent of the magnetic meridian. The coils can be used differentially, and small movable adjusting coils in the centre of the larger ones afford means for obtaining an exact balance if the magnetic action of the large coils is not precisely the same for each pair.

Fig. 3 shows a portable modification of an astatic mirror galvanometer. The central frame, carrying the coils, is made of solid copper with a narrow slot for the astatic bell magnet system. This frame serves at the same time as a very effective copper-damper. The instrument is very dead-beat, as shown by test, which proves that it is quite sufficient to have the greater amount of copper in the direction of the poles of the magnet in its zero position. In both the latter instruments the system of compensating and directing magnets is noteworthy. It consists of two magnets which are moved independently by a train of wheels; a very complete compensation of the earth's magnetism

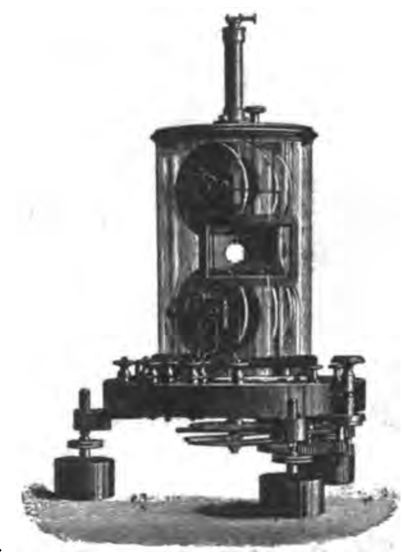

FIG. 2.—ASTATIC MIRROR GALVANOMETER.

can be effected by compensating first approximately with one of the magnets, and by making a final adjustment by placing the second magnet in a cross-position to the first.

The large slide-wire bridge, shown in part in Fig. 4, is a very complete and excellent piece of apparatus. The

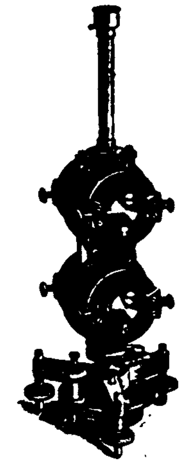

FIG. 3.—PORTABLE ASTATIC MIRROR GALVANOMETER.

wire is of platinum-iridium, two metres long and doubled up, so that the two ends come close together. The wire is protected against sudden changes of temperature, as, for instance (from the hand of the experimenter), by a perforated sheet of copper. The contact on the wire is made simultaneously from above and from below by two small platinum wheels. In the position shown in the illustration, the springs carrying the contact wheels are lifted by an eccentric. On raising the small handle on the slide contact, the springs press the contact wheels against the wire always with the same tension, preventing a kinking and notching of the wire. The fine adjustment is made by a

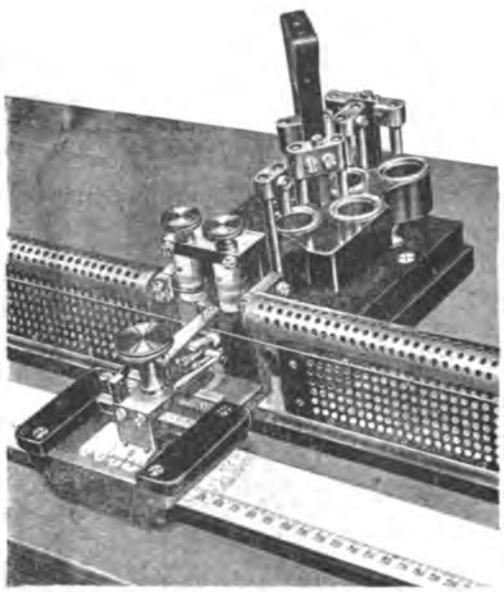

FIG. 4.—LARGE SLIDE WIRE BRIDGE.

rack-and-pinion movement. A very simple mercury commutator on an ebonite base allows of the commutation of the test and standard pieces.

GUTMANN'S ELECTRIC HEATERS.

BY

L. Gutmann

THE problem of electric heating has not yet received proper attention from electrical engineers on account of the alleged great cost of current as compared with coal or gas; nevertheless, proper analysis shows that there is considerable scope for electric heaters, as in the following cases, which have led the writer to construct a number of such devices for commercial purposes.

1. Electric heaters are a source of revenue in central stations operated by water-power; therefore they are especially adapted for supplying heat in mountainous countries and in cities around Niagara Falls. 2. To supply heat for local plants, such as large hotels, where there must be at all times ample power for lighting, running elevators, fans, etc. 3. For railway trains, to increase the safety of the public, and especially to prevent the setting on fire of cars after an accident. 4. To supply this commodity to residences or other places where comfort is the first, and cost a secondary, consideration.

In constructing electric heaters, continuous, alternating, pulsating, or intermittent electric currents may be used; but it will be found that the alternating or pulsating current, as in the distribution of light, will be the more advantageous one, as shown by the methods described below, which can be applied for this purpose:

1. Continous currents applied to a bare conductor or covered by incombustible material. 2. Alternating or intermittent currents applied to a bare conductor for raising its temperature. 3. Alternating, pulsating, or intermittent currents applied to magnets whose primary, secondary, or tertiary currents are used to heat a bare conductor or conductors imbedded in incombustible material. 4. Alternating, pulsating or intermittent currents applied to an open magnet whose flow of lines of force induce secondary currents in neighboring conductors. 5. Alternating, pulsating or intermittent electric currents whose primary, secondary or tertiary currents induce others in neighboring conductors by induction.

In the construction of heaters the following points at once force themselves upon the attention of the constructor:

a. To make a commercial heater we should use as small a current as possible, so as to have the least possible waste of energy in conveying the current to the place of consumption; *i. e.*, a device whose cost of supply is reasonable.

b. The law $C \times R$, which is in opposition to the condition *a*, according to which the heat developed increases as the square of the current, would indicate as a desirable feature the use of currents as large as possible. *c*. Also, that *C*, the current, can be made small and constant if *R*, the resistance, is increased; but in this case the pressure would necessarily have to be increased also. The aim of the writer has been to combine the contradictory conditions of *a* and *b* in constructing heaters, and while at first sight this solution seems impossible, it has been solved in a very simple manner, by means of apparatus illustrated in the accompanying engravings.

Fig. 1 shows diagrammatically such a system of heat distribution. From a central station alternator or pulsator, indicated by the collecting rings, the current is supplied to a converter at the place of consumption; the secondary currents may operate with a pressure of, say, 50 volts up to 200 volts.

The heaters are shown connected in parallel with one another, and are of special construction. In its simplest form the heater consists of an electromagnet whose magnetic circuit is closed by a grate or a corrugated conductor, and a screen separating the greater part of the electromagnet from the grate. A comparatively small current is supplied to the electromagnets whose magnetic circuit is partly closed by the grate in close proximity to the poles.

The action is as follows: The small current circulating through a coil of many turns around the laminated core establishes at its poles a field of rapidly varying intensity, which finds a path from one pole to the other through the

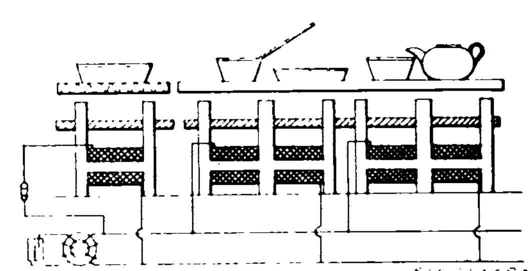

FIG. 1.—GUTMANN ELECTRIC STOVE.

grate, made of wrought or cast iron. The latter, not being laminated, will become heated rapidly, owing, first, to the heavy secondary currents circulating through the grate whose flat strips or bars and frame form a number of closed secondary circuits of very low resistance, located at right angles to the flow of lines of force of the energizing magnet; secondly, on account of eddy currents and hysteresis. The heat radiated is readily applied for heating or cooking purposes.

The perforations in the conductor, which at the same time may serve as support for the kitchen utensils while in use, have, besides the functions mentioned above, still others to perform. It will be evident that the grate develops the maximum heat at the lower surface and at points near the magnet poles; if the conductor is without perforations and forms a plate, the heat would have to penetrate through it to the other side, and that radiated at the side near the magnet would be apt to destroy the energizing coils. The perforations, therefore, supply a convenient

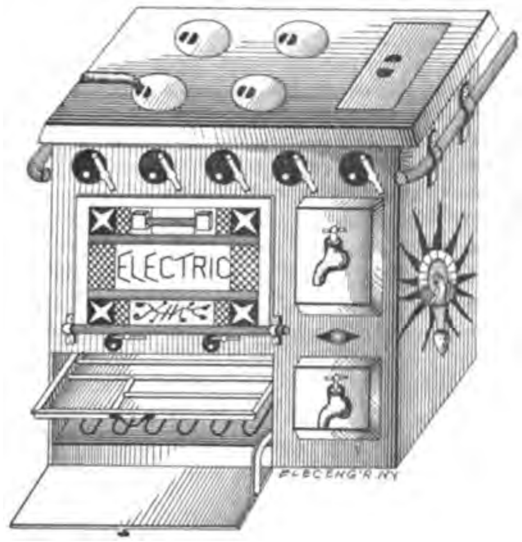

FIG. 2.—GUTMANN ELECTRIC STOVE.

passage for the heated air from the lower surface to the articles to be heated. To still further decrease the effect of heat radiation on the energizing magnet a screen of non-heat-conducting material is mounted on the limbs of the magnet.

Fig. 2 represents in perspective a heater or range, which, externally, has all the appearance of an ordinary stove, with the one vital difference that not all compartments are required to be heated simultaneously, as in the coal stove. They may be operated simultaneously, or each separately, every compartment being provided with a separate heater. The circuit is closed by the main switch on the right-hand side of the stove while the grates on top are separately controlled or turned off by the five switches which are seen below the guard rail, shown broken away. The baking oven and broiler are similarly controlled by the two switches mounted on the front side between the two compartments.

Fig. 3 is a cross-section of the same apparatus showing the application of a different kind of heater, in which the currents, alone or in combination with the magnetic circuit they establish, are used for heating purposes.

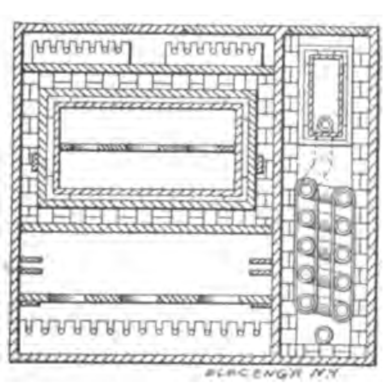

FIG. 3.—GUTMANN ELECTRIC STOVE.

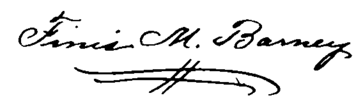
To economize and preserve the heat as long as desirable inside the stove, the inner walls are lined with tiles, which has the further advantage for the operator over coal and gas stoves in that the air surrounding the stove is not much raised in temperature.

WEIGHING ELECTROLYTIC METER PLATES ELECTRICALLY.

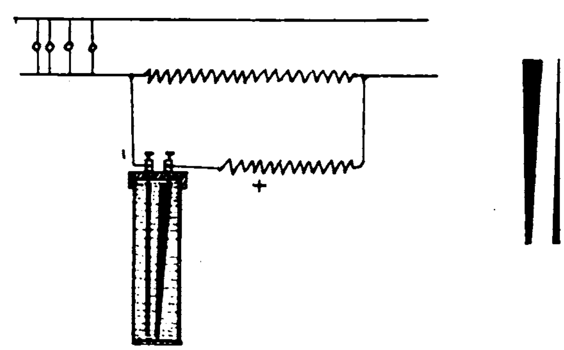
BY



THE demand for a means of measuring the amount of current consumed has given rise to numerous methods of measurement, of which the Edison electrolytic method forms one very generally used because of its simplicity, low first cost, and reliability. The fact that electric light stations which use a meter get more money for the same amount of current used is a strong one in favor of all adopting a meter, especially in plants of considerable output.

But one of the drawbacks to the electrolytic meter is the cost and care required in its manipulation, the renewal of plates, chemicals, and weighing, etc.

If we reduce the size of the plates and amount of chemicals used, and thereby diminish the cost of operating, we increase the degree of sensitiveness which is necessary to obtain accurate weights, and therefore multiply the errors to which we are liable. It is to obviate the necessity of weighing and to give a more accurate means of ascertaining the amount of current consumed that forms the subject of this article, and I hope soon to put the meter into practical operation.



FIGS. 1 AND 2.—WEIGHING ELECTROLYTIC METER PLATES ELECTRICALLY.

The method used is that of balancing resistances by means of a Wheatstone bridge or a differential galvanometer. The more we diminish the size of the electrodes used in the electrolytic method, the more we increase their resistance, and, therefore, the more perceptible any little change of that resistance and the more accurate our measurements. This will necessitate the diminishing of the strength of the current passing through the electrodes to avoid too great a deposit.

Fig. 1 shows a modified cell somewhat similar to the Edison cell. If we place two long and slender electrodes parallel in a solution and give them current, the greater amount of current will pass near the top of the fluid, and the deposit of metal will be unequal; the inequality of this deposit will be in proportion to the resistance of the electrodes and the strength of current, and may be balanced by inclining the electrodes to each other. This inclination must be in proportion to the resistance of the electrodes and fluid, and as the resistance of the electrodes is constantly changing, the inclination must also be changed in proportion. This change is effected automatically by taking an electrode of uniform size and tapering it gradually, somewhat like a wedge, as shown in Fig. 2, in front and side views, respectively. The resistance is uniform throughout its entire length. This wedge is placed with its flat end toward the top and with its edge toward another electrode of uniform size, and slightly inclined thereto, being closer at the bottom, and is connected to the positive terminal. As the electrode wastes away it increases in resistance, and as the distance between the top of the electrodes increases faster than the bottom, the deposit is thereby maintained uniform throughout their entire length. If the resistances of the electrodes are equal, they are placed with their nearest edges parallel.

Before placing in circuit, the resistance is balanced, as shown in Fig. 3, and the amount of deflection noted and tagged. It will be noticed that in this measurement we obtain simply the relative proportion of resistance between the electrodes, and the same deflection may be obtained between two pairs, though they differ greatly in size. I therefore have what I call a standard cell, through which

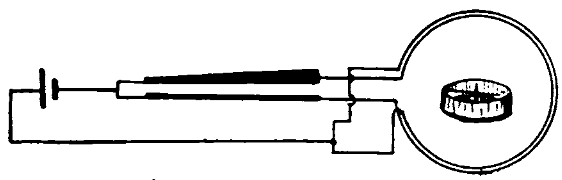


FIG. 3.—WEIGHING ELECTROLYTIC METER PLATES ELECTRICALLY.

a known current has been passed, say, the one thousandth part of one ampere for 1,000 hours; the electrodes are taken out and the deflection again noted. The difference between the two deflections must denote the ampere hour.

If now we wish to measure the amount of current consumed by 20 lamps, we would require electrodes with 16 times the amount of metal in the standard size. The deflection is noted, the resistances in shunt circuit being the same, and after an unknown current has passed an unknown length of time, the electrodes are taken out and the deflection again noted. The difference between the two deflections, multiplied by 16 (the difference in the size of the electrodes) times 1,000 (the part of current measured), will give the total current consumed. In this method the electrodes are paired and deflections noted and weights taken at the factory and numbered and tagged, and do not need to be separated when measured.

THE CAPACITY AND SELF-INDUCTION OF OVERHEAD TELEGRAPH LINES.

IN a recent note in the *Comptes Rendus* M. Massin calls attention to the lack of data with regard to the capacity and self-induction of overhead telegraph lines, caused by the difficulty of making the necessary measurements owing to the proximity of "live" wires. M. Massin, however, found means for obtaining these data for three circuits. A line, 18 kilometres long, iron wire, 3 mm. in diameter; two wires about 40 centimetres apart, and 4.5 metres from the ground. B line, 50 kilometres; C line, 50 kilometres; copper wire 2.5 mm. in diameter; two wires about 50 centimetres apart, and 5.5 metres from the ground. The following results were obtained:

Line.	Kilometric capacity in microfarads with respect to earth.	Ditto of the looped wires.
A	.0097	.0070
B	.0099	.0069
C	.0092	.0065

The two wires have, therefore, when looped, seven-tenths the capacity of either separately. On underground lines the capacity is exactly halved. The coefficients of self-induction per kilometre of looped wire were found to be as follows: Line A, .0121 henry; line B, .0129 henry; line C, .0025 henry.

ELEMENTARY GEOMETRICAL THEORY OF THE ALTERNATE-CURRENT TRANSFORMER.—XII.

BY

Chas. Steinmetz.

Now we produce the curve of magnetic lag, k, either the cubic parabola, as explained before, or, better, here,—where we want to consider the phenomena over a larger range of magnetization,—the true curve of magnetic lag, as calculated from the experimental determinations of the magnetic constants of the iron used.

This curve is shown in Fig. 24 as k. For any value of *resulting* M. M. F., $F = \overline{\text{O F}}$ we get the *impressed* M. M. F. by drawing $\text{F K} \parallel \text{O A}$, as $K = \overline{\text{O K}}$.

The *secondary* M. M. F., L_1 is the horizontal line cut out between the curve of magnetic lag, k, and the quadrant of primary M. M. F., c, because of the parallelogram of M. M. F.'s. Therefore the secondary M. M. F., and the *secondary current* are given by $L_1 = C_1 = \overline{\text{O C}_1} = \overline{\text{K C}}$; and the *primary* M. M. F. or the *primary current* is, $L = C = \overline{\text{O C}}$.

The resulting M. M. F., F, gives the *induced* E. M. F., $E_1 = \overline{\text{O E}_1}$.

The *primary resulting* or *heating* E. M. F. is constant, because of the constancy of the primary current. Hence E lies on the quadrant e, and has the value $E = \overline{\text{O E}}$.

$\overline{\text{O E}_1}$ combining with $\overline{\text{O E}_e}$ to the resulting E. M. F., $\overline{\text{O E}}$, by the parallelogram of E. M. F.'s, $O\,E_1\,E\,E_0$, gives the *primary impressed* E. M. F., $\overline{\text{O E}_0} = E_0$.

$\frac{E_1}{C_1} = r_1$ is the secondary resistance, where this diagram corresponds to angle $\omega = \text{C O E}_0$ the difference of phase between primary current and impressed E. M. F., etc.

From this diagram, Fig. 24, we see that, when the secondary resistance increases from its value at short circuit, $r_1{}^0$, up to infinity, the resulting M. M. F. increases from the minimum F^0 up to a maximum value F^{∞}. The impressed M. M. F. increases, K traveling on curve k up to K^{∞}.

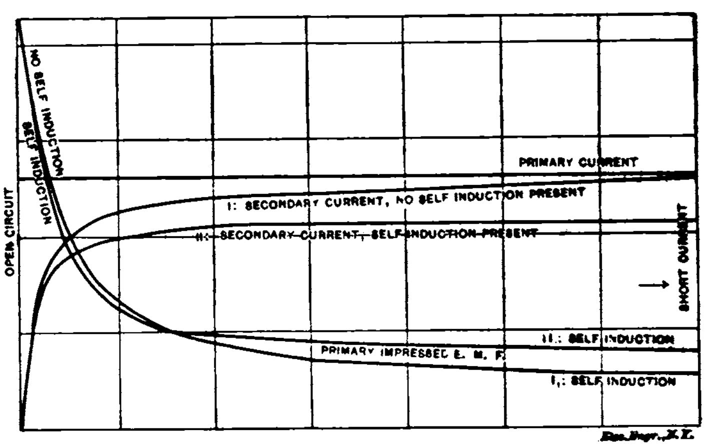

FIG. 25.

The phase of the primary current, and the difference of phase between primary current and impressed E. M. F., increase from about zero at short circuit, up to a maximum value for open circuit. The primary impressed E. M. F. increases from minimum, $E_0{}^0$ at short circuit, up to maximum $E_0{}^{\infty}$ at open circuit. The secondary M. M. F., L_1, and the secondary current, $C_1 = \overline{\text{K L}}$, decrease for increasing secondary resistance, from their maximum values $L_1{}^0$ and $C_1{}^0$ at short circuit, first slowly, then faster and faster down to zero.

This decrease of the current being first very slow, within a certain range, that is, below a certain maximum of resistance, the transformer compounds fairly well for constant current, and only when the secondary resistances overstep this value, does the secondary current fall off more rapidly.

For *decreasing* secondary resistance r_1, the ratio of the currents approaches an inverse proportionally to the ratio of turns:

$$\frac{C_1}{C} \sim \frac{n}{n_1} = 1, \text{ in our case.}$$

The *secondary* E. M. F., E_1 increases for increasing resistance, from its minimum value at short circuit, first almost proportionally to the secondary resistance, then slower, and reaches a maximum for open secondary circuit, that is, when L reaches the point of intersection of l and k; that is, $L^4 = C^4$.

Then the *magnetization* and the M. M. F. have reached its maximum also, $F^4 = \overline{O F^4}$. *The primary* E. M. F. varies from its minimum value, $\overline{O E_0{}^0}$, at short circuit, up to its maximum value, $\overline{O E_0{}^4}$ at open circuit.

The energy consumed by the converter, and also the energy converted by it, is a minimum for short circuit, increases with increasing secondary resistance, reaches a maximum and then decreases again to a minimum for open circuit, while in a constant potential transformer, the energy consumption and conversion steadily decrease from minimum permissible resistance down to open circuit.

For the constant potential transformer a short circuit is destructive, and open circuit the normal condition for no load. For the constant current transformer, short circuit is the normal condition for no load; open circuit, although it wastes no energy but that consumed in hysteresis and eddy currents, must be avoided because of its enormous waste of potential.

So far as the danger of destruction by overload is concerned, a constant current transformer is decidedly safer than a constant potential transformer, because the former cannot be overloaded to a destructive degree, it being able to transmit only a certain amount of energy, as its maximum capacity.

Fig. 24 shows the diagrams of the constant current transformer for the secondary resistances:

0. short circuit: $r_1{}^0 = .8$ ohms.
1. " $r_1{}^1 = 6$ "
2. " $r_1{}^2 = 12$ "
3. " $r_1{}^3 = 34$ "
4. open circuit: $r_1{}^4 = \infty$ "

The dependence of the secondary current, and of the primary impressed E. M. F. upon the resistance, or rather its inverse value, the electric conductivity of the secondary circuit, is shown in Fig. 25 as curves *I* and *II*.

From the diagram, Fig. 24, we derive the values:

		0.	1.	2.	3.	4.	
Primary current, C	=	65	65	65	65	65	amp.
Primary impressed E. M. F., E_0	=	23	58	79	147	214	volts.
Primary resulting E. M. F., E	=	20	20	20	20	20	volts.
Secondary current, C_1	=	64	58	54	39	0	amp.
Secondary E. M. F., E_1	=	2.6	19	60	130	208	volts.
Resulting M. M. F., F	=	156	1140	3600	7500	12480	amp. turns.
Angle of magnetic lag, α	=	30°	33°	25°	19°	16°	
Angle of phase bet. prim. cur. ω and impressed E. M. F.	=	0°	7°	12°	33°	66°	
Effective secon. energy, $\frac{E_1 C_1}{2}$	=	83	551	1620	2535	0	watts.
Eff. prim. energy, $\frac{E_0 C \cos \omega}{2}$	=	715	1821	2508	4062	2828	watts.

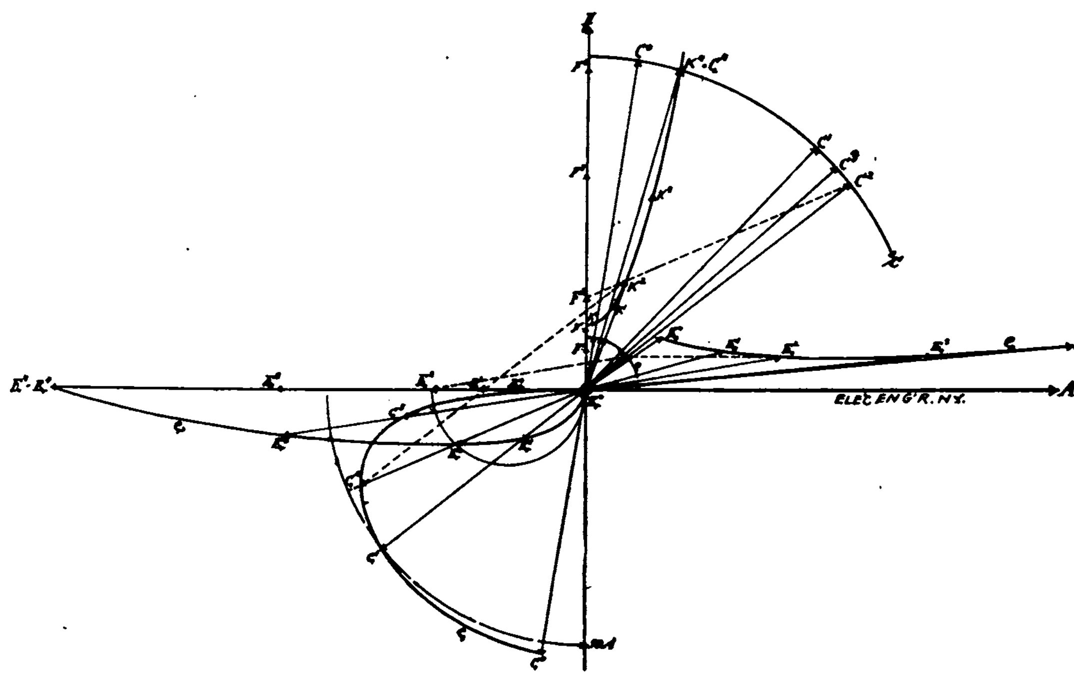

FIG. 26.

Ratio of transformation, $\frac{C_1}{C}$	=	.99	.89	.83	.60	0

As will be seen, the secondary current decreases with increasing resistance first slowly, then faster, down to zero. The E. M. F.'s, and the resulting M. M. F. increase with increasing resistance, up to maximum values. The angle of magnetic lag decreases, while the angle of shifting of phase between primary current and impressed E. M. F. increases with increasing resistance. The energy increases to a maximum and then decreases again. The ratio of transformation, $\frac{C_1}{C}$, reaches almost the ratio of the number of turns, $\frac{n}{n_1}$, for short circuit.

To secure still better compounding, the constant current transformers are generally built so as to afford a large magnetic leakage, that is, with a high self-induction in the secondary circuit.

In Fig. 26, the diagram of a constant current transformer is produced, which has a certain amount of self-induction in its secondary circuit.

The constants of the transformer are the same as in the transformer given in Figs. 24 and 25.

The self-induction of the secondary circuit may, for each ampere of secondary current, induce a counter E. M. F. of 4 volts.

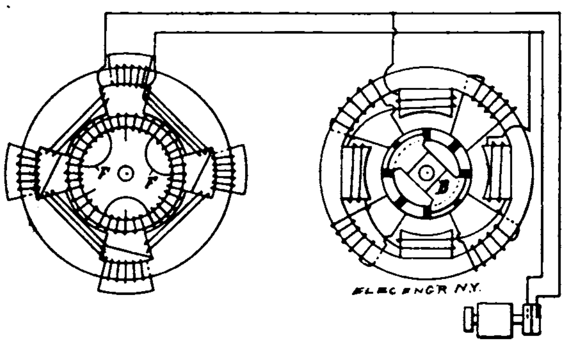
The primary current, C, and the primary M. M. F., L, lie again on the quadrant of the circle, c.

The primary resulting, or heating E. M. F., E lies on the quadrant, e.

Here the parallelogram of M. M. F.'s assumes a somewhat different form, because the phase of the secondary current is shifted against that of the secondary E. M. F., as explained before, in chapter VII.

GUTMANN'S ALTERNATING CURRENT MOTOR.

In alternating current electric motors there have appeared, up to the present time, only very small two-wire machines, while for larger powers either synchronous or Tesla three-wire motors have been used. The accompanying en-



FIGS. 1A AND 1B.—GUTMANN'S ALTERNATING MOTOR.

gravings represent a new type of motor designed for large capacity and adapted to operate on two-wire circuits, by Mr. Ludwig Gutmann, of Pittsburgh, Pa. Having noticed the very powerful effect of a short circuit in the armature of a continuous or alternating current motor, Mr. Gutmann has based the construction of his new motor on the every principle which is generally so detrimental, and is dreaded in any other motor. Figs. 1A and 1B represent, in diagram, two different motors. Fig. 1A shows especially the armature, while the field-magnet construction adopted in practice is shown in Fig. 1B. The armature shown is of the Gramme

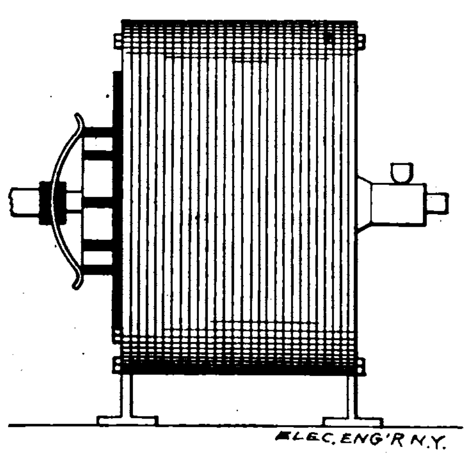


FIG. 2.—GUTMANN'S ALTERNATING MOTOR.

type, wound in the well-known manner, but the commutator is omitted, and instead there are three permanent short circuits, F, short-circuiting a portion of the armature winding. To prevent dead points it will be noticed that the short-circuited parts differ in number from that of the field-magnet poles. In Fig. 1A the field-magnet winding consists of primary coils connected to a generator or converter while a number of secondary coils are closed, each upon itself.

In Fig. 1B the arrangement is altered. The secondary coils are connected to terminals or to a commutator, in con-

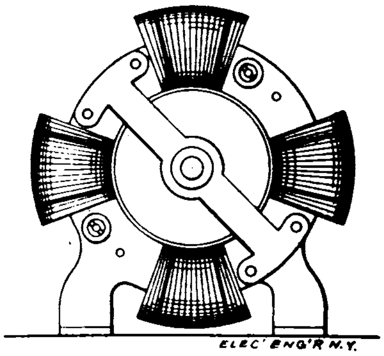

FIG. 3.—GUTMANN'S ALTERNATING MOTOR.

tact with which is a brush adapted to rotate with the armature. As the latter is repelled it shifts the position of the brush, and thus also the position of the secondary poles. It will thus be clear that the motor operates with a true alternating current field, which is influenced by a rotating secondary field of constant intensity, though intermittent in nature.

The action is as follows: The short-circuited coils, situated in a maximum magnetic field are repelled, and thus the brush, B, which is rigidly attached to the armature shaft, changes the position of the secondary poles which move in front of every short-circuited group or coil. As one of these approaches a field-magnet pole its power is weakened by the approaching secondary pole until the centre of the closed coil has passed that of the field pole. When this point has been reached the secondary pole has moved also; the primary pole again develops its full force and repels the coil in the same direction in which the armature has been moving. In this special form this process is repeated twelve times per revolution, and two of the coils are always active while the third one is inactive.

It will be noticed that the primary energizing circuit is permanently connected to the line, and that no circuit changers are connected with it, while the armature is of simple construction, and the commutator is in connection with low potential secondary circuits. The complete motor, of the iron-clad type, is shown in Fig. 2, while Fig. 3 shows an end view of a motor in which the energizing coils are partly external to the core.

SOME RESEARCHES IN MAGNETISM.

In a recent number of *Wiedemann's Annalen*, Karl Fromme states that some earlier experiments led him to the conclusion that the maximum value of the permanent (residual) magnetic moment P. M. attained by a body previously unmagnetized through the repeated application of the same magnetizing force P, could neither be raised nor changed by the application of a force equal to or smaller than P, and acting in the same direction. Later tests, however, had convinced him that this was incorrect. The magnetized bodies consisted of bundles of iron wire, pieces of wrought iron, and mild steel. One experiment was as follows: A piece of iron was magnetized to a constant value of P. M. by means of repeated applications of a current of one ampere and then subjected to the influence of a smaller current. In all cases the application of the weaker force due to the smaller current effected at first an increase in P. M. until it reached a maximum, and then a decrease through the original value to a negative maximum, and finally an increase again.

THE OERLIKON THREE-PHASE ALTERNATOR.[1]

The electric transmission of power for industrial purposes has now become an every-day affair, and, owing to the distances which in the majority of cases separate the waterfalls from the places where their energy is to be utilized, high pressures are necessary. Owing to the ease with which they lend themselves to transformations of pressure, and for other reasons, alternating currents are eminently adapted to the purpose, and when these currents are of the multiphase character, satisfactory motors are also forthcoming. The Oerlikon Works, which have for a long time made a specialty of transmission of power installations, are about to lay down several plants on the multiphase system, devised by Mr. C. E. L. Brown.

In Fig. 1 we have a general view of a 300 h. p. Brown "multiphaser," running at 150 revolutions. The armature circuits are arranged to give three alternating currents lagging 120 degrees, one behind the other. Each of the three circuits of the machine is wound for a pressure of 50 volts and a current of 1,400 amperes. The current output being large, rubbing contacts have been avoided by making the armature stationary and the field-magnets revolve. The armature conductors are 29 mm. in diameter, and consist of massive bars of copper, insulated inside abestos tubes, and buried in holes punched out of the iron close to the internal periphery. Foucault currents, which would attain enormous values in such large copper conductors, if they were arranged in the ordinary way, are by this device avoided; in fact, experiments made with "buried" conductors, 50 mm. in diameter, did not show that any power was lost by Foucault currents. This method of arranging the armature conductors is mechanically strong, and, as it enables asbestos to be used as an insulator, results in an armature which is absolutely incombustible. Moreover, the reduction in the air space, and the consequent improvement of the magnetic circuit, reduces the exciting current.

1. London *Electrician*.

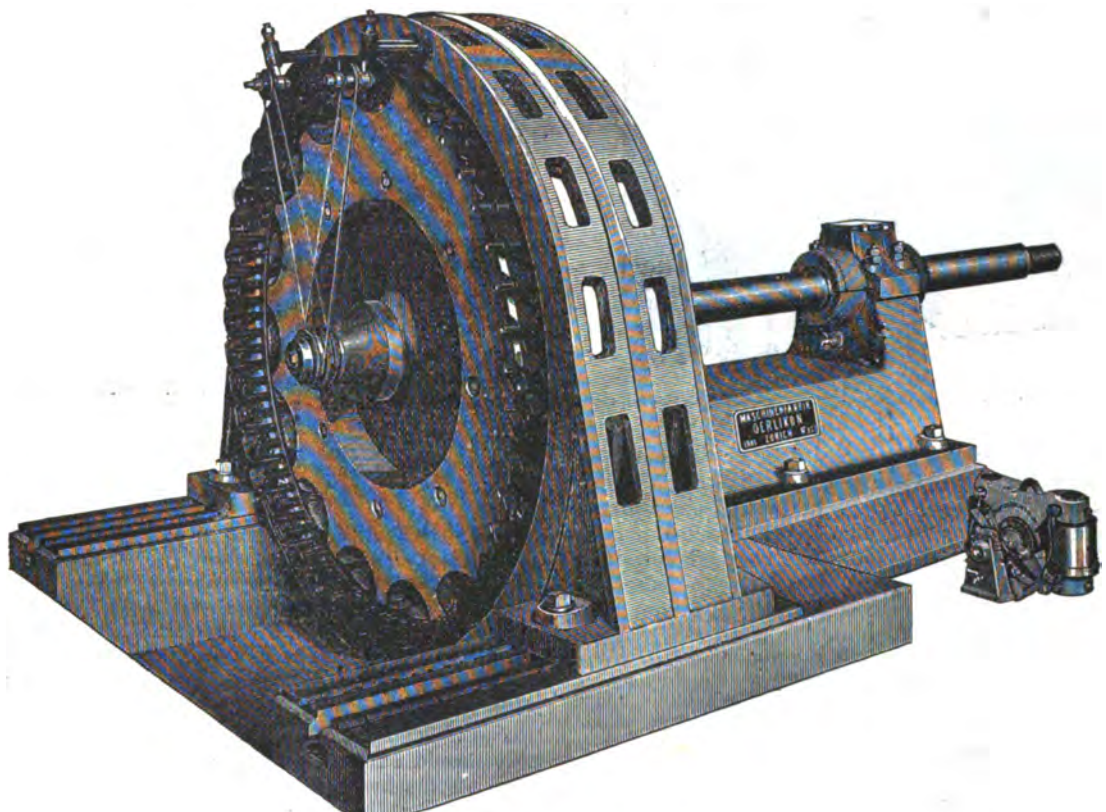

FIG. 1.—OERLIKON 300 H. P. THREE PHASE ALTERNATOR.

Corresponding to the 32 poles of the field-magnet, each circuit of the armature has 32 copper bars, connected in series by transverse pieces. There are, therefore, in all 96 (3×32) bars on the armature. The three circuits are joined up to each other in a manner similar to the three circuits of the Thomson-Houston arc machine. The armature core is surrounded by a cast-iron frame, and the whole can be moved along the bed-plate for cleaning and other purposes, leaving the field-magnet open to view, as shown in Fig. 2.

The exciting circuit is coiled round a sort of cast-iron pulley. Two steel rims, each armed with 16 horns forming pole-pieces, are bolted on to the pulley, one on either face, in the manner shown in detail in Figs. 3 and 4. This arrangement permits of the maximum utilization of the magnetic flux, and both the copper and the exciting current are reduced to a minimum. The construction of a field-magnet of this type is very simple, the 32-pole magnet being in only four separate parts, an inestimable advantage in a piece of moving mechanism subject to heavy stresses.

The exciting current is taken to the field magnets by means of two metallic bands, each of which passes round a grooved ring on the spindle, and round a pulley connected to a terminal. (See Fig. 1.) The armature is overhung, the massive spindle being carried on a double bracket bolted to the bed-plate.

A machine of this type can work equally well as a synchronizing motor, but it differs from an ordinary alternate current motor, inasmuch as it can be made to start without difficulty.

A few figures may not be without interest. The total weight of copper on the field-magnet is 300 kilogrammes; that is to say, a fraction of the copper usually required for other machines of the same size. To excite the machine so as to give 50 volts on open circuit, only 100 watts are required; that is to say, one-twentieth per cent. of the output. At full load, owing to the reaction of the armature, this amount is slightly increased, but it never exceeds a fraction of one per cent. At full speed, and with normal volts, the friction losses amount to 3,600 watts, about 1.6 or 1.7 per cent. of the maximum output. The $C^2 R$ loss in the armature conductors at full load is 3,500 watts. Adding all these losses up, we still have a commercial efficiency of 96 per cent. With such small losses the heating is, of course, quite negligible. The total weight of the machine without bed-plate is 9,000 kilogrammes.

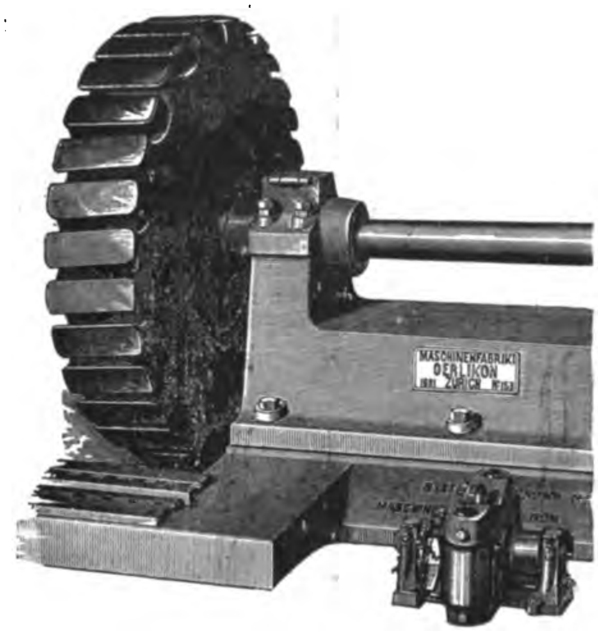

FIG. 2.—FIELD MAGNET OF OERLIKON THREE PHASE ALTERNATOR.

The Oerlikon Works have completed, or have in the course of construction, several dynamos of this type. First of all comes the Lauffen-Frankfort transmission plant. Machines are also built for 10 kilometres at Heilbronn and at Zurich; while three generators with vertical spindles, for coupling direct to turbines, and two motors with hori-

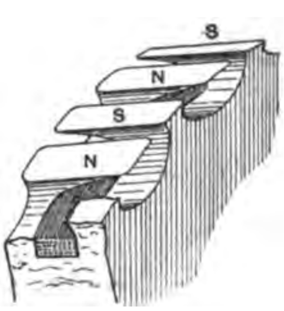

FIG. 3.—DETAIL OF FIELD MAGNET

zontal spindles, are to be employed to drive the whole of the machinery at the Oerlikon Works from a waterfall 23 kilometres distant.

THE GRASSOT ELECTROLYTIC METER.

THE electrolytic meter devised by M. E. Grassot has certainly the merit of originality. It consists of a silver wire 5 mm. in diameter, placed in a glass tube, and dipping for a distance of about 3 mm. into a solution of nitrate of silver. The silver wire is an anode to a cathode of zinc, and as it loses weight it is made to descend and pull round a drum actuating a train of clock wheels and indicating dials.

THE VIBRATION OF A WIRE TRAVERSED BY A CONTINUOUS ELECTRIC CURRENT.[1]

BY M. D. HURMUZESCU.

A FINE metal wire stretched between two supports, one of which is provided with a strainer or spring for regulating the tension, on being traversed by a *continuous* current begins to vibrate. The amplitude of the vibrations, which is at first very small, increases as the time goes on, and

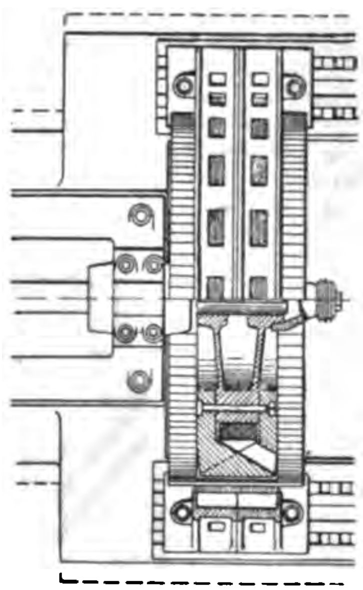

FIG. 4.—PLAN AND HALF SECTION OF FIELD MAGNETS.

quickly arrives at a maximum, which it maintains as long as the current is passing through, provided that the surrounding atmosphere remains in the same condition, or, at any rate, does not undergo any sudden change. The vibrations may thus continue indefinitely; they stop in a few seconds when the current is interrupted.

For a given tension, the amplitude of the vibrations seems to depend (according to the experiments which I have made up to the present) on the difference in the temperature of the wire and of the surrounding atmosphere. Now, as it is the intensity of the current which produces this difference of temperature in a given wire, the amplitude should vary according to the intensity. The explanation of this fact seems to me to lie in the interchange of heat between the wire and the surrounding atmosphere; this constitutes really a *thermic motor*, in which the energy expended is supplied by the current, and the principle of the conservation of energy can be applied to it.

Any cause producing a change, in any manner whatever, in the mode in which this interchange of heat takes place, will modify the phenomenon in some way or other. We can foresee that the finer the wire the more rapid will the vibrations be; this is confirmed by experiment. I repeated the experiment with wires of different natures, and found that the phenomenon always preserves the same character. If we put the wire in a large glass tube the movement is regular, because the wire is sheltered from the movements of the air. On closing the two ends of the tube, I observed no change in the rapidity of the vibrations. I hope soon to bring forward the law of this phenomenon from the points of view of the tension of the wire, the difference of temperature between the wire and the surrounding atmosphere, and the manner in which the interchange of heat between the two sources is effected.

---

ELECTRIC DISCHARGE IN VACUUM TUBES.

BY

Nikola Tesla

IN THE ELECTRICAL ENGINEER of August 12, I find some remarks of Prof. J. J. Thomson, which appeared originally in the London *Electrician* and which have a bearing upon some experiments described by me in your issue of July 1.

I did not, as Prof. J. J. Thomson seems to believe, misunderstand his position in regard to the cause of the phenomena considered, but I thought that in his experiments, as well as in my own, electrostatic effects were of great importance. It did not appear, from the meagre description of his experiments, that all possible precautions had been taken to exclude these effects. I did not doubt that luminosity could be excited in a closed tube when electrostatic action is completely excluded. In fact, at the outset, I myself looked for a purely electrodynamic effect and believed that I had obtained it. But many experiments performed at that time proved to me that the electrostatic effects were generally of far greater importance, and admitted of a more satisfactory explanation of most of the phenomena observed.

In using the term *electrostatic* I had reference rather to the nature of the action than to a stationary condition, which is the usual acceptance of the term. To express myself more clearly, I will suppose that near a closed exhausted tube be placed a small sphere charged to a very high potential. The sphere would act inductively upon the tube, and by distributing electricity over the same, would undoubtedly produce luminosity (if the potential be sufficiently high), until a permanent condition would be reached. Assuming the tube to be perfectly well insulated, there would be only one instantaneous flash during the act of distribution. This would be due to the electrostatic action simply.

But now, suppose the charged sphere to be moved at short intervals with great speed along the exhausted tube. The tube would now be permanently excited, as the moving sphere would cause a constant redistribution of electricity and collisions of the molecules of the rarefied gas. We would still have to deal with an electrostatic effect, and in addition an electrodynamic effect would be observed. But if it were found that, for instance, the effect produced depended more on the specific inductive capacity than on the magnetic permeability of the medium—which would certainly be the case for speeds incomparably lower than that of light—then I believe I would be justified in saying that the effect produced was more of an electrostatic nature. I do not mean to say, however, that any similar condition prevails in the case of the discharge of a Leyden jar through the primary, but I think that such an action would be desirable.

It is in the spirit of the above example that I used the terms "more of an electrostatic nature," and have investigated the influence of bodies of high specific inductive capacity, and observed, for instance, the importance of the quality of glass of which the tube is made. I also endeavored to ascertain the influence of a medium of high permeability by using oxygen. It appeared from rough estimation that an oxygen tube when excited under similar conditions—that is, as far as could be determined—gives more light; but this, of course, may be due to many causes.

Without doubting in the least that, with the care and precautions taken by Prof. J. J. Thomson, the luminosity excited was due solely to electrodynamic action, I would say that in many experiments I have observed curious instances of the ineffectiveness of the screening, and I have also found that the electrification through the air is often of very great importance, and may, in some cases, determine the excitation of the tube.

In his original communication to the *Electrician*, Prof. J. J. Thomson refers to the fact that the luminosity in a tube near a wire through which a Leyden jar was discharged was noted by Hittorf. I think that the feeble luminous effect referred to has been noted by many experimenters, but in my experiments the effects were much more powerful than those usually noted.

WHO SHALL DO THE WIRING?

BY

Ea. Harris

THE editorial on "Putting in Wires and Fixtures," in the August 5th issue of THE ELECTRICAL ENGINEER, convinces me that, like myself, others are believers in the oft-repeated statement that "electric light companies should leave the putting in of wires and fixtures to some one else" (in many cases to those more competent than the employees of the local company).

I am glad to see a growing interest in this subject, and would like to see a general expression of opinion through these columns from the various cities. There is no doubt in my mind that the New England town spoken of is "torn wide open" on the subject, as it is one that is causing various companies no end of trouble. Dallas was shaken from "stem to stern" when the new order of things went into effect. Previous to that time the local companies, in order to gain the supremacy, made the wiring a secondary consideration and the results can well be imagined. They could not afford to go to the expense of doing fancy work, as they were not charging for it, and consequently it was "fearfully and wonderfully done." The paramount idea in everybody's brain was to get the lights in and as soon as possible. This worked very nicely until the plant was installed, and all the lights put in that could be, and then the question arose as to what was to be done with the large gangs of wiremen. A number were discharged, but a very respectable number were retained, in the event that some one might want lights—which they did—but the employment of 10 or 12 well-paid men for the purpose of wiring two or three places a week soon played havoc with the receipts. The company passed through a series of vicissitudes, as all companies will that are run upon such an uneconomical basis, and finally passed into the hands of the parent company. A new order of things was inaugurated. It was given out that in future consumers would be expected to pay for everything, the company simply furnishing the current, and the consumer to get whom he pleased to put in his wires and fixtures. It was a difficult matter to overcome the existing idea that "it didn't cost anything to have lights put in," but they finally learned that it did, and after nearly two years' experience it is plainly to be seen that the step was a wise one for all.

The wiring was given over entirely to local contractors, who made it to their interest to introduce as many lights as possible, resulting in general good to all. Of course, abuses crept in, as a few people found out that they could have it done more cheaply by employing a discharged employee, or one who would do it after work hours; so much so that a concerted action on the part of the contractors and the local company resulted in the municipal authorities taking up the subject. A city electrician was appointed, ordinances and rules were drawn up and adopted, and matters began to brighten. All new work was done *strictly* in accordance with the rules, and even more so in special cases. All old, bad work was condemned and made new at the expense of the consumer, outside lines rebuilt, and in place of continued dissatisfaction on the part of the consumers, caused principally by lights going out, broken wires, burned-out fuses, etc. etc., "peace reigns o'er all."

The city electrician is absolute authority as to the merits of the work done, its safety being the first point considered, its general neatness and adaptability to the purposes intended being also considered. Inspection of the work is made during its progress before its use, and whenever any additions or alterations are made. The contractors are required to make application for the interior work, and submit diagrams showing the various circuits, location of cut-outs, sizes of wires, etc., etc., at the same time the application for the exterior work is made, and, upon completion of the installation, both the contractor and the company receive their official permit. The company make the connections with their circuits, the contractor makes his report to the company, and everything is lovely. Infractions of the rules are punishable by heavy fines and imprisonment. The result is apparent. The consumer sleeps securely in the thought that there is no danger of fire through bad wiring; the company knows how many, and where, lights are burning; the insurance companies rest easy, and the contractor knows that he has done a good job and no kick will be coming.

A year's experience under the new "régime" more than exceeds our fondest hopes, and has increased the list of consumers for the Electric Light Co. over 100 per cent. At the time that the new order of things began there were but 2,000 incandescents in use in the city. Now the total capacity—4,500—is taken, and the company will put in an additional 1,000 lighter in the near future. At the same time there were but 240 arcs in use, city lights and all; now, over 500. The power circuit was started in January, 1889, and up to the present there are 180 motors of various sizes, ranging from ⅛ to 20 h. p., on all classes of work. Where there was but one contracting firm then, there are three now, employing, at the dullest season, not less than 25 men.

One can but draw the very best conclusions from these facts, and they are, that it is best for electric light companies *not to do their own wiring.* While it would be rather embarrassing for companies in small towns not to do their wiring, it is very easy for companies in larger cities to adopt the rule and *stick to it*, as in nearly every large city there will be found competent persons to do the work. Of course, where it is not under municipal inspection, the company will only have to require the installation made under certain rules, and not allow it to be used until fully up to the standard. Nearly every city at the present time has a superintendent of fire-alarm, who can make it his duty to inspect wires. True, he may be far from being a practical electrician (God save the mark!), but he can see that the standard rules are carried out, and with a little co-operation on the part of the company and the contractors, he will soon be able to judge whether the splices are covered with tinfoil or with solder.

I have in my mind one company that believes in controlling the entire "shooting match," going so far as to carry a stock of bells, annunciators, etc., and doing a general supply and construction business. They have never been known to pay a dividend. I trust that the matter will be taken up by every one until an electric company putting in wires and fixtures will be a "rara avis."

ELTRINGHAM'S TEMPERED ELECTRIC LIGHT CARBONS.

In a patent just issued to Mr. Wm. P. Eltringham, the inventor describes a method of heating or tempering electric light carbons by the use of borax, which is claimed to increase their life. For 100 pounds of product the following ingredients are used in about the following proportions: Coke, 72 per cent; pitch, 23 per cent.; borax, any equivalents of borax, such as borate of sodium, sodium pyroborate, and disodic tetraborate, all commonly known as "borax," 5 per cent. This forms a mass, which is moulded and baked in the usual manner. The use of borax is claimed to increase the life of the carbon three hours and to give a stronger, clearer and whiter light than can be obtained with the ordinary carbon.

THE MANUFACTURE OF BARE AND INSULATED WIRE.

While wire in its various forms is employed probably in every industry, there is certainly none in which its use is so extensive as that of the electrical arts, and certainly none in which the consumption of copper wire is so great as in this.

We believe, therefore, that a short account of the methods employed in the manufacture of wire, as carried out in one of the largest wire-making establishments in the country, will prove of interest to our readers, having through the courtesy of Dr. F. A. C. Perrine, electrician to the company, been permitted to study the processes adopted by the John A. Roebling's Sons Company in their famous works at Trenton, N. J.

The treatment received by the wires, whether they be iron or copper, differs very little in the first stages of their manufacture. In either case a bloom of metal measuring four inches square by two feet long, and weighing about 135 pounds in the case of iron, and 150 to 200 in the case of copper, is heated in a Siemens gas furnace, and roughed in a three-high train, which reduces it to a rod one square inch in section. This is then passed automatically through guides into a set of rolls called the intermediate train, where its section is still further reduced, and the length of the rod increased proportionally. The rod then passes to the finishing train, which alternately rolls it square and oval; when passing from the square to the oval, the rod passes through a curved guide called a repeater; but when passing from an oval to a square roll, the rod has to be caught by a man who sticks it into the next succeeding pass. From the last pass it emerges as a round rod No. 5 B. W. G., at a rate of 1,500 feet a minute; as it shoots out from the rolls the wire is caught on a reel which automatically winds it into a coil, which is taken from the reel and bound with tie wires.

The finishing train employed at these works rolls nine different sizes at once, and is of the type known as the Belgian roll. In the other system of rolling most generally employed, the "continuous train," the wire passes straight through from roll to roll, whereas in the Belgian system all the rolls are in the same axial line. The advantages of the Belgian train are its simplicity of construction, since it is operated entirely without belting or gearing, either of which is always liable to cause a breakdown. On the other hand, one of the advantages of the continuous mill is that the loss of metal due to scaling is only one-half that encountered in the Belgian train. This is due to the fact that a shorter amount of rod is exposed to the air at one run. In fact, the scaling in the Belgian train amounts to as much as five per cent. of the total weight; nevertheless, this type of train is the one most generally employed at the present time.

Up to this point the treatment of iron and copper wire is practically identical, save that the copper is worked at a lower temperature than the iron and requires fewer passes through the roll. As the rods leave the train they are covered with scale, which must be removed before they can be passed through the draw-plate. This is accomplished by lowering the rods into tanks containing a weak solution of sulphuric acid, heated by steam. After being submerged for a considerable time, they are drawn out, rinsed with water and dipped in whitewash and baked, in order to dry them and to drive out the hydrogen which has been occluded in the cleaning process. This baking becomes necessary as the hydrogen makes the iron brittle. The rods then go to the wire-drawing mill, where they are "ripped," that is, drawn down by great reductions; after passing through three successive draw-plates the wire is annealed, again cleaned and coated with lime. The annealing furnaces in which this is done consist of iron pots set in fire-brick wells and fired by oil-burners from below. The wire is then again drawn down to the desired size.

The larger sizes of wire up to No. 10 B. & S. are drawn through chilled cast-iron dies, while the finer sizes pass through crucible steel dies. In the chilled dies the holes are simply reamed to correct size, and when worn away a little from the correct size are reamed out to the size larger. In the crucible steel die the art of the wire-drawer comes into play. These dies are usually kept at the same

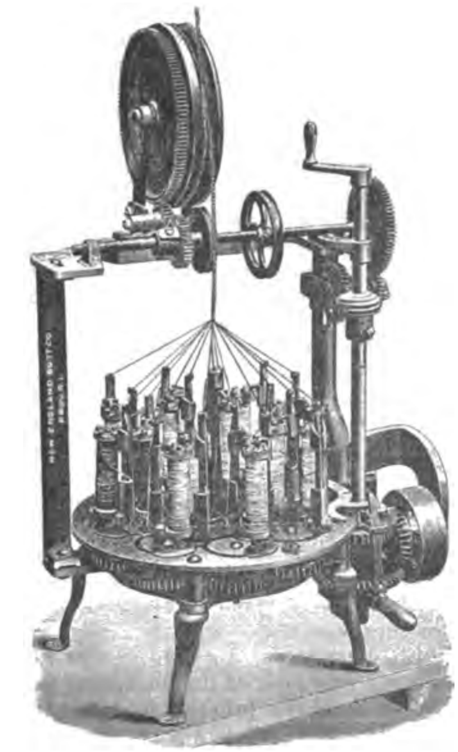

FIG. 1.—BRAIDING MACHINE.

size, and the wire-drawer must "set-up" these dies by hammering on the face and reaming out to the correct size.

The wire-block which draws the wire through the plate has a continuously revolving spindle, which is set in motion by a clutch thrown in by the attendant, and on the small sizes of wire is arranged to stop automatically upon the breaking or running out of the wire. When the product desired is galvanized iron telegraph wire, the latter, after being thoroughly annealed, is cleaned, baked and coated with lime, and then welded electrically into half-mile lengths, which are run through soldering acid and then through a pan of molten zinc; after which it is rolled up into a coil ready for shipping.

In the case of copper wire, unless the same be used for hard-drawn telegraph or telephone wire or trolley wire, it is first annealed, cleaned and carefully gauged. For magnet wires a variation of $\frac{1}{1000}$ inch is allowed during the process of manufacture, while for line wire a slightly greater variation is permitted; never, however, exceeding more than 2 per cent. from the correct size.

The bare copper wire drawn down to the various sizes required is now ready for the various insulating and protecting covers demanded in electrical work. Outside of the wire directly employed in the construction of electric machinery, the type of conductor most largely in demand is the weather-proof line wire. As a very high grade of insulation is not demanded in these conductors, they are simply passed through a hot compound, braided, and soaked again in the compound. They are finished with a polish in order to give them a clean surface and to prevent the adhesion of ice in winter. Larger sizes of this wire are shipped in coils and the smaller ones on wooden reels. No brazed joints of any kind are made in this wire, all the welds being made electrically on the Thomson welding machine, of which there are seven distributed in various parts of the Roebling works, which were among the very first to adopt these machines. The braiding is done on the machines illustrated in the accompanying engraving, Fig. 1. This represents the sixteen-strand braider of the New England Butt Co., a large number of which are in use in the works, besides not a few specially designed at the company's works for their own special uses.

Underwriters' wire is braided through paint, then externally painted, and polished by rapidly revolving plates pressed against the wire. This process hardens it and serves to keep out the water better.

Annunciator, office, and small cable wires, usually of No. 18 B. & S., are wound or braided with cotton, either single or double, dried and soaked in paraffine or other compound. The winding machine, illustrated in Fig. 2, also manufactured by the New England Butt Co., consists of two tiers of bobbins, which are kept revolving in opposite directions, and give the wire a double layer of cotton at one passage through the machine.

Magnet wire, after being carefully gauged, is electrically welded into uniform lengths of 150 pounds each. It is then covered by winding with one-ply cotton, as fine as No. 150. Most wires, however, are not covered with so fine a cotton, No. 100 cotton being more generally employed.

For this purpose only the best cotton is employed, and it is interesting to note that, notwithstanding the reputed superior quality of the Manchester, Eng., yarns, the American cotton has been found of better quality, being evener, whiter and stronger. Before being applied to the wire every length of cotton is tested in a special machine, and, if below a certain tensile strength, is rejected.

The manufacture of flexible cord also has received special attention at these works; this cord is composed of No. 30 B. & S. copper wires wound with cotton and twisted together, a tape of the finest Para rubber being afterward applied; then, after being again wound with cotton,

FIG. 2.—WINDING MACHINE.

it is braided in colors with silk or glazed cotton and finally twisted in pairs. The employment of the finest Para rubber for the tape is made necessary owing to the fact that it is the only quality of rubber which can be slivered down to a fine strip. Besides the various types of conductors above mentioned, there are many special wires, which are called for in different trades, and which are here produced.

Thus far we have treated only of single conductors, but the requirements of modern electrical distribution frequently call for heavier wires, either single, or grouped in the form of cable encased in lead. The lead-encased electric light cables are, as a rule, composed of strands consisting of wires not larger than No. 12 B. & S. These are wound with jute, cotton or paper, thoroughly dried and saturated with an insulating compound; after which the lead covering is formed around them by hydraulic pressure. The lead press employed for this purpose exerts a pressure of 7,000 lbs. to the square inch on a fifteen-inch

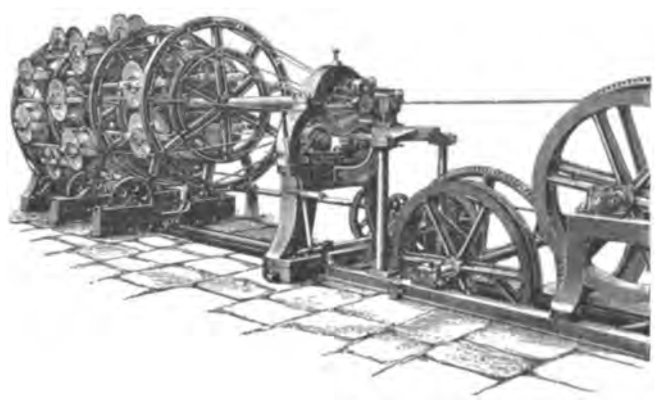

Fig. 3.—Cable Armoring Machine.

water ram, being the equivalent, therefore, to a pressure of 600 tons. This pressure is transmitted to a six-inch ram in the lead cylinder. The lead is not maintained at a molten state during this process, but, after being poured molten into the lead cylinder, is allowed to solidify. This practice is followed, owing to the fact that the lead as it passes from the liquid to the solid state passes through a state of shortness or brittleness, and the temperature is kept just below that point. Of the insulations mentioned above, the experience at the Roebling works indicates that cotton gives the least favorable results as to insulation, capacity, etc. Jute and paper are almost identical in these respects, but paper, on account of its solidity gives the highest spark-resisting power.

In the manufacture of electric light cables the paper is laid on as compactly and smoothly as possible, while for telephone cables it is applied as loosely as possible. In the latter case it is laid on in the shape of two strips laid straight along the wire and lapping each other, being held in place by a thread wound around them. This method gives a large air-space and small contact between wire and paper, thus insuring a low electrostatic capacity and high insulation. The cable is dried with the greatest care and lead-covered immediately, so as to prevent the re-absorption of moisture.

The advances made in the reduction of the electrostatic capacity of cables by the application of paper insulation is well illustrated by the fact that the specifications for telephone cables now call for a capacity of .085 microfarad per mile, whereas but a short time ago .18 was permitted. Recent cables laid in Boston, New York and Philadelphia, manufactured at the Roebling works, show a capacity of .082 with a No. 18 wire, while now .085 is required on No. 19 wire.

Some doubt has been expressed with regard to these cables as to whether they would retain their insulation at all, if, by reason of imperfect manufacture or carelessness in splicing, any moisture were admitted; but since there is no electrolyte present in dry paper, the effect of the small amount of moisture locally present, provided the sheath does not continually admit moisture, is that the dry parts of the cable absorb the moisture from the defective portion, and so quickly raise again the insulation to a workable point. As illustrating the correctness of this assumption, we may cite the case of a 100-conductor telegraph cable recently laid. Through the carelessness of the employees of the telegraph company the holes for the drawing-in wires were left unsoldered for some days. The cable, when spliced up, was found to have a dangerously low insulation resistance. The emergency of the case demanded that the cable be immediately put in service with ticker wires on the outside, with the proposed object of breaking down the cable if possible. These tickers are operated by alternate current at 350 volts. After a few days the cable was again measured, and was found to have improved in insulation resistance, which improvement has continued up to the present time. The cable is, indeed, now considered perfectly safe.

For submarine work the core or insulated conductor is tested under a pressure of 8,000 lbs. to the square inch. This pressure breaks up any air bubbles which may exist. This cable, used as a single conductor, is covered with tanned jute, tarred jute having been found to reduce the insulation of the gutta-percha. If used as a multiple conductor cable before juteing, the cores are twisted together in a cabling machine. The jute acts as a cushion to protect the core from the pressure of the armor wires; the latter are then laid on in an armoring machine, one type of which is illustrated in the accompanying engraving, Fig. 3. The armor wires are applied with as long a lay as possible, so as to give the cable the greatest possible longitudinal strength. Great care is taken with the galvanizing of the armor wires, and, wherever it is necessary to make a joint, the latter is regalvanized.

The above description, though necessarily brief, will serve to give a fair idea of the numerous processes which are required to enable the finished product to be placed upon the market. The demands of the present as to insulation conductivity and capacity are now so exacting that a fault in any one of these processes may lead to the rejection of the wire; hence the constant care required at every step. It is also worthy of note that our manufacturers have kept well abreast of the demands in every respect, in some cases even anticipating the requirements of consumers and offering a product superior to that which it was thought possible to manufacture and still possess all the necessary requirements.

SWINBURNE'S NON-INDUCTIVE WATTMETER.

Great difficulty has always been found in measuring power with alternating currents. The ordinary wattmeter,

Swinburne's Non-Inductive Wattmeter.

though accurate with direct currents when a correction is made for the power taken by the instrument itself, is of little value for use with alternate currents, as the time constant of the fine wire circuit is appreciable. If the pressure and current are in step, as is the case when an alternate pressure is applied to a resistance, such a wattmeter reads too low. If a pressure is applied to an inductive circuit, on the other hand, the reading may be much too high.

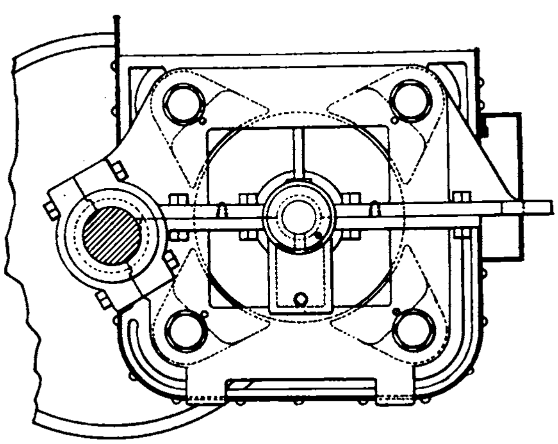
Messrs. Swinburne & Co. of London, have brought out a wattmeter specially designed to avoid these errors, which is illustrated in the accompanying engraving. The moving coil contains but few turns, and these are wound on a light mica frame. The coil is held by top and bottom stretched wires. External resistances are supplied, and these are wound with the alternate layers right and left handed; the time-constant of the fine wire circuit is thus made sensibly equal to zero.

Readings are taken by means of a torsion head in the usual way; but for measurements of minute powers, such as hundredths of a watt, a mirror is used. These wattmeters are wound to suit any range from 3,000 volts, and from 25 amperes downwards. They are said by the makers to read accurately on non-inductive resistances, and on inductive circuits in which the product of the pressure and current is 50 times the real power.

The wattmeter has the advantage over electrometer methods in that it does not involve the very serious troubles with resistances. Mr. Swinburne recently described an electrometer which reads power directly, which, though it does the work of the three voltmeters discussed by Messrs. Ayrton, Sumpner, and Swinburne soon after, unfortunately needs resistances. Dr. Fleming has enormously improved the instrument method by substituting ampere-meters, etc.; we thus have unimpeachable means of checking the wattmeter. If this wattmeter does what the makers claim for it, it will be exceedingly valuable to alternating circuit engineers.

THE MAILLOUX ELECTRIC STREET CAR MOTOR.

In railway motors of the usual construction it is necessary, when the armature is to be repaired, to raise a trap-



Mailloux's Electric Street Car Motor.

door in the floor of the car, and, after unbolting and removing one of the field magnets, to lift the armature out of its bearings, frequently a difficult and troublesome operation, and always taking a good deal of time.

In order to facilitate this operation, Mr. C. O. Mailloux, of this city, has devised an arrangement by which the armature may be readily removed for repair from beneath, the car being run over a pit for the purpose. This is accomplished without completely dismantling the motor or removing it from its support.

For this purpose the motor frame, as shown in the accompanying illustration, is made in two parts, one of which is supported upon the car axle or truck frame, while the other, upon which the armature is supported, is attachable and detachable from below, and may be lowered with the armature, leaving the main portion of the motor supported in its normal position. The field-magnet frame is divided into two parts, the lower of which supports the armature, and, when lowered, carries the armature with it, while the upper portion is supported upon the axle or frame, as usual.

It will be seen that the end plates are provided with journal bearings, and are mounted parallel to one another upon the car axle by sleeving the yoke-pieces. These are bisected and are bound together by the four parallel cross-rods which support the field-magnet pole-pieces. These rods form part of the field-magnet circuit and the energizing coils are wound upon them, the end plates thus having the function of magnetic yoke-pieces.

To protect the motor from dust and water, the yoke-pieces are connected by a thin shield, which is fastened to the flanges at their edges, and completely covers the working parts. This shield has an opening at the end, by means of which access may readily be had to the motor when necessary. It will be noticed that this shield and the detachable part of the motor are removed together when the two parts of the frame are disconnected one from the other.

THE McDOUGALL STORAGE CAR SYSTEM.

At the invitation of Mr. W. M. McDougall, we have had the pleasure of witnessing a trial trip of the storage battery car designed by him and which is now undergoing trial on the Steinway & Hunter's Point Railroad. Mr. Alfred D. Moulton, the general manager of this road, is a man of progressive ideas, and as such is thoroughly alive to the fact that the operation of his 33 miles of track by means of horses must eventually be accomplished by means of electricity in some form or other, and believing that the storage system embodies the least objectionable elements, so far as city traffic is concerned, he has readily granted Mr. McDougall facilities to demonstrate the feasibility of his system on that road.

The car is equipped with 100 cells of storage battery and a single motor with the McDougall flexible suspension. The system adopted by Mr. McDougall is such that the motor is left entirely free from shocks due to unevenness of track. It was fully illustrated and described in our issue of July 23, 1890.

The road traversed was something over 3 miles, but the ammeter readings, considering the condition of the track, were very low. The track, at best, is a very poor one and there are several sharp curves and considerable grades. On a level straight track the ammeter generally stood at 20 to 23 amperes, at times going as low as 15 where the track was good. On the curves the ammeter would gradually climb up from 55 to 90 amperes, according to the radius of the curve; but this was only a momentary reading, which immediately fell off to the normal value when a straight section was reached.

As showing the powers of the car, it may be mentioned that on the grade in Flushing avenue, which is perhaps equal to 3½ per cent., the McDougall car overtook one of the horse cars with a team which could not be induced to make the schedule time of the road. The electric car easily pushed the one ahead of it up the grade without the assistance of the horses, whose traces were slack during the whole time.

The car has what is called a 7-mile per hour equipment; that is, it will make 7-miles per hour over the road as it comes, good or bad. It will, however, easily run 10 miles per hour on a level straight track, and made 8½ miles per hour recently between the car stables and Silver Spring, counting the whole time of a round trip exclusive of the time that the car was actually motionless, but including the stopping and starting, the time being taken on a passenger trip. On the trial trip above mentioned Mr. McDougall was assisted by Mr. Townsend Walcott. Although the system embodies a double-reduction gear, the peculiar method of suspension made the car remarkably smooth running, and the noise and vibration were almost imperceptible.

The nomenclaturist should not seek the reward of his labors in the Patent Office.—Judge Coxe.

ELECTRIC LIGHTING STATISTICS OF THE CENSUS.

ALTHOUGH special provision has been made in the census for electrical statistics, various figures touching electrical industries have already been included in reports on other branches of industry, such, for instance, as those pertaining to street railway work. Another batch may now be found in the return on the "Social Statistics of Cities," prepared by Mr. H. Tiffany, under the direction of Dr. John S. Billings. The return deals with paving, shade trees, waterworks, sewers, police, fire service, street cleaning, and street lighting, and may be welcomed as an important contribution to the data of a very interesting class of subjects.

It would appear from Mr. Tiffany's figures that 309 American cities, with a population of 16,335,659, have for their streets 182,671 gas lamps, 53,696 electric, and 57,480 oil. These lights are maintained at the rate of one per 56 of the population, and cost annually $10,390,147, or 64 cents per head. In other words, each of the 293,847 lights costs $35.50 per annum. This table shows that gas lighting in the cities enumerated is over 60 per cent. of the total, and also brings out the fact that oil lamps are still so plentiful that they slightly outnumber the electric. But the fact that the census year is a period of transition is brought out in another table, showing that gas is now used exclusively for street lighting in only 13 of these cities, whereas electricity is exclusively used in no fewer than 125. It is noteworthy that a little further analysis shows the lights in these 125 cities to cost only $82 per year each, while in the 13 cities the gas lamps cost $23 each; so that the electrics cost at the rate of about four gas lamps, although they yield much more than four times the effective illumination.

Another table of interest is that containing the condensed figures of cities up to 100,000 inhabitants. In 278 of these with a population of 7,018,653 there are 35,191 electrics compared with 35,127 gas; and it is noticeable that with this much higher percentage of electrics the cost per head of population is only 60 cents, or four cents less than where the proportion of gas lamps is so much larger. Of these 278 cities, no fewer than 115 are in the class between 10,000 and 15,000, and there the average cost per head is only 56 cents. Evidently the electric light has proved its cheapness and efficiency in such communities.

Comparison between gas, oil and electricity would be more easily made from these tables if the candle power of the lights was expressed or integrated in some way. If this had been done, Mr. Tiffany would have saved himself one or two bad breaks. Thus he tells us gravely that: "The annual cost of each electric lamp varies from $440.67 in San Francisco and $237.25 in Boston to $58.46 in Denver and $68 in Chicago." The figure in San Francisco is wildly absurd. The rates were a "leetle high" when Mr. M. D. Law took out the pioneer plant there about ten years ago for the California Brush Co., but at the present time they are about the same as anywhere else. In all probability Mr. Tiffany has been misled by taking the price on a cluster of eight 2,000 c. p. lights and has put that down as the price per lamp. The comparison is as useless and wrong as would be the price for the tower lights that once lit up the whole of Madison Square in this city, when placed alongside the price for one of the many low-pole lights that now do the same duty. As an offset to this, we are told that the lights in Chicago cost only $68. Well, perhaps somebody believes that. We don't, and with all due respect to Prof. Barrett, never shall until more proof is adduced. "Municipal plant" figures are open to very grave suspicions.

The value of the electric lights is brought out by the table which furnishes details as to the number of lamps to the mile of street. Thus in New York, where there only 1,369 electrics to 25,483 gas lamps, there are 46.92 lamps to each mile. In Buffalo where there are 1,223 electrics to 4,377 gas, there are only 15.05 to each mile. Denver with 1,750 electrics, and no other lights, has only 2.31 to the mile. Portland, Me., 439 electrics, and no other, has 7.84.

We recommend these figures in their entirety to our readers, but believe a caution to be necessary in arriving at conclusions from them. As we have said, there are gaps that leave room for doubt. After all, we must wait until the statistics of Messrs. Foote and Foster make their appearance, which will, we venture to believe, by their very fullness, show how favorable the case for electric lighting is. Some of us were probably under the impression that the field for street lighting had been pretty well occupied. Mr. Tiffany's figures as to oil lamps, to say nothing of the gas burners, show that there is plenty to be done in the streets. It has been estimated that street lighting is about

5 per cent. of the whole. In the 309 cities enumerated, there are 53,696 electrics on the streets, against 240,151 gas and oil. If we admit the electrics to be the equal of the others, in the ratio of one taking the place of four, electricity will there have about captured 2½ per cent. out of the possible 5. Such being the case, there is no time yet to rest and be thankful. On the contrary, the situation should stimulate to greater activity than ever.

MUNICIPAL COAL YARDS.

It is with positive satisfaction that we find our good friends, the Nationalists of Boston, afflicted with a new craze, or rather, with the old craze in a new form. They have just been petitioning the City Council for the establishment of municipal coal yards which should supply all purchasers at cost price. This idea seems to have struck many people around Boston as a joke, but it certainly is not intended to add to the gayety of nations. Its object, indeed, is to add to the glory of Nationalism, for once Boston got its coal that way, who could draw the line?

In opposing strongly as we have done throughout the Nationalistic principles in electric lighting, we have had the feeling that while electric light men made the fight because their ox was gored, it would not be long before other industries would be attacked and the scene of struggle be shifted. There is going to be an irrepressible conflict right along these lines of the liberty of the individual and the public monopoly of every industrial function, and the fight might just as well come now as later. Every argument that has been used for freedom of enterprise, in the case of electric lighting, applies to coal, and it might be said that the Nationalists are really carrying their plan one step further, for, while electric light plants might be deemed to have a place within the category of public works, it would be rather a flight of the imagination to put coal yards there.

If not coal, why not oil, and if oil, why not bread, and if bread, why not games? By all means, let this thing be pushed to the issue, and fought out.

FUSIBLE CUT-OUTS.

While the many rules and regulations of various boards of fire underwriters have, with good reasons, been so framed as to insure the thorough insulation of the circuit at all points, and the erecting of wires properly proportioned to carry the currents with safety and without undue heating, there has, we believe, not yet been given sufficient attention to another essential safety device which is now in almost universal use on electric circuits. In the early days of the art, conductors were frequently guarded from the effects of dangerous currents, produced accidentally, by the insertion of electromagnetic cut-outs. These, however, were soon superseded by the more simple and far less expensive fusible cut-outs. The latter have indeed done good service, but if electrical distribution is to be made safe in the future it will be necessary to change certain vicious methods which are, we are inclined to believe, not on the decrease at the present time. We refer more particularly to the indiscriminate use of fuse wires, the carrying capacity of which is frequently an unknown factor of the safe limits of the conductor it is supposed to protect. Electrical engineers will frequently have encountered in their practice instances in which fuse wires actually carried currents 100 per cent. in excess of that for which they were intended, and for which they were sold. If to this we add the fact that wiremen frequently reduce the carrying capacity of fuse wires to accommodate circuits of lesser capacity, by paring down the wire with a knife, it will be evident that a radical change in the employment of this useful device is necessary. A good step in advance in this direction could, we think, be made if the use of fuse wire unprovided with proper terminals and with the carrying capacity stamped thereon were prohibited. Of course even this will not always guarantee the cutting-out of a circuit at its proper limit, if the fuse wire itself be not of the proper quality; but that is a defect which can be guarded against by obtaining supplies from reputable manufacturers and testing them, in addition. That the importance of this subject is thoroughly realized in certain quarters is evidenced by the article appearing in another page descriptive of the large variety of fuses employed in the work of a well-known electrical company. There is no reason why a fuse wire cannot be constructed to operate within a small fraction of its desired current-carrying capacity. The return to electromagnetic cut-outs, as we have noted recently in some instances, is, if not a step backward, at least one hardly warranted by the facts.

INSURANCE INSPECTION REPORTS.

We have had an opportunity within the last few days of looking over some insurance inspection reports on a city not far from New York, and are surprised to see so many things referred to and criticised that one would expect to be obsolete after so many years of experience in the art of wiring. Thus, for instance: "The service wires entering this building were found passing through the same hole in the woodwork." In another place: "Wires for arc lamp in front of store found twisted together and lying on wood cornice." Elsewhere: "The wiring in store is very poor; underwriter's wire is used fastened in a number of places with metal staples and the wires hanging about in a loose manner." Fortunately the current has been shut off there, and will stay shut off until the place is rewired. In another place: "The wires enter the building through a metal-roofed window; no bushing is used to protect the insulation, and no means taken to prevent water from entering the building." In several instances the wires are reported in close contact with the gas pipes, even being twisted around them. We note also the use of single-pole cut-outs. Much of the work is not available for inspection, for the reason that it is imbedded in plaster. The situation is summed up in the remark: "A great deal of the work shows either gross carelessness or utter incompetency." We can only hope that every inspector will be sustained who puts his foot down sternly and is severe in his condemnation of bad work. There is no excuse that will hold, and none should be listened to. The welfare of the whole art demands the use of the best materials and the most approved methods; and it does not take long to find out what they are.

NEW FORMS OF ELECTRIC HEATERS.

The statements that have been made from time to time to show that electric heating cannot compete in economy with the methods now in general use are, we think, destined to be as rudely thrust aside as were those by which it was attempted to show that electric lighting could never compete with gas. While the cost of electric lighting may hardly be said to have yet reached the low point of the cost of gas except on the candle-power basis, it is nevertheless a magnificent success commercially, and the time is not far distant when electricity for lighting purposes will be sold for less than gas. The course which electric heating will pass through will be similar to that of the electric light. At first scoffed at, it is now being introduced not only for the special purposes of heating electric cars and steam railway trains, but we know of an actual case in which a large block of apartment houses is being equipped with electric heaters. Naturally, electrical engineers are beginning to pay some attention to the apparatus placed in their hands for this class of work.

In this issue Mr. Ludwig Gutmann describes a new type of electric heater in which he utilizes the iron core of an induction coil as the secondary itself, and thus obtains the entire heat available in the energy of the current by turning to useful account the heat due to hysteresis and eddy currents, as well as that generated in the core used purely as a secondary.

THE AREA OF SMELL.

Few people realize how great is the work of the electric car, and the cable car, too, in reducing the number of horses kept in our cities. President Wilson, of the New York Board of Health has recently said that the Health Inspectors find that the total number of horses in this city is 50,000. The mere substitution of the cable on the Broadway and Third avenue lines will dismiss about 6,000 of those from service, and the streets will be proportionately cleaner and longer lasting. Then the stables are banished also, and with them go many nuisances that no care can keep under. The horse car stables in this city all have their area of smell, and what that smell is a good many passengers on the New York Elevated road know intimately. The stench from the stables at Fiftieth street and Sixth avenue makes itself felt pungently for hundreds of feet around, and at some times much worse than at others. The public does not yet resent these nuisances as it might, for the horse car has been an enormous boon, but by-and-by they will not be tolerated.

Electric Weighing of Electrolytic Meter Plates.

In a recent issue we published an ingenious type of electrolytic meter devised by Mr. Tesla, in which, it will be remembered, the plates, instead of being removed from the cell, taken apart and weighed, were gauged electrically by measuring the change in electric resistance caused by the reduction or increase respectively in area as the result of electrolytic action. In this issue Mr. F. M. Barney describes an arrangement in which a similar method is employed to determine the loss or gain in weight in the respective plates. While the removal of the meter plates from the customer's premises to the station and their weighing may not involve so great an inconvenience as might be supposed, it is, nevertheless, true that a method by which this present drawback can be avoided would give an additional value to this type of meter. A simple ohm-meter kept permanently on the premises of the consumer or carried about by the meter man would suffice to give the indication required for calculating the proper charges for this system.

The Oerlikon Three-Phase Generator.

The experiments on the transmission of power from Lauffen to Frankfort were expected to call forth considerable ingenuity as well as originality, not only in the methods of distribution, but also in the detail of the apparatus employed. Fortunately the hands in which this power transmission has been placed have been thoroughly equal to the necessities of the case, and the details as they are published from time to time leave little doubt of the ultimate success of the plant. In this issue we describe the three-phase alternator designed by Mr. C. E. L. Brown the able engineer of the Oerlikon Works. The design of this machine is excellently worked out and shows the wide range which can be drawn on to work out a particular case.

Alternating Current Motors.

The variation which is possible in continuous current apparatus, of either the generator or motor class, is comparatively limited, but as has been proved to be the case in other forms of apparatus employing the alternating current, the alternating motor is susceptible of a considerable number of modifications in detail. This is well shown by the excellent résumé of the subject given by M. Hospitalier and printed in another column. The classifications adopted and the examples of each will serve to point out to the student the various directions in which work can still be accomplished in this field.

The Park Place Disaster.

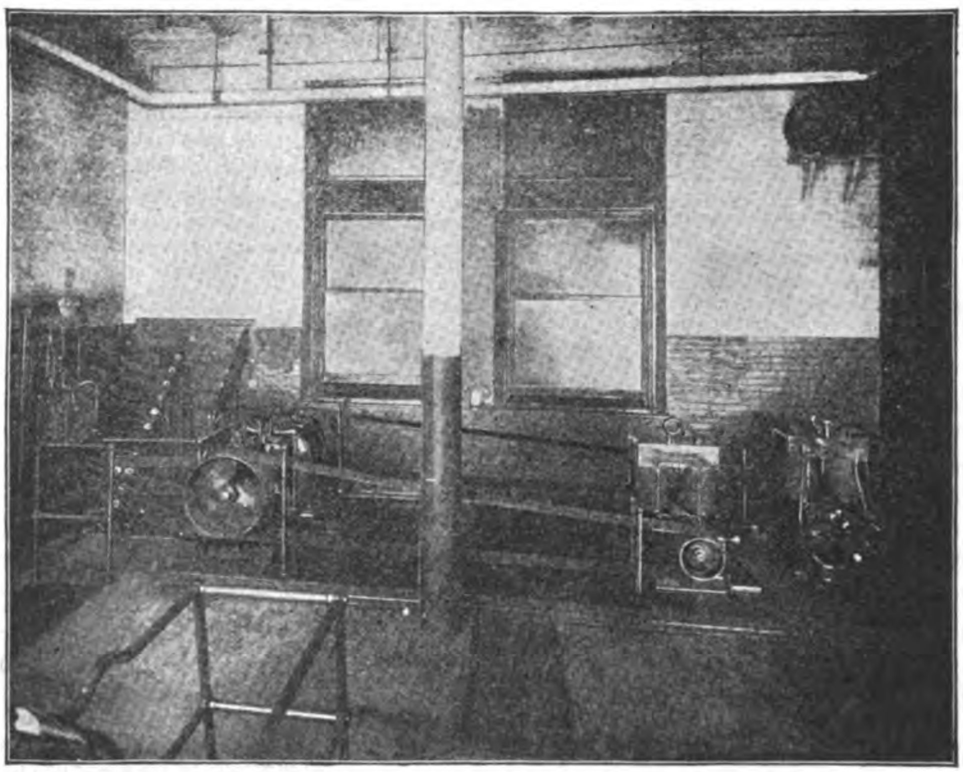
Our readers will have become aware, through the newspapers, of the great and sad disaster that visited Park Place, in New York City, last Saturday. The buildings destroyed abutted directly on the pressrooms of The Electrical Engineer, and obtained power from its shafting, and the fire necessitated an immediate shutting down, with the resort to such measures as were needed to prevent the spreading of the flames. Much time was lost on Saturday and Monday, therefore, through this catastrophe, but by special effort not more than an hour or two of delay has occurred in the issuance of the paper.

The Trip to Montreal.

It had been intended to make the N. E. L. A. trip to Montreal over the West Shore road, but at the last minute the West Shore officials find that they cannot furnish the facilities. The run will therefore be made over the New York Central, the special train leaving New York on Sunday morning, September 6, as already proposed. Mr. C. O. Baker will announce the details in a few days, so that every needed arrangement may be made.

A "C. & C." MOTOR DRIVING A DYNAMO.

It might at first sight appear paradoxical to install a motor to drive a dynamo for the purpose of generating current when the current itself is available in the first instance; but upon further consideration it will be apparent that where it is desirable to effect a change in pressure without reducing the same by means of dead resistances, or in other cases, the application of the motor-dynamo principle may effect considerable economy. This was found to be the case in the practice of the Edison Illuminating Company of Brooklyn, where a sub-station, placed at some distance from the main station, has its generators driven by a motor deriving the current from the main station. In an article[1] by Mr. W. S. Barstow, superintendent of the Edison Illuminating Company of Brooklyn, was demonstrated very clearly the saving that could be effected by this method and the reasons why it was adopted in place of installing engines at the sub-station.



C. & C. Motor Driving a Dynamo.

The plant, which is illustrated in the accompanying engraving, consists of a 50 h. p. C. & C. motor with a pulley at both ends of the armature, the motor being connected to the station bus. Two No. 6 Edison compound generators are connected to the motor, and the plant shows an average commercial efficiency of over 75 per cent., while the efficiency of the large station, by reason of the extra motor load, is increased over 10 per cent. The advantage of this arrangement can be better appreciated when, as pointed out by Mr. Barstow, on a station unit the loss of power due to engine friction and belting on an average load of 224.9 (at the engine) is 38½ h. p.; the low efficiency of the unit with a load of 50 h. p. can be easily appreciated.

The mission of this motor-dynamo plant is nothing more than to transform the bus pressure of the first district station to a variable pressure required at the station end of the large feeder in order to maintain a constant pressure at the standard sub-feeder extremity. The little motor-dynamo plant furnishes current from 2 A. M. to 6 P., M. and until the evening load was sufficient to be carried on a station unit the motor-dynamo plant was in operation 21 hours a day and 7 days per week.

1. See The Electrical Engineer, May 6, 1891.

THE PROPOSED UNDERROUND ELECTRIC RAILWAY IN PARIS.

A French engineer, M. Berlier, has asked the Paris Municipal Council to grant him a concession for the construction of an underground electric railway in that city, on lines similar to the City and South London Railway. The railway would consist of two tracks laid in one tunnel, and the length of the line would be eleven kilometres. The Works and Ways Commission recommends the council to include this scheme in its investigations concerning rapid transit in Paris.

A USEFUL FORMULA.

The following is a simple formula for determining the insulation resistance between a dynamo circuit and its frame :—

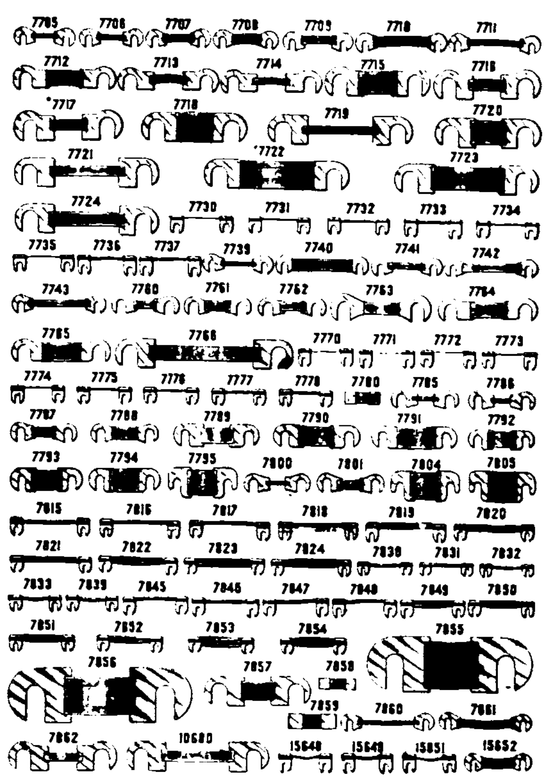
$$R = \frac{E - \varepsilon}{\varepsilon} \times r,$$

where R=insulation resistance in ohms, E=the terminal E. M. F. of the machine, ε=the sum of the volts observed between the positive brush and the frame, and between the negative brush and the frame, and r=the resistance of the voltmeter, which must be very high.

Mr. S. H. Southwick, for many years connected with the old Sprague Co. and the Thomson-Houston Co., has been appointed electrician of the Essex Electric Co., of Salem, Mass., and has begun work in that capacity.

THE FUSIBLE CUT-OUTS OF THE THOMSON-HOUSTON CO.

The simplicity of the fusible cut-out as a safety device in connection with electrical distributing circuits has made this type of protector the favorite one. It is true that the electromagnetic cut-out can be made to act with a greater delicacy, but the handiness of the metal fuse will probably make this the favorite one for some time to come. In order to give our readers an idea of the many details involved in the working out of a complete system of electric lighting and power distribution, we illustrate in the accompanying engraving the various sizes and types of fuses designed by the Thomson-Houston Electric Company for their varied work. These fuses are applied to circuits varying from 3 amperes up to 640 amperes, and designed for circuits varying from 50 up to 2,000 volts. The various types illustrated are designed in the shapes shown to accommodate the various types of generators, stationary motors, elevator motors, stationary motor cut-out boxes,



Thomson-Houston Fusible Cut-Outs.

railroad fuse boxes, and cut-outs in general. For feeder boards and boxes of the alternating type the fuses are covered with rubber so as to prevent accidental short-circuiting across them. Besides the fuses illustrated there are a large number of others intended for various purposes, which makes the aggregate number kept in stock amount to several hundred.

THE SANDY AND EASTER LEAKAGE DETECTOR.

An apparatus for detecting the leakage of electricity upon house or other mains has been lately brought out by Messrs. Sandy and Easter, of Peckham, England. The arrangement consists of a small board on which are three keys. The connections are so made that by pressing the centre key the potential between two terminals may be read off upon a voltmeter connected to them, and by pressing the centre and either the right or left hand key down together, the potential to earth on the positive or negative mains respectively may be read off on the voltmeter. Below the voltmeter terminals are two pins, for the purpose of holding a piece of pole-testing paper, so that if there be a leakage which is too small to be detected upon the voltmeter it will still be noticeable by the effect produced upon the paper, thus showing that the insulation resistance is low. The makers supply papers for detecting leakage upon circuits of 100 volts potential, where the insulation resistance is from 1 to 3 megohms, and these papers only change color when the insulation resistance is below the standard for which they are supplied. The makers state that with the apparatus they have succeeded in detecting the leakage in an experimental installation, having an insulation resistance of five megohms with an electromotive force of 100 volts.

OSBO-PREMIER PRIMARY BATTERY.

A battery has been designed under the above name for supplying light to small installations up to 30 lamps or so. The cell is of the single-fluid type, of carbon and zinc, and contains, in addition, a reoxidizing apparatus for reoxidizing the depolarizer, which becomes reduced in the course of working by the nascent hydrogen. Besides the outer vessel and the elements, the cell contains a porous tube with perforated bottom. This tube is tightly packed with the depolarizer, and only requires renewal every six to nine months. In the upper part of the porous pot is a glass tube (with side tube and glass stopper), the side tube going down into the depolarizer itself. When it is to be used, a reoxidizing bag is put in the tube with the addition of a little water, and the tube closed. A chemical action is thereby set up, which results in the liberation of oxygen, which flows through the tube into the depolarizer, hence reoxidising that which has been reduced.

The reoxidising bag consists of a special mixture of chloride of lime with a few crystals of nitrate of nickel; this, when acted upon by water or moisture, disengages oxygen, more especially if warmed. The battery solution provides for this, as in consequence of the chemical action it is always slightly above the temperature of the surrounding air. There is no action on open circuit with this solution, as the zincs are heavily amalgamated; nor is there smell or fumes. If it were not for the formation of zinc salts in the working of the cell, the same solution might be used indefinitely. The battery solution has to be changed, not because the depolarizer is exhausted, but because the solution becomes finally clogged with the zinc salts. Theoretically, the battery may be said to run by consumption of zinc and chloride of lime. The 12-cell battery is stated to run 30 hours, yielding a constant output of 14 amperes at 24 volts, and using 30 lbs. of zinc at $2\frac{1}{4}$d., $2\frac{1}{4}$ lbs. of depolarzier at 5d., and two dozen reoxidizing bags at $2\frac{1}{8}$d. per dozen. The cost is thus given as $14 \times 24 \times 30 =$ 10,080 watts, or 10 B. T. U. for a cost of 7s. The labor of changing is small. The battery seems an interesting departure, and we are informed that an installation will shortly be exhibited in London showing the battery in operation.

PRACTICAL ELECTRO-MAGNETIC UNITS.[1]

BY PROF. JOHN PERRY, F. R. S.

I would suggest that the practical unit of magnetic flux (or induction or force) be 10^8 C.-G.-S. units, and that it receive a name. That the magnetic permeability of air shall no longer be assumed to be unity, but, in the practical system of measurement, be tabulated like the permeability of any other substance; —the permeability of air will be $4\pi \times 10^{-9}$, and that in future no substance shall have unit permeability. That the unit of total magnetomotive force in a magnetic circuit be 1 ampere turn. The unit of magnetomotive force gradient would be 1 ampere turn per centimetre. It will follow that:

I. A wire one centimetre long, moving at 1 cm. per second across unit field, generates an E. M. F. of 1 volt.

II. If a wire 1 cm. long conveys 1 ampere, the power used

1. Abstract from the London *Electrician*.

(or developed) in moving it across the unit field at 1 cm. per second is 1 watt.

III. A magnetomotive gradient of one ampere turn per centimetre produces unit induction (magnetic flux or force) per square centimetre if the permeability is 1.

IV. Change of induction (magnetic flux or force) at the rate of one unit per second produces 1 volt per turn of wire.

If it were allowable to use 1 inch as the unit of length, and this would delight every electrical engineer in English-speaking countries, we can, by altering the above units, have all our rules quite simple, such as:

I. A wire 1 inch long, moving with the velocity of 1 inch per second across unit field (per square inch) generates the E. M. F. of 1 volt.

II. If a wire moving across unit field at 1 inch per second is conveying 1 ampere, the power used or developed per inch of its length is 1 watt.

III. The integral of the magnetomotive force all round any elementary solenoid in a magnetic circuit is exactly the number of ampere turns.

IV. Change of induction (magnetic flux) at the rate of one unit per second produces 1 volt per turn of wire.

ALTERNATE CURRENT MOTORS.[1]

BY E. HOSPITALIER.

ALTERNATE current electric distribution, in America at least, is comparable in size and extent with continuous current distribution, and they would be much more extensive if we knew how to conveniently utilize electric energy when distributed by means of alternate currents in connection with electro-chemical operation. It would increase the number of such plants, also, if we could store the energy supplied by alternate currents, and if we could easily transform alternate current electric energy into mechanical work; for such applications the continuous current motor has remained up to the present superior to the alternate current motor. The drawbacks that I have ennmerated are, however, compensated for by several advantages, viz., the simplicity of construction and cheapness of alternators, the easy production and transformation of the highest potentials (it being difficult to obtain more than 3,000 volts with continuous currents), simplicity and ease of insulation, simplicity and ease of transformation by means of inert apparatus, containing no moving parts, and having as high an efficiency as 95 per cent.

If the use of alternate currents for electro-chemical and storage purposes has scarcely yet been admitted (the partial solutions of the problem being still of an experimental character), the same cannot be said of alternate current motors. The various principles put forth, and the types based upon them, are already so numerous as to render necessary the summary classification given in the table below:

A.—CONSTANT FIELD OR SYNCHRONOUS MOTORS.

SEPARATELY EXCITED..	*Magnets.*—Magneto-Alternators.
	Electro-Magnets.—Dynamo-Alternators.
SELF-EXCITED.	"*Redressed*" *Current.*—Zipernowsky.

B.—ALTERNATE FIELD MOTORS.

Series-Wound Dynamo	Continuous current motor, with laminated field-magnets.
Shunt-Wound Dynamo	Continuous current motor, with laminated field-magnet.
Electro-dynamic Motors.......	Elihu Thomson meter.
Partially "Redressed" Field.	Mordey.
Closed-Circuit Armature......	Elihu Thomson.

C.—ROTARY FIELD MOTORS.

Ordinary or Single-Circuit Alternators.... ..		Ferraris.
		Tesla.
		Shallenberger.
		Hutin and Leblanc.
Multiple Phase Alternators.	*Three wires and two currents.*	Ferraris.
		Tesla.
		Borel.
	Three wires and three currents.	Dolivo-Dobrowolsky.
		Brown.
		Haselwander.
		Bradley.
		Wenström.

An alternate-current motor does not differ essentially in principle from a continuous-current motor. The same two essential parts are always to be found; the magnetic field, or inducing magnet, and an induced system rotating with reference to the other. While, however, the magnetic field of a continuous-current motor is always constant, that of an alternate-current motor is constant, alternating, or rotary, according to circumstaces.

Constant Field Motors.—This, the oldest type of motor experimented with, is based upon the principle of the reversibility of alternators. The alternate current is sent through the armature coils, which rotate in a constant magnetic field produced by a permanent magnet or by an electromagnet. The simplest is that formed by a Siemens double T coil revolving between the poles of a permanent magnet, or of an electromagnet excited from an external source. In this motor, if it has been brought up to the speed corresponding to the frequency of the alternate-current supplied (for example, 50 revolutions per second if the frequency of the alternator is 50), it revolves in synchronism with the alternator, following all its variations of speed unless a load of more than a certain amount is suddenly applied to it. If this is done the motor is thrown out of synchronism and immediately stops. The theory of these machines was developed in 1884 by Dr. Hopkinson. The necessity for synchronism at the start, and for an external source of electric energy for exciting the field magnet when large motors are wanted, and the necessity for running at a rigorously constant speed, have prevented these motors from receiving many commercial applications. Zipernowsky caused the two most serious of these inconveniences to disappear by rendering the motors self-exciting, the exciting current being derived from a shunt circuit containing a "redressing" commutator. A motor of this kind will start by itself when unloaded, and quickly attains its normal speed, which it keeps perfectly in spite of sudden variations of load. The efficiency of these motors is very satisfactory, attaining 80 per cent. in 4-kilowatt machines. In spite of—or, more exactly, owing to—the synchronism necessary for the running of these machines, a few of them have been used for the purpose of long-distance transmission of power.

Alternate Field Motors.—Any continuous-current dynamo supplied with alternate currents will start and continue revolving with considerable mechanical effort. A machine of this kind is comparable to an electro-dynamometer, the torque of which always remains the same in spite of the alternations in the direction of the current. A motor of this kind, however, possesses numerous and serious defects. The rapid alternations of current develop Foucault currents in the field-magnets, greatly reducing the efficiency of the motor, unless the precaution has been taken to laminate the cores. Moreover, the high inductance of the motor reduces the current, and consequently the output, of a motor of given dimensions. For these reasons motors of this type are but little employed except where small power is wanted, as in the case of motors driving small domestic ventilating fans, taking one to two amperes at a pressure of 50 volts, such as are in actual use in America. The exciting circuits of these motors are either arranged in shunt or series. If we suppress the iron in the field-magnets and in the armature, we obtain an electro-dynamic motor of small output, the motive couple of which is at any instant proportional to the currents traversing the armature and field coils. The energy meter of Prof. Elihu Thomson comes under the heading of an electro-dynamic motor. To avoid losses by Foucault currents and hysteresis due to the rapid reversals of magnetism of the field-magnets of motors of this type, Mordey has suggested passing the alternate current through a commutator on the shaft of the motor. On starting, the commutator has no effect, but as the speed increases the current becomes more and more "redressed;" that is to say, the losses caused by reversals of magnetism are reduced and the efficiency improved.

Closed-circuit motors also come under the head of motors with alternating fields. The electro-dynamic repulsion experiments of Professor Elihu Thomson have shown that a closed circuit placed in an alternating field tends to move so as to render the coefficient of mutual induction a minimum; in other words, it tends to reduce to a minimum the flux threading the coils. If we place a series of movable coils revolving round a common axis in an alternating field, and arrange the brushes so that each coil is successively short circuited at the moment when the flux threading it is a maximum, and open-circuited when the flux is zero, and so on, there will be exerted on each coil a certain torque, which, owing to the multiplicity of coils, will be sensibly constant. In motors of this type there is no connection between the field and the armature. The field coils are closed on the supply wires and the motor coils are closed on themselves. Such a motor can easily be realized by means of a small Gramme or Rechniewsky two-pole machine, if we take care to give the brushes a forward lead of about 45 deg. Alternate field motors are but little used, and no experiments as to their efficiency have as yet been published.

Rotary Field Motors.—Professor Ferraris, in March, 1888, was the first to make public the principle of these alternate current motors, the development of which now seems likely to cause a revolution both in long-distance transmission work and in the distribution of electric energy for small motors. The following is the principle established by Ferraris: When two alternate currents of the same period, lagging one behind the other by a quarter period, are passed through two circuits arranged at right angles, the result is a constant rotary magnetic field revolving at

1. Paper read before the Société Francaise de Physique.

a constant speed, making one complete revolution per period. If now a closed magnetic circuit is placed in this rotary field, it will be the seat of induced currents, and these induced currents will tend to turn the induced circuit in the same direction as the rotary field. With the exception of the method of producing the rotary field, the rotation thus obtained is identical with that of the classical "Arago" experiment, known under the name of "Magnetism of Rotation."

One might state with accuracy that the rotary field motor works in virtue of the Foucault currents, of which it is the seat. These Foucault currents would be zero if the circuit was stationary with regard to the field, that is to say, if the circuit revolved at the same speed as the field; and it is to fulfil this condition of relative immovability that the circuit turns within in the field, and in the same direction. In short, the circuit runs after the field.

Although of relatively recent invention, rotary field motors are already very numerous, and varied in principle and arrangement. They are distinguished amongst themselves chiefly by the mode of producing the rotary field, and by the generator which supplies current to the motor. I will now examine the ordinary alternate current motors, and the motors supplied with multiple phase currents.

There are several means of obtaining an ordinary alternate current, two alternate currents lagging a quarter phase behind each other, and capable, therefore, of producing a rotary field. Ferraris employed two circuits—one supplied with current direct from the alternator, the other connected to the secondary of a transformer, the primary of which was connected to the main leads of the alternator. Tesla employs two circuits arranged in shunt, and possessing widely different time-constants. Shallenberger employed a closed-circuit armature placed obliquely with reference to the primary circuit supplied with current from the alternator, and the reactions of the primary circuit and of the armature circuit producing a rotary field. In the Hutin and Leblanc motor the rotary field is produced by two sets of coils connected in parallel, a condenser being interposed in one of the circuits. In this way the quarter phase lag necessary for the production of a rotary field is easily obtained.

The above solutions of the problem are suitable in the case of distribution to comparatively small motors. For the purpose of long-distance transmission on a considerable scale, it is preferable to have recourse to special generators, no longer producing ordinary alternate currents, but several alternate currents lagging a fraction of a phase one behind the other, that is to say, "polyphasal" alternate currents. We may either employ two currents and four wires, or only three wires, using one as a common return. Devices of this kind have been brought out by Ferraris and Tesla. Being obliged to use three wires, some have preferred to employ three currents of equal periodicity, but lagging one behind the other one-third of a period. By taking advantage of the employment of three currents retarded in this way, we can make the algebraical sum of the currents at any instant zero, and one of the three wires can always serve as a return to the currents traversing the other two. Such is the principle of the motors supplied with "polyphasal" currents, devised less than two years ago by Dolivo-Dobrowolsky, Haselwander, Bradley and Wenström. A 300 h. p. transmission of power plant of this kind, due to Brown of Oerlikon, is now in process of erection between Frankfort and Lauffen.

This rapid enumeration of the methods actually employed or investigated for the convenient transformation of the energy of alternate currents for mechanical purposes shows that we may consider the problem as solved. It will doubtless be the same soon as regards the utilization of alternate currents for electro-chemical and storage purposes. Alternating currents will then assume a commercial importance superior to that of continuous currents, and we shall witness a new evolution of electric systems, while awaiting that which the employment of alternating currents of high frequency will some day give rise to.

ELECTRIC LIGHTING FIGURES IN CANADA.

THE council of an Ontario town recently sent inquiries to nearly all the cities and towns of Canada as to the yearly cost of each electric lamp in use for street lighting. The lights are paid for from 200 to 365 nights per year. The figures are: Montreal, $146; Toronto, $108.59; Hamilton, $102.10; Ottawa, $80; Halifax, $79; London, $94.05; Kingston, $65.80; St. Catherines, $77.10; Brantford, $105; St. Thomas, $102.20; Windsor, $80.30; Peterborough, $60; Stratford, $66; Belleville, $105; Woodstock, $56.50; Brockville, $101.50; Berlin, $60; Galt, $66; Cornwall, $17; Cobourg, $62.50; Truro, $85; Lindsay, $48; Barrie, $70; Yarmouth, N. S., $80; Ingersoll, $60; Bowmanville, $65.05; St. Marys, $39; Orangeville, $57; Paris, $58 50; Whitby, $45; Brampton, $64; Simcoe, $50; Kincardine, $52.80; Mount Forest, $75; Newmarket, $45; Wingham, $60; Palmerston, $45; Markham, $36. The figures are interesting, but are very incomplete. Many of these plants are run by water-power. Data is wanting also as to number of lights, length of lighting hours, and candle power of lamps.

ELEVENTH REUNION OF OLD TIMERS AND THE U. S. M. T. C., AT WASHINGTON.

THE annual meeting of these two societies began at the Ebbitt House, Washington, D. C., on August 19, at 10 a. m. The attendance was very large and unusually representative, due largely to the fact that it was the first gathering in Washington since the war, and that many of the members were busily engaged in the city in confidential and responsible positions during that great struggle.

About 100 were in the red parlor when President G. C. Maynard called the convention of Old Timers to order. He delivered an able and interesting address from the chair, reminding his auditors that Washington was a city filled with memories of Morse, Henry, Vail, Kendall, and others, whose labors brought the telegraph from a doubtful experiment to a practical success, as well as of the Ellsworths, the friends of Morse in his days of trial and waiting. But for the cheer given by Miss Ellsworth and her father to the great inventor, it was doubtful whether he would have secured help from Congress or carried his work through. From the very first, as it happened, women were associated with the telegraph, and on the old Erie and Michigan line, with 13 offices, not less than 6 women were employed.

Mr. Maynard made touching allusion to the recent dead, and dwelt on the attachment to the profession and the close feeling of union that telegraphers always manifested. He considered that telegraphers were still in the van of progress, the reason being that the telegraph was one of the best schools in educating men for practical business, and in affording high mental discipline.

A number of new members were then elected, showing a healthy state of growth, and Mr. W. J. Dealy, the secretary and treasurer, reported that there was a balance in hand of $355.

In the course of a few informal remarks Mr. Maynard then offered a few suggestions as to the work that lay before the association. He called attention to the fact that the effort to secure records of Old Timers by issuing circulars, in order to replace the documents destroyed in the Western Union fire, had already resulted in the accumulation of 500 reports, and they were coming in at such a rate that he expected to hear from at least 1,500 more. Those reporting had also suggested hundreds of names to be sent to, and he thought they would have 10,000 before they got through. It was an interesting fact to note that nine out of ten had begun in the business before they were fifteen years of age. Mr. Maynard also suggested that a plan should be adopted for securing the interchange of the portraits of all, and that the preservation of the relics of the early days of the art be given special attention.

A number of letters of regret at absence were read, including ones from Hon. J. D. Reid, Jesse Bunnell, Judge J. J. Wickham, George Kennan, the Siberian annalist; T. D. Lockwood, and D. H. Bates.

Mr. G. E. Gilliland handed in a check for $50 from Mr. J. R. McLean, of the *Cincinnati Enquirer*, as a contribution to the funds, in lieu of badges which he had intended to present to each member.

On motion of Mr. Plum, a historical committee was constituted, with Mr. G. C. Maynard as chairman, and it was also agreed that the present and past presidents of the two societies act together in this important matter.

Mr. Ives brought up the question of bringing down the year of admission a little later than 1869, so that Old Timers of a year or two later date might come in. This brought on an interesting discussion, and Mr. Dealy remarked that in 1894 the second twenty-five years would close, and then it would be time to think of the younger brood. On motion, however, of Mr. Talcott, a committee on revision of the constitution to deal with this point was voted for.

The meeting then adjourned till after the convention of the U. S. M. T. C.

The meeting of the U. S. M. T. C. was called to order at 3 p. m., by President W. R. Plum, of Chicago, who in a very eloquent address reviewed the history and work of the Corps, showing that it had numbered 1200 brave men, in the flower of youth, who had constructed 15,389 miles of military telegraphs during the war and sent 6,500,000 telegrams. This work was done amid all the perils of warfare, and many of the men had sacrificed their lives in the discharge of duty. Such was the success of the Corps, every civilized government had since established a system of the same kind, yet up to date no recognition of their services had been rendered them. Mr. Plum then went on to tell how the agitation for recognition had been kept up during the past four years, and urged its continuance on well-defined lines. "We solicit no pension," he said, "nor bounty, nor further compensation. Ours is not a raid upon the Federal Treasury, but an insistence upon a *de jure* recognition of a *de facto* status." He cited many eloquent testimonials from Grant, Sherman and others as to the value of their work, and insisted that they should be satisfied with no recognition short of an honorable discharge from the army, of which they had been a vital and integral portion. He concluded with the remark: "Here in the capital of a united and loyal nation let us again resolve, as we did last year at Kansas City, that a discharge from the army is a *sine qua non* to any acceptable certificate."

Secretary Pettit reported a balance in hand of $354, and stated how he proposed to deal with members in arrears.

The committee on Congressional action reported progress, covering the same ground as President Plum, and considered that the goal was nearer.

A motion was then adopted eulogistic of Gen. Sherman, and recognizing his appreciation of the work of the Corps. It was supported in a very eloquent and manly little speech by Mr. Ives.

The committe on place of meeting then reported Omaha, for the third Wednesday in August, 1892. Agreed to.

Mr. Dealy then cast the ballot of the meeting for Mr. W. R. Plum as president. Mr. W. B. Wilson was elected vice-president and Mr. Pettit, secretary and treasurer.

The Old Timers now reconvened, and Mr. Bliss nominated Mr. E. Rosewater, of Omaha, the editor and proprietor of the *Omaha Bee*, as president. This was unanimously carried. Mr. Dugan, of Tennessee, was elected vice president, and Mr. W. J. Dealy, secretary and treasurer. Messrs. P. J. Hutchinson, J. M. Turner, J. Q. Mason and W. B. Wilson were elected as the executive committee.

The convention then adjourned.

A very interesting display of mementoes and relics was made under the auspices of Mr. Maynard at the National Museum, where the permanent collection was supplemented by several special loan exhibits, among which were the Ellsworth and Morse portraits, loaned by THE ELECTRICAL ENGINEER; a number of Morse papers, books, etc., loaned by T. C. Martin; and a large collection of portraits, loaned by the *The Telegraph Age*. The whole was inspected with very great interest by the delegates and their friends.

The issue of THE ELECTRICAL ENGINEER of August 19, containing as it did so much of interest to both the Old Timers and the U. S. Military Telegraph Corps, was in great demand and was very eagerly read by all the delegates, many of whom had been participants in the scenes illustrated and described.

The whole of Wednesday was devoted by the Old Timers to junketing of a most delightful nature. The White House, Corcoran Gallery, National Museum, Capitol and other places of interest were visited, and a group photograph was taken on the steps of the Treasury. From the fact that so many telegraphers, old and new, are employed in positions of responsibility in the various departments, it was easy enough to obtain access everywhere.

On Wednesday evening a reunion was held in the armory of the National Rifles, under the auspices of the local committee. Congratulatory dispatches were received in the hall from all over the country, and one came from the City of Mexico. Several speeches were made, notably by President Maynard, Mr. W. W. Burhans, of the United Press; Assistant Secretary Nettleton, of the Treasury; Col. Whitfield, of the Post Office Department; Assistant Secretary Willits, and Assistant Secretary of War Grant. A letter was also read from Hon. James D. Reid. Prof. Watkins, of the Smithsonian, urged the collection of relics of the early days of the art. Then came a choice collation, accompanied and followed by music.

On Friday the party made an excursion to Mt. Vernon, the home of Washington, and despite the bad weather, greatly enjoyed the inspection of the old mansion and the many relics it contains. Most of the delegates returned home the same evening. The fact that not a few of them were accompanied by their wives and daughters made the whole convention one of the brightest in its social aspects that the two societies have ever had.

Great praise is due to the local committee for its work, especially Messrs. M. W. Barr, the chairman; G. C. Maynard, Fred. Royce, M. Marean, W. H. Young, A. B. Talcott, H. G. Safford. Every attention possible was shown to the delegates, and in addition to the general programme there was a large amount of private entertainment.

"EARLY PRESENTATION OF THE BEST NEWS."

MR. E. H. CROSBY, of the *Boston Post*, says: "I am a constant reader of your valued paper and I am pleased to add my testimony to that of many others as to its accurate and reliable electric information. Its news is of the latest and most authentic, and it stands far in advance of all similar publications in regard to the early presentation of the best news. I would not be without it for twice the subscription price."

MR. C. M. PARKER, the electrical engineer of the Metropolitan Electric Railway Co., of Springfield, Mo., has resigned to accept a similar position in St. Louis.

MECHANICAL TABULATION OF CENSUS STATISTICS.[1]

DR. BILLINGS said that the data collected by the census for each living person, or in systems of death registration for each decedent, might be recorded on a single card or slip by punching small holes in different parts of it, and that these cards might then be assorted and counted by mechanical means according to any selected grouping of these perforations, as was first suggested by him in 1880. This suggestion was taken up by Mr. Herman Hollerith and by him has been elaborated into practical shape the system which is now in use in the population and vital statistics division of the eleventh U. S. census, and which has been adopted for the compilation work of the recent Austrian and Canadian censuses.

For each individual living in the United States June 1, 1890, as shown by the census schedules, the facts relating to sex, age, color, conjugal condition, birthplace, birthplace of each parent, occupation, number of children, etc., have been indicated on a piece of stout manilla paper 6⅝ inches long by 3¼ inches wide, by punching holes in different parts of it. For each decedent during the census year the same facts are reported, and, in addition, the cause of death and the month of death. The place of residence, by State and district, is indicated in like manner.

The number of subdivisions which can be distinguished in recording the different classes of facts in this way is very great. For example, in forty-eight spaces it is possible to record the distinction for each of 45,000 different districts, as is actually done by the gang-punch system for the census.

The cards thus punched are passed through machines in which an electrical connection is made by the passage of a metal rod through the cards wherever a hole has been punched, and the currents thus produced actuate a series of small dials on which the number of the data is recorded. About forty of these dials are usually used at once, each of which records a single class of facts. For example, the first dial may be set to count males under one year of age, or all white males under one year of age, or all white males born in Pennsylvania under twenty years of age, or all white male butchers in Pennsylvania whose mothers were born in Germany and who are between twenty-five and thirty years of age. If no record has been punched on the card for age, birthplace, etc., the machine does not record, and the attention of the operator is called to the fact that the card is defective.

The machine not only records certain groups of facts on the dials, but has a series of assorting boxes which also have electrical connections by means of which the cards, as they pass through the machine, can be assorted into groups on any system required; as, for instance, into groups of ages, into groups of birthplace, or according to birthplace of mothers, or according to occupations, etc.

In the population division, after a little training, the average number of cards punched per day by each operator was 766, some punching 1,200 to 1,400 per day. In punching death records the work was a little slower, but ten clerks averaged over 1,000 per day each.

The accuracy of the work in punching by each person was tested at the beginning in what was called practice work, and no one was allowed to enter upon the work of punching until the percentage of error made in practice work had been reduced to the minimum. A certain proportion of cards punched by the clerk in his particular section was each day carefully compared and verified, and the number and character of errors made recorded and reported.

The number of cards which can be passed through the machine in a day's work of seven hours depends on the number of readings which have to be taken from the dials, which, of course, depends upon the size of the unit of area for which the reading is taken. At the commencement the daily average number of cards passed through the machine for each worker, with an average of five readings copied off, was 8,404. At the end of July the average number for each worker, with an average number of nine daily readings, was 7,000. Taking the ten most expert operators in July, the daily averages were 7,879, 8,723, 9,008 and 9,368. In the vital statistics divisions the highest daily average for four months are as follows: January, 12,404, with sixteen readings; February, 11,912, with thirteen readings; March, 12,021, with nineteen readings; April, 12,665, with eighteen readings.

With these figures may be compared those for transcribing census data on cards and compiling by assorting these cards, as was done in preparing the statistics of the insane, deaf and blind. The average number of individual records copied in script per day per clerk was 164. For the last week it was 252. These records contain all the data on the population schedule and also the special data of the class. In assorting these cards about 1,750 per day would be distributed by one clerk and the readings taken.

The conclusion is that the data on population schedules and schedules of deaths can be copied from 25 to 50 per cent. more rapidly by punching than by transcribing, and that, with punched

1. Abstract of a paper read by Dr. John S. Billings before the Economic Science and Statistics Section, A. A. A. S., at Washington.

cards and the electric counting machine, the usual tables can be compiled from four to eight times more rapidly than by assorting the written cards. The relative accuracy of the results of the two methods is about the same.

The saving in time and clerical labor effected by the use of punched cards and the electric counting and assorting machine depends on the number and complexity of the different tables compiled and on the number of individual records. For the work of the eleventh census the saving thus effected is estimated as being at least half a million of dollars.

FUNCTIONS AND NATURE OF ETHER IN SPACE.

In the admirable address delivered by Prof. F. E. Nipher, before the Physics Section of the American Association for the Advancement of Science, at Washington, he took up the various phases through which the study of the ether had passed, and remarked that in former days many reasons given for the existence of the ether do not seem conclusive now. We could hardly subscribe to the sentiment that there must be an ether or nature would be disgusted with the greater portions of space and the planets and stars would fall to the ground.

We have other needs for an ether, which to us seem important and pressing; still we may perhaps wonder occasionally, with Theophratus Such, what kind of hornpipe we are dancing now.

For 25 years it was taught that light was an elastic pulsation in an uncompressible jelly-like medium. Some of the mathmetical deductions of Green he could only reconcile with the observed phenomena by making the ether incompressible.

In 1865 Maxwell proposed his theory that light was an electric displacement in a plane at right angles to the line of propagation. Maxwell's theory met with great favor. It afforded simple and natural explanations for phenomena which had previouly been clouded by rather strained assumptions.

Twenty-three years later, in 1888, Sir William Thomson brought a powerful reinforcement to the elastic theory. He showed, as did Green, that the compression wave, which theory called for and which did not exist in fact, might be got rid of in the theory by making the volocity of the compression wave zero instead of infinite. Thomson found what had escaped Green, that this assumption did not involve an unstable condition of the medium, and that, therefore, it was admissible. It was also shown at once by Thomson, Willard Gibbs, and Fitzgerald that this new and rather startling suggestion placed the elastic and electric theories on the same logical basis if the ether was considered incompressible in the electric theory, and to have a rigidity zero for a compression wave in the elastic theory. It is, in fact, worthy of remark, as a matter of congratulation, showing how far scientific men have emerged from the intellectual pugilism of the last century, that Thomson's audacious departure was met with pleased surprise instead of with angry polemics against a new heresy.

The showing up of light in space occupied by matter shows that the ether within must either be more dense (as Fresnel believed) or less elastic than that existing in free space. It is certainly very difficult to understand what there can be in the molecules of matter which can increase the density of an incompressible medium. The beautiful experiment of Michelson and Morley shows apparently that the ether at the surface of the earth moves with it. It is dragged along as if it were a rigid liquid. The field of a steel magnet is, however, a rotational phenomenon. It is a spin which is maintained permanently without the expenditure of energy. It seems, therefore, that the resistance to shear which shows itself in the adhesion of the ether to the moving earth must be a rigidity due in some way to motion. Other experiments of Michelson and Morley on the motion of light in moving columns of water have been taken as proof that the ether in water is condensed to nine-sixteenths of its volume in air. The ether in water certainly behaves as if it were more dense, but it is another matter to say that it is so. It seems improbable. It is still a mathmetical fiction which covers a gap in our knowledge of the ether. The speaker thought that the experiment should be repeated with water at rest within a tube which should be mounted on elastic supports in a moving railway car. The water tube and observer's seat should be rigidly connected and swung on dampened spring supports from the top and sides of the car. The question to be settled is whether the ether, or any part of it, is at rest in space, and does it sweep through the interior of bodies which move through it as wind sweeps through the leaves and branches of a tree. This form of the experiment is the one contemplated by Eisenlohr's analysis leading to Fresnel's formula, and it is capable of great variations in the conditions of experiment. It is, however, more difficult and more expensive than the one so well executed by Michelson and Morley. Whatever its results may be, it promises to add greatly to our knowledge of the physics of the ether.

Gen. C. H. Barney, late of the "A. B. C." Company, has been apppointed by President Huntley as officer in charge of the exhibition at the coming Montreal Convention.

Letters to the Editor.

Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents.
Anonymous communications cannot be noticed.
The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.
In order to facilitate reference, correspondents, when referring to any letter previously inserted, will oblige by mentioning the page on which it appears.
Sketches and drawings for illustrations should be on separate pieces of paper.
All communications should be addressed Editor of The Electrical Engineer, *150 Broadway, New York city.*

DROP IN POTENTIAL ON UNDERGROUND FEEDERS.

The last sentence in your very interesting article on the Insulation Resistance of the Street Railway Mains in the City of Minneapolis, Minn. (The Electrical Engineer, August 19, page 224), reads as follows: "The drop in the potential at the terminals of the feeders employed in the conduit is 5 per cent., while in the other systems, where the overhead feeders are used, 10 per cent., and over, is the result."

Of course, to an engineer, the meaning is plain enough. Lest, however, some beginner be led into error, it may be well to point out that the mere insertion of the feeders into a conduit system cannot be relied upon to save 5 per cent. potential loss more than would occur were the same wire strung overhead, this last being the natural inference from the statement quoted.

The number of volts lost in the conductors being, of course, in both cases a question only of cross-sectional area (circular millage) disregarding special cases involving the condenser effects of electrostatic capacity.

J. Stanford Brown.

New York City.

Society and Club Notes.

SOME OF THE EXHIBITORS AT MONTREAL.

We give below a partial list of the firms and individuals to exhibit at Montreal:

Eureka Tempered Copper Co., North East, Pa.; Charles A. Schieren & Co., New York; Standard Underground Cable Co., Pittsburgh, Pa.; W. J Johnston Co., Limited, New York; Standard Electrical Time Co., New Haven, Conn.; Standard Paint Co., New York; Fort Wayne Electric Co., Ft. Wayne, Ind.; Electrical Engineering & Supply Co., Syracuse, N. Y.; Eugene F. Phillips Electrical Works, Limited, Montreal, Can.; Felten & Guilleaume, Cöln, Germany; International Okonite Co., New York; Weston Electrical Instrument Co., Newark, N. J.; The Johns-Pratt Co., Hartford, Conn.; The Ball Electric Light Co., Toronto, Can.; The Electrical Engineer, New York; Interior Conduit & Insulation Co., New York; Robert Mitchell & Co., Montreal, Can.; Thomson-Houston International Electric Co., Boston, Mass.; Toronto Construction & Electrical Supply Co., Toronto, Can.; H. Ward Leonard, New York; Dominion Wire Manufacturing Co., Montreal, Can.; T. W. Ness, Montreal, Can.; Edison General Electric Co., New York; Norwich Insulated Wire Co., New York; Excelsior Electric Co., Boston, Mass.; Canadian Electrical Construction, Manufacturing & Supply Co., Montreal, Can.; Russell Electric Co., Boston, Mass.; *Electric Power*, New York; McGill University, Montreal, Can.; La Boiteaux Electric Motor & Fan Co, Cincinnati, O.

Obituary.

Mr. John C. Folger, an attaché of Mr. Frank Ridlon's office, and well known to many in Boston as an enthusiastic electrician, died suddenly recently. Newspaper reports had it that he died from an electric shock, but upon inquiry it was found that the electric shock was sustained two weeks previous to his death, and that he had been carried off by typhoid fever. Mr. Folger was a young man of 18, and was well esteemed by all who knew him as a bright, energetic and promising electrician.

The Insulated Wire Department of the National India Rubber Co., of Bristol, R. I., is now in full operation, and, under the direction of Mr. Frederick S. Minott, is furnishing rubber line wire and lead-covered underground cables for any desired voltage.

This company, having had 25 years' experience in the manipulation of india-rubber, is peculiarly well fitted to produce a reliable compound, and the use of the best materials together with the employment of careful workmen and expert electricians will undoubtedly insure its success. The new catalogue and price list issued by the company gives full information regarding its various products.

TRADE NOTES AND NOVELTIES

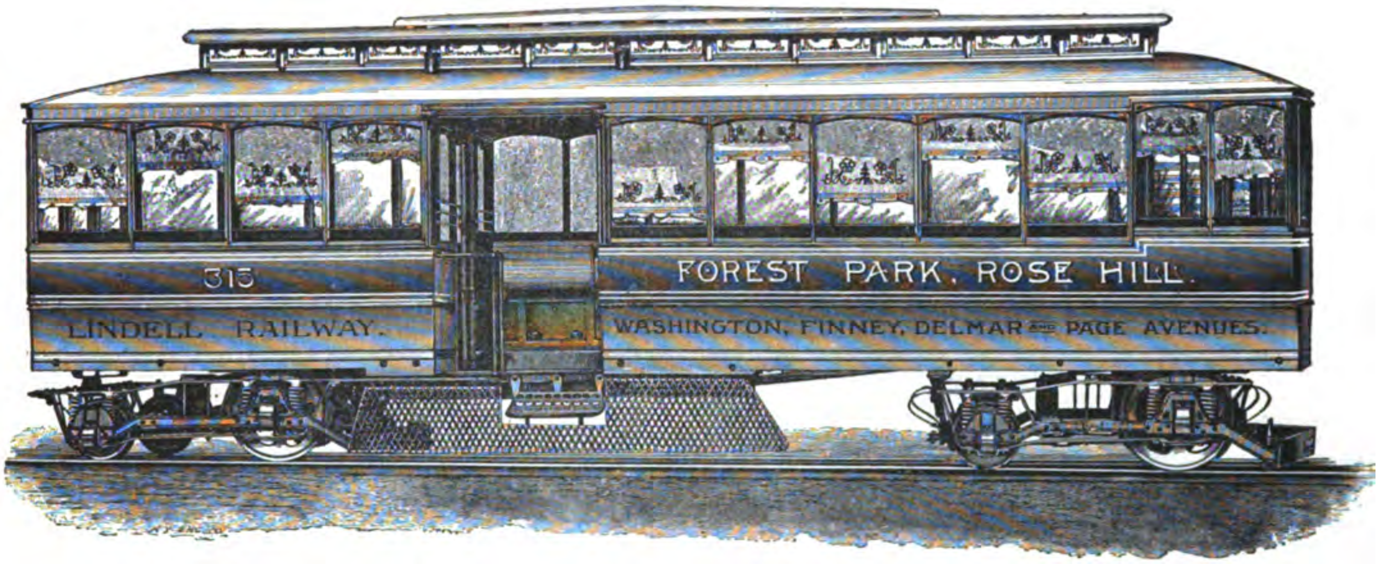
AND MECHANICAL DEPARTMENT.

A liberal advertiser has good crops every year.

A NEW DEPARTURE IN ELECTRIC AND CABLE CARS.

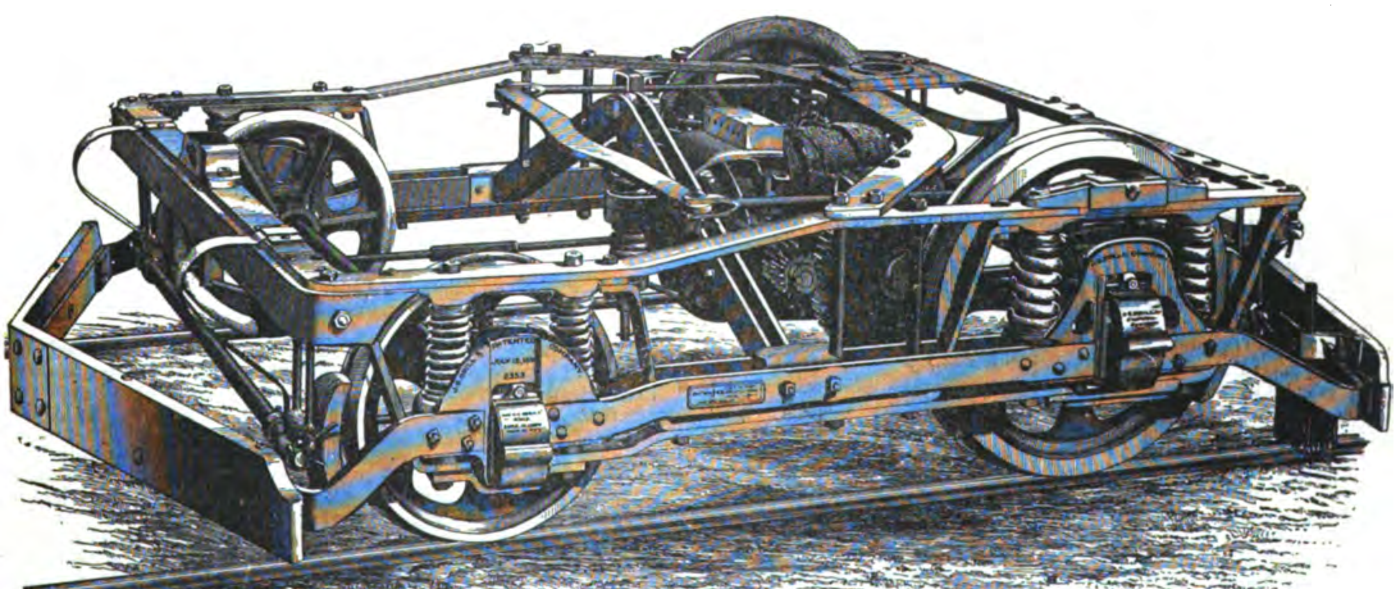
A GROWING tendency to the use of longer cars where the motive power is other than animal power has developed the fact that but very little can be added to the length of a car of the ordinary type without considerable sacrifice of the time taken to load and unload passengers, and an increased difficulty in collecting fares on long cars having a platform at each end. The adoption of electricity and cables as motive powers, and the consequently quicker transit, has increased in a wonderful degree the number of passengers carried, and the railroad companies naturally seek to add to their carrying capacity in the most economical manner. To increase the seating capacity in a car without adding to the length occupied on the street by the present horse car, and to attend to the passengers and collect the fares by the employment of one man as conductor, are the two directions by which this economy is reached.

In a new car just completed for the Lindell Railway Co., of St. Louis, by J. G. Brill Company, the economical features above referred to are accomplished. This car is the invention of Mr. Jno. A. Brill, vice-president of the J. G. Brill Company, and the novel features embraced in it are covered by three patents. The most evident novelty is that the car has no end platforms, but has a vestibule or platform enclosed on three sides near the centre of the car, which is open only on one side of the car, and connects with the two compartments by door-ways. The front platform of an ordinary car has no use except for the motorman, carrying no passengers, and in this car the whole of one platform with its unnecessary length and weight is dispensed with.



THE NEW BRILL CAR.

The car is divided into two compartments separate from each other; the forward compartment is for the usual mixed passengers and the rear compartment is intended primarily for the use of smokers, the larger being 17½ feet long and the smaller 10½ feet long. The seats in this car are placed transversely, with capacity for two persons on a seat, on each side of the aisle, and there is a seat on the closed side of the vestibule for three persons. At one end of the single step there is a convenient space guarded by a stout hand rail of polished brass for the conductor to stand in, from which point he has complete control of the car, and can easily reach passengers who require his assistance in getting on or



THE NEW BRILL TRUCK.

off the car. The seats in the car can be arranged if preferred in the usual manner of street cars, that is, longitudinally on the sides. The total seating capacity of the car is 46 persons.

With this arrangement of the entrance near the middle of the car it is evident that the passengers will not require so long a time to get to or from their seats as they would in cases where the entrance is placed at one end, and for the same reason the conductor can reach both ends of the car for collecting the fares with greater facility; and having this advantage, one man can collect all the fares and attend to all the passengers. An ordinary horse car is 23 feet long, and, with the horses attached, occupies 35 feet in the street, seats 22 persons and requires one conductor. The new style of car is only 31 feet 6 inches, extreme length, and seats 46 persons, and can be worked with equal ease by one conductor. As it carries as many passengers as two ordinary horse cars, there is a saving of one conductor for a given number of passengers. The saving in wages alone on a line using 100 cars is from $200 to $250 per day, representing an annual saving of over $70,000, an amount sufficient alone to pay a dividend greatly in excess of the average dividend on street railroads.

In cities with crowded streets like New York, Philadelphia, Chicago, the saving of one-half the street space of cars is an item of enormous advantage; and this car is only 7½ feet longer than the adopted size of motor cars with vestibuled ends, which seats only 22 persons.

The motorman stands in a place four feet long and two and a quarter feet wide, well sheltered, but with complete view of the track. This space is partitioned off with mahogany panels and plate glass sash, by which he is freed from all crowding and interference by passengers. Another important advantage which this long car has over a train of motor car and "trailer" is the superior control in stopping the car by which the train cannot be made to act as promptly as desired unless by use of the automatic brake, which is effective, but costs $300.

The Lindell Railway Company, with its characteristic enterprise and desire to give its patrons the very best that can be had, has ordered this car to be finished in the most elegant manner, with solid mahogany, polished plate glass, embroidered linen shades, polished brass mountings, and seats where a passenger will not have to struggle for the 17 inches usually alloted to him. The successful working of this long car with electric motors is dependent, however, on the use of Brill's patented "Maximum Traction Trucks," on which more than 90 per cent. of the traction is upon the two pairs of driving-wheels of the trucks; and the peculiar form of the truck entering the bottom frame of the car body sets the car so low that it required only a single step of the usual height at the entrance. The use of this style of truck on the Newark passenger railway has made a great success of the operating of long cars at a time when the company was on the point of abandoning their use as being a failure, by reason of the deficient traction and excessive height of the car body, which caused two steps to be necessary.

THE LIEB OVERHEAD WIRE CONSTRUCTION.

THE accompanying illustrations show two forms of construction employed by the Lieb Machine Works, of this city, in overhead electric railway work.

In Fig. 1 is seen the method used in city lines. Here the Lieb insulated turn-buckle not only plays the part of a perfect insulator of great length and strength, but it also entirely obviates the necessity of a pole ratchet. All the slack necessary can be taken up with the turn-buckles, and the span-wire, being insulated from the trolley by the insulated hanger and from the poles by the insulated turn-buckle, a double insulation is thus secured. This insulated turn-buckle, like the wooden insulator, can be used in various ways to make combination appliances for line work.

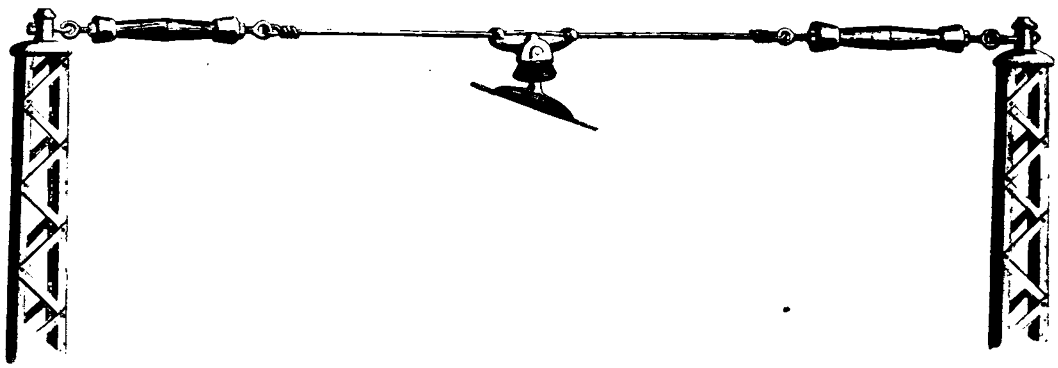


FIG. 1.—OVERHEAD CITY CONSTRUCTION.

Fig. 2 shows one of the many ways in which the Lieb wooden insulators can be applied in line construction. In this case the trolley-wire bell usually employed is entirely dispensed with, and a metal piece substituted for it. The first cost is thus greatly reduced. The outer ends of the span-wire are thoroughly insulated, the small section only between the wooden insulators being alive.

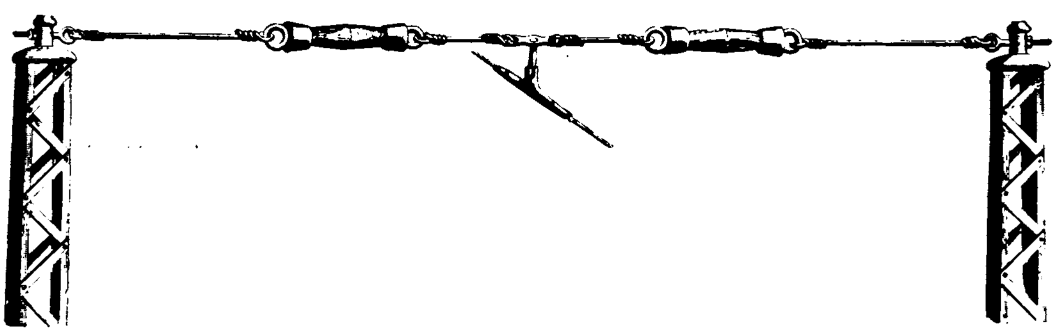

FIG. 2.—OVERHEAD SUBURBAN CONSTRUCTION.

For suburban work, where there are few telegraph wires, this construction has been found wholly satisfactory.

H. WARD LEONARD & CO.

WITH regard to the above new concern, it may be stated that H. Ward Leonard & Co. is a corporation organized under the laws of the State of New Jersey. Its present authorized capital is $200,000. The original subscription was for $50,000. $32,000 of which was subscribed by the incorporators. The revenues of the company will be of a character such that comparatively little capital will be required considering the net revenue. The shares of the company are $100.00 each. The present stockholders include some of the most prominent of the various leading electrical companies. None of the stock of the company is issued for anything but absolute cash or its equivalent, and every shareholder is on exactly the same terms as every other shareholder. That is, there will be no issuing of stock for contracts, patents, franchises or similar considerations having an indefinite value.

The company is already preparing actively for business, and is getting its offices in the Electrical Exchange into order, so as to take up the work that has already begun to flow in.

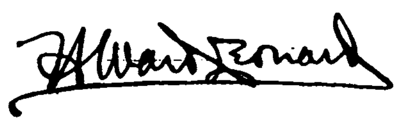
THE

Electrical Engineer.

VOL. XII. SEPTEMBER 2, 1891. No. 174.

MINIMUM FIRST COST OF PLANT AND MAXIMUM ECONOMY OF OPERATION IN THE ELECTRICAL TRANSMISSION OF POWER.

BY



A GREAT deal has been, and is being, written and said about the condition governing the minimum first cost of a plant for the transmisson of power by electricity, and also about the conditions governing the maximum economy of operation of such a plant, and some radical errors and false deductions have been made by those who are considered authorities upon this subject, so that it is not surprising that a somewhat erroneous idea at present exists in the mind of the electrical public upon this question.

As a rule, the theories and deductions developed by the various papers on this subject have given as a conclusion certain formulæ and laws, the application of which is practically impossible because of the necessity of using factors, the determination of the value of which is fully as great, if not greater, a problem than that, the solution of which is attempted. The result of this has been that vital errors in some of the most noteworthy papers on the subject have remained unnoticed by most readers, and even if others besides the writer have been familiar with these errors, they have probably felt, as he did, that no good purpose would be served by calling attention to them, as no practical application seemed to have been attempted of these formulæ or laws.

The recent publication, however, of a compilation entitled "Electric Transmission Hand-Book," by F. B. Badt, makes it appear of importance to call attention to the serious errors contained therein, for Mr. Badt not only publishes all the original errors of the authorities he quotes, but he proceeds to carry the erroneous deductions further and to give and solve practical problems in a manner such that the reader cannot but receive a clear and definite, although entirely incorrect, understanding of the subject. Furthermore, some of the formulæ published by Mr. Badt, and for which the present writer is responsible, have been interpreted by means of erroneous laws laid down by Mr. F. J. Sprague, and consequently an entirely false meaning has been given to formulæ which, when properly interpreted, are entirely correct. In order to point out the errors mentioned in as clear a manner as possible, I shall first treat the subject generally and deduce the correct laws, and then point out the inconsistencies and inaccuracies of the conclusions, formulæ and laws given by Mr. Sprague and Mr. Badt.

Under date of August 16, 1886, the writer published a general formulæ for the determination of the size of conductors which should supply devices arranged in multiple arc, the form of which was as follows:

$$M = \frac{\text{K. W.} \times D \times 21{,}400}{V(E-V)}; \qquad (1)$$

in which M = Circular millage of conductor.
K. W. = Kilo-watts at terminals of translating device.
D = Distance of transmission in feet.
E = E. M. F. at generator brushes.
V = Volts lost in transmission.

For the sake of explicitness I will indicate the derivation of the formulæ.

Res. of 1 foot-cir. mil of commercial copper = 10.7 ohms.
Res. of 2 D feet of conductor of 1 cir. mil = 21.4 D.
Res. of 2 D feet of conductor of M cir. mil $= \frac{21.4\ D}{M}$.

$$M = \frac{21.4\ D}{R}. \quad \text{Now } R = \frac{V}{C} = \frac{V}{\frac{1{,}000\ \text{K.W.}}{E-V}} = \frac{V(E-V)}{1{,}000\ \text{K. W.}}$$

$$\therefore M = \frac{21.4\ D \times 1{,}000\ \text{K. W.}}{V(E-V)} = \frac{\text{K. W.} \times D \times 21{,}400}{V(E-V)}. \qquad (1)$$

Weight of 1 foot cir. mil of copper = .000003027 lb.

∴ Calling T the weight of conductor in lbs. and allowing 3 per cent. for sag, etc.

$$T = \frac{D^2 \times \text{K. W.}}{V(E-V) \times 7.5} \qquad (2)$$

Calling B the cost of conductor in dollars, we have, with copper at L cents per lb.

$$B = \frac{D^2 \times \text{K. W.} \times L}{750\ V(E-V)}. \qquad (3)$$

∴ The cost of the conductor per K. W. at motor brushes is

$$\frac{B}{\text{K. W.}} = \frac{D^2\ L}{750\ V(E-V)}. \qquad (4)$$

Calling G, the cost of dynamo electric machinery per K. W. at brushes, and $\frac{A}{\text{K. W.}}$, the cost of generator per K. W. at motor brushes, we have

$$\frac{A}{\text{K. W.}} = \frac{100\ G}{100-P}, \qquad (5)$$

where P = the percentage of loss in the conductor; this may also be expressed as follows:—

Cost of generator per K. W. at motor brushes,

$$\frac{A}{\text{K. W.}} = \frac{G\ E}{E-V} \qquad (6)$$

The cost of the generator and of the bare copper for the conductor are the only two elements of the cost of a power transmission plant which it is necessary to consider in the determination of the condition of Minimum First Cost of Plant, for the other factors of the cost of the plant, such as the development of the motive power, the labor of erecting the line, etc., are not proportionate to the power delivered, and hence should not be considered in the determination of the minimum conditions.

With any given initial E. M. F. and distance, it is evident that the more volts we lose in the transmission, the less will be the cost of the conductor; but at the same time the cost of the generator per unit of power transmitted will be increased because of the additional generator capacity required to take care of the increased amount of energy lost in the conductors.

Hence it is evident that for any given initial E. M. F. and distance there must be some particular loss in the conductor which will make the combined cost of the generator and conductor a minimum. We can determine the minimum value by placing the first differential of the expression indicating the sum of the costs of the generator and the conductor, equal to zero.

From (4) and (6) we have, cost of generator plus cost of conductor

$$= \frac{A+B}{\text{K. W.}} = \frac{G\,E}{E-V} + \frac{D^2\,L}{750\,V(E-V)} \quad (7)$$

Placing the first differential $= 0$ we have:

$$\frac{G\,E}{(E-V)^2} - \frac{750\,D^2\,L\,(E-2\,V)}{750^2\,V^2\,(E-V)} = 0. \quad (8)$$

From which we get, $D^2 = \dfrac{750\,G\,E\,V^2}{L\,(E-2\,V)}$. (9)

This last equation expresses the relation existing under the conditions of Minimum First Cost of generator and conductor, and consequently of the entire plant.

Since $\dfrac{E}{(E-2\,V)} = \dfrac{100}{100-2\,P}$, (10)

we have from (9) and (10)

$$D^2 = \frac{75{,}000\,G\,V^2}{L\,(100-2\,P)}. \quad (11)$$

Calling $\dfrac{B_M}{\text{K. W.}}$, the cost of conductor in dollars per K. W. at motor brushes under condition of minimum first cost of plant, we have from (4) and (11)

$$\frac{B_M}{\text{K. W.}} = \frac{G\,E\,V}{(E-V)\,(E-2\,V)} \quad (12)$$

$$\text{and} = \frac{100\,G\,P}{(100-P)\,(100-2\,P)} \quad (13)$$

Calling $\dfrac{A_M}{\text{K. W.}}$ the cost of generator in dollars per K. W. at motor brushes under conditions of minimum first cost of plant, we have from (6) and (9)

$$\frac{A_M}{\text{K. W.}} = \frac{D^2\,L\,(E-2\,V)}{750\,V^2\,(E-V)} \text{ and} \quad (14)$$

$$= \frac{D^2\,L\,(100-2\,P)}{750\,V^2\,(100-P)}. \quad (15)$$

When the cost of dynamo is \$33 per K. W. at brushes and copper is 20 cents per lb., that is, when $G = 33$ and $L = 20$, we have, from (11),

$$D^2 = \frac{123{,}750\,V^2}{100-2\,P} \quad (16)$$

From (3) we have $D^2 = \dfrac{\dfrac{B_M}{\text{K.W.}} \times 750\,V\,(E-V)}{L}$. (17)

With any fixed initial E. M. F. and a certain percentage of loss, we can get by (13) the value of $\dfrac{B_M}{\text{K.W.}}$, the cost of the conductor under conditions of minimum cost; and knowing the cost of the conductor, we can by (17) get the value of D. Thus for any initial voltage and percentage of loss we can determine the cost of conductor and the distance of transmission which corresponds to the minimum first cost of plant. By determining such values at 10, 12½, 15, 20, 25, 30 and 40 per cent., we are able to plot the lines of minimum first cost as given by the accompanying CHART I.

By the use of CHART I we can quickly determine the percentage of loss necessary for any initial E. M. F. and distance, in order that the cost of plant shall be a minimum; and we also learn at the same time the corresponding cost of the generator and of the conductor.

Thus, if we have an initial E. M. F. of 3,000 volts and a distance of 50,000 feet we must, in order to secure the minimum first cost of plant, operate with a loss of 30 per cent., and in such case the cost of generator = \$47.15, and cost of conductor = \$35.35 per K. W. at motor brushes; so that, adding the cost of motor, \$33 per K. W., we have, total cost of generator, conductor and motor = \$115.50. (*Example* 1.)

Similarly if we have a distance of 30,000 feet and 3,800 volts initial E. M. F. we must operate at 20 per cent. loss, and the total cost of generator, conductor and motor will be \$88.00. (*Example* 2.)

Now, it by no means follows, because we are working with the minimum first cost of plant for a certain voltage and distance, that we are working at the highest economy, for, evidently, it is possible that if we work with a less percentage of loss in the case cited in Example 1, although our investment be increased thereby, the interest and depreciation on this increase of investment may be much less than the saving we would effect, due to the reduction of the loss of energy in the conductors. In other words, we must consider the variation in the interest and depreciation upon the investment, as well as the variation in the value of the energy wasted in the conductors, and must make the sum of the interest and depreciation on investment plus the value of the energy wasted in the conductor, a minimum, in order to operate at the maximum economy.

The interest on the investment can be definitely determined, but the value of the energy wasted it is very difficult to determine before the installation is made, for the reason that it is usually impossible to ascertain exactly how much of our total power will be transmitted in the future, as this is usually dependent upon an unknown demand. In addition to this, the value per K. W. of the power wasted will frequently be almost nothing in the beginning, when a large water power is available and there is a demand for but a small portion of it, but later the value per K. W. of the energy wasted would probably be much greater.

Thus, while we can determine with absolute accuracy the Minimum First Cost, the question of the Most Economical First Cost is a question almost entirely for the investor to decide. We should be able to tell him not only the minimum first cost and its corresponding percentage of loss, but also the cost corresponding to any other loss than that demanded for the minimum cost.

In order to accomplish this I have designed CHART 2, which gives not only the cost of plant and necessary percentage of loss for any case, of initial E. M. F. and distance under the conditions of Minimum First Cost, but also gives the cost of plant for the given initial E. M. F. and distance with any other percentage of loss.

Thus if, as in Example 1, the distance is 50,000 feet and the initial E. M. F. 3,000 volts, we find, by examining the curve in which the initial E. M. F. equals 60 volts per 1,000 feet, that the minimum first cost of plant will be realized when we operate at 30 per cent. loss, and that the corresponding cost of generator and conductor is \$82.50, making the total cost of generator, conductor and motor \$115.50.

We also learn that if, with the same initial E. M. F. and distance, we operate at various losses, the cost of generator and conductor varies as follows:

30 per cent. loss....	\$82 50
25 " "	83 20
20 " "	87 20
15 " "	90 60
10 " "	119 00

If, now, we have a superabundance of water power and are transmitting but a small fraction of it and the value of the energy wasted is consequently negligible, we would do

CHART NO. 1.

TRANSMISSION OF POWER.

BY H. WARD LEONARD.

Showing Minimum First Cost of Plant, under Varying Distances and Initial E. M. F.'s.

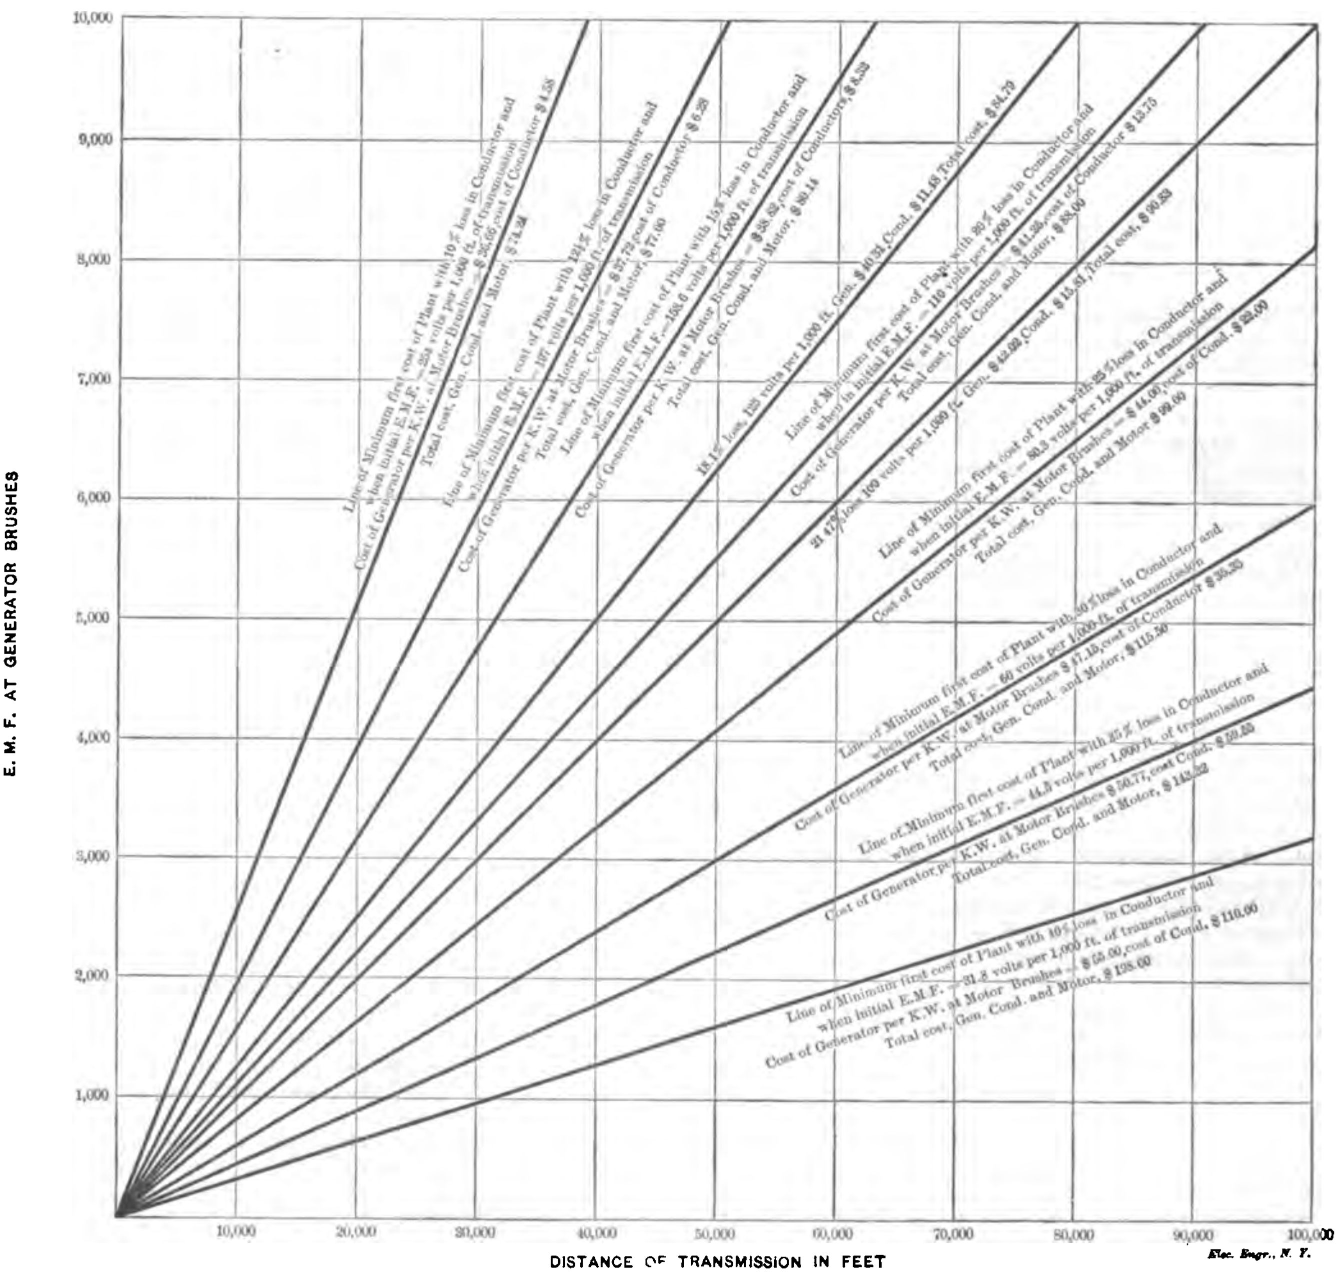
D = Distance of transmission in feet.
E = Initial E. M. F.
V = Volts lost in transmission.
G = Cost of dynamos per $K.W.$ at brushes.
L = Cost of bare copper in cents, per lb.
$\frac{A_M}{K.\ W.}$ = Cost of generator per $K.W.$ at motor brushes under conditions of minimum first cost.
$\frac{B_M}{K.\ W.}$ = Cost of conductor per $K.W.$ at motor brushes under conditions of minimum first cost.

Under conditions of minimum first cost of plant and when G = \$33.00 and L = 20 cents

$$D^2 = \frac{123{,}750\,V^2}{100 - 2\,P};$$

$$\frac{A_M}{K.\ W.} = \frac{D^2\,L\,(E - 2\,V)}{750\,V^2\,(E - V)} = \frac{D^2\,L\,(100 - 2\,P)}{750\,V^2\,(100 - P)};$$

$$\frac{B_M}{K.\ W.} = \frac{G\,E\,V}{(E - V)\,(E - 2\,V)} = \frac{100\,G\,P}{(100 - P)\,(100 - 2\,P)}.$$



better to operate at 30 per cent. loss and reduce our investment to a minimum. But if our power be limited and valuable so that the value of the energy wasted becomes an important consideration, we must then, for the highest economy, operate at such a loss in conductors that, although the cost of plant may not be a minimum, the sum of the interest and depreciation on such cost, plus the value of the energy wasted, will be a minimum.

It will be evident that when such sum is a minimum we will be operating at the highest economy. To determine this minimum, let us call I the rate of interest and depreciation on the investment, expressing I in per cent. Let U

be the value of 1 K. W. at the brushes of the motor, used as it will be used in practice. Then from (7) we have

$$\left.\begin{array}{l}\text{Interest and depreciation on}\\ \text{capital invested in genera-}\\ \text{tor and conductor per K. W.}\\ \text{at motor brushes}\end{array}\right\} = \frac{I}{100}\left(\frac{G\,E}{E-V}+\frac{D^2\,L}{750\,V(E-V)}\right) \quad (18)$$

The value per K. W. at motor brushes of the energy wasted in the conductor per annum will be $\frac{V\,U}{E-V}$ (19)

The sum of (18) + (19) is that portion of the cost of operating subject to variation by a variation in the loss in the line, and to learn when this is a minimum we will place the first differential of

$$(18) + (19) = 0.$$

Doing this, we find that the equation expressing the condition of Minimum Operating Expenses, or, in other words, Maximum Economy of Operation, is

$$D^2 = \frac{750\ E\ V^2\ (I\ G + 100\ U)}{L\ I\ (E-2\ V)}. \quad (20)$$

From this, calling B_s the cost of conductor under conditions of maximum economy, we find

$$B_s = \frac{E\ V(I\ G + 100\ U)}{I(E-V)\ (E-2\ V)}. \quad (21)$$

and calling A_s the cost of generator under conditions of maximum economy, we find,

$$A_s = \frac{D^2\ L\ (E-2\ V)}{750\ V^2\ (E-V)} - \frac{100\ E\ U}{I\ (E-V)}. \quad (22)$$

From this relation we can plot curves which will enable us to quickly determine the conditions of maximum economy in practice. A set of such curves is shown in CHART 3.

CHART 3 is designed for transmissions in which 100 volts are allowed per 1,000 feet of transmission. Two sets of curves are plotted, one, marked X, assuming the combined interest and depreciation to be 10 per cent. per annum, and the other set assuming 15 per cent. for these items.

The value of the energy wasted is also plotted when the value of the energy is $5, $10, and $20 respectively, per kilo-watt at motor brushes; and then each of these latter curves is combined with each of the former, giving as a result the operating cost under six different conditions and indicating the maximum economy in each case, and also the variation in the expense due to any deviation from the loss corresponding to the maximum economy.

Example 3. For instance, suppose a transmission of 30,000 feet with 3,000 volts initial E. M. F., and suppose we value interest and depreciation at 15 per cent. per annum. Also, suppose our power to have a value at first of $5 per K. W. at generator brushes. By CHARTS 2 and 3 we find that the maximum economy will be realized when we operate at 17 per cent. loss, although the minimum first cost of plant alone would be realized when we operate at 21.47 per cent.

If later on in this same plant the increasing scarcity of power makes its value $20, instead of $5, per K. W. we find that we must arrange our plant as we increase it, so that the loss shall be 11½ per cent, since by CHART 3 we find we will then be operating at the maximum economy.

It will be seen that by the use of these formulæ and their resultant curves any problem in the transmission of power can be readily and accurately determined. The value of these curves will be evident, when attention is called to the fact that there is in use in this country a plant put in by one of the leading companies, in which the equivalent of the following conditions prevails: Initial E. M. F. 2,200 volts; distance 50,000 feet; loss in conductor 50 per cent. The company who installed this plant even now consider it satisfactory; yet we see from CHART 2, by examining the curve of 44 volts per 1,000 feet, that with exactly the same cost of generator and conductor they could have operated at 22 per cent. loss instead of 50 per cent., making a net gain in the power delivered of 56 per cent.; or they might have made a saving in their investment of $10 per kilo-watt delivered by conductor with an increase in power of 30 per cent., had they worked at 35 per cent. loss in conductor, which is that required for minimum first cost.

The following examples will serve to give a clear idea of the use of these curves:

Example 4. Suppose a proposed transmission of 30,000 feet, and that 6,000 volts is the highest voltage we have dynamos for; that is, 200 volts per 1,000 feet. By CHART 1 we learn that for minimum first cost we must lose 12½ per cent. in conductor. That the cost of bare copper conductor will be $6.28 per K. W., that of the generator $37.72; total cost of generator, conductor and motor $77.

Example 5. If we have but 3,000 volts available for the initial E. M. F., we must, for the mimimum first cost, lose 21½ per cent. The cost of conductor will be $15.81, that of generator, $42.02; and that of generator, conductor and motor $90.83.

Example 6. If, instead of 12½ per cent. loss, we wish to lose less, we find from CHART 2 that the cost of such generator and conductor will be, as follows: 6,000 volts and 5 per cent., $50; 6,000 volts and 10 per cent., $43.25. Knowing the value of the power and the rate of interest and depreciation, we can determine which loss to operate at. It will be noticed that with 6,000 volts, we should, under no circumstances, lose more than 12½ per cent. in the conductor, as with greater losses not only the waste of energy increases, but also the cost of plant.

There are four factors in a transmission plant—the distance, the initial E. M. F., the percentage of loss, and the cost of plant, and knowing any three we can by CHART 2 get the fourth. We have already considered the case of fixed distance initial E. M. F. and per cent. of loss.

Suppose now, distance, loss, and cost be fixed and we want to determine initial E. M. F. necessary.

Example 7. Suppose distance as before 30,000 feet, and that the loss must not exceed 20 per cent., and that the cost of generator and conductor must be $55 per K. W. invested in the best possible way. By CHART 2 we find that with 110 volts per 1,000 feet, that is, 3,300 volts initial E. M. F., our loss will be exactly 20 per cent. and the cost exactly $55. Also, that with 7,620 volts initial we need only lose 10 per cent., and still the cost will be only $41; and by using 3,750 volts and 11 per cent. the cost will still be but $55; also by using 6,000 volts initial and 3½ per cent. loss the cost would be only $55.

The next case will be where distance, initial E. M. F. and capital to be invested are fixed, and we wish to determine the percentage of loss necessary.

Example 8. Suppose distance 30,000 feet; initial E. M. F., 1,800 volts; capital to be invested, $100 per K. W. for generator and conductor. Having 60 volts per 1,000 feet available, we find that we must operate at 14 per cent. loss.

Now, suppose investment, initial volts and permissible loss to be fixed, and we want to find the maximum possible distance of transmission.

Example 9. Suppose investment in generator and conductor fixed at $60; initial volts, 2,400; percentage of loss, 15 per cent. We find that the maximum distance corresponding is 24,000 feet.

Let us now briefly examine the formulæ and laws which have been referred to by Mr. Badt in his "Electric Transmission Hand-Book." Mr. Badt quotes freely from a paper by Mr. F. J. Sprague, read before the Franklin Institute, which was printed in the *Journal* of the Franklin Institute for April, 1889. By careful examination of the paper it will be found that, after having assumed the value of the E. M. F. at the motor brushes and the distance also being fixed, the error is made afterward of considering the results obtained as applicable to cases in which these values are variable. Hence it is not surprising that we find Mr. Sprague saying: "That is, with fixed conditions of cost and efficiency of apparatus the number of volts fall to get

CHART No. 2.

TRANSMISSION OF POWER.

BY H. WARD LEONARD.

Showing Minimum First Cost of Plant for any Distance and Initial E. M. F., *with Corresponding Necessary Loss in Conductor, and also Showing Variation in Such Cost Occasioned by Losses other than those Necessary for Minimum First Cost.*

D = Distance of transmission in feet.
E = Initial E. M. F.
V = Volts lost in transmission.
G = Cost of dynamos per $K. W.$ at brushes.
L = Cost of bare copper in cents, per lb.

$\frac{A_M}{K. W.}$ = Cost of generator per $K. W.$ at motor brushes under conditions of minimum first cost.

$\frac{B_M}{K. W.}$ = Cost of conductor per $K. W.$ at motor brushes under conditions of minimum first cost.

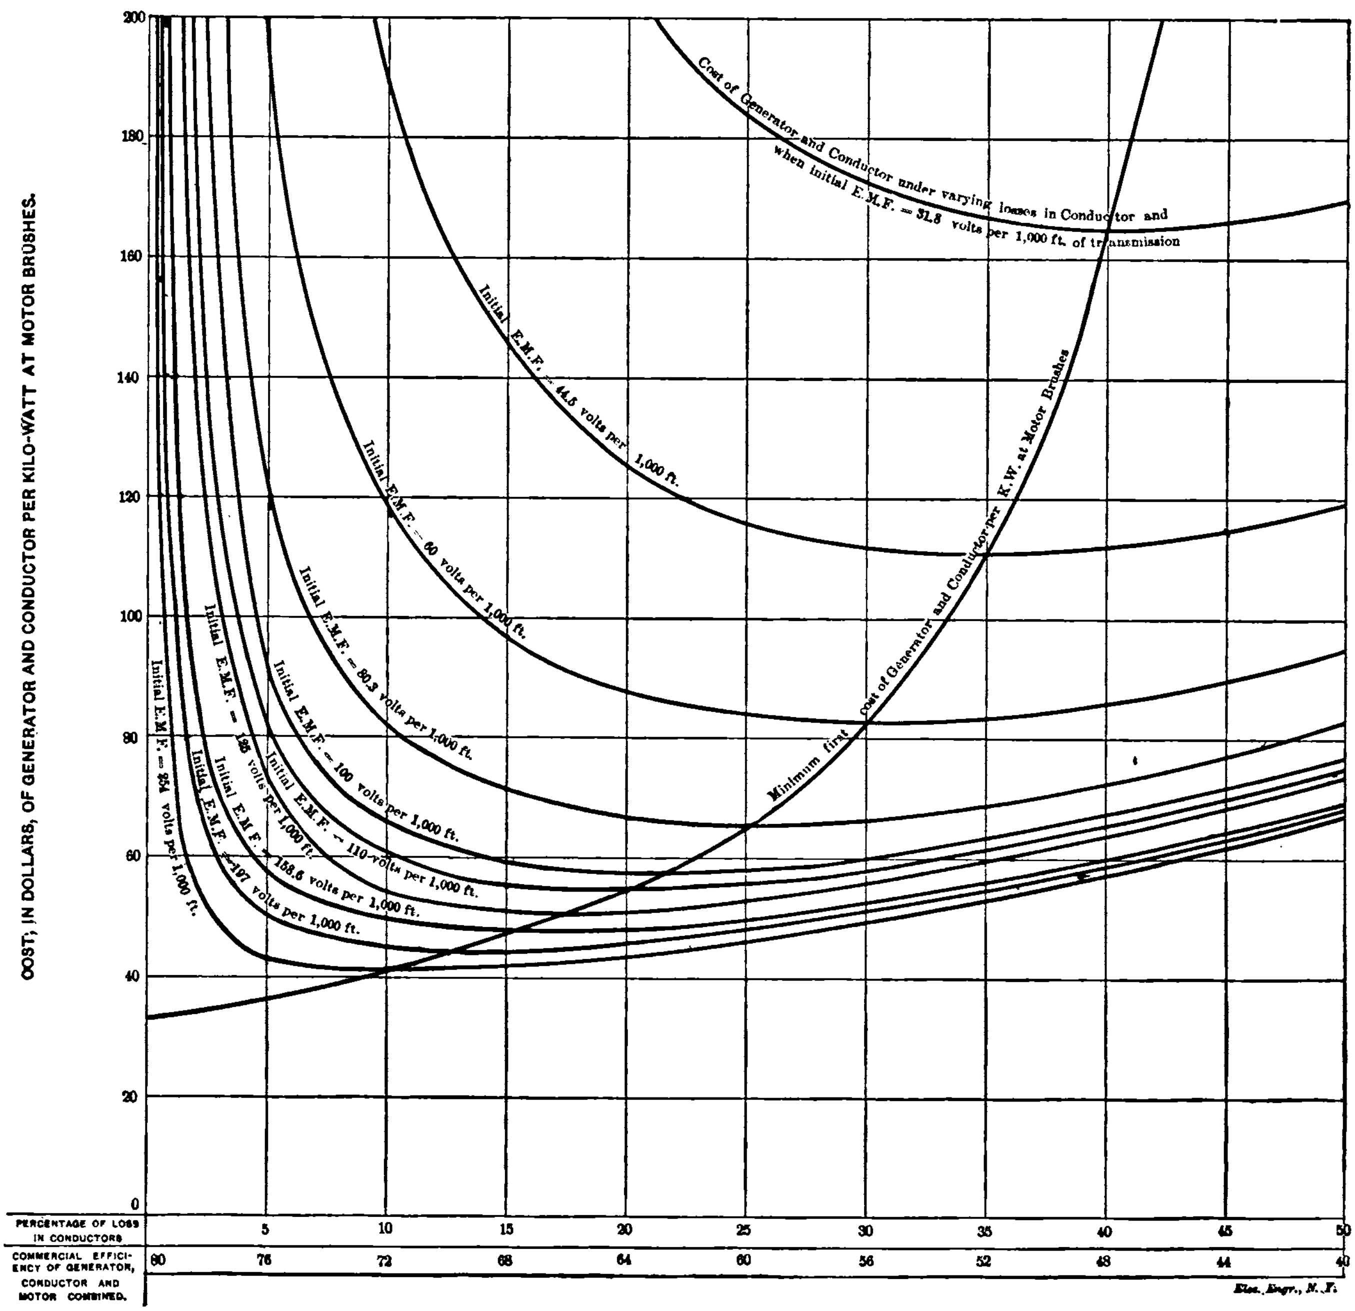
Cost (in dollars) of bare copper conductor per $K. W.$ at motor brushes $= \frac{D^2 L}{750\, V (E - V)}$ (general case).

Under conditions of minimum first cost of plant and when $G = \$33.00$ and $L = 20$ cents,

$$D^2 = \frac{123{,}750\, V^2}{100 - 2\,P}.$$

$$\frac{A_M}{K. W.} = \frac{D^2 L (E - 2\,V)}{750\, V^2 (E - V)} = \frac{D^2 L\, (100 - 2\,P)}{750\, V^2\, (100 - P)}.$$

$$\frac{B_M}{K. W.} = \frac{G. E. V.}{(E - V)\,(E - 2\,V)} = \frac{100\, G. P.}{(100 - P)(100 - 2\,P)}.$$



the minimum cost is a function of the distance alone and is independent of the E. M. F. at the motor, a somewhat startling conclusion."

In the light of what we have already seen it will be evident that this statement is entirely incorrect. To make this more clear (*Example* 10) suppose that with the same distance as in *Example* 1, that is, 50,000 feet, and the same efficiency of apparatus, that is, 30 per cent. loss in conductor, we use the initial E. M. F. of 6,000 instead of 3,000, and consequently have an E. M. F. at the motor of 4,200 volts, instead of 2,100 volts, as before. Now, according to Mr. Sprague, the "minimum cost of plant is a function of the distance alone and is independent of the E. M. F. used at the motor;" yet it will be evident that in "*Example* 10" the cost of the conductor is only ¼ of that in *Example* 1 and the cost of the generator is the same; hence the total cost is much reduced. In other words, while, if we fix the initial E. M. F. and distance, there is a definite loss in conductor at which we must operate in order to have a minimum first cost of plant, it by no means follows that if we fix the distance and percentage of loss there is a definite initial E. M. F. which corresponds to a minimum first cost of plant; for, evidently, the higher we make the initial E. M. F., meantime keeping the percentage of loss constant, the more we reduce the cost of plant, and there is no minimum value under these conditions.

Following out the same error, Mr. Sprague also lays down the following incorrect law: "With any fixed couple and commercial efficiency the cost of the wire should bear a definite and fixed ratio to the cost of the generating plant." It will be evident from what we have just seen regarding the preceding law, that this one is equally as incorrect and formulæ (13) and (15) clearly indicate the impossibility of either of them being correct. In his paper Mr. Sprague gives several tables based upon these laws, and since this same error is maintained throughout, his results are entirely erroneous.

Mr. Badt has not only followed Mr. Sprague blindly, but has gone much further and has finally brought up with such remarkable results, that we find him, after stating some of these surprising conclusions, saying: "At the same time it seems somewhat startling that for the minimum cost of the installation under given conditions as mentioned before (*i. e.*, fixed cost and efficiency of apparatus), the volts lost in the conductor are dependent upon the distance alone."

It seems almost impossible that such a statement as this could be seriously made by an electrical engineer of practical experience, yet we find Mr. Badt giving examples and tables in which it is surprising that he did not see the absurdity of this statement. For instance, on page 28 he gives "*Example* 1. Distance, including 5 per cent. for sag, 7,000 feet; E. M. F. at motor terminals, 500 volts. What must be the loss in the wire and E. M. F. of generator for minimum cost of plant?"

Mr. Badt, by the aid of Mr. Sprague's laws, with his own additions, concludes that he must have 20 per cent. loss in conductor; hence 625 volts at the generator. Since the E. M. F. at the motor is fixed, is it not evident that the higher the initial E. M. F. and the less the percentage of loss in the line, the less will be the cost of plant? In other words, if the cost be a certain amount at 20 per cent. loss in conductor with 625 volts initial, would it not be less with 10,000 volts initial and 1,000 volts loss in conductor, that is, 10 per cent?

Similarly, "*Example* 2. Distance (including 5 per cent. for sag), 50,000 feet; we want to obtain at least 55 per cent. (efficiency from generator pulley to motor shaft). What is the voltage to be employed at motor and generator for minimum cost of plant?"

Mr. Badt finds that the E. M. F. at generator must be 2,741 and that at the motor 1,850, with a loss in conductor of 32.5 per cent. Is it not evident that by using 5,482 volts at generator and 3,700 at motor the cost of generator is the same and the cost of conductor only ¼ what it was, and that there is no limit to the possible reduction in cost of the conductor, and hence no minimum value?

Mr. Badt, following the law that, "the number of volts to get the minimum cost of plant is a function of the distance alone," finds that for every 1,000 feet we must lose 17.5 volts, and with fixed cost and efficiency of apparatus no other factors need be considered. This, certainly, has the beauty of simplicity, and the tables built upon this conclusion leave little to be desired in that direction; but the transmitter of power who follows these tables will pay heavily for his faith in them.

Another law which Mr. Badt deduces, after making the assumption that "$\frac{D}{V}$, the relation of distance to volts drop for minimum cost of plant, is a constant," appears on page 37, and is as follows: "For minimum cost of plant the total weight of the conductor per horse power delivered by the motor shaft remains the same at a certain percentage of loss in the conductor, regardless of the voltage of motor and the distance." This involves the same erroneous assumptions and is evidently absurd, as is another law on page 39: "For minimum cost of plant the weight of the conductor depends only on the percentage of loss in the conductor and the number of mechanical horse power delivered by the motor."

Mr. Badt, on page 42, quotes from Mr. Sprague another equally misleading rule, viz: "For minimum initial cost of plant, and assuming certain prices per horse power of motors, generators and power plants (all erected and ready for operation), and assuming a certain price per pound of copper (delivered at the poles), the total cost of plant, excluding line construction, is a constant for a certain efficiency of the electric system, no matter what the E. M. F. of the motor and the distance may be." The absurdity of this is evident from what we have seen and is clearly shown by CHART 2.

We now come to a consideration of the conditions governing the maximum economy of operation.

Sir William Thomson, in a paper entitled "The Economy of Metal Conductors of Electricity," read before the British Association in 1881, stated the following law: "The most economical area of conductor will be that for which the annual interest on capital equals the annual cost of energy wasted."

This law has been accepted ever since that date with slight modifications, but upon close and practical investigation it proves to be entirely incorrect as applied to maximum economy of operation of a plant, for the very surprising reason that no account whatever is taken of the fact that the cost of the generator per horse power transmitted will vary as the loss in the line varies.

Since the variation in the cost of the generator is the principal factor, it is not surprising that the correct minimum, and that obtained from Thomson's law, are widely different. In fact, it will often be impossible to apply Thomson's law, as it will frequently occur that the interest on the plant, even when at its minimum cost, will far exceed the value of the energy wasted; and, evidently, if we depart from the condition of minimum first cost with an endeavor to increase the loss and thereby to make the value of the increasing loss in the line finally equal the interest on the increased cost of plant—since we are increasing both items, we evidently are not approaching a minimum value. CHART 3 clearly shows that, frequently, the curve of interest and depreciation and the curve of value of energy wasted will never cross, and hence will never be equal under any conditions of loss.

Formulæ (21) and (22) clearly show that no such relation can exist, and CHART 3 makes it evident graphically. *Example* 11. We find that, by Sir William Thomson's law, if the power is worth \$20 per K. W at generator brushes, and the interest and depreciation is 10 per cent., we should work at 22½ per cent. loss; whereas, in reality, for the maximum economy we should work at 10 per cent.

We also find that in all the seven other cases indicated

CHART No. 3.

TRANSMISSION OF POWER.

BY H. WARD LEONARD.

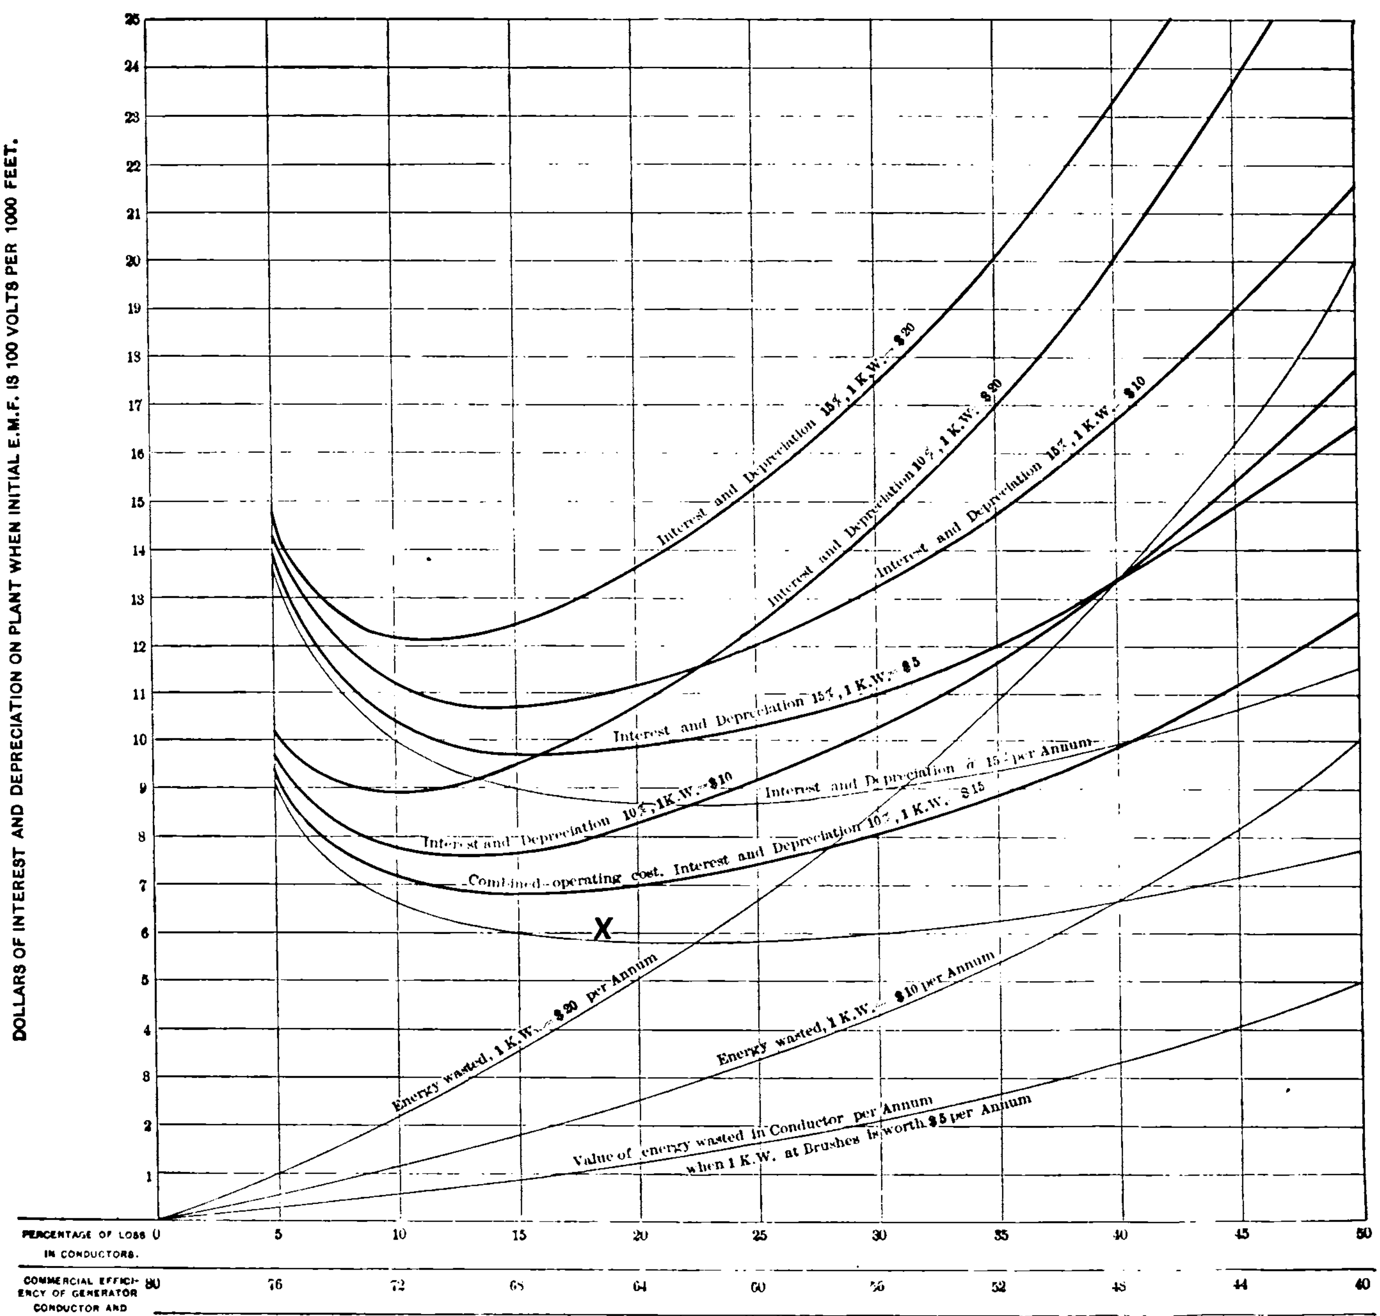
Showing Maximum Economy of Operation when 100 *Volts per* 1,000 *Feet are Used, and when Interest and Depreciation on Plant is* 10 *per cent. and* 15 *per cent., and when Value of Power at Generator Brushes is* $5.00, $10.00, *and* $20.00 *per K. W., respectively.*

A_2 = Cost of generator per *K.W.* at motor brushes under conditions of maximum economy of operation.
B_2 = Cost of conductor per *K.W.* at motor brushes under conditions of maximum economy of operation.
L = cost of bare copper in cents per lb.
D = Distance of transmission in feet.
E = Initial E. M. F.
V = Volts lost in transmission.
G = Cost of dynamo per *K.W.* at brushes.
I = Interest and depreciation on cost of generator and conductor per *K.W.* at motor brushes.
U = Value of 1 *K.W.* per annum at brushes of motor as used.

$$D^2 = \frac{750\,E\,V^2\,(I\,G + 100\,U)}{L\,I\,(E - 2\,V)}$$

$$B_2 = \frac{E\,V\,(I\,G + 100\,U)}{I\,(E - V)\,(E - 2V)}$$

$$A_2 = \frac{D^2\,L\,(E - 2\,V)}{750\,V^2\,(E - V)} - \frac{100\,E\,U}{I\,(E - V)}$$



by the curves it is impossible to apply Thomson's law, as we cannot, by any means, make the interest on capital outlay and the value of energy wasted equal.

Both Kapp and Ayrton and Perry have discussed Thomson's law and made certain limitations and modifications, but have only complicated, and not corrected, it. In Mr. Badt's present work he refers to Kapp's latest formulæ contained in a lecture of March 2, 1891, a copy of which lecture I have not as yet seen; hence the formulæ quoted by Mr. Badt cannot be commented on by me further than that Mr. Kapp's formulæ as given by Mr. Badt points to one fact which is very evident from formulæ (13) and (21), Chart I amely, that under no circumstances will it be economical to lose more than 50 per cent. in the conductor, for when $E = 2V$, we have $E - 2V = 0$, and an infinite cost of conductor as a resulting condition.

ELEMENTARY GEOMETRICAL THEORY OF THE ALTERNATE-CURRENT TRANSFORMER.—XIII.

BY

Chas. Steinmetz.

The ideal hysteretic current has the same phase as the secondary current. But the secondary current, C_1 lagging behind the secondary E. M. F., E_1 by an angle δ, because of the self-induction, the line $\overline{KF}$ makes an angle δ with the horizontal line. This angle is a maximum, almost $= 90°$ for short circuit, and decreases for increasing secondary resistance, reaching zero for open circuit.

Thus we produce in this diagram, Fig. 26,[1] the curve of magnetic lag, k, by adding the ideal hysteretic current $\overline{KF}$ on $\overline{OF}$ under the angle δ, of shifting of phase of secondary current, and thereby derive a somewhat different shape of curve k. As seen, this curve k does not start at the zero point O, but at a higher M. M. F.

To produce now the diagram for any value of F, we draw line $\overline{KF}$ under the angle δ, which corresponds to this particular value of F, and continue $\overline{KF}$ to its intersection with the circle c at C; then $\overline{KC}$ gives the secondary M. M. F. or the secondary current $= \overline{OC_1}$ and the primary current, $C = \overline{OC}$ intersects the quadrant e in the primary resulting or heating E. M. F., E. F gives the induced E. M. F., E_1, and E_1 and E the primary impressed E. M. F., E_0.

Drawing a half-circle with $\overline{OE_1}$ as diameter, gives us the E. M. F. of self-induction of the secondary circuit $E_s = \overline{e_1 e_r}$ and the heating or resulting secondary E. M. F., $E_r = \overline{OE_r}$ and in $\frac{E_r}{C_1} = r_1$ the secondary resistance.

In producing thus the diagram for different secondary resistances, r_1, we derive the curve of resulting secondary E. M. F., e_r, of secondary current, that is, secondary M. M. F., c_1, of primary impressed E. M. F., e_0, etc.

From this diagram Fig. 26, we see that the shifting of phase of the secondary current is a maximum for short-circuit, and then decreases with increasing resistance r_1, first very fast, then slower, reaching zero at open circuit. Hence for short-circuit the secondary current is almost entirely independent of the secondary resistance, r_1, but is determined by the secondary self-induction.

The secondary current decreases for increasing resistance, r_1, but first very slowly, and only after the self-induction of the secondary circuit has become imperceptible the decrease of secondary current becomes more marked and more rapid.

The ratio of currents $\frac{C_1}{C}$ therefore, does not approach the ratio of transformation, $\frac{n}{n_1}$ for decreasing resistance, but is considerably smaller, and is given in the accompanying table.

Even for short-circuit, the induced E. M. F., E_1, and therefore the resulting M. M. F., F, are quite considerable. The primary impressed E. M. F., E_0 is even, for short circuit, considerably larger than the heating E. M. F. accounts for. The phase of the primary impressed E. M. F. decreases with increasing secondary resistance, r_1.

The phase of the primary current is a maximum for short-circuit, decreases with increasing resistance, reaches a minimum, and increases again to a maximum for open circuit.

The difference of phase between primary current and impressed E. M. F. is a maximum for short-circuit, decreases, passes a minimum, and increases again to a maximum for open circuit.

In Fig. 26, the diagrams are produced for:

0. short circuit: $r_1^0 = .8$ ohms.
1. $r_1^1 = 6$ "
2. $r_1^2 = 12$ "
3. $r_1^3 = 34$ "
4. open circuit: $r_1^4 = \infty$ "

To compare the compounding of this transformer with that of Fig. 24, which has no self-induction in the secondary circuit, the dependence of the curves of secondary current and of primary impressed E. M. F., upon the electric conductivity are shown in diagram, Fig. 25, curve I., corresponding to the transformer without self-induction in the secondary circuit, in Fig. 24, and curve II., corresponding to the transformer with self-induction in the secondary circuit, in Fig. 26. From the diagram, Fig. 26, we derive the values of the electric quantities of the converter.

		0.	1.	2.	3.	4.	
Primary current, C	=	65	65	65	65	65	amp.
Primary impressed E. M. F., E_0	=	35	55	76	135	214	volts.
Primary resulting E. M. F., E	=	20	20	20	20	20	volts.
Secondary current, C_1	=	52.5	50.5	47.5	36	0	amp.
Induced secondary E. M. F., E_1	=	26	40	60	120	208	volts.
Resulting secondary E.M.F., E_r	=	4	31	55	108	208	volts.
Resulting M. M. F., F	=	1560	2400	3600	7200	12480	amp. turns.
Angle of magnetic lag, α	=	5°	17°	20°	18°	16°	
Differ. of phase bet. prim. cur. and impressed E. M. F., ω	=	47°	32°	29°	37°	70°	
Differ. of phase bet. sec. cur. and induced E. M. F., δ	=	81°	39°	23°	9°	0°	
Effective secon. energy, $\frac{E_r C_1}{2}$	=	105	788	1306	1944	0	watts.
Eff. prim. energy, $\frac{E_0 C \cos \omega}{2}$	=	777	1514	2161	3486	2379	watts.
Ratio of transformation, $\frac{C_1}{C}$	=	.81	.78	.73	.55	0	

It will be understood, that the compounding of the transformer for constant current, and for constant potential, in practice is much better fulfilled than in the transformer here under consideration, where the constants were chosen unusually unfavorable, to show even the losses on a large scale.

AN ELECTRICAL TRANSFORMER FOR MEDICAL PURPOSES.

In a recent number of the *Lancet* appears an illustrated description of an electrical transformer for surgical, medical and dental purposes, which has been designed by A. B. Woakes, M. R. C. S., L. R. C. P. In the transformer there are three pairs of terminals, the first for supplying current to the electrical cautery, the second for illuminating a surgical incandescent lamp, and the third for supplying Faradic shocks, so that in one instrument the surgeon has at his command electricity for any of these three purposes. For the purposes of the cautery a maximum current of 20 amperes at 6 volts can be obtained.

1. For the figures referred to see the issues of August 12 and 26.

THE FRANKFORT INTERNATIONAL ELECTRICAL EXHIBITION—VI.

BY

Richard O. Heinrich.

YET another very compact and useful instrument is the slide-wire bridge for very low resistances. Fig. 1 shows the instrument itself, Fig. 2 the diagram of connections, and Fig. 3 the diagram for the use of the instrument. It will be seen from Fig. 2 that the arrangement is that of the Thomson method of testing low resistances. B is the battery, with key C in the circuit; also the standard slide-wire D and the test-piece W, the resistance of which, X, between *b* and *b* is to be measured. Two separate circuits are branched off at the points *o* and *a* of the slide-wire, and *b* and *b* of the test-wire forming the sections *m*, *n*, *p*, *o*, connected by the mirror galvanometer G with the key *C* in the circuit. Decadic resistances only can be inserted in the branches *m*, *n*,

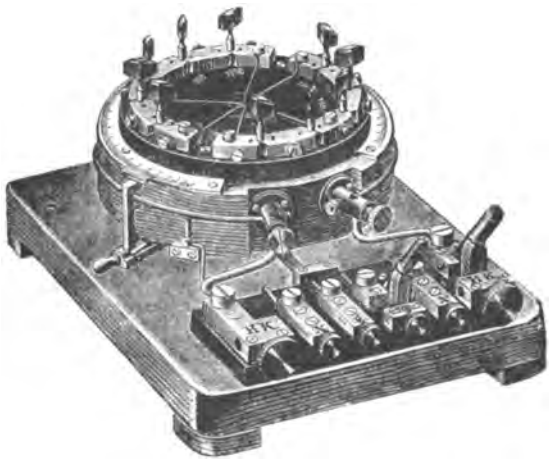


Fig. 1.—Slide-Wire Bridge for Low Resistances.

p, *o*. If the resistance $m = n$ and $p = o$ no current flows through the galvanometer G, provided the resistance N between *e* and *a* is equal to the resistance X between *b* and *b*. The resistance N is made variable with a sliding contact; in this way resistances up to the total resistance of the slide-wire may be measured. If, however, N and X are very different, *m*, *n*, *p*, *o* are varied, but always in such a

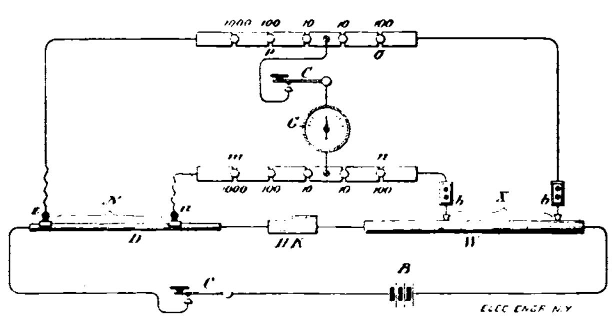

Fig. 2.—Slide-Wire Bridge for Low Resistances.

way that $n : m = o : p$, and then, if no current flows through the galvanometer, $X = N\frac{n}{m} = N\frac{o}{p}$.

Since $\frac{n}{m}$ and $\frac{o}{p}$ have decadic values, and the resistance in ohms of the slide-wire is directly read off the scale on the instrument, the values of X are easily and quickly obtained in ohms also.

The instrument is especially valuable for the measurement of resistances of dynamos, cables with large cross-sections, and for the determination of specific resistances. The range of the instrument in connection with a good mirror galvanometer is from 0.000001 to 0.1 ohm.

In connection with these instruments may be mentioned a rheostat made for the special purpose of taking a current

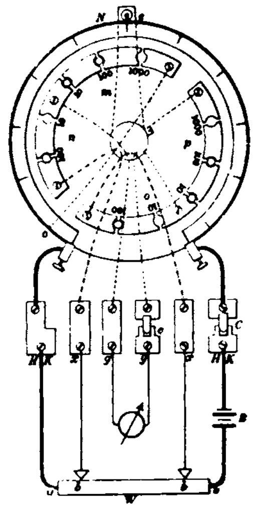

Fig. 3.—Slide-Wire Bridge for Low Resistances.

up to 3,000 amperes. A set of 18 tubes of different sizes are arranged around an iron water reservoir. These tubes are connected in pairs by many metal pieces, as shown in Figs. 4 and 5, the length of tube in circuit being regulated by the slide contact. The tubes communicate with the interior of the reservoir through the metal pieces and short china tubes, so that they are always filled with water to the same

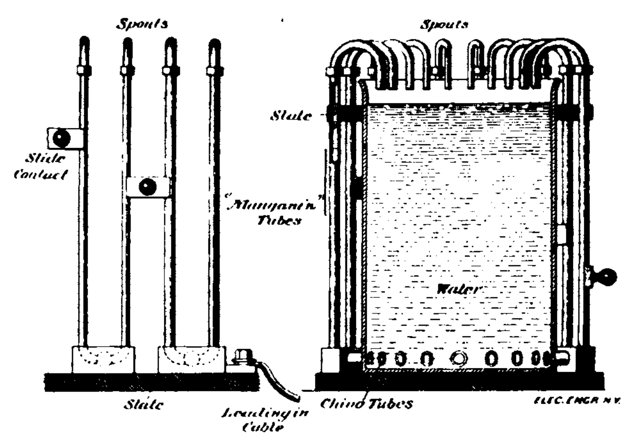

Fig. 4.—"Manganin" Rheostat for 3,000 Amperes.

height as the reservoir. These tubes are well insulated from each other since they rest on, and are held, by a slate base and a slate collar. If the tubes are heated by a very heavy current passing through part of them, the water is heated and eventually boils. The boiling water rushes through the attached spouts into the large reservoir, and in this way heating above the boiling point of water cannot take place.

The material used for these tubes is the so-called "manganin," a manganese-nickel bronze, with a very small temperature coefficient.

As soon as information can be obtained I shall give some particulars about this alloy, which seems to be very similar to the alloy invented by Mr. Edward Weston, who is using it very effectively in his standard ammeters and voltmeters, avoiding in this way temperature corrections.

NOTES ON A UNIPOLAR DYNAMO.

BY

Nikola Tesla

It is characteristic of fundamental discoveries, of great achievements of intellect, that they retain an undiminished power upon the imagination of the thinker. The memorable experiment of Faraday with a disc rotating between the two poles of a magnet, which has borne such magnificent fruit, has long passed into every-day experience; yet there are certain features about this embryo of the present dynamos and motors which even to-day appear to us striking, and are worthy of the most careful study.

Consider, for instance, the case of a disc of iron or other metal revolving between the two opposite poles of a magnet, and the polar surfaces completely covering both sides of the disc, and assume the current to be taken off or conveyed to the same by contacts uniformly from all points of the periphery of the disc. Take first the case of a motor. In all ordinary motors the operation is dependent upon some shifting or change of the resultant of the magnetic attraction exerted upon the armature, this process being effected either by some mechanical contrivance on the motor or by the action of currents of the proper character. We may explain the operation of such a motor just as we can that of a water-wheel. But in the above example of the disc surrounded completely by the polar surfaces, there is no shifting of the magnetic action, no change whatever, as far as we know, and yet rotation ensues. Here, then, ordinary considerations do not apply; we can not even give a superficial explanation, as in ordinary motors, and the operation will be clear to us only when we shall have recognized the very nature of the forces concerned and fathomed the mystery of the invisible connecting mechanism.

Considered as a dynamo machine, the disc is an equally interesting object of study. In addition to its peculiarity of giving currents of one direction without the employment of commutating devices, such a machine differs from ordinary dynamos in that there is no reaction between armature and field. The armature current tends to set up a magnetization at right angles to that of the field current, but since the current is taken off uniformly from all points of the periphery, and since, to be exact, the external circuit may also be arranged perfectly symmetrical to the field magnet, no reaction can occur. This, however, is true only as long as the magnets are weakly energized, for when the magnets are more or less saturated, both magnetizations at right angles seemingly interfere with each other.

For the above reason alone it would appear that the output of such a machine should, for the same weight, be much greater than that of any other machine in which the armature current tends to demagnetize the field. The extraordinary output of the Forbes unipolar dynamo and the experience of the writer confirm this view.

Again, the facility with which such a machine may be made to excite itself is striking, but this may be due—besides to the absence of armature reaction—to the perfect smoothness of the current and non-existence of self-induction.

If the poles do not cover the disc completely on both sides, then, of course, unless the disc be properly subdivided, the machine will be very inefficient. Again, in this case there are certain points worthy of notice. If the disc be rotated and the field current interrupted, the current through the armature will continue to flow and the field magnets will lose their strength comparatively slowly. The reason of this will at once appear when we consider the direction of the currents set up in the disc.

Referring to diagram in Fig. 1, *d* represents the disc with the sliding contacts B B′ on the shaft and periphery. N and S represent the two poles of a magnet. If the pole N be above, as indicated in the diagram, the disc being supposed to be in the plane of the paper, and rotating in the direction of the arrow D, the current set up in the disc will flow from the centre to the periphery, as indicated by the arrow A. Since the magnetic action is more or less confined to the space between the poles N S, the other portions of the disc may be considered inactive. The current set up will therefore not wholly pass through the external circuit F, but will close through the disc itself, and generally, if the disposition be in any way similar to the one illustrated, by far the greater portion of the current generated will not appear externally, as the circuit F is practically short-circuited by the inactive portions of the disc. The direction of the resulting currents in the latter may be assumed to be as indicated by the dotted lines and arrows *m* and *n*; and the direction of the energizing field current being indicated by the arrows *a b c d*, an inspection of the figure shows that one of the two branches of the eddy current, that is, A B′ *m* B, will tend to demagnetize the field, while the other branch, that is, A B′ *n* B, will have the opposite effect. Therefore the branch A B *m* B that is, the one which is *approaching* the field, will repel the lines of the same, while branch A B′ *n* B, that is, the one *leaving* the field, will gather the lines of force upon itself.

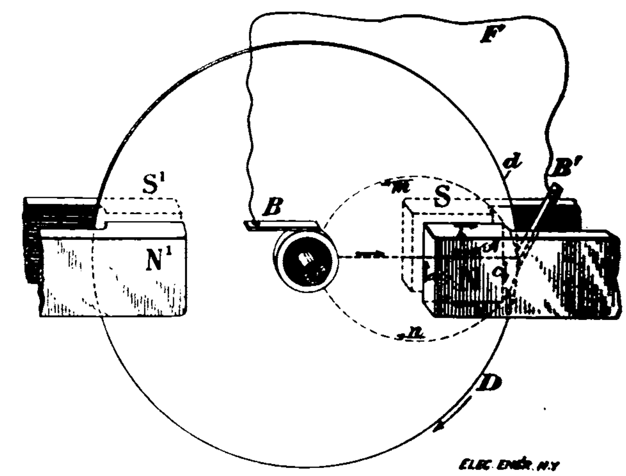

Fig. 1.

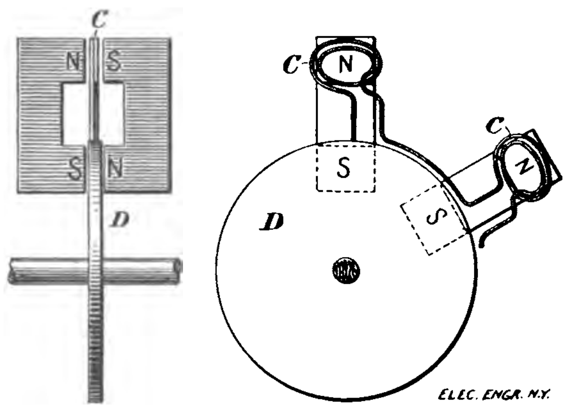
In consequence of this there will be a constant tendency to reduce the current flow in the path A B′ *m* B, while on the other hand no such opposition will exist in path A B′ *n* B, and the effect of the latter branch or path will be more or less preponderating over that of the former. The joint effect of both the assumed branch currents might be represented by that of one single current of the same direction as that energizing the field. In other words, the eddy currents circulating in the disc will energize the field magnet. This is a result quite contrary to what we might be led to suppose at first, for we would naturally expect that the resulting effect of the armature currents would be such as to oppose the field current, as generally occurs when a primary and secondary conductor are placed in inductive relations to each other. But it must be remembered that this results from the peculiar disposition in this case, namely, two paths being afforded to the current, and the latter selecting that path which offers the least opposition to its flow. From this we see that the eddy currents flowing in the disc partly energize the field, and for this reason when the field current is interrupted the currents in the disc will continue to flow, and the field magnet will lose its strength with comparative slowness and may even retain a certain strength as long as the rotation of the disc is continued.

The result will, of course, largely depend on the resistance and geometrical dimensions of the path of the resulting eddy current and on the speed of rotation; these elements, namely, determine the retardation of this current and its position relative to the field. For a certain speed there would be a maximum energizing action; then at higher speeds, it would gradually fall off to zero and finally reverse, that is, the resultant eddy current effect would be to weaken the field. The reaction would be best demonstrated experimentally by arranging the fields N S, N′ S, freely movable on an axis concentric with the shaft of the disc. If the latter were rotated as before in the direction of the arrow D the field would be dragged in the same direction with a torque, which, up to a certain point,



FIGS. 2 AND 3.

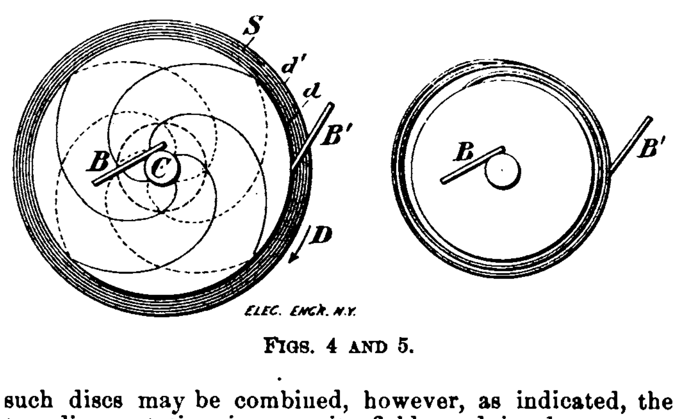
would go on increasing with the speed of rotation, then fall off, and, passing through zero, finally become negative; that is, the field would begin to rotate in opposite direction to the disc. In experiments with alternate current motors in which the field was shifted by currents of differing phase, this interesting result was observed. For very low speeds of rotation of the field the motor would show a torque of 900 lbs. or more, measured on a pulley 12 inches in diameter. When the speed of rotation of the poles was increased the torque would diminish, would finally go down to zero, become negative, and then the armature would begin to rotate in opposite direction to the field.

To return to the principal subject; assume the conditions to be such that the eddy currents generated by the rotation of the disc strengthen the field, and suppose the latter gradually removed while the disc is kept rotating at an increased rate. The current, once started, may then be sufficient to maintain itself and even increase in strength, and then we have the case of Sir William Thomson's "current accumulator." But from the above considerations it would seem that for the success of the experiment the employment of a disc *not subdivided* would be essential, for if there would be a radial subdivision, the eddy currents could not form and the self-exciting action would cease. If such a radially subdivided disc were used it would be necessary to connect the spokes by a conducting rim or in any proper manner so as to form a symmetrical system of closed circuits.

The action of the eddy currents may be utilized to excite a machine of any construction. For instance, in Figs. 2 and 3 an arrangement is shown by which a machine with a disc armature might be excited. Here a number of magnets, N S, N S, are placed radially on each side of a metal disc D carrying on its rim a set of insulated coils, C, C. The magnets form two separate fields, an internal and external one, the solid disc rotating in the field nearest to the axis, and the coils in the field further from it. Assume the magnets slightly energized at the start; they could be strengthened by the action of the eddy currents in the solid disc so as to afford a stronger field for the peripheral coils. Although there is no doubt that under proper conditions a machine might be excited in this or a similar manner, there being sufficient experimental evidence to warrant such an assertion, such a mode of exciting would be wasteful.

But a unipolar dynamo or motor, such as shown in Fig. 1, may be excited in an efficient manner by simply properly subdividing the disc or cylinder in which the currents are set up, and it is practicable to do away with the field coils which are usually employed. Such a plan is illustrated in Fig. 4. The disc or cylinder D is supposed to be arranged to rotate between the two poles N and S of a magnet, which completely cover it on both sides, the contours of the disc and poles being represented by the circles d and d' respectively, the upper pole being omitted for the sake of clearness. The cores of the magnet are supposed to be hollow, the shaft C of the disc passing through them. If the unmarked pole be below, and the disc be rotated screw fashion, the current will be, as before, from the centre to the periphery and may be taken off by suitable sliding contacts, B B′, on the shaft and periphery respectively. In this arrangement the current flowing through the disc and external circuit will have no appreciable effect on the field magnet.

But let us now suppose the disc to be subdivided spirally, as indicated by the full or dotted lines, Fig. 4. The difference of potential between a point on the shaft and a point on the periphery will remain unchanged, in sign as well as in amount. The only difference will be that the resistance of the disc will be augmented and that there will be a greater fall of potential from a point on the shaft to a point on the periphery when the same current is traversing the external circuit. But since the current is forced to follow the lines of subdivision, we see that it will tend either to energize or de-energize the field, and this will depend, other things being equal, upon the direction of the lines of subdivision. If the subdivision be as indicated by the full lines in Fig. 4, it is evident that if the current is of the same direction as before, that is, from centre to periphery, its effect will be to strengthen the field magnet; whereas, if the sub-division be as indicated by the dotted lines, the current generated will tend to weaken the magnets. In the former case the machine will be capable of exciting itself when the disc is rotated in the direction of arrow D; in the latter case the direction of rotation must be reversed. Two



FIGS. 4 AND 5.

such discs may be combined, however, as indicated, the two discs rotating in opposite fields, and in the same or opposite direction.

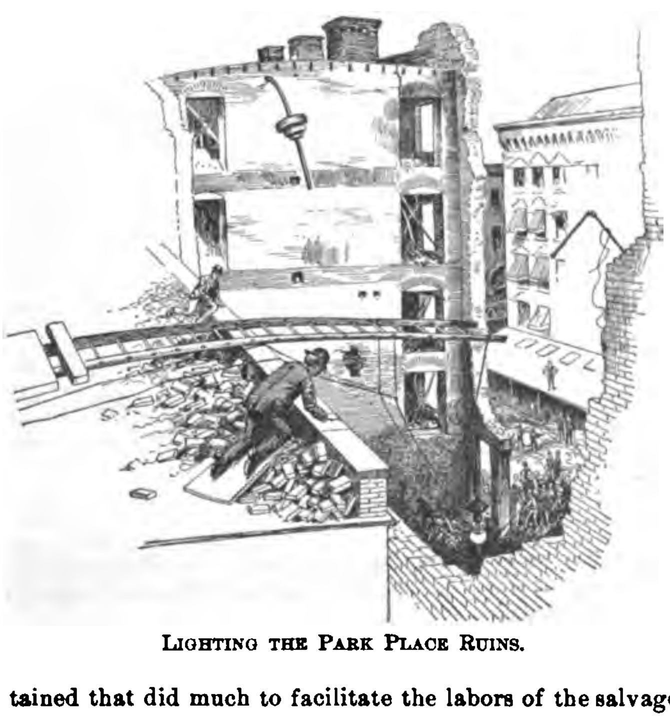
Similar dispositions may, of course, be made in a type of machine in which, instead of a disc, a cylinder is rotated. In such unipolar machines, in the manner indicated, the usual field coils and poles may be omitted and the machine may be made to consist only of a cylinder or of two discs enveloped by a metal casting.

Instead of subdividing the disc or cylinder spirally, as indicated in Fig. 4, it is more convenient to interpose one or more turns between the disc and the contact ring on the periphery, as illustrated in Fig. 5.

A Forbes dynamo may, for instance, be excited in such a manner. In the experience of the writer it has been found that instead of taking the current from two such discs by sliding contacts, as usual, a flexible conducting belt may be employed to advantage. The discs are in such case provided with large flanges, affording a very great contact surface. The belt should be made to bear on the flanges with spring pressure to take up the expansion. Several machines with belt contact were constructed by the writer two years ago and worked satisfactorily, but for want of time the work in that direction has been temporarily suspended. A number of features pointed out above have also been used by the writer in connection with some types of alternating current motors.

LIGHTING UP THE PARK PLACE RUINS.

On Saturday, August 22, the sudden collapse of a large building in Park Place, New York City, resulted in a fire and the loss of many lives, no fewer than 62 bodies having been recovered from the ruins. The accident was a very peculiar one, and still remains to be explained, although it is certain that the operation of a large number of heavy lithographic presses on the upper floors of the building was the chief cause, their weight and vibration at last bringing down the walls. It became desirable and necessary immediately after the accident to begin work on clearing away the ruins and recovering the bodies, and in order to push operations it was determined to dig all night. The great question lay in obtaining light for the purpose, and electricity was resorted to. Our sketch shows the very novel and ingenious manner in which one of the lights was suspended over the big hole in which the débris lay. A long ladder was placed on the roof of the building in the rear, so as to project considerably. This ladder was held down at one end by the scuttle of a skylight, weighted with stones, &c. Then the circuits were brought up from the street and stapled, and the lamp allowed to swing clear. By this means a very effective illumination was obtained that did much to facilitate the labors of the salvage corps.

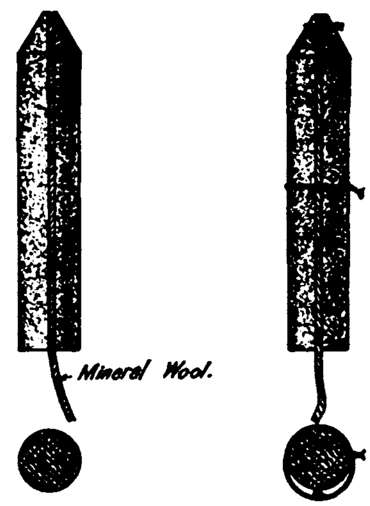


Lighting the Park Place Ruins.

One feature of this disaster which has so far escaped notice deserves mention. The building destroyed took its power from the shafting of The Electrical Engineer's composing and press-rooms, and the intervening wall had been pierced so that the line of shafting might be carried through. When the fire broke out after the collapse of the building, causing the Engineer to shut down, and exposing it to no small danger, that hole in the wall became a grave menace, and was closely watched by the firemen. Had the wind been from the west, or had the fire occurred at night, the existence of that hole would in all probability have caused the sacrifice of the Engineer building. But it is evident that in the distribution of power electrically, this dangerous piercing of fire walls is dispensed with, whether between adjoining buildings or between the various floors of one structure.

THE RICHARDS ARC-LIGHT CARBON.

In the construction of carbon electrodes for arc lamps, in which a liquid hydrocarbon is led to the burning end of the electrode, and there converted into gas to intensify and improve the quality of the light, it has heretofore been customary to employ tubular carbons having a longitudinal passage entirely surrounded by the material of the electrode and containing a capillary conductor of refractory material extending through the burning end of the electrode at the point where the heat is greatest.



The Richardson Arc Carbon.

In order to overcome certain objections attendant upon this construction, Mr. Walter S. Richards, of Natick, Mass., has adopted an arrangement having a refractory capillary conductor extending longitudinally along the exterior of the electrode, and exposed to the air throughout its entire length, so that it is only attacked and destroyed by the heat at the immediate point where the arc is formed, and the hydrocarbon is converted into gas more rapidly and completely.

In the accompanying drawings, Fig. 1 represents a side view of a carbon electrode and a capillary conductor, the electrode having in its surface a longitudinal groove, which receives the capillary conductor and retains it in place, at the same time exposing it to the atmosphere. Fig. 2 represents a section of Fig. 1.

Figs. 3 and 4 show the conductor as bearing on the surface of the electrode, no grooves being provided in the latter. In this case the conductor is held in place by independent fastenings, which are here shown as bands of wire. These fastenings will be readily consumed by the electric action when the electrode burns down to the point where they are located. It will be seen that by placing the conductor at the exterior of the electrodes the conductor is so exposed to the atmosphere that it cannot be destroyed by the heat at a point far enough from the arc to prevent the hydrocarbon gas carried by the conductor from properly entering the arc, and also that the free access of the atmosphere to the conductor facilitates the conversion of the liquid hydrocarbon into gaseous form.

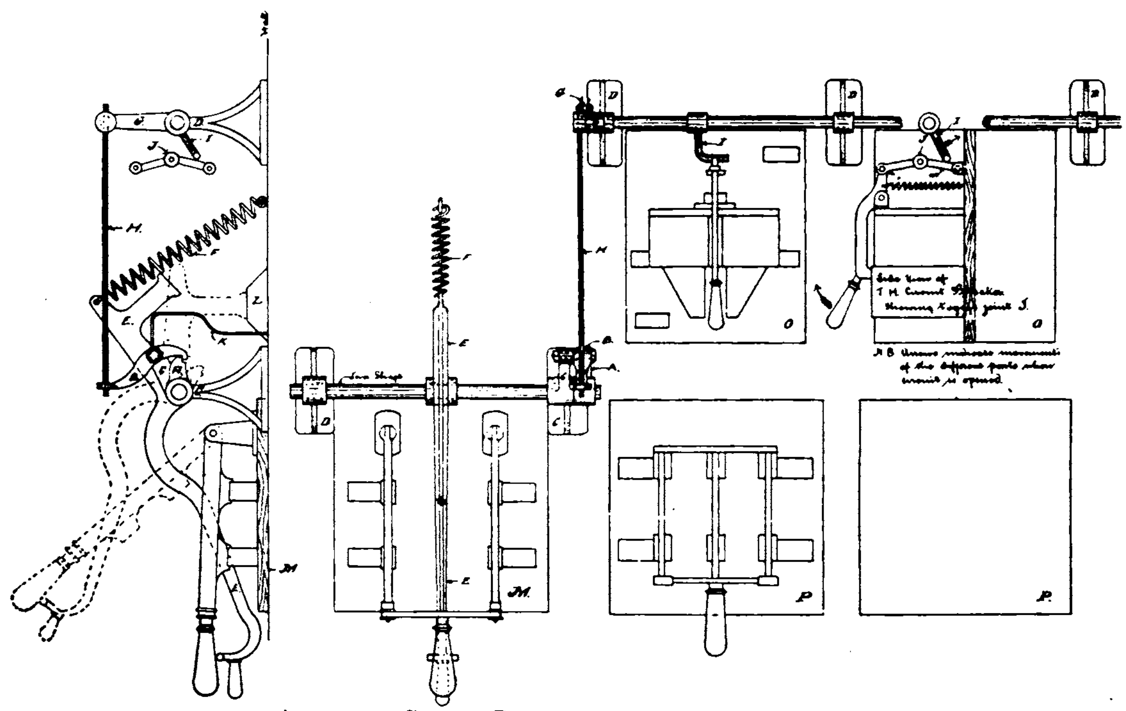
IMPROVED AUTOMATIC CIRCUIT BREAKER FOR RAILWAY CIRCUITS.

BY

Willis D. Gordon

Considerable trouble was at one time experienced in the power house of the Seattle Consolidated Street Railway Co., Seattle, Wash., by short circuits; besides this the machines were very heavily loaded and the circuit would frequently be opened by an overload. Sometimes the circuit breaker with which the station is equipped would refuse to act and, of course, the fuse on the generator would "go." This caused considerable inconvenience, and to obviate this the writer devised the arrangement, shown in elevation and side view in the accompanying engravings, for opening the main line switch.

The operation of the device is very simple. A shaft, to which is keyed the lever E and cam A, is supported by wall brackets, D and C. The lower arm of lever E is directly under the switch-handle, while the upper arm holds in tension (when set) the spring F. The trigger B is pivoted on an arm of the bracket C, and is held in position by a piece of spring wire, K, which, as shown, keeps B always in the same position. The rod H connected to the trigger B is connected to the crank G on the end of the counter-shaft. To this counter-shaft are fastened as many arms, I, as we have circuit breakers.



Automatic Circuit Breaker for Railway Circuits.

Now when any one, or all, of the circuit breakers, open, it moves the arm or arms I. These being fastened to the counter-shaft will turn it slightly, force the rod H down, release the cam A and allow the spring F to act on lever E and open the circuit. The diagram shows the position of the lever E when the switch is both open and closed.

The cut-out is operated by any one, or all, of the circuit-breakers; it could evidently easily be operated with either a solenoid or a horseshoe magnet. It could also be used on street cars and prevent the burning out of a fuse by pulling the switch.

By a very simple attachment of a cylinder and piston the movement of the lever could readily be applied to direct a blast of air against, and thus blow out, the arc from the switch points.

THE ELECTRICAL DETERMINATION OF "J."

A note has been received by the Paris Académie des Sciences from M. Constantin Miculesco on a new determination of the mechanical equivalent of heat. The principle of the method was the same as Joule's, viz., the production of heat in a calorimeter by means of friction. The whole of the work done by Joule's experiments, however, was small, and hence a good time was required to obtain a sensible heating of the calorimeter, and some difficult corrections had to be made. To prevent this, M. Miculesco used an electric motor to supply the work which was to be turned into heat. The apparatus comprised a 1 horse-power Gramme electric motor, carried on a frame suspended on knife edges, the motor-shaft being central with the line of these supports. On a separate frame was mounted a calorimeter consisting of two concentric cylinders, so that the axes of the cylinders coincided with the centre line of the motor shaft. By means of a flexible connection this shaft was coupled to one bearing paddles, which it caused to revolve in the water in the cylinders. Under such circumstances the frame carrying the motor tended to swing on its knife edges in oder to balance the torque on the motor shaft, and by correcting this tendency, by carefully adding weights, this torque could be measured with great accuracy. The result obtained was $J = 777.7$ foot-pounds.

THE LUGO SECONDARY BATTERY.

The loss of energy in secondary batteries due to chemical action when the battery is not in use, having always proved a fruitful source of trouble, Dr. Orazio Lugo, of this city, has devised a battery in which a neutral electrolyte is used which acts primarily upon neither element, but secondarily upon both.

The plates of the Lugo battery are of lead and zinc respectively, covered with lead oxide, and are separated one from another by an absorbent substance, such as blotting paper, and immersed in a bath of borate of ammonia.

The voltage and ampere capacity are claimed to be very high and the internal resistance low. The battery can be charged by very heavy currents and also discharged with a maximum ampereage without in the least injuring the plates as electrodes. The constancy is supposed to be due to the influence of the positive element on the active material in contact with it in preventing oxidation.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XII. NEW YORK, SEPTEMBER 2, 1891. No. 174.

It is to our patent law—which has given to such knowledge a practical value in the hands of these men—that we are indebted for the possession of the most intelligent and skillful body of laboring men in the world.—Chauncey Smith.

PRIORITY IN ALTERNATING CURRENT MOTORS.

THE work which has already been performed by alternating motors and the much larger opportunity now opening up for them, have served to call attention to the value of the discovery of the rotating-field principle. As usual in such cases, a number of claimants for the honors of priority have appeared, but the dispute, so far as the fundamental principle is concerned, is limited to Prof. Ferraris and Mr. Tesla. We cannot believe that any one who has thoroughly examined the record of the work done, and published, can for one moment be in doubt as to whom the credit of having first made the discovery belongs. But that there are some who are still of doubtful mind is evident from statements that have been put forth in electrical journals, especially in Europe.

Without wishing to prolong a controversy that has probably had its origin in the fact that Mr. Tesla has obtained patents based on this discovery, we deem it a duty to correct the erroneous impressions due to lack of thorough knowledge of all the work done in this country. When even so impartial and well-informed a man as M. Hospitalier, whose otherwise excellent résumé of alternating-current motors appeared in our last issue, does not credit Mr. Tesla with that which is but his, we feel constrained to lay before our readers the simple facts as we know them.

Prof. Ferraris has been credited with the discovery now in controversy, on the strength of his admirable paper read before an Italian scientific society in March, 1888, and published in Italian shortly afterwards. But, five months before this, in October, 1887, Mr. Tesla had already filed applications for patents embodying the discovery, and several months again before that time had so far perfected his invention that a company had been formed to exploit it. Many prominent persons, including several electricians, then saw the Tesla motors at work; and during the winter of 1887-8 one of the best known scientific men in this country examined and reported favorably upon them. Some time in April one of the present editors of THE ELECTRICAL ENGINEER, knowing of this new work, saw the motors which had then been running for some time in a temporary laboratory, and induced Mr. Tesla to bring his discovery before the May annual meeting of the American Institute of Electrical Engineers. The Secretary of the Institute assisted at these negotiations, and as a result the motors were actually shown, before a large gathering in this city.

On May 1, 1888—the same year—patents were issued to Mr. Tesla in this country as the result of his applications in October, and were then accessible at once in every European country. But the work of Prof. Ferraris was not brought to light in English-speaking countries, and others, too, for that matter, until it was first given prominence by the publication of it in the May 18, 1888, issue of *Industries*. That interesting article was freely copied here and abroad, as it well deserved, and its publication in this wise created the false idea that Prof. Ferraris' striking work was simultaneous with that of Mr. Tesla, or even prior. But the description of the Tesla invention must evidently have been made public in the patent, in England and other countries, before the date of the *Industries'* article; and, besides the issuance of the patents, there is the fact that our contemporary, the New York *Electrical Review*, had given a short illustrated description of the Tesla motors on May 12.

More than this. In his essay of March, 1888, Prof. Ferraris expressly denied the practicability of motors that Mr. Tesla already had in successful operation! He hinted at the possibility of using a proper generator for such motors, but no further did he go. Mr. Tesla had already taken coal out of the mine before Prof. Ferraris made his geological survey of the region. With this admission from Prof. Ferraris, it was not very likely that practical men would recognize the great value of the new principle.

On examination of Mr. Tesla's now familiar work, we find that he, on the contrary, had not stopped short at a mere rotating field, but dealt broadly with the shifting of the resultant attraction of the magnets; that he had evolved the multiphase system; that he had shown the broad idea of motors employing currents of differing phase in the armature with direct currents in the field; that he first described and used an armature with a body of iron and closed coils symmetrically wound; that he had shown both synchronizing and torque motors; that he had shown how machines of ordinary construction might be adapted to his system, and had with specific purpose advanced boldly into new territory of which there was not the slightest hint or suggestion in the work of Prof. Ferraris.

In other words, Mr. Tesla not only went to the bottom of the fundamental principles, but tried them in every detail that inventive ingenuity could hit upon. If this is not so, it is time to have the contrary state of affairs proved before Mr. Tesla loses the credit that such work must give him.

THE FRANKFORT-LAUFFEN LONG-DISTANCE POWER TRANSMISSION.

The work which has now been in course of construction for several months, both on the generators and motors, as well as the line between Lauffen-on-the-Neckar and Frankfort-on-the-Main, has now been practically completed, and we are in receipt of a cablegram from our Frankfort correspondent, under date of August 26, informing us that at the preliminary trial made on that day 100 h. p. was successfully transmitted.

The distance between generator and motor is 112 miles, and a pressure of 30,000 volts is employed. The generator used in this installation was described in our last issue, and, as will be recalled, is of the 3-phase type. The current from the generator is transformed upward by a step-up transformer, the secondary of which is connected to the line, and at Frankfort a step-down transformer furnishes current to a set of so-called "rotary-phase" transformers, designed by Von Dolivo-Dobrowolsky for the Allgemeine Elektricitäts-Gesellschaft, of Berlin, who are carrying out this work in connection with the Oerlikon Works, of Zurich, Switzerland, of which Mr. C. E. L. Brown is the electrical engineer. The results already obtained leave little room for doubt that the enterprise will prove a complete success.

THE INCANDESCENT LAMP SITUATION.

In The Electrical Engineer of July 29, some observations were made in reference to the commercial situation in the incandescent lamp business, as affected by the decision of Judge Wallace sustaining the Edison patent. The case has now gone to the new appellate court, and a final determination of the matter may therefore be looked for within a few months at farthest. Whether the decision of the circuit court be sustained or reversed, is, of course, a matter vitally affecting the interests of the now somewhat numerous lamp manufacturers of the United States. The position of the defendants in the particular case decided, as the remarks of the judge at the time of granting the stay of proceedings unmistakably indicate, is materially stronger than that of other manufacturers, and moreover, the United States Company has many valuable patents of its own on lamps, details and processes of manufacture, dating back to the very beginning of the industry. In consideration of these facts, and especially in view of the remarks of Judge Wallace at the time of granting the stay of proceedings, it would seem obvious that if by any possible means an adjustment of the matter could be brought about by the parties in conflict, it would be an eminently wise, not to say profitable, procedure. Such a course, it will be remembered, was many years since pursued in connection with the sewing-machine patents, all of which were necessarily subject to the Howe patent of the eye-pointed needle. The various manufacturers in the combination, each of which was able to contribute valuable patents to the making of a successful machine, were permitted to go on, paying a royalty to the owners of the Howe patent on each machine turned out. The result was that the several concerns became so well established in their business, that even to this day, with all the patents expired, it has been found a practical impossibility for any new concern to get a foothold in the business, while the profits of the original syndicate can only be computed by millions, no small share of which would otherwise have found its way into the pockets of the legal fraternity. In the incandescent lamp industry, such a policy would at least have the effect of suppressing irresponsible manufacturers, as well as of maintaining a high standard of quality in the product, a consummation which could not but inure to the direct and permanent benefit of the consumer.

UNIPOLAR DYNAMOS.

There is, perhaps, no better known fact in electrical science than that first demonstrated by Faraday in the generation of current by the rotation of a conducting disc in a uniform magnetic field. The fundamental character of this experiment excites interest not only in the student, but in the experimenter, who still finds it a subject worthy of further research. That new and useful facts may still be gleaned in this field will be apparent on a perusal of Mr. Tesla's interesting Notes appearing on another page. The remarks bearing on Sir William Thomson's well-known "current accumulator" may be read with profit. A point of considerable practical value is that brought out in connection with the operation of alternating motors. It shows the great importance of observing the proper conditions in working such machines, which conditions involve the various elements of construction as well as the frequency employed. Mr. Tesla also points out some interesting methods for exciting dynamos.

LONG-DISTANCE POWER TRANSMISSION.

The comparison of efficiencies of various methods of transmitting power to a distance has long since demonstrated the superiority of electricity for the majority of cases occurring in practice, and involving the utilization of natural forces. But far more than any other method, the electric method permits of a wide range of conditions of working, and to select those which will result in the most economical operation has by no means always been an easy task in the past. In an elaborate discussion of this subject, Mr. H. Ward Leonard, in this issue, shows the relation to one another of the various factors which enter into the solution of a problem of this nature, and the results obtained by him, as exhibited in the charts, will, we are certain, be welcomed by every one interested in electric power transmission. Much of the discussion on this subject has been confined merely to a consideration of the cost of conductors. While this item is, no doubt, a large factor in the equation for economy, it is not by any means the only one, and it is therefore desirable, as pointed out by Mr. Leonard, to have a handy means of comparing all the factors without elaborate calculations.

THE NEW SHORT RAILWAY GENERATOR.

Among the pronounced developments of modern electrical engineering, and especially electric railway engineering, none has been more conspicuous than the ever-increasing size of power generators called for. We remember very well when a 75 h. p. generator was considered quite large for this class of work, but the demands of the present have already brought out 250 h. p. generators, and even these are now being exceeded by still larger ones.

As an instance of this we may cite the recent progress made in this direction by the Short Electric Railway Co., of Cleveland, Ohio, who are now prepared to furnish generators of no less than 500 h. p. Their new type of machines just brought out is illustrated in the accompanying engraving, which represents the 150 h. p. generator.

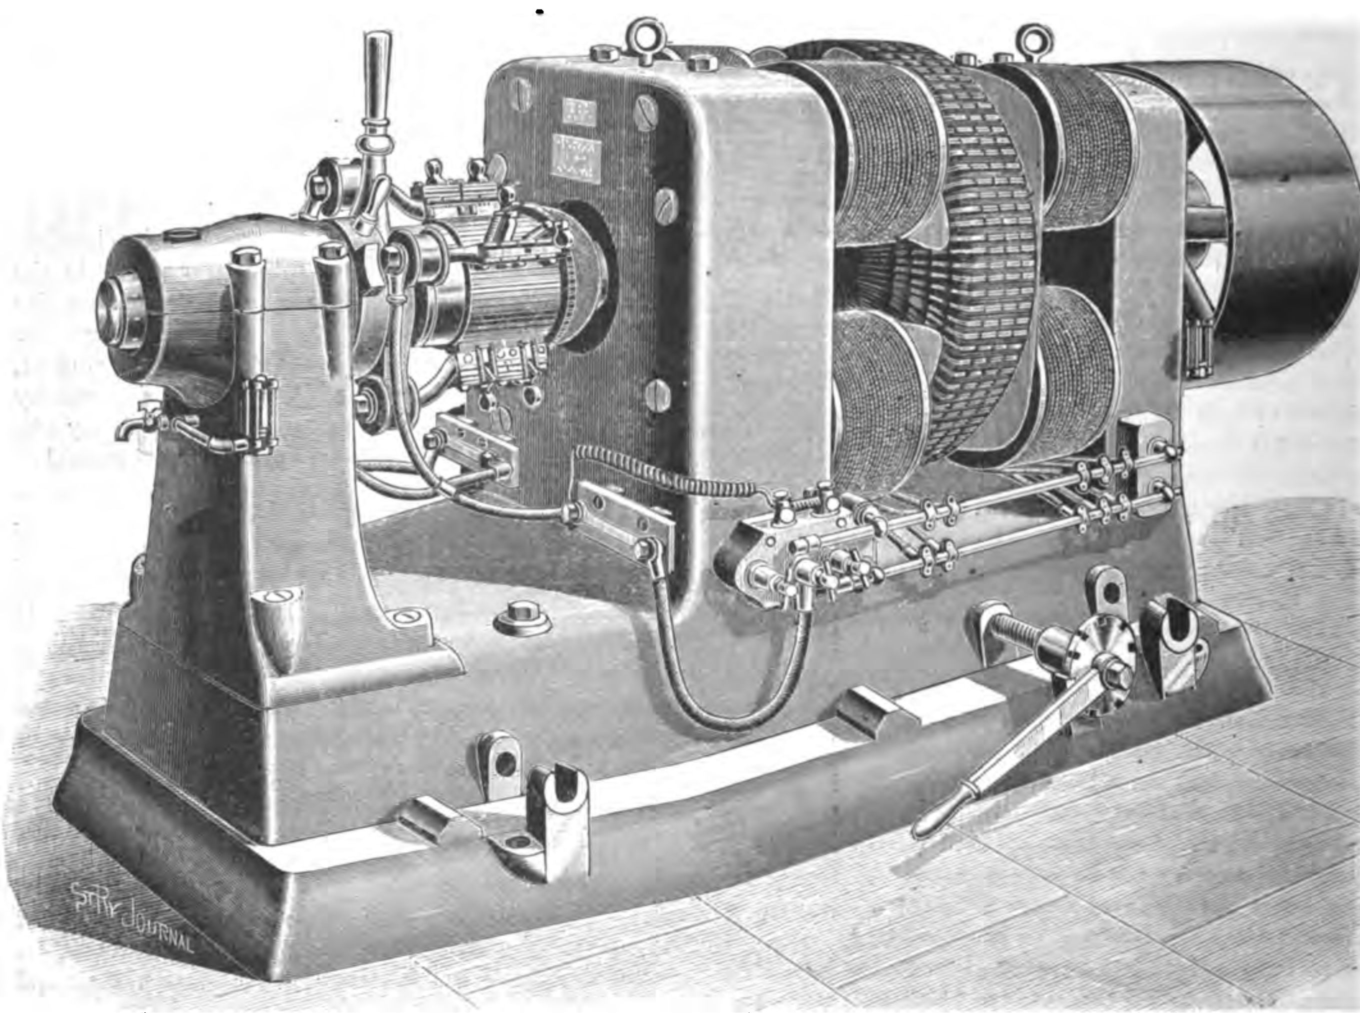
The illustration gives an excellent idea of the 150 h. p. generator, capable of delivering in continuous service 225 amperes at a pressure of 500 volts, equivalent to a total electrical output of 112,500 watts, and having, in fact, a reserve capacity above the normal of at least 30 per cent. in both current and voltage.

The great field-magnet frame is one of the largest and most perfect single castings ever made for electric work. It weighs over 8,000 pounds, and nothing but the softest and purest iron is used in the melting pots. It is annealed very slowly in the moulds, and when finished is so soft that it can easily be indented with a hammer. For properly finishing up the casting it was necessary to build a monster planing machine, one of the largest to be obtained.

To this heavy frame are bolted eight field magnets, carrying the shunt and series coils, and provided with pole-pieces of peculiar shape, arranged for side presentation to the armature, and so disposed as to make a powerful and almost perfectly uniform field of force within a narrow magnetic gap of large diameter.

Within this space revolves the armature, which is a distinctive feature of the machine. Its peculiar construction is well known to all who are familiar with the past practice of the Short company, which was the earliest, and for a long while the only, prominent advocate of what is known as the "Gramme Ring" construction for railway motors and dynamos now being generally introduced.

Upon a shaft nine feet long by six inches in diameter is keyed a massive spider carrying the foundation ring, upon which the armature is built up. The armature core is formed of thin sheet-iron wound spirally on the foundation ring and riveted firmly together. The outside circumference of the ring is somewhat wider than the remainder, and this portion is milled out into notches, forming a modified Pacinotti ring. The coils are then wound on the core around the hollow ring, the method being such that every one of the 200 coils is entirely exposed to the air on all sides, thus securing perfect ventilation. The projecting coils are, in fact, a sort of fan, and, in standing before the machine, the current of air set in motion by the armature can be detected ten or fifteen feet away. As a consequence, both armature and field run cool, and it is almost impossible to burn out a coil even with heavy overloads. Moreover, the destruction of a single coil does not



The New Short Railway Generator.

affect adjacent coils, and it is even possible, in case of necessity, to run the machine for several days without rewinding a burned-out coil. A burnt-out coil can be wound by any good mechanic at a cost of two or three dollars and a half day's labor. One of the most noteworthy features of the armature is its large diameter, viz., 36 inches, which is also, by the way, the diameter of the pulley usually employed with high-speed engines. The centre of gravity is low and the machine runs smoothly and quietly.

The details of construction are carefully worked out. The armature shaft runs in large self-centering and self-oiling bearings, the lubrication being accomplished by rings carried by the shaft and drawing oil from a reservoir in the usual way. The height of the oil is indicated by the little sight glass on each box. At the commutator box is also found an adjustable ball-bearing thrust collar containing several hundred balls, and so arranged as to carry the armature thrust in either direction without the slightest heating. This is an entirely novel feature in this class of machinery.

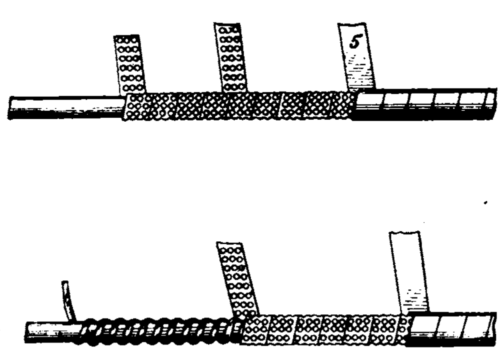
The commutator is carefully built and unusually large in diameter, viz., 20 inches. It has 200 bars, so that the pressure between the adjacent bars is very small and the sparking nil. The brushes are four in number, and are carried by two independent collars and sets of brush holders. In order to secure perfect adjustment at the neutral points multiple carbon brushes are used. The terminals of the field coils are carried to two heavy bars held securely in place on each side of the base of the machine. The plan of connection is simple and in plain sight, and the machines are so exactly duplicates of each other that there is no necessity for other adjusting devices, beyond the ordinary field rheostat box. The dynamo is placed on a heavy foundation plate and moves on V-shaped rails by means of an ordinary ratchet and screw.

The electrical properties of the machine are quite as noteworthy as the mechanical. The magnets always work far below the saturation points, even at heavy overloads. The compounding has been so carefully calculated that the pressure curve is a straight line, passing from 500 volts at no load to 525 volts at full load, with speed maintained constant at 500 revolutions.

The Short company is building this type of generators in five sizes, viz., 75 h. p., 100 h. p., 150 h. p., 300 h. p., and 500 h. p. The last-named size will run at about 100 revolutions and will be connected direct to a vertical compound engine, thus doing away with all belts and shafting. It is probably that even larger sizes will be built later on, to accommodate the heavy railway work which is in immediate prospect.

THE DEGENHARDT ELECTRIC CONDUCTOR.

In order to decrease the static capacity of electric conductors, Mr. Frederick E. Degenhardt, of Chicago, has



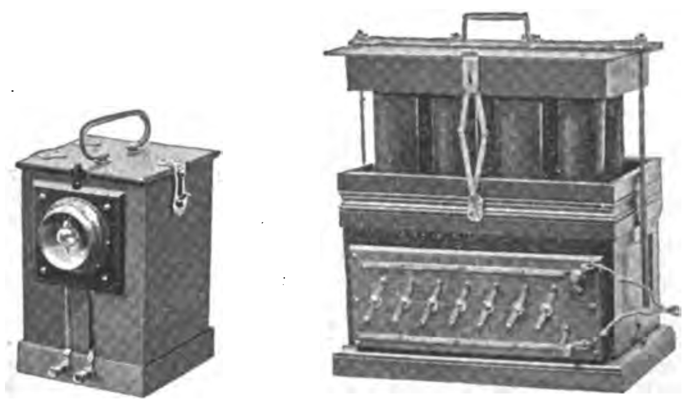
Figs. 1 and 2.—Degenhardt's Electric Conductor.

devised a system of porous insulation by means of which air or gas is retained between the conductor and the protective covering. As will be readily understood by reference to the accompanying illustrations, Figs. 1 and 2, a strip of perforated paper is wound about the wire either immediately, as in Fig. 1, or outside of a cord, as in Fig. 2. If the strip is comparatively thin, a second or even a third perforated winding is used. Over these is wound a solid strip whose edges overlap, and finally a non-conducting sealing material is applied.

When the conductors are made into cables, the solid strip about each is omitted. The wires covered with the perforated paper are twisted together, and wound with another perforated strip covering the whole, after which the covering of the cable is completed, as in the case of the single conductors, and a lead covering is added.

THE HUBBELL PORTABLE ELECTRIC LAMP AND BATTERY.

The accompanying illustrations, Figs. 1 and 2, show the lamp and battery manufactured by the Hubbell Portable



Figs. 1 and 2.—The Hubbell Portable Lamp and Battery.

Electric Lamp and Power Co., of 35 Broadway, this city. The type A, 4-cell battery lamp, Fig. 1, consists of a small battery 4½ inches square and 6 inches high, weighing, when fully charged, about 4 lbs., and capable of sustaining a standard 3 c. p. lamp for 10 hours at a cost of two cents for the entire time.

The-8 cell battery, type B, Fig. 2, is 12 x 6 x 7 inches, and when charged weighs 15 lbs. It is capable of running a 10 c. p. standard lamp for 10 hours at full incandescence, or a 12-inch fan or sewing machine for the same period of time at a cost of 5 cents for the entire period. Two batteries of this type coupled up in series will give 35 volts on open circuit and 10 amperes on short circuit.

It is the intention of this company, when the facilities for manufacturing are completed, to produce various other types for street-car lighting, wreckers' use, medical batteries for cautery purposes, carriage and cab lighting, propelling pleasure boats, isolated lighting, small batteries for stage and spectacular effects, and for bicycles.

NEW SWISS CABLE RAILWAY.

The water-power of Buochs, which is already used for working the Burgenstock Railway, is about to be employed in operating a cable line on the Stauserhorn. The water will actuate a turbine and dynamo, the current from the latter to be transmitted just over three miles to the three electric motors which will work the cable railway. The line will be nearly two miles long, and will be divided into three sections, each of which will be independent, and will be worked by a motor of 50 h. p.

Mr. Morton Edward Eden, of the Brush Electric Co., Cleveland, O., has been called to Europe to superintend some heavy electric railway construction in Spain, to be put in by an English concern.

ELECTRICAL SUBWAYS.[1]

BY ROSSITER W. RAYMOND.

THE final report of the Brooklyn Board of Commissioners of Electrical Subways, issued 2 years ago, still remains the best summary statement of the municipal problem with which it deals. In one noteworthy particular the opinion and prophecy of the board have received a striking confirmation. I refer to the matter of the corrosion of lead in conduits of creosoted wood. This evil was at one time very threatening, and so important that, although it constituted the only serious objection to the use of such wooden conduits, it might have counterbalanced, if the remedy had proved impracticable, all the great advantages of that material. One concern, at least, engaged in the manufacture of lead-covered cables, declined to guarantee them if laid in creosoted conduits.

The remedies suggested were two: The alloying of the lead with about 4 per cent. of tin—which, however, rendered the cables both more expensive and more difficult to manufacture—and the use of a fibrous covering, which was somewhat objectionable on other grounds. The Brooklyn board, however, caused careful laboratory tests and analyses to be made, and announced in its final report that, in its opinion, the corrosive agent is "phenol, which, being highly volatile, either escapes from the wood in the process of seasoning, or could be expelled more rapidly, if required, by artificial means." The frequent occurence of the phenomenon of corrosion in different cities was no doubt due to the haste with which underground conduits were everywhere constructed during that period of spasmodic reform under scientific legislation. Experience has proved that the Brooklyn board was right. The 2-year-old Brooklyn conduits do not now corrode lead—even pure lead—appreciably; and in some other cities where the authorities and electrical companies were almost ready, in a panic, to abandon the system, the simple lapse of time has cured the difficulty.

The underground system in Brooklyn seems to be running so peacefully and successfully that it is never heard of. If the Legislature had not summarily abandoned the whole experiment that city might now be a model in the extent, as it is confessed to be in the simplicity and perfection, of its subways. The present situation in Brooklyn is that there is no interference with the extension of overhead wires of all kinds, and no official control of their installation. In the final report of the late board an important list of all the electric light wires was given, with careful designation of every line where the insulation was dangerously defective. This list the Brooklyn newspapers did not reprint; nor have the city authorities, so far as I know, taken any action upon it. Meanwhile, by the lapse of later statutes, the old law of 1884, with certain amendments of 1885, has been left in force; overhead wires are prohibited; there is no authority anywhere to authorize or control their installations; and it is the duty of the municipal government to remove them—all of which is, of course, a dead letter.

As for the situation in New York City—who can tell what it is?

ELECTRICAL WORK IN MINES.[2]

BY ALBION T. SNELL.

AFTER calling attention to the growing use of electricity in mining operations in all parts of the world, Mr. Snell proceeded to describe a few of the more important plants now running successfully in Great Britain. The installation at the Newbridge Rhonda Colliery is, he continued, typical of the system in which use is made of over-compounded dynamos, and hence, is worthy of special notice. The problem here was to drive two pumps off the same set of mains. It was required to make the two pumps, 700 yards apart, independent, and it was also imperative that the electric light should be used at the pumping station, at the pit bank and pit bottom; and, further, there was to be only one dynamo. These conditions assumed that the pressure would be practically constant throughout the circuit. In practice, it is, of course, impossible to secure an absolutely constant pressure all over the system, owing to the resistance of the mains themselves; but by over-compounding the dynamo, so as to give a constant pressure at a point near the centre of the system, it is possible to approximate very closely to the required conditions. How well the case has been met is apparent from the fact that both the pumps can be switched off without appreciably raising the voltage of the lamps. The dynamo is of the Sh. D. C. $\frac{1}{1}\frac{3}{6}$ type, and running at 800 revolutions per minute gives a pressure of 300 volts and 60 amperes. Each of the motors gives 7 b. h. p., and runs at 800 revolutions per minute. The lamps are coupled in series of three. The pumps are three-throw rams, 4 in. in diameter by 9 in. stroke. The plant has been perfectly successful from the first.

An interesting application of the compound parallel system is the installation at Andrew's House Pit, Durham. The plant comprises a dynamo, three motors, cables, and three dip pumps. The pumps are respectively 1,500, 1,800, and 2,000 yards in bye; the one nearest the shaft is driven by a 4 h. p. motor; the others each work by motors of 2 h. p. The dynamo gives 250 volts and 40 amperes. The total capacity of the plant is thus small, but it is interesting on account of the distance between the pumps and the length of the cable. A few lamps are run at each of the pump stations, and also in the engine-house. The dynamo is arranged to compound for constant potential at about 1,500 yards in bye. Each of these motors has replaced a crank which required twelve horses for 24 hours work.

At the Standard Tin Company's St. Mauritius Mine, in Bohemia, the dynamo is placed below ground and is driven by a turbine, the water being led down a shaft by pipes. The motor is arranged to work a pair of lift pumps with spears 40 metres long, and also to wind ore through the same vertical distance. When the installation was first made the lower levels were drowned out, and the electric plant had to pump them dry before work could be resumed. This was successfully accomplished in a shorter time than the engineers expected, and ore is now being regularly raised by the plant. The power of the motor is about 20 horse. At Eger, at one of the brown coal mines the main ventilation is produced by a fan driven by electricity. The dynamo is driven by a turbine about half a mile away from the fan house, and the current is carried by bare wires mounted on poles with fluid insulators. The power of the motor is approximately 25 horse. The fan has now been running for about 12 months, and the manager reports that it is working perfectly satisfactorily.

Other examples might be given, but the preceding cases are fairly representative of the work now being done.

Mr Snell then referred to the risks attending electrical installations in mines, the first of these being the danger from shocks, and stated that, as no casualty from this cause has been reported from any mine in England, in one of which a working pressure of 700 volts has been used for three years, this risk may be considered practically negligible.

The second risk is that from fire, which may occur from the ignition of gas by the sparking of the brushes, or the burning of timber through faulty insulation. Marsh gas and air explode at about 1,000 deg. C. (1,832 deg. F.), according to the mixture. It would appear that although under normal conditions there would be little danger of a motor igniting gas, yet, if by any means the brushes and commutator became heated beyond a certain intermediate point, this danger would arise; and if motors are to be used in fiery mines it will be necessary to protect them by enclosing the entire armature and commutator in a dust-tight metal box sufficiently strong to resist the force of the explosion of possible gas within it, or to box in the commutator and brushes only. The former method has the advantage of also guarding against sparks caused by a possible short circuit on the armature. The second method does not protect the armature winding at all, but it reduces to a minimum the volume of gas which may be exploded by sparks.

1 *Engineering and Mining Journal*, August 8, 1891.

2. Abstract of paper read at the annual meeting of the South Wales Institute of Engineers.

THE PROPAGATION OF ELECTRIC DISTURBANCES ALONG CONDUCTING WIRES.

IN *La Lumière Électrique* of August 8th, Prof. Hertz offers some remarks on a contribution to that journal by M. J. Blondin, which appeared in its issue of July 18th. M. Blondin opened his article with the following remarks: "According to Maxwell, an electric disturbance should be propagated along an insulated conducting wire with the same speed as through the dielectric medium surrounding it. To show that this is so would, therefore, constitute an invaluable verification of the truth of the theories of the English *savant*. The determination of the speed of propagation of electric waves in metallic wires has been of late the subject of much work, the most important of which has been described in this journal (*La Lumière Électrique*). Unfortunately, the contradictory results arrived at, so far from confirming the theory of Maxwell, seemed to show that it could not be applied without modification to propagation along conductors, and it is only quite recently that the question has been definitely settled in a sense favorable to Maxwell's ideas by the work of MM. Sarasin and de la Rive. I therefore think it useful to take up the systematic study of the propagation of periodic electric disturbance along a conducting wire."

To this systematic study Prof. Hertz replies as follows: "M. Blondin treats in an extremely just and kind manner certain errors which, it seems, have crept into my researches. I have scarcely anything to add to the very clear explanation of M. Blondin, and I am only desirous of taking this opportunity of myself stating in this journal that the conclusions which M. Blondin arrives at are in perfect accord with my present conviction, although they disagree with the results of the experiments which I published a few years ago. When I began these experiments I was inclined to think that they ought to furnish two identical speeds, and I was astonished and disappointed to find that experiment gave unequal speeds. On this account I am fairly confident that I did not carry out my experiments with preconceived ideas, and in repeating them at the same place and under the same conditions I over and over again obtained the results published in my Papers. This does not preclude the idea that local conditions, either unknown or badly interpreted, had a disastrous influence, and falsified the results. To see if this were so, I endeavored to repeat the reflection experiments in my present amphitheatre, which is a fine room, 17 metres long, 12 metres broad, and five metres high, without iron pillars to interfere with the experiments. I was, therefore, hopeful of obtaining excellent results and certain success. Unfortunately, the benches, which I was unable to remove, were ranged one above another in tiers in such a manner that I was obliged to give to the waves a somewhat inclined direction, unsymmetrical with regard to the horizon and the walls of the room. Under these conditions for waves several metres in length the experiment succeeded very badly. The interference phenomena were much less pronounced than I had usually found them; the nodes were so ill-defined that their true position remained doubtful to within more than a metre. Once again, therefore, I was obliged to give up the idea of personally experimentally verifying the facts.

"Nevertheless, these experiments enabled me to ascertain how great may be the influence of local conditions on long waves in a room of moderate dimensions and not completely empty. I even think that any such closed space complicates vibrations and produces effects analogous to acoustic vibrations in cubic tubes; that is to say, tubes the dimensions of which are approximately all the same. If this is so, the intensity of the disturbance and its distribution in space will depend in a large measure on the relation which exists between the period of the exciter and the period of the vibrations proper to the closed space, on the position of the exciter relative to the nodal surface of the simple vibrations, &c., &c.

"Perhaps we shall find in these considerations a possible explanation of the diverse results obtained; in any case I do not publish them as a proven explanation. However, it does not seem to me that the beautiful experiments of MM. Sarasin and de la Rive were carried out under better conditions than were my own. If any physicist has at his disposal a large gallery, eight metres high and eight metres broad, and from 20 to 40 metres long, I think that even now it would not be lost labor to repeat these experiments on a large scale in order to remove the last uncertainty from science. I do not doubt that such an experiment would verify the results of the Geneva physicists. In a laboratory of ordinary dimensions I think it would be very difficult to get a certainty greater than that already obtained."

CONTRIBUTIONS TO THE THEORY OF SECONDARY CELLS.[1]

BY F. STREINTZ.

This paper considers the capacity and efficiency of elements with positive plates of various sizes. For the experiments E. P. S. plates, supplied by Messrs. Getz and Odendall, of Vienna, were sawed up so that the cut passed through the middle of the lead framework. The active material was thus not interfered with. Three elements were tested: In I., the positive plate contained 5x5 meshes of the lead network; in II., 5x6; and in III., 6x6; the distances between the elements in each case were 1.5 cm. In a larger vessel was placed an amalgamated zinc plate in dilute sulphuric acid; by means of a glass syphon this could be put into communication with the contents of each of the three elements, for the purpose of determining the potential difference between the zinc and the plates of the accumulators.

The experiments were conducted as follows: The element was first charged by a known current for several hours beyond the point at which the negative plate began to give off hydrogen. It was then discharged with the same resistance in the conductors until the current strength fell 10 per cent. below its stationary value. This discharge, during which the potential and current strength were taken every hour, served to determine the capacity. On the following day it was again charged at the same current, but this time the charging was stopped as soon as hydrogen began to be given off; finally came a discharge under similar conditions, following usually immediately upon the charge. The observations taken during the second charge and discharge served to determine the efficiency.

The tests showed that the capacity, *i. e.*, the number of watt hours which an element was capable of giving out before the current strength fell 10 per. cent., increases as the current strength diminishes. The element II. showed the highest capacity of the three. It was demonstrated that a reduction in the size of the positive plate conduces to an increase in the capacity, the efficiency at the same time not being lowered.

[1] *Wied. Ann*, Vol. XLIII.

WHY TELEGRAPH WIRES ARE UNDERGROUND IN CHINA.

The following is not without interest:

"A superstitious reverence for the dead accomplished years ago in China something that regard for the comfort and safety of the living, even when aided by judicial mandates and radical municipal methods, has been only partially able to accomplish in this country," said a telegraph lineman who was in the employ of the company that established the first telegraph line in China.

"The telegraph wires are placed underground there, and if the company had not so disposed of them there would have been no telegraph lines in China to this day. Dead ancestors are held in peculiar reverence in that curious country, and the casting of a shadow upon the grave of an ancestor is looked upon by the Chinese as an insult not to be borne, and it is always resented with impetuous rage. Now there are no cemeteries or general burying grounds in China, but every family's ancestors, particularly in the rural districts, are buried on the family premises. Consequently, every yard or garden is a receptacle of ancestral remains, and as China is thickly populated, the revered bones of dead and gone Mongolian progenitors may be found resting beneath every few rods of earth. When the telegraph company went to work to put up the poles on which to hang its wires the workmen were embarrassed every little while by wrathful Chinamen, who would rush angrily upon certain poles and chop them to the ground, and warn the workmen with much furious chatter that they would put them up again at their peril. The cause of this interference was unknown to the workmen, who were at last forced to discontinue the work, and explanation was demanded by the authorities. Then it was learned that the poles that were cut down had cast a shadow some time during the day on the graves of revered ancestors of Chinamen, and the insult could be wiped out in no other way but by summarily removing the poles. It was found that this superstition was too sacred a one among the Chinese to be overcome by persuasion or bribery, and at last the telegraph company, as a matter of economy and self protection, laid their wires beneath the surface, where they have been ever since."

SEARCH LIGHTS IN THE NAVAL MANŒUVRES.

Many years' experience of search lights in naval sham fights, says *The London Times* correspondent, convinces me that these machines, which in certain circumstances are invaluable, are too often so utilized as to be of far more assistance to the attack than to the defence. When an ironclad, believing that torpedo boats are near her, but seeing none of them, begins flashing her search lights in order to discover the enemy, she greatly helps her foe, who thenceforward knows exactly where and how she lies, and to what quarter her uneasy suspicions are directed. By all means cover the mouth of your anchorage with permanent and steady beams of light, so that any craft entering must cross the beams and so reveal herself; but do not let these beams proceed from battleships, or, indeed, from big ships of any sort. They should be thrown only from small craft and from boats, or, still better, from points on shore. The only time, in my humble opinion, when a threatened battleship should use her light is when she has already clearly discovered an approaching enemy. Then let her flash it full into his eyes. It will blind and puzzle him, and, falling on his hull, guns and paintwork, it will give her a capital target for gun fire. Splendid, when thus used, was the effect of the light upon torpedo boat No. 25, in Luce Bay, on the morning of July 27th. From the moment when the beam struck the boat she was as good as destroyed, for she stood out so clearly that only very bad gunners could have missed her. The light ought not to be worked from any point very near the guns which are to be fired. The ideal position is as far as possible below them. It is, all things considered, a mistake to mount lights on bridges and chart-houses; they cannot be too close to the surface of the water.

CRYSTAL PALACE ELECTRICAL EXHIBITION.

We are informed that the directors of the Crystal Palace, in deference to the wish of the Electrical Trade Section of the London Chamber of Commerce, have finally decided to postpone the opening of the Electrical Exhibition from November, 1891, till January 1, 1892, on which date the exhibition will be formally opened. The following are a few of the gentlemen who have consented to act as an Honorary Council of Advice: Prof. W. Grylls Adams, Prof. W. E. Ayrton, Mr. H. R. Beeton, Mr. Shelford Bidwell, Major Cardew, Sir Daniel Cooper, Bart., Mr. J. I. Courtenay, Prof. W. Crookes, Mr. W. B. Esson, Mr. S. Z. de Ferranti, Mr. J. E. H. Gordon, Mr. E. Graves, Mr. J. H. Greathead, Mr. R. Hammond, Dr. Hopkinson, Prof. D. E. Hughes, Mr. Gisbert Kapp, Prof. A. B. W. Kennedy, Mr. A. E. Mavor, Mr. W. M. Mordey, Mr. W. H. Preece, Prof. Henry Robinson, Sir David Salomons, Bart., Mr. Alexander Siemens, Prof. W. C. Unwin, and Major-General C. E. Webber.

Literature.

LEGISLATION RELATING TO COMPANIES THAT OPERATE UNDER MUNICIPAL FRANCHISES.

ONE of the most important publications affecting electric light and electric railway interests is that about to be issued by Robert Clarke & Co., of Cincinnati. It is entitled "Economic Legislation of all States Relating to Incorporated Companies Operating under Municipal Franchises," and is the production of Allen R. Foote and Charles E. Everett, the latter being a member of the Cincinnati bar. In the preparation of the work these gentlemen have had the assistance of a competent attorney in each State. The prospectus gives a list of them, making it clear that the highest legal ability has been secured; many of the names being already associated with literary legal work. The book will be in two divisions, the first, by Mr. Foote, a discussion of the economic principles involved in this legislation; and the second, by Mr. Everett, comprising all the economic legislation in question. The second division will embrace an introductory chapter of an analytical nature, tracing out differences and similarities in the laws of various States; then the State sections written by resident attorneys, and lastly a concordance index. All the sources of information will be drawn upon, particularly the State constitutions, legislative enactments, judicial decisions and municipal ordinances. In the State sections, the subject will subdivide itself into Historical, Franchise Companies, Franchises, and Municipal Ownership.

The value of this most important work will be found in its accuracy, completeness and arrangement. Every citation will be fully and clearly made, and each of the authors has been impressed with the idea that it is a good rule never to spoil a meaning to save a word. Such a work is indispensable to members of legislatures and municipal councils, officers and stockholders of companies, investors, jurists and economists, editors, and the public generally, and is likely, we think, to find also a great many readers abroad, where the course of American social and economic legislation is very closely watched.

It must be evident to all that the preparation of such a work, extending over two years, and representing so much expert ability, must be very costly. Mr. Foote, however, has placed the price of the book at only $10 per copy, and hopes that it will reach a sale of, say, 5,000 copies, recouping the outlay that has been risked on it, and preparing the way for other desirable efforts in the same field. Questions of municipal ownership are daily more and more discussed, and the agitation is very largely based on misconception of the facts. Such a book as this is timely and is likely to be one of the determining factors in the greatest politico-economic movement of modern years. Subscriptions should be forwarded to Mr. Foote, P. O. Box 482, Washington, D. C.

Dynamo Construction. By John W. Urquhart. New York: *D. Van Nostrand Co.*, 1891. 113 illus., 352 pages. 7½ x 5. Price, $3. Cloth.

THIS is a work of a thoroughly practical nature. It contains little history, and not overmuch of theory, but forms a most useful manual of the mechanics of the dynamo. The various questions relative to the framework, winding of field magnets and armatures, compounding, dimensions of cores, characteristic curves, and the like, are treated in detail, and with much clearness as well as with accuracy. Chapter 18 is very practical indeed, dealing as it does with a number of points in the erection of dynamos, and their operation under the conditions of station and plant work. We note, by the way, at the end of Chapter 17, a statement that with the Brush and Thomson-Houston machines at least, or even more than, 50 arc lights can be run in a single circuit. This is true, but far below the mark, for with the new Excelsior machine, and, unless we are mistaken, with the new Wood machine, the number goes over 100. It may be said that this requires a dangerous potential, but we cannot see any difference in that respect between 2,500 volts and 5,000, while the latter limit offers many additional advantages.

It is possible that the author might have said more about motors and the special principles of their design, whether for stationary or traction work. What is said is good, but some of it is antiquated, and far behind the date of American practice. But taken generally, the book is a very creditable addition to electrical literature, and will find many readers.

Wire: Its Manufacture and Uses. By J. Bucknall Smith, C. E. New York: *John Wiley & Sons*, 1891. Cloth. Illus., 347 pages. 11 x 7. Price, $3.

MR. SMITH is entitled to thanks for this very interesting and valuable contribution, to which he has evidently given a very large amount of time and thought. While in every way a technical treatise, it is full not only of data as to processes, but embodies a large quantity of useful and even amusing notes on the many uses to which wire is or has been put. Mr. Smith has traveled extensively in the practice of his profession, and seems at every step to have found something that would be worthy of adding to his collection of matter on this subject. Chapters 1 and 2 deal with the different kinds of wire, *i. e.*, iron, steel, copper, platinum, &c.; and the 3d relates to gauges. Chapter 4 is of special interest to electrical engineers, being devoted to electrical conductors. It is true that only bare, or uninsulated, wires are spoken of, but otherwise the chapter is complete; and it contains moreover some good tables of resistances, weights, strains, &c.

The book is divided into two sections, and Chapter 4 begins the second with a very full account of the various uses of wire ropes. This part includes cable cars, rope haulage, &c., and abounds in data that the electrical engineer very often is in need of in the discussion of the relative merits of electricity and the cable, &c. Then comes a chapter devoted to wire netting and woven fabrics and one on wire fencing.

There is a careful index to the book, with a full synopsis also of the contents of each chapter and a list of the illustrations. It is to be regretted, therefore, that the cuts in each chapter are numbered separately. The book is well bound and printed, and, as we have said, is unusually interesting.

Reports of Companies.

AMERICAN BELL TELEPHONE CO.

THE instrument account of the Bell Telephone Company shows:

Month to Aug. 20.	1891.	1890.	Increase.
Gross output	5,773	4,322	1,451
Returned	4,309	2,761	1,548
Net	1,464	1,561	*97
Since Dec. 20.	**1890–91.**	**1889–90.**	**Increase.**
Gross output	48,396	42,686	5,710
Returned	27,708	17,752	9,956
Net	20,688	24,934	*4,246

The instruments now in use amount to 504,478.

SECOND AVENUE RAILWAY, PITTSBURGH.

DURING the year ending June 30, 1891, the Second Avenue Passenger Railway Company, of Pittsburgh, operating the Thomson-Houston and Westinghouse electric systems, carried 1,808,993 passengers, according to its report recently filed at Harrisburg, and but twelve persons were injured, the accident, however, having been due to the carelessness or inattention on the part of the injured persons. The receipts of the road for the year were $88,-492.45, and the expenses, $61,094.94.

WEST END RAILWAY FIGURES FOR JULY.

THE July figures of the operation of the West End Street Railway Company have been compiled by the auditor, and are published herewith:

	Total.	Electric.	Horse.
Gross receipts	$554.431	$144,552	$409,878
General expenses	27,718	6,955	20,657
Track and car expenses	179,853	43,891	135,954
Motive power	142,670	26,398	116,271
Total operating expenses	350,137	77,239	272,888
Net earnings	204,294	67,303	136,990
Miles run	1,497,468	377.191	1,120,377
Ratio mileage	100.00	25.19	74.81
Per cent. operating expenses	63.15	53.44	66 58
Earnings per mile run	37.02	38.32	36.58
Expenses per mile run motive power	09.53	07.00	10.38
Car repairs	00.75	01.17	00.61
Damages	06.07	00.12	00.06
Conductors and drivers	07.71	06.92	08.23
Other expenses	05.12	05.37	05.07
Total ex. per mile run	23.38	20.48	24.35
Net earnings per mile run	13.64	17.84	12.23

The report for July shows a decrease of $7,965 in net earnings as compared with June, but an increase of $88,359 over April, and $38,770 over May. June is the banner month in the street railways of Boston, and it is expected that net earnings will gradually decrease from June figures until such time at least as the increase of electric lines brings about a decrease in operating expenses. Operating expenses for July were 63.15 per cent. for the system as it stands to-day, and while this is in contrast with 61.37 per cent. for June, the company can pay ten per cent. upon its present common stock with operating expenses at seventy per cent. The real point of West End earnings is to be found in the electric lines expense account. As the new power houses of the West End come into operation the result is seen in the reduced cost of motive power. In April and May the motive power for a horse car cost 10.86 cents per mile, while in June and July it could not be gotten lower than 10.38 cents. The motive power for an electric car has been brought down to seven cents per car mile, and will be lower in future. President Whitney is keeping his expenses per electric car mile very close to twenty cents, and a year hence they should be a good deal lower.

Society and Club Notes.

NATIONAL ELECTRIC LIGHT ASSOCIATION.

THE Committee on Transportation, finding that, owing to the inability of the West Shore R. R. Co. to make suitable connections on the return trip, making a change of trains necessary, have deemed it advisable to change the route.

A special train will leave the Grand Central Station, at 42d street, at 9.10 A. M., Sunday September 6th, arriving in Montreal at about 9.35 P. M.

Fare from New York, round trip, to Montreal......$12.00
" " " " " " (cert. plan) 13.33
" " " to Montreal, one way......... 10.00
Extra, each way, for parlor car accommodations... 2.00

Delegates from the South and West desiring to take this train should purchase through tickets *via* N. Y. C. & H. R. R. and Central Vermont R. R.

For the convenience of the New York delegates, to avoid the rush at the station, railroad tickets and information can be obtained at the Electric Club, 17 East 22d street, New York City, on Saturday, September 5th, from 3 to 5 P. M.

The excursion tickets will be good to return until the 20th of September. Railroad tickets and parlor car accommodations can be secured at the office of the N. Y. C. & H. R. R. R. Co., 413 Broadway, New York City. For further information, address C. O. Baker, Jr., chairman, New York, care National Electric Light Association, 136 Liberty street, New York City.

College Notes.

UNIVERSITY OF NEBRASKA.

MR. R. B. OWENS, of Greenwich, Conn., has just been appointed Professor of Electrical Engineering at the University of Nebraska, Lincoln, Neb. It is an adjunct professorship, being within the jurisdiction of Prof. D. B. Brace, who is in charge of the Department of Physics; and the course extends over two years. Mr. Owens is a young man, but has already made an enviable record. He began his studies at Johns Hopkins, and afterwards became connected with the Baxter Motor Co., of Baltimore, and the Excelsior Co., of New York. He was then put in charge of the Thomson-Houston station at Greenwich, Conn., which he constructed and operated; and while thus actively engaged he took the post-graduate course in electrical engineering under Prof. Crocker at Columbia College, receiving his E.E. degree this summer. He will assume his new duties at the fall term, and is already busy in making a judicious expenditure of $15,000 in equipment of apparatus and instruments. The plant will include a 500 light alternating outfit and one of 500 lights direct, with a 100 h. p. tandem engine. Representing as he does the best training of the East, as a graduate of Johns Hopkins and Columbia, and being acquainted with the practical side of the electrical engineer's profession, Prof. Owens starts out well equipped for his new work. We look for excellent results from Lincoln.

Obituary.

LOUIS H. SPELLIER.

LOUIS H. SPELLIER, the inventor of a time telegraph clock and of several improvements in the transmission of time by electricity, died at his home, No. 219 North Sixteenth street, Philadelphia, on Saturday, Aug. 22d, in his 48th year. Mr. Spellier was a member of the Franklin Institute and was an authority on electrical matters. He will be remembered by many electricians throughout the country on account of the active part he took in promoting the success of the International Electrical Exhibition at Philadelphia in 1884.

FREDERICK ROBINSON.

WE regret to announce the sudden death of Mr. Frederick Robinson, who is well known in the electrical trade as a dealer in slate specialties for electrical work. He was found dead in his bed on August 20.

"THE AMERICAN MANUFACTURER AND IRON WORLD," of Pittsburgh, J. D. Weeks, editor, has recently made a decided improvement by adopting the quarto shape, ENGINEER size, and by conforming its typographical dress thereto. In its new form it will be more valuable and useful to its readers than ever.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSTED AUGUST 18, 1891.

Accumulators:—

Plate for Secondary Batteries, A. F. Madden, 457,880. Filed Jan. 2, 1891.
For keeping the electrodes separated, employs a plate having separator-plugs molded therein with a shank extending through the plate and heads on each side.

Conductors, Conduits and Insulators:—

Method of Insulating Electric Conductors, Thomas E. Morford, 457,828. Filed Dec. 26, 1890.
Relates especially to the insulation of conductors in electric heating devices such as sad-irons, cooking utensils, etc.

Joint for Electric Conductors, George T. Manson, 457,865. Filed April 1, 1891.
Relates to the protection of joints, with especial regard to the exclusion of moisture from the joint. Employs an elastic tube surrounding the insulation of the conductors on both sides of the joint, and clamping devices to compress the elastic tube into water-tight engagement with the insulation.

Dynamos and Motors:—

Electromotor-Engine, Sebastian Ziani de Ferranti, 457, 875. Filed Sept. 24 1888.
A motor adapted to be driven by alternating currents, and designed especially to facilitate starting from a state of rest. Employs an auxiliary synchronizing-motor coupled with a non-synchronizing motor.

Electric Motor, Charles J. Kintner, 457,902. Filed June 14, 1890.
Claim 1 follows:—
The method of diminishing friction between the rotary and fixed parts of an electric motor consisting in causing the magnetism developed in the field magnets, and the work done by the motor to act conjointly against the force of gravity on the rotary part, and to thereby hold it off its lower end journal-bearing, substantially as described.

Lamps and Appurtenances:—

Illuminator for Electric Lamps, John von der Kammer, 457,830. Filed Jan. 10, 1891.
Makes a filament of a quantity of cellular threads which have been cleansed and subjected to a slightly destructive action of acid; they are then immersed in a paste of ground shoe-blacking, dried and heated.

Electric Arc Lamp, Elihu Thomson, 458,025. Filed April 27, 1891.
Directed to securing a refined and positive feeding motion and to compactness and moderate length in the lamp itself.

Metal Working:—

Method of Electric Bending and Straightening, E. Thomson, No. 458,115. Filed May 21, 1886.
Brings the section or part of a bar, or other piece to be operated upon, to a working heat by passing a heavy electric current through it by means of suitable clamps.

Miscellaneous:

Electric Stop Mechanism, Washington H. Kilbourn, 457,838. Filed Dec. 24, 1890.
Electro-magnetic device for stopping machinery; particularly adapted for automatically closing a valve.

Electric Door-Opener, Richard J. Ward, 457,906. Filed Sept. 15, 1890.

Railways and Appliances:—

Closed Conduit System for Electrical Propulsion, William B. Heron, 457,778. Filed March 27, 1891.
Claim 1 follows:—In a closed conduit system, the combination of a conduit, a traveling armature in said conduit, a wheeled vehicle, a motor and a magnet on said vehicle, a source of electrical energy leading to the motor to operate it, and an auxiliary source of electrical energy leading to the magnet to energize it to attract the armature, substantially as described.

Electric Car Truck, Thomas Tripp, 457,802. Filed April 17, 1891.
Claim 1 follows:—In an electric truck, the axles provided with loose geared wheels, each wheel being provided with the roller-carrying ring, to which are secured the roll-carrying pins and the sets of rolls which are located between the wheel-hub and the axle, and the thrust-plate mechanism consisting of the thrust-plate, which is secured to the wheel and in operation, rotates between the thrust-plate collars, which are firmly fastened to the axle, substantially as set forth.

Electric Railway Appliance, Frederick E. Degenhardt, 457,836. Filed Oct. 13, 1890.
Relates particularly to devices for conducting current through a fixed concealed conductor to the moving car.
Claim 1 follows:—The combination of an electrical conductor with a series of chambers through which it successively passes, said chambers made air-tight by a fluid seal and contactors disposed along such conductors and adapted to engage the same within such chambers when depressed, and an exterior contact surface connected with such contactors and adapted to be engaged by a conductor connected with a moving motor.

Railway Signal, L. F. Munger, 457,855. Filed Jan. 15, 1891.
Electro-magnetic semaphore system.

Electric Railway System, Milton Shoemaker, 457,870. Filed Nov. 3, 1890.
Employs underground conductors. "Object is to provide a system for operating cars by means of electricity without the use of poles, overhead wires, or any wires whatever, except the one through which the current of electricity is conducted."

Electric Railway System, Samuel E. Wheatley and John W. Schlosser, 457,944. Filed April 15, 1891.
Employs sectional working conductors, and relates specially to devices for contact between the sectional conductors, a continuous conductor, and a motor.

Electric Wire Crossing, Charles H. McKee, 458,063. Filed Jan. 26, 1891.
For electric railway junctions.

Telegraphs:—

Automatic Telegraph, David Kunhardt, 457,816. Filed Sept. 23, 1890.
A system of automatic transmission, employing sectional contact wheels and an elaborate system of circuits.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED AUGUST 25, 1891.

Accumulators :—

Secondary Battery, O. Lugo, 458,424. Filed May 26, 1891.
Designed to preclude chemical action when the battery is not in use. Consists of a relatively positive metal, such as zinc, and a relatively negative metal, such as lead, placed in a solution of borate of ammonia, which will not act primarily upon either electrode, but will act secondarily upon both.

Secondary Battery, O. Lugo, 458,425. Filed May 26, 1891. See p. 281, this issue.
Similar to the next above with the addition that both electrodes are coated with a suitable oxide.

Clocks :—

Electric Alarm-Clock, C. Lester, 458,178. Filed April 10, 1891.

Electric Alarm-Clock, L. Winterhalder, 458,206. Filed Dec. 4, 1890.

Electric Alarm-Clock, J. O. Newton, 458,372. Filed May 25, 1891.

Conductors, Conduits and Insulators :—

Electric Conductor, F. E. Degenhardt, 458,316. Filed Sept. 1, 1890.
Winds a conductor spirally with a cord and superposes a strip or strips provided with air-filled perforations.

Insulating Compounds, J. L. Marmaud, 458,551. Filed May 19, 1891.
Consists of calcined lixiviated infusorial earth, talc or soap-stone, lamp-black, sulphur, litharge, rosin, silicate of soda, rubber, bi-sulphide of carbon, fir-balsam and benzine or naphtha.

Dynamos and Motors :—

Electric Motor, L. Gutmann, 458,162. Filed Dec. 1, 1888.
For alternating currents. Invention consists in passing an alternating current through the field coils of a motor (with subdivided or laminated cores) and short-circuiting a part of the armature coils.

Method of Operating Alternating Electric Motors, L. Gutmann, 458,164. Filed Feb. 4, 1890.
See The Electrical Engineer, August 26, 1891, page 230

Armature for Dynamo-Electric Machines, L. A. McCarthy, 458,236. Filed Feb. 18, 1891.
Has cores projecting radially from its periphery and wound in the manner of an electromagnet.

Ignition :—

Automatic Gas-Lighting Apparatus, G. D. Clarke, 458,154. Filed Dec. 30, 1890.
Adapted for the lighting and extinguishing of gas jets at predetermined intervals of time ; employs clockwork.

Electric Gas Lighter, H. A. Pinkham, 458,486. Filed Oct. 25, 1890.

Lamps and Appurtenances :—

Electric-Lamp Socket, H. E. Swift, 458,242. Filed March 23, 1891.

Portable Electric Lamp, L. Bristol, 458,279. Filed Aug. 28, 1890.
Includes a closed secondary battery.

Arc-Lamp Electrode, W. S. Richards, 458,376. Filed Jan. 8, 1891.
Carbon has a capillary conductor of refractory material extending along its exterior.

Electric Arc Lamp, N. M. Garland, 458,386. Filed Dec. 29, 1890.
Aims to prolong the life of the carbons ; employs a movable protecting cap or hood of refractory material surrounding the carbon rod near its coned end, together with a metallic sleeve connected to the frame of the lamp by good conductors of heat ; the hood and metal sleeve adapted to move with the carbon as the latter is consumed.

Electric-Arc Lamp, N. M. Garland, 458,387. Filed Dec. 29, 1890.

Electric-Arc Lamp, N. M. Garland, 458,388. Filed Dec. 29, 1890.

Electric-Arc Lamp, N. M. Garland, 458,389. Filed May 18, 1891.
The three patents above are for improvements in amplification of the invention shown in No. 458,386 above.

Electric-Arc Lamp, H. W. Sander, 458,500. Filed May 4, 1891.
Employs carbon rods made in the form of an arc of a circle.

Medical and Surgical :—

Electric Uterine Supporter, G. F. Mohn, 458,536. Filed Mar. 26, 1891.

Metal Working:

Art of Electric Welding, H. Lemp, 458,176. Filed May 31, 1890.
Intended to secure improved contact between the clamps and the article to be welded. Employs a continuous layer or film of liquid between the clamps and the piece or pieces to be worked, thus excluding air.

Adjustable Electric Clamp, H. Lemp, 458,177. Filed Oct. 9, 1890.
For use in electric welding.

Electric Clamp, E. Rasmussen, 458,188. Filed Dec. 19, 1890.
For use in electric welding ; employs a yielding material of good conductivity between the clamps and work pieces.

Miscellaneous :—

Alternating Electric Current Heater, L. Gutmann, 458,163. Filed Dec. 9, 1889.
See The Electrical Engineer, August 26, 1891, p. 226.

Electric Coal-Mining Machine, E. C. Morgan, 458,184. Filed Sept. 15, 1890.
Employs an electric motor, a tubular tool-holder, and a spring partially enclosed by the tool-holder and interposed between it and the frame.

Electric Stop Mechanism, E. Boening, 458,278. Filed July 24, 1890.

Circuit Closer, P. D. Richards, 458,343. Filed Mar. 30, 1891.

Cut-Out, W. F. Irish, 458,396. Filed Sept. 15, 1890.

Railways and Appliances :—

Insulator, M. C. Chase, 458,221. Filed Nov. 14, 1890.
Specially adapted for supporting trolley wires.

Electric Power-Brake, C. V. Greenamyer, 458,242. Filed Dec. 2, 1890.
Specially adapted for use on railway cars as an emergency brake.

Motor Apparatus for Vehicles, R. J. Sheehy, 458,274. Filed Nov. 24, 1890.
Includes devices for storing the mechanical energy of the motor when it is not employed in driving the car, and means for applying such stored energy to assist in starting.

System of Electrical Propulsion for Vehicles, W. S. Richards, 458,377. Filed Jan. 19, 1891.
An induction system, avoiding the necessity for contact with the line conductor.

Support for Trolley-Wires, J. H. Palmer, 458,427. Filed Dec. 19, 1890.

Electric Signal and Switch-Moving Mechanism, J. Ramsey, Jr., E. W. Harden, C. M. Wilder, 458,489. Filed Feb. 5, 1891.
Electromagnetic devices for operating a switch rail, a signal or a gate.

Electric Motor, C. E. Egan, 458,545. Filed Nov. 28, 1890.
This patent is not for an electric motor, but is for devices for the application of batteries upon electric motor cars.

Telephones and Apparatus:—

Spring Jack Commutator for Telephone Switchboards, L. A. Berthon, 458,258. Filed Jan. 30, 1891.

Telephone, E. Noriega, 458,479. Filed Feb. 4, 1891.
In a telephone receiver employs a U-shaped magnet and two electromagnets facing the diaphragm.

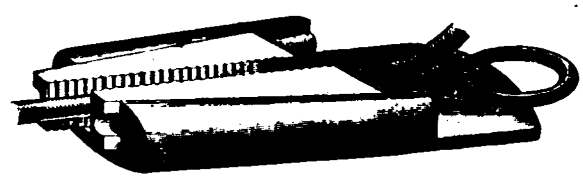
TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

The best "Come-Along" for holding trade is a good "Ad."

THE COPE AUTOMATIC "COME-ALONG."

We herein give an illustration of a device for holding or gripping electric and other wires and cables, invented by T. J. Cope, No. 8 North 6th street, Philadelphia. The most prominent claim for this "Come-Along" is that it does not break the insulation, but the simplicity of the tool and its self-acting, both in gripping



The Cope Automatic "Come-Along."

and releasing are features of merit. It consists of two parallel jaws, slightly corrugated on the inner sides and working loosely in two stationary supporting jaws in such a manner that when the wire or cable is placed between the loose parallel jaws and drawn, the jars are closed from mere contact to sufficient pressure to hold the cable or wire. It will be seen that there is no more pressure on the insulation or wire than is necessary to hold the same, and the direct pull and long jaws prevent twist or kink in the wire or breaking of the insulation, and is easily released by merely reversing the pressure on the tool.

ELECTRIC MINE HOISTS.

The Pleasant Valley Coal Company, of Salt Lake City, Utah, have for the past year at the Castle Gate Mine, in Utah, used a hoist or haulage drum, operated by electricity. The drum was made by the Lidgerwood Manufacturing Company, of New York, and the electric motor and the electrical equipment were furnished by the Thomson-Van Depoele Electric Mining Co., together with all the electrical apparatus for the power station.

Trains of sixteen large pit cars run out of the mine by gravity, dragging the tail rope after them. The empty trains are hauled back into the mine by the haulage drum located nearly 2,000 feet from the chute in the interior of the mine. The operation of this apparatus has proved so satisfactory and so economical that the company have ordered two more electric hoists of more powerful type.

In every way the electrical apparatus has been so satisfactory that for the Winter Quarters Mine, operated by the same company, they have ordered an electric locomotive and the equipment of nearly two miles of underground railway with the Thomson-Van Depoele system.

ENGINEERING EQUIPMENT CO.

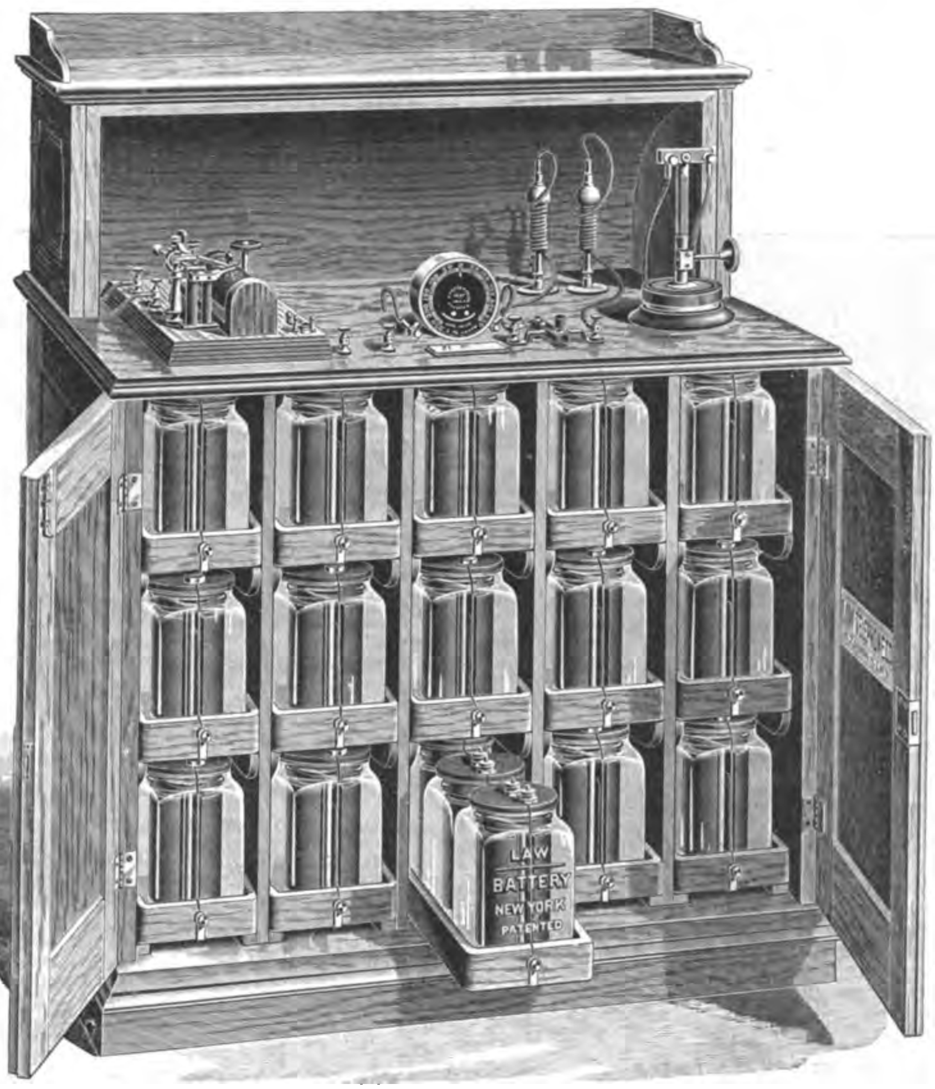
Among recent shipments made by the Engineering Equipment Co., general Eastern agents for the Boston trolley and Anderson's line materials, have been complete trolleys delivered at New York, McKeesport, Schenectady, Scranton, Buffalo, Chicago and Denver, Colo., together with poles, wheels, and other parts at Portland, Ore.; Ridgeland, Ill.; Colorado Springs, Butte City, Mont.; Pottsfield, Pa., Long Island City, McKeesport, Connellsville, Buffalo, Augusta, Ga., Dallas, Texas, and other places.

THE LAW ELECTRO-THERAPEUTICAL OFFICE OUTFIT.

THE accompanying illustration represents the new battery cabinet manufactured by the Law Telephone Co., of 85 John street, this city, for the use of physicians. On the left is seen the faradic coil; in the centre is the milliammeter, and close beside it, the pole-changing switch. On the right is the current regulator or controller. The two binding-posts at the right of the milliammeter are for use only with the galvanic current, and those at the left with the faradic, and are so marked.

The drawers in which the batteries are placed are arranged to hold four cells each, the connections from which are made through strips of metal on the bottom of the drawers to strips of metal on the slides, and the apparatus will not work unless the cells are correctly placed in the drawers and the drawers in the cabinet. The current from the zinc of the battery is led through a Bailey current-regulator to the polarity-switch, and the current from the carbon of the battery is led to the polarity-switch and thence to the milliammeter. The throwing of the polarity-switch changes the direction of the current, and the handle or knob of the polarity-switch indicates by its position which binding-post is positive.

The outfit is arranged with one red and one green cord for connecting the electrodes, thus permitting the physician to readily trace the positive current by means of the handle of the switch and the cord to the patient.



THE LAW ELECTRO-THERAPEUTICAL CABINET.

UNDERWOOD COTTON-LEATHER BELTING.

THE recent business on the Underwood cotton-leather belting shows a marked improvement over any previous record. The long list of large belts which is shown by the Engineering Equipment Company, the selling agents, gives strong proof of the large volume of business done lately in this excellent belting. Among the orders for large belts are the following: Willimantic Linen Co., seven belts; Schuyler Electric Co., Middletown, Conn.; Buffalo Street Ry. Co., several belts; Springfield, Mass., Electric Light and Power Co., one 66-inch belt, 128 feet long, and several others; Newark, N. J., Passenger Ry. Co., two belts; Fort Orange Paper Co., 38-inch and 40-inch belts; also many others in the United States and foreign countries. Besides this class of trade in the larger belts there has been a lively demand for smaller sizes of cotton-leather. All this speaks well for the growing reputation of the belting made by the Underwood Manufacturing Co. It is probably generally known that the first leather belt made in this country was manufactured by Henry Underwood. The Engineering Equipment Company, contractors for steam and electrical equipment materials, represent the Underwood interests at 143 Liberty street, New York, and 126 Pearl street, Boston.

THE CORLISS STEAM ENGINE CO.

THE above company, of Providence, R. I., have favored us with a framed albertype picture of their latest improved Corliss engine of the single cylinder type. It is a very handsome piece of work, and makes a neat ornament for an office. The engine itself is a model of strength and beauty.

NATIONAL TELEPHONE MANUFACTURING CO.

AT the annual meeting of the stockholders of the National Telephone Manufacturing Company, held at Portsmouth, N. H., the following board of directors were elected: S. K. Roberts, Woodward Emery, L. B. Russell, James D. Leatherbee and John B. Bennet. The report of the treasurer showed that the company could pay all of its indebtedness with a handsome surplus, besides holding nearly 10,000 shares of stock in the treasury.

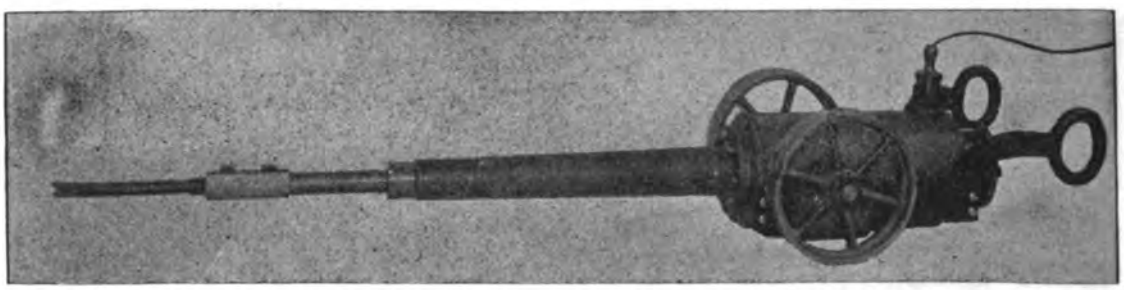
THE VAN DEPOELE SOLENOID COAL CUTTER.

IN some grades of coal it is found desirable to make the under cut with a machine concentrating its power upon a single reciprocating shaft, carrying a chisel at its extremity. This type of cutter or drill is very compact and is controlled by one man, the direction of the blow being varied as occasion demands. Several machines of this type, operated by steam or compressed air, are on the market, and are in many ways satisfactory, but the application of electricity as the motive power possesses many decided advantages.

The illustration shows the Van Depoele solenoid coal cutter, manufactured by the Thomson-Van Depoele Electric Mining Co., of Boston. The type shown is the present standard form, though modifications can be made to suit special requirements. The operation of the cutter may be easily understood from an inspection of the illustration, and no extended explanation is required. The direction of the blow is determined by the operator, who sits on the floor facing the breast, his feet resting against the wheels, and his hands grasping the handles at the rear of the cylinder, thus obtaining a double leverage, by which the machine, being almost exactly balanced, is easily turned on its points of support.

A simple switching device turns the current on or off, as desired, while lights, pumping apparatus, electric ventilators, etc., may be run on the same system of wires which supply power to the coal cutter, if desired.

The weight of the apparatus is a little over 700 pounds, the number of strokes usually from 300 to 350 per minute, although the rapidity of the blow can be varied at pleasure. The stroke is from five to six and one-half inches. The tension guide is made in different lengths, according to the depth of undercut desired.



VAN DEPOELE SOLENOID COAL CUTTER.

THE MONTREAL CONVENTION.

ALL the arrangements have now been perfected for the convention, and there is every prospect of a most successful meeting. In view of the misery that has often been experienced by delegates through the poorness of the hotel accommodations, it is some satisfaction to know that this time the Association has the advantage of enjoying as its headquarters a hotel of such well-deserved reputation as the Windsor. It is not often that so large a gathering of Americans is seen at a Canadian hotel, and the management is on its mettle to show that the Windsor cannot be surpassed, if equalled, even in the United States, in studying the comfort and welfare of its guests and in lavishly providing for every want of the traveler.

NEW ENGLAND TRADE NOTES.

BEACON VACUUM PUMP AND ELECTRICAL COMPANY.—Mr. Heilborn, of this company, is still in Europe, and reports that the Beacon Vacuum Pump is attracting much attention among the European manufacturers of incandescent lamps. Several of these companies are now negotiating with him for the use of the pump for lamp purposes, and Mr. Heilborn has been requested to prolong his visit for the purpose of consummating some arrangement with them. The European lamp companies have already had numbers of samples of lamps exhausted by the Beacon pump, and state that they are as good as, if not better than, they require. The Beacon Pump Company are diligently at work on a meter, the invention of Mr. William Edson, which will soon be ready to put on the market. It has been fully tested and pronounced a success.

S. C. NIGHTINGALE & CHILDS, of Boston, New England agents for the magnesia sectional covering, report that they have just received orders to cover with plastic magnesia the 27 engine cylinders, the nine air-pump cylinders, 18 receivers, and nine sets of connecting pipes between the cylinder and the receivers, of the nine large triple-expansion engines now being set in place by E. P. Allis & Company, of Milwaukee, for the West End Street Railway Company, of Boston. The steam cylinders will be coated with magnesia, 1¼ inches thick, the receivers 1¼ inches thick, and the piping one inch thick. Magnesia is surely coming forward as the most reliable protection against radiation of heat.

WHITMAN & ROBINSON have now got comfortably settled down in convenient quarters at No. 133 Essex street, Boston, and have got a very complete laboratory of electrical instruments for all kinds of electrical testing and calibrating. They have already expended a large sum of money on these instruments, and when the laboratory is completed they will be well equipped for making the most elaborate tests. They have recently made a specialty of acting as consulting electricians for cities looking toward municipal lighting, and have just completed an elaborate set of tests on the arc lights of the city of Haverhill for the city authorities.

THE EDISON GENERAL ELECTRIC COMPANY, through their Boston office, have closed a contract with the town of Waterville, Me., for a municipal plant of 100 arc lamps. They are also engaged installing a small central station at Charlton City, Mass., and are at present installing a very fine plant in the St. Paul School, at Concord, N. H.

THE HOLTZER-CABOT ELECTRIC COMPANY have now got thoroughly settled down in their new quarters at No. 92 Franklin street, and have fitted up a very handsome suite of offices and show-room on the second floor, measuring 80 feet by 40 feet. On the floor above they have another room of the same size, conveniently fitted out as a stock-room. Their business has been steadily increasing for the past year, and they will now be better able to handle it with promptness and care, as well as having pleasant offices for their patrons to visit.

MR. H. A. CLEVERLY, of Philadelphia, was in Boston this week calling on his numerous friends. He has been recruiting for a week or so after his arduous labors at "The" Clambake.

WESTERN TRADE NOTES.

OKONITE VS. KERITES.—The much-talked-of ball game between the Okonite Baseball Club, composed of employés of the Central Electric Company, and the Kerite Club, made up of the pick of the Western Electric Company, of this city, was played at Lincoln Park, Chicago, on the 15th ult., and resulted in a victory for the Okonites by a score of 11 to 7. The feature of the game was the invincible battery of Messrs. Cushing and Stacey. The Kerites played a very brilliant game, but did not seem to be able to "get on" to the tough curves and high-tension pitching of the Okonites.

THE W. D. GRAVES ELECTRICAL AND MANUFACTURING CO., manufacturers of the Graves Multiplex Arc Lamp, of Cleveland, O., have secured an order for two 15 h. p. C. & C. motors from the *Cleveland World* for operating their two large printing presses. These presses are capable of turning out 14,000 copies per hour. They have also installed another 15 h. p. motor in the Union Gospel News Co. for similar work.

THE ELECTRIC MERCHANDISE COMPANY, of Chicago, will be "at home" in parlors 14 and 16 Windsor Hotel, Montreal, during the convention, and will be represented by Messrs. D. B Dean and W. R. B. Wilcox. An exhibit of some specialties in line material will be made, and also some sets of the Burton Electric Heater will be shown in operation.

☞ ***Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Miscellaneous, etc., will be found in the advertising pages.***

THE

Electrical Engineer.

VOL. XII. SEPTEMBER 9, 1891. No. 175.

THE FRANKFORT INTERNATIONAL ELECTRICAL EXHIBITION—VII.

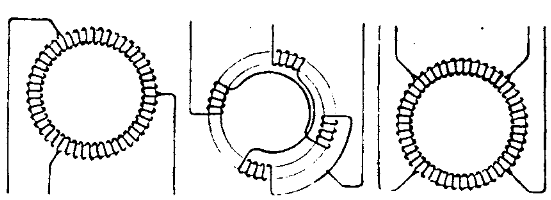
BY

Richard O. Heinrich.

The Multiphase Alternating Current.

TO all appearances the contracting parties for the Lauffen transmission will keep their word. At this writing the report comes that the line is completed and all the machinery in place. The 16th and 17th of August are to be devoted to experimental trials, and before this article has reached the other side the cable will have announced the fact, for which every electrician is looking with intense interest, whether this great scheme is a success or not.

The idea is rather a neat one, in which the perfect cycle of conversion of energy will be illustrated. The power is taken from the Neckar-Falls, at Lauffen, is converted into electrical energy, and is transmitted to Frankfort, where the electric motor is intended to drive a centrifugal pump. This pump will lift a steady stream of water to the top of a ledge of artificial rocks, being, as it were, a part of the original power, rushing down over a steep incline made of



FIGS. 1, 2 AND 3.

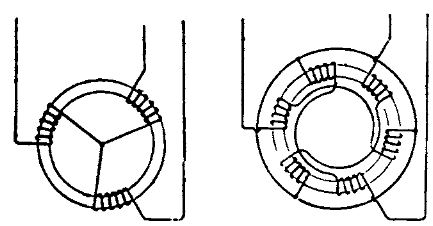
glass plates, illuminated from below from the same source of electrical energy.

It may be well to say a few words about the principle of this multiphase alternating current as applied to motors. Those who have read the articles of Mr. Tesla on his different types of alternating current motors will find old acquaintances in many respects. In fact, the subject is not at all a new one.

By way of explanation we will say that the coils on the armature of an alternating current machine are divided into a number of sections, so that between the coils of each section there exists separate electrical connection. The way in which this may be effected is shown in Figs. 1 to 5.

It is evident that we obtain as many successive current impulses as there are sections in the armature, as represented by the curves of Figs. 6 and 7. In the case of three sections the current wave II. is increasing when I. is decreasing, and III. is increasing from 0 to a maximum when II is decreasing and I. is attaining a negative maximum.

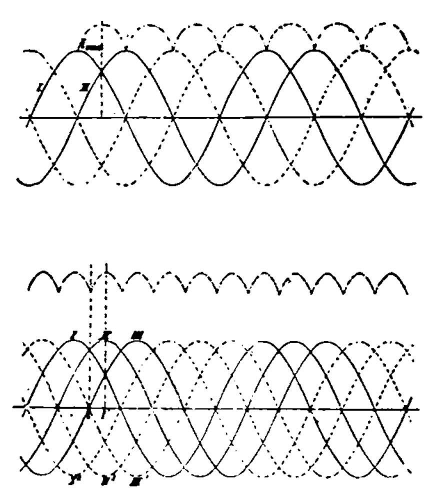
To use this three-phased current with a system of transformers it is only necessary to have three leads, if we arrange the primaries of the transformers as shown in diagram in Fig. 8. The primary of transformer A is traversed by currents over the leads III., II., from the first section of coils on the armature, B from the second section, and C from the third. The lead I. goes to the common junction of the primaries of transformers B and C. Wire III. is then the common lead for current impulses from the end of the first section of coils and the beginning of the second section; wire I. from end of second section and beginning of the third; and II. from end of third section and beginning of the first section. The same order prevails for the secondaries of the transformers.



FIGS. 4 AND 5.

If we follow the current impulses through the branches I., II., III., and 1, 2, 3, Fig. 8, and compare with Fig. 7, we shall find that in no part of the circuit do the current impulses act against each other. If we consider the magnetization in this three-part transformer, we find that, if the current increases in transformer A, the magnetization increases also; after having passed their maximum both current and magnetization decrease in transformer A, but increase in transformer B; finally the magnetization increases in C when that of B decreases and that of A attains a negative maximum. We may say that the magnetization travels from A over B to C and to A again, etc.

The same would be the case if we send this current into the armature of a machine similar to the generator. The polarity of this armature will continuously be changing in



FIGS. 6 AND 7.

a cycle around the armature and hence the name rotary current (Drehstrom), which was given to the arrangement by Herr von Dolivo-Dobrowolsky, of the Allgemeine Elektricitäts-Gesellschaft.

Herr von Dolivo-Dobrowolsky, however, makes claim to a distinction between his invention and that of Tesla, Ferraris, Haselwander, Bradley and others. Where only two or three phases are used, he speaks of an "elementary rotary current." In his own system more than three phases are used in general, so that his motors are driven by alternating currents of a very small difference of phase, using however only three leads for distribution. I shall describe the details of his system in the account of the Lauffen transmission.

In describing his invention, Herr von Dolivo-Dobrowolsky points out that the sum of the effects of a number of alternating currents displaced towards each other in their phases is not constant. Consequently the intensity of the magnetization is not constant, but more or less pulsating. He states, for example, that with two currents with a phase difference of 90° the pulsations amount to 40 per cent; with three currents of 60° phase difference, to about 14 per cent.; the magnitude of these pulsations decreases therefore very rapidly with the number of phases used. As long as the alternating current motor runs in synchronism, the effect of these pulsations is not injurious, but the efficiency of the motor is decreased considerably, if it does not run in synchronism. It is claimed as an advantage for the rotary alternate current motor that it runs with good efficiency without synchronism; in fact, they will always begin to rotate with considerable force as soon as the circuit is closed, and do not stop with suddenly increased load. But a pulsation of the magnetic field produces very strong induced currents in the field-winding of the motor, which is closed upon itself, and these induced currents have a retarding and braking effect and cause a loss of energy.

Three systems of multiphase alternating current are represented at the exhibition, namely, that of Schuckert & Co.,

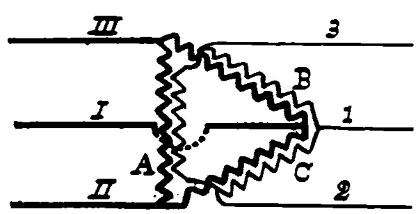


FIG. 8.

Nuremberg; Lahmeyer & Co., Frankfort (Haselwander patent); and the Allgemeine Elektricitäts-Gesellschaft, Berlin (Dolivo-Dobrowolsky).

Little information can be gained regarding the efficiency, advantage and disadvantage of the different systems, and it is to be hoped that the examining committee will throw some light on this subject. Under the circumstances I am only enabled to give a short description of the machinery used in the three systems, supplemented by some data supplied by the manufacturers.

The system of Schuckert & Co. would, strictly speaking, not come under the head of rotary current apparatus. The reason that I describe it in connection with the systems of this class, and take it up first, is that I consider Schuckert's system as a transition from the ordinary alternating current to multiphase alternating current.

The dynamo for the generation of the two-phase alternating current is identical in general appearance and construction with the continuous-current dynamo of that firm; the difference lies in the connection of the armature coils and the addition of four collector rings, shown on the left of the left-hand bearing of the machine, Fig 9. Fig. 10 illustrates the connection of the armature coils. The armature is a flat Gramme ring, and connections of the coils are made, as ordinarily, with corresponding commutator bars. Besides this, however, connections are made from four symmetrically situated points with the four collector rings, Figs. 10 and 11. In this respect the machine resembles a self-exciting alternating current machine, with the difference, however, that two alternating currents are obtained with a phase difference of 90°, represented by the curves of Fig. 12. In this way the efficiency of the machine as an alternating-current generator is greatly increased. If the continuous current machine were to be used as an alternating-current generator by omitting the commutator and substituting only two collector rings, the efficiency of this alternator would be about 30 per cent. less than it would be if used as a continuous-current machine. With this

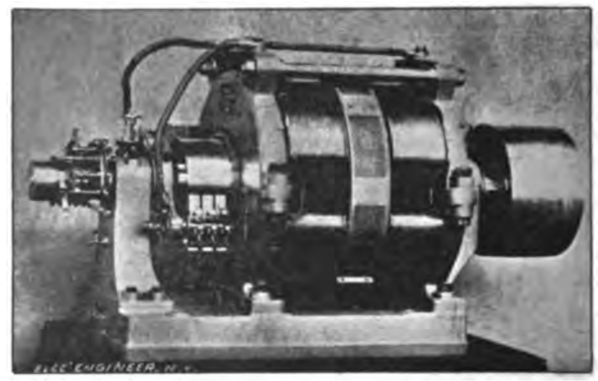

FIG. 9.—SCHUCKERT DYNAMO FOR MULTIPHASAL CURRENT.

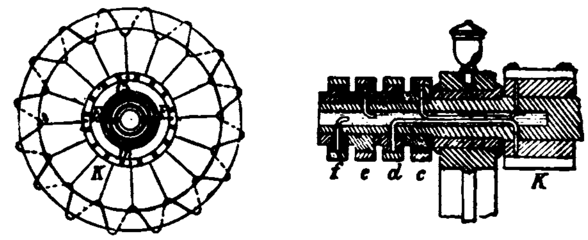
combination of commutator and collector rings, nothing is changed in the machine; it may be used as a continuous-current machine, or it may deliver alternating currents for one or two circuits, and continuous current for a third one at the same time.

It is evident from what has been said before that we obtain an electric motor if we send this two-phase current into the armature of a machine similar to the generator. The armature of this machine, if fed with this two-phase current, will begin to rotate by means of the cyclic shifting of the magnetic polarity around the ring and the corresponding action of the iron of the field magnets, magnetized by induction. As soon, however, as the field magnets of the machine are excited by a continuous current and the motor runs synchronously a current is generated in this armature; in fact, it is a generator-motor, since it is immaterial whether the armature is rotated in a magnetic field by means of a belt and pulley or by means of a current. It is not necessary that the motor run in synchronism, although it will attempt to attain synchronism. If the field were to be excited with alternating current it would necessitate its being constructed of laminated iron,



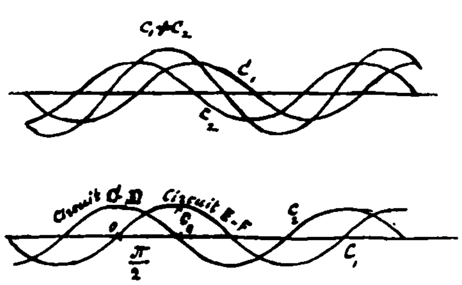
FIGS. 10 AND 11.—SCHUCKERT MULTIPHASAL ARMATURE AND COMMUTATOR.

and there would besides be a considerable loss of energy in the frequent change of magnetization. The field is, therefore, excited by continuous current, either from a separate source or directly from the commutator of the machine. This excitation, however, should only begin when the motor runs in synchronism. A very simple way of determining this point of synchronism is adopted by Schuckert & Co. As long as the motor runs without synchronism a current is induced in the field winding, since the magnetic circuit of the lines of force emanating from the armature takes place through the air or through the iron of the field magnets, corresponding to the respective position of the armature-polarity and the field magnets. Consequently, a voltmeter in the field-magnet circuit will show a large deflection as long as the motor is far from synchronism; this deflection decreases as the motor approaches synchronism and is zero with perfect synchronism. At this moment the brushes are placed on the commutator and the motor becomes self-exciting.

This construction gives a great flexibility to the system, and the machine may serve for the following purposes:

1. As a continuous-current machine. 2. As a self-exciting alternator, furnishing alternating currents of one phase or of two phases with 90° displacement. 3. As a continuous-current motor. 4. As an alternating-current motor. 5. As a transfomer of continuous current into alternating currents and *vice versa*. Using the machine as a continuous-alternating current transformer, the result will be as shown in Fig. 13. The current generated in the armature is displaced in its phase 45° towards the phases of the two primary alternating currents and its intensity will be $= c_1 + c_2$, and therefore 1.4 times as great as any one of the primary currents. The direction of rotation is determined by the position of the leads and may be changed at will, if the connections of one circuit are kept and the connections of the second circuit are interchanged.

Schuckert's system is exhibited in two places. One is the short transmission of 50 h. p. from a two-phase alternator in Machinery Hall to a synchronizing motor which drives the centrifugal pumps for the water-fall of the grotto. The field of this motor is separately excited, so that the motor is precisely like the generator, with only four collector rings, as shown in Fig. 14. Narrow double brushes are used on the collector rings, so that these rings may be made narrow. Since the distance of transmission is short, transformers are not used; without the use of transformers 4 leads are necessary for transmission. The generator makes 330 revolutions per minute, and furnishes for each of the two circuits 35 amperes at 550 volts pressure. The transmission from the "Palmengarten" ($\frac{3}{4}$ miles from the exhibition) to the exhibition is intended to illustrate a central power and light station in connection with long-distance distribution, for the special case where water power is available at some distance from a city. Generator and motor-transformer for this purpose are illustrated in Fig. 9. The generator is a self-exciting two-phase alternator, slow speed, running very smoothly and quietly; this is the case with all of Schuckert's machines, and is so marked that it requires close inspection to see whether the machine is running or not. From the four collector rings the current is taken at 80 volts pressure by



FIGS. 12 AND 13.

four leads to a step-up ring transformer, as described in THE ELECTRICAL ENGINEER, August 5, p. 133. The transmission to a step-down transformer at the distant station is made at 1,600 volts pressure, only three wires being necessary, the third wire serving as a common return for the two currents; it is also proposed to use only two cables and have the lead casing of the cables for the return circuit. Four leads go from the secondaries of the step-down transformer to the four collector rings of the motor generator, which runs in synchronism with the first generator. In the machine exhibited only continuous current is taken from the commutator of the motor generator, part being used to excite the field magnets, part to drive seven smaller continuous-current motors in the workshops of the exhibition and part for illuminating purposes. Alternating current of high and low voltage could also be used directly. As mentioned before, generator and motor run very noiselessly and the transformers do not hum. The flexibility of the system is well shown, so that it only remains to prove the efficiency of the transmission and transformation.

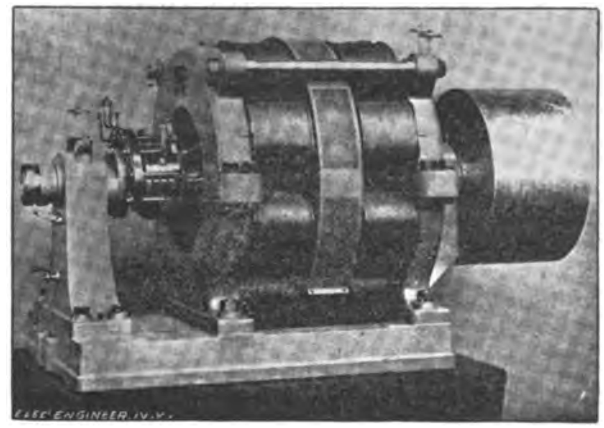


FIG. 14.—SCHUCKERT MULTIPHASAL CURRENT MOTOR.

THE LOCALIZATON AND REMEDY OF TROUBLES IN DYNAMOS OR MOTORS.—I.

(*Copyright.*)

BY

PROF. FRANCIS B. CROCKER

AND

DR S. S. WHEELER.

THE promptness and ease with which any accident or difficulty with electrical machinery may be dealt with, whether by the inspector of construction or by the operator in charge of running, will always have much to do with the success of the plant and of those dependent upon it. It is therefore likely that any method to eliminate or reduce these troubles would be very welcome to those handling dynamos and motors. With the object of obtaining such a method, we have prepared a list of troubles, symptoms and remedies, based upon quite an extensive experience with the various types and sizes of dynamos and motors in common use.

It is evident that this subject is somewhat complicated and difficult to handle in a general way, since so much depends upon the particular conditions in any given case, every one of which must be included in the table in such a way as to distinguish it from all others. Nevertheless, it is quite remarkable how much can be covered by a systematic and reasonably simple statement of the matter, and we feel confident that nearly all of the cases of trouble most likely to occur are covered by the table, and that the detection and remedy of the defect will result from a proper application of the rules given.

It frequently happens that a trifling oversight, such as allowing a wire to slip out of a binding-post, will cause as much annoyance and delay in the use of electrical machinery as the most serious accident. Other troubles, equally simple but not as easily detected, are of frequent occurrence. In such cases a very slight knowledge on the part of a man having the machine in charge, guided by a correct set of rules, will enable him to overcome the difficulty immediately and save much time, trouble and expense.

It must not be supposed that this method for treating dynamo and motor troubles is given because these machines are particularly liable to such difficulties. On the contrary, no machine in existence is mechanically simpler than the dynamo or motor. The only wearing parts about the machine, with the exception of the commutator and brushes, which are specially made to stand almost unlimited wear without interfering with the action of the machine, are the two bearings. In this respect, therefore, the dynamo or motor is as simple as an ordinary grindstone, and infinitely simpler than a steam engine, which often has a dozen or more oil cups and several dozen wearing parts. Even a sewing machine is far more complicated mechanically than any dynamo or motor. In fact, it would be useless to attempt to give a method for detecting and curing dynamo and motor troubles if it were not for the fact that these machines consist of very few parts, which makes it reasonably possible to locate the trouble.

The rules are made, as far as possible, self-explanatory, but a statement of the general plan followed and its most important features will facilitate the understanding and use of the table.

USE OF THE TABLE OF TROUBLES.

In the use of this table the principal object should always be to clearly separate the various causes and effects from each other. A careful and thorough examination should first be made, and as far as possible one should be perfectly sure of the facts, rather than attempt to guess what they are and jump at conclusions. Of course general precautions and preventative measures should be taken *before* any troubles occur, if possible, rather than wait until a difficulty has arisen. For example, see that machine is not overloaded or running at too high voltage, and make sure that the oil cups are not empty. Neglect and carelessness with any machine are usually and deservedly followed by accidents of some sort.

The general plan of the table is to divide all dynamo and motor troubles which are liable to occur into eight classes, the headings of which are the eight most important and obvious bad effects produced in these machines, viz :

No. 1. Sparking at Commutator.
No. 2. Heating of Armature.
No. 3. Heating of Field Magnets.
No. 4. Heating of Bearings.
No. 5. Noise.
No. 6. Speed abnormally high or low.
No. 7. Motor stops or fails to start.
No. 8. Dynamo fails to generate.

Any one of these general effects is very obvious, even to the casual observer, and still more so to any one making a careful examination, and every one of these effects is perfectly distinguishable from any of the others without the least difficulty. Hence, this classification is perfectly definite and makes it easy to tell, almost at the first glance, under which one of these heads any trouble belongs, thereby eliminating about seven-eighths of the possible cases. The next step is to find out which particular one of the six or eight cases in this class is responsible for the trouble. This, of course, requires more careful examination, but, nevertheless, can be done with comparative ease in most cases. Of course one cause may produce two effects, and, vice-versa, one effect may be produced by two causes ; but the table is arranged to cover this fact as far as possible. In a very complicated or difficult case it is well to read through the entire table and note what causes can possibly apply, and they will generally not be more than two or three, then proceed to pick out the particular one by following the directions which show how each case may be distinguished from any other. The table is intended for the use of those who build, test, install, own or operate electrical machinery, and all statements apply equally well to both dynamos and motors, unless otherwise specially noted.

SPARKING AT COMMUTATOR.

1. Cause.—*Armature carrying too much current*, due to (*a*) overload (for example, too many lamps fed by dynamo, or too much mechanical work done by constant potential motor); or (*b*) excessive voltage on a constant potential circuit or excessive amperes on a constant current circuit. In the case of a motor on a constant potential circuit, any friction, such as armature striking pole-pieces or shaft not turning freely, will, of course, have the same effect as overload in producing excessive current. The armature of a motor on a constant-current circuit does not tend to heat more when overloaded, because the current and the heat it produces in the armature (C^2R) are constant. In fact, armature can be stopped with full current without injury except loss of ventilation.

Symptom.—Whole armature becomes overheated and belt very tight on tension side and sometimes squeaks, due to slipping on pulley. Overload due to friction is detected by stopping machine and then turning it slowly by hand. See Heating of Bearings and Noise, No. 2.

REMEDY.—(*c*) Reduce the load; (*d*) decrease the size of driving pulley, or (*e*) increase the size of driven pulley; (*f*) decrease magnetic strength of the field in the case of a dynamo or increase it in the case of a motor. If excessive current cannot satisfactorily be overcome in any of the above ways it will probably be necessary to change the machine or its winding. Overload due to friction is eliminated as described under Heating of Bearings and Noise, No. 2.

2. Cause.—*Brushes not set at the neutral point.*

Symptom.—Sparking varied by shifting the brushes with rocker arm.

REMEDY.—Carefully shift brushes back and forth until sparking is reduced to a minimum. This may be done by simply moving the rocker-arm, provided the brushes are set so as to touch diametrically opposite points on the commutator. If the brushes are not exactly opposite they should be made so, the proper points of contact being determined by counting the commutator bars or measuring with a piece of string or paper.

THE ELECTRIC LIGHTING OF ODESSA HARBOR.

The Odessa Harbor electric lighting plant, constructed by the Thomson-Houston International Electric Company, was taken over on July 8 by the Russian Government. There are in regular working sixty-four 2,000 c. p. arc lamps and eight 125 c. p. incandescent lamps. The arc lamp-posts vary in height from 43 feet to 30 feet. There have been used about 10 miles of armored cable, manufactured by Felten and Guilleaume, and also about 1,000 yards of submarine cable 126 sq. mm. in cross-section, steel-wire armored. Where the submarine cable joins the land cable a Thomson-Rice cut-out is placed, allowing the cutting out of the submarine cable in case of fault. The generating plant consists of four 35-light series-wound arc dynamos, driven by belting from two central-valve condensing Willans & Robinson high-speed engines. The two boilers are supplied by the Babcock & Wilcox Company.

ELEMENTARY GEOMETRICAL THEORY OF THE ALTERNATE-CURRENT TRANSFORMER.—XIV.

BY

Chas. Steinmetz.

IX. Magnetic Susceptibility and Saturation.

In the former chapters we have followed the phenomena going on in transformers, either when acted upon in the

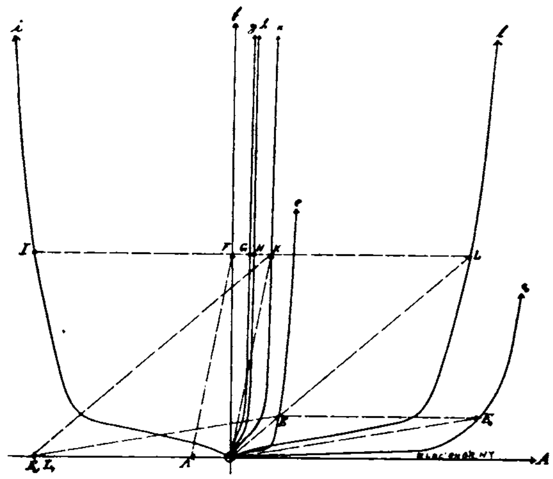

FIG. 27.

primary circuit by *constant potential*, or by *constant current*. We have determined the conditions, which must be fulfilled in a well-designed transformer, and have considered the *changes* which take place, when *one*, or a part, of its constants are changed, thereby showing its admirable ability of *compounding*, for *constant secondary* E. M. F. as well—when connected into a constant potential primary circuit—as for *constant secondary current*—in a circuit of constant effective strength of primary current.

We have shown the influence of *self-induction* and of *magnetic leakage*, and have also taken into consideration the phenomena caused by *eddy-currents*, and by *hysteresis*, and their representation in the *polar-diagram of alternate currents.*

But in all the former diagrams we still maintained one assumption, which, though it is for simplicity's sake nearly always made, nevertheless is very far from being true, as it holds only within narrow limits.

We have supposed that the induced E. M. F.'s, E_1 and E_1, are proportional to the resulting M. M. F., F, by the equation,

$$E_1 = \frac{2 \pi n^2 N F 10^{-8}}{P},$$

that is, that the magnetism M is proportional to the M. M. F., F, by the equation, $M = \frac{F}{P}$, where the magnetic resistance (reluctance), P, is a *constant* of the magnetic circuit, independent of the magnetization, and determined by the equation, $P = \frac{\rho\, l}{q} = \frac{l}{\mu\, q}$ where, $\mu = \frac{1}{\rho}$ is the *magnetic susceptibility*.

But the magnetic susceptibility of the iron is not at all constant, but on the contrary, very variable; it is a minimum for very low magnetization, increases up to a maximum for medium magnetization, and decreases again, when *saturation* sets in, until for enormously high M. M. F.'s it is almost as poor as that of air.

For instance, the magnetic susceptibility of *air* assumed as *unity*, the susceptibility of good sheet-iron for low magnetization—13,000 lines of magnetic force per square inch—is about equal to 1,100, rises to a maximum of 1,800 for medium magnetization—40,000 to 50,000 lines per square inch—and decreases again, reaching 260 for a magnetization of about 100,000 lines per square inch, decreasing still further for higher magnetization. Ewing followed its decrease up to magnetizations near 300,000 lines per square inch, and found the susceptibility there nearly 2.

All the high-frequency transformers, as for instance the Westinghouse converter, must, because of the loss of energy due to hysteresis, work with a magnetization which is still far below the point of maximum susceptibility, corresponding to a susceptibility of about 1,500 (test).

It is impossible to assume as constant, a coefficient which is as variable as the magnetic susceptibility μ. Hence we have to introduce into the transformer-diagram the *variability of magnetic susceptibility*, that is, of *specific magnetic resistance.* To do this, first the dependence of the magnetic susceptibility of that iron, which is intended to be used, upon the magnetomotive force, that is, the magnetizing current, has to be determined. This is the "*characteristic curve of the iron.*"

A large number of such curves are given by Hopkinson, Ewing and others. They are generally determined by means of the *ballistic galvanometer*. But their determination should be carried out under the same conditions that are met with in transformers, that is, by means of *alternate currents*, by building up a closed magnetic circuit of known length and cross-section of iron, sending alternating currents around the wire coil surrounding the magnetic circuit, and computing, from the measured counter E. M. F. of self-induction of the wire coil, its known number of turns and the frequency of the alternate current, the maximum magnetizations corresponding to different values of magnetizing alternate current.

This way of determination has the advantage of making the result entirely independent of the difference of "*rising*" and "*decreasing*" magnetism, because it corresponds to the value of magnetic conductivity for the maximum

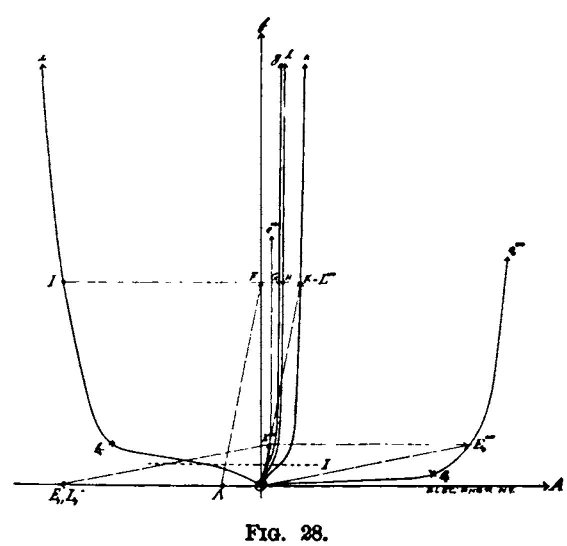

FIG. 28.

point of the complete magnetic cycle, that is, just that value which we need in designing transformers.

Besides, this method is the most convenient and quickest working for determinations of magnetic susceptibilities, and best suitable for use in factories. For use in designing transformers, and considering the phenomena therein, we produce the characteristic curve of the iron in a somewhat different shape. The *induced* E. M. F., denoted I, is proportional to the *magnetism* M, by the equation,

$$I = 2\, \pi\, n\, N M\, 10^{-8}.$$

The *magnetism* M, depends upon the M. M. F., F, by the "characteristic curve," $M = f\,(F)$. Hence we can produce the characteristic curve as the *dependence of the induced* E. M. F., *I*, *upon the resulting* M. M. F., *F*,

$$I = 2 \pi n N f (F) 10^{-8}.$$

Such a curve is shown in Figs. 27 and 28, as *i*. There the horizontal distances, $I = \overline{FI}$ of the points of the curve, *i*, from the vertical line, *f*, give the *induced* E. M. F.'s, the vertical line, $F = \overline{OF}$ the corresponding M. M. F.'s.

A NEW GALVANO-PLASTIC PROCESS FOR GIVING TO NON-CONDUCTORS A CONDUCTING COATING.

A NEW process has been proposed in Berlin by R. Falk, says the London *Electrical Review*, the object being the deposition of a conducting layer or envelope upon the surface of bodies which do not conduct electricity of themselves. The substances experimented with successfully include wax, gutta-percha, wood, plaster, paper, fabrics, glass, &c., and it is stated that flowers, anatomical preparations, the bodies of insects, &c., have been successfully dealt with. The essential features of the process consist in dissolving a salt of silver, such as the nitrate, chloride, bromide, &c., in collodion or in a solution of gelatine, albumen, varnish, or other similar substance. Into the solution thus prepared are immersed the objects to be galvanized, or these objects may be painted over with the solution. When the objects have been thus prepared they are treated with a solution of sulphate of iron, or pyrogallic acid, hydroquinone, ammoniacal copper oxide, &c., substances which will reduce the silver salt to the metallic condition. A fine pellicle thus coats the object, and scattered through this pellicle the metallic silver which has been reduced, and which thus confers upon it conducting powers. All that now remains to be done is to coat the objects with any desired metallic deposit according to any well-known method.

THE TESLA-FERRARIS CONTROVERSY.

IN our issue last week we gave the facts relating to this controversy, stating reasons for our belief that Mr. Tesla is fully entitled to the credit of priority in the discovery and application of the rotating field principle. We are glad to note the following from *Industries* of August 21, that paper having been the first to acquaint the English-speaking world with the work of Prof. Ferraris :

"There has been considerable discussion as to who really invented double and triple current work. The credit seems to lie between Mr. Tesla and Professor Ferraris. The former patented a practical and commercial motor on that principle, and surely he should have the full credit of the invention. We think Mr. Tesla has done far more to make it a practical success than any one, and we hope he will get, not only full credit, but something more substantial than abstract credit as well. At any rate, the invention was not English. Such modifications as using closed coil armatures or triple currents with three wires may be great improvements or not, but they can, in comparison, never rank as original inventions."

Judging from the concluding sentence quoted above, it would seem that our contemporary is still unacquainted with the full scope of Mr. Tesla's work.

FIG. 2.—DYNAMO ROOM, BRUSH ELECTRIC LIGHT STATION NO. 2, BUFFALO, N. Y. (See page 279.)

THE BRUSH ELECTRIC LIGHT STATION AT BUFFALO, N. Y.

C. R. Huntley.

THE fact that the president of the National Electric Light Association, Mr. C. R. Huntley, is secretary and general manager of the Brush Electric Light Co., at Buffalo, gives special interest to the station there, and we take the opportunity of presenting some views of the plant, with a vignette portrait of Mr. Huntley. The station shown is used entirely for arc lighting, but it deserves mention that the management is thoroughly committed to the idea of rendering whatever electric service may be called for, and is preparing for work on a larger and more comprehensive scale. The station is located at a convenient point for central distribution all over the

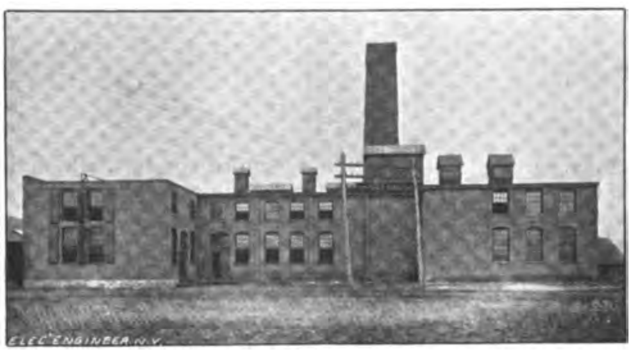

FIG. 1.—BRUSH ELECTRIC LIGHT STATION, BUFFALO.

company's territory, and is also advantageously situated for obtaining an ample supply of water for condensing purposes. Originally it was intended to operate the station by independent high-speed engines, but this plan was abandoned after a trial, and the large engine they now have was installed, the makers being Allis & Co. The en-

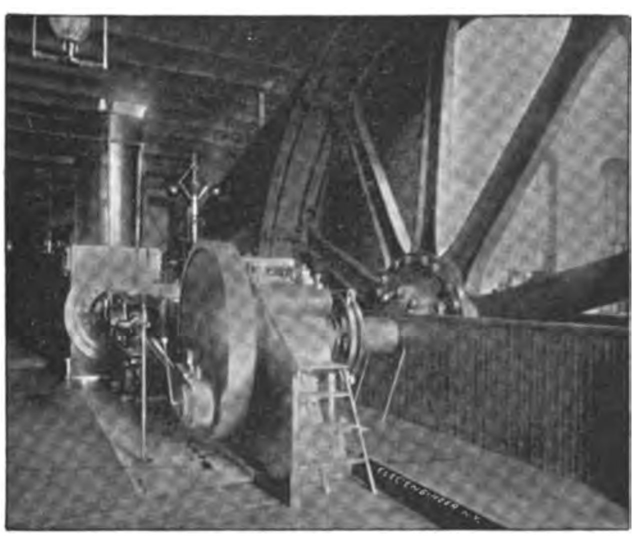

FIG. 3.—ALLIS-CORLISS ENGINE, BRUSH ELECTRIC LIGHT STATION, BUFFALO.

gine is attached to one end of the line shafting and is of the type known as the tandem compound. This line of shafting has 18 clutch pulleys, to which the dynamos are belted, all being upon the same floor, as shown. In this way each dynamo is under absolute control, and as independent as if connected to a separate engine.

As a general thing, the switchboard is one of the show-pieces of a station. At Buffalo, however, nothing special

FIG. 4.—BOILER ROOM, BRUSH ELECTRIC LIGHT STATION, BUFFALO.

is seen in this respect, but the company intends putting in a slate switchboard soon. As a whole, the station (known as the No. 2) is a very economical one. It was designed, and is run, simply for the purpose of making money. The company has avoided any extravagant engineering, and has built upon a common sense plan. There are many things about it that experience shows might have been done better, but, as a rule, those who visit the station commend it for its simplicity.

The boiler capacity of the plant is 900 nominal horse power. It is so arranged that the coal from the cars is thrown directly in front of the boilers, and they are thus able to have a supply of over 1,000 tons in front of the boilers at any time, and that with but a single handling.

The station is already being enlarged, and, as stated above, to accommodate 16 more dynamos, as well as another engine. This new engine will be of 1,500 h. p. and will be used alternately with the present engine. At the present time the company is lighting 1,298 arcs every night, and has a load also of 6,000 incandescents. This may seem a small incandescent business, but, so far, the electric light in Buffalo, is regarded as a necessity—not as a luxury nor as a medium for advertising.

THE THERMAL POTENTIAL FOR DILUTE SOLUTIONS.

IN a paper by E. Riecke in the *Annalen der Physik und Chemie*, the author discusses the thermal potential for dilute solutions. He calculates the potential for the components of a dilute solution, taking as his basis the fundamental equation due to Gibbs. He then applies his results to the consideration of the various phenomena that dilute solutions exhibit, and succeeds in deducing the various laws which govern the lowering of the vapor pressure, the depression of the freezing point, the dissociation of electrolytes, the distribution of a substance between two solvents, osmotic pressure, diminution of solubility and the absorption of gases. It is interesting to notice that the results thus obtained by Riecke from mathematical deduction are indentical with those which have been derived theoretically by other methods of reasoning, and also identical with those obtained experimentally.

MR. HOWARD FISK has been given charge of the steam and electric plant at the Leland Stanford University, Menlo Park, Cal.

THE LAKE SYSTEM OF ELECTRICAL CONDUITS IN WASHINGTON, D. C.

One of the first cities in the country in which the running of wires underground was made compulsory upon the companies was Washington, D. C., and among the very first to undertake the burying of electric light wires was the United States Electric Lighting Company, of that place. Starting in with a bitumen conduit, Mr. Miner Renshaw, the superintendent of the company, after protracted trials of various types of conduit, finally settled upon the Lake underground system of the Washington Conduit Co., a

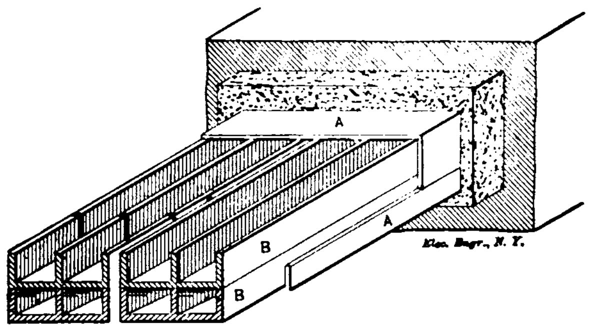

Fig. 1.

considerable amount of which is now in operation and has proved eminently satisfactory. The main idea embodied in this conduit is to provide a system which shall permit of the ready insertion and withdrawal of the conductors, while at the same time being of a nature such that its life is practically indefinite. Evidently a construction embodying only terra-cotta and concrete employed in a suitable manner fulfills these conditions exactly, and the manner in which these have been applied is shown in the accompanying illustrations. Here Fig. 1 shows a type of conduit designed for eight ducts. It is composed of ducts built up in two tiers of terra cotta in the shape of double troughs, the

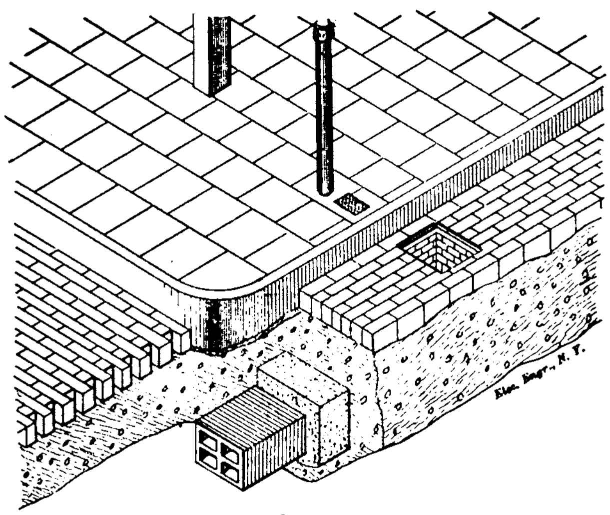

Fig. 2.

bottom of the upper forming the top of the lower. These ducts are covered above and below by a cover, A A. This is set in a bed of concrete, which also completely surrounds the ducts and keeps them firmly in position. A type of conduit with four ducts is shown in Fig. 2, which represents the hand-hole by which connection is made with the wires leading to the lamppost at the curb. The construction adopted where more conduits are required is shown in Fig. 3. Here the conduits are composed of four units of four conduits, each set in concrete as before. The joints between the consecutive lengths are effected by bracket-shaped pieces, D, Figs. 3 and 4, which clasp the conduits and which are held firmly in position by the concrete as it is rammed about them. The system has also been thoroughly provided with the various hand-holes and manholes necessary for getting at the wires, the manhole arrangements being illustrated in Fig. 5.

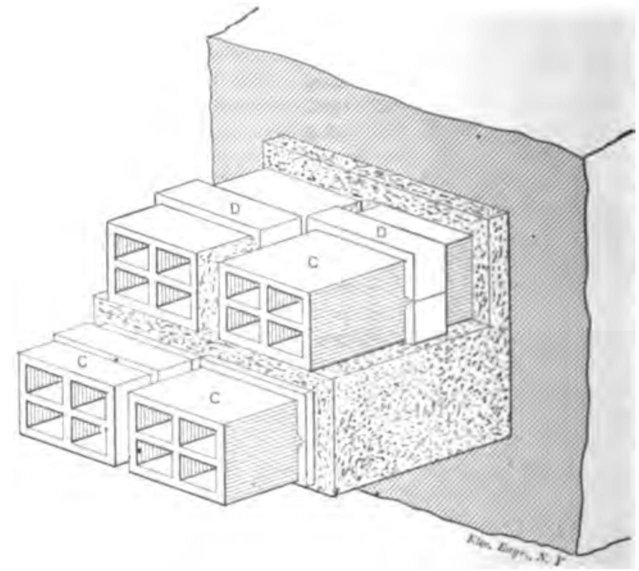

Fig. 3.

It may be mentioned that this form of conduit, which is the invention of Mr. Wilmot Lake, has not only been very successfully used in electric lighting, but is now being introduced in Washington for the telephone lines throughout the city. In fact, the conduit is highly approved of

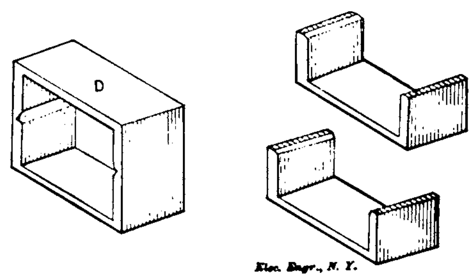

Fig. 4.

by all who have witnessed its operation there, and bids fair to find a very general appreciation all over the country. The United States Electric Lighting Co., in Washington, has 30 to 35 miles of it with a cable capacity of over 500 miles. The Chesapeake & Potomac Telephone Co. are now completing five miles with a cable capacity of at least 250

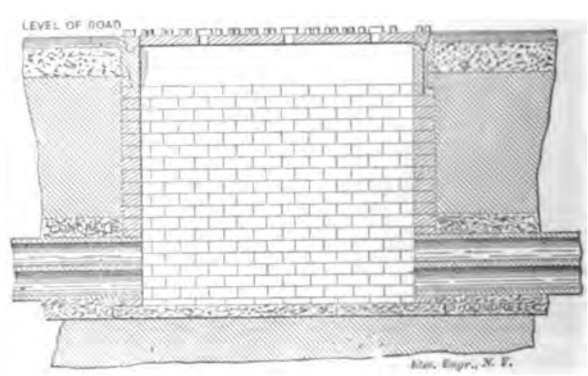

Fig. 5.

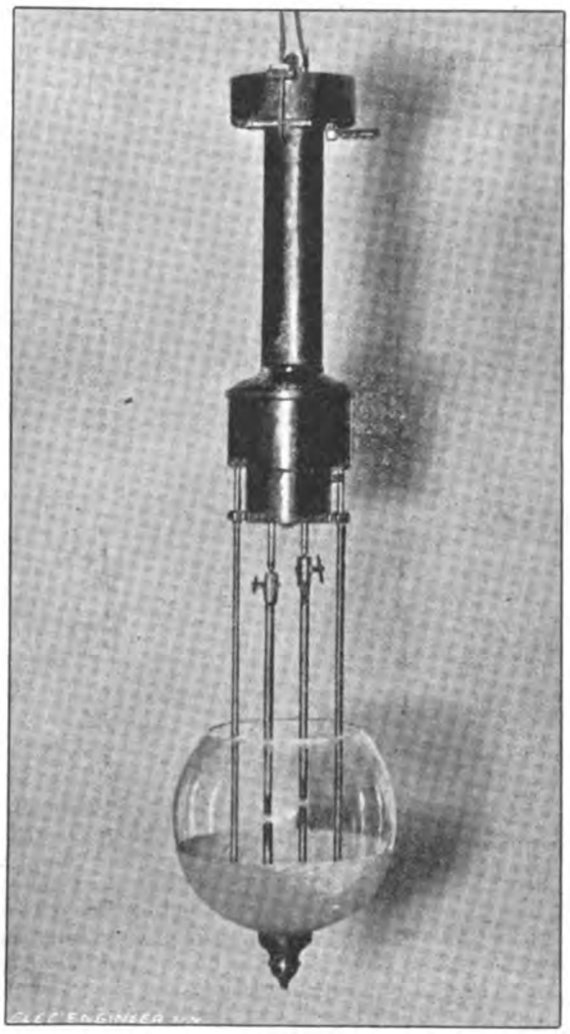
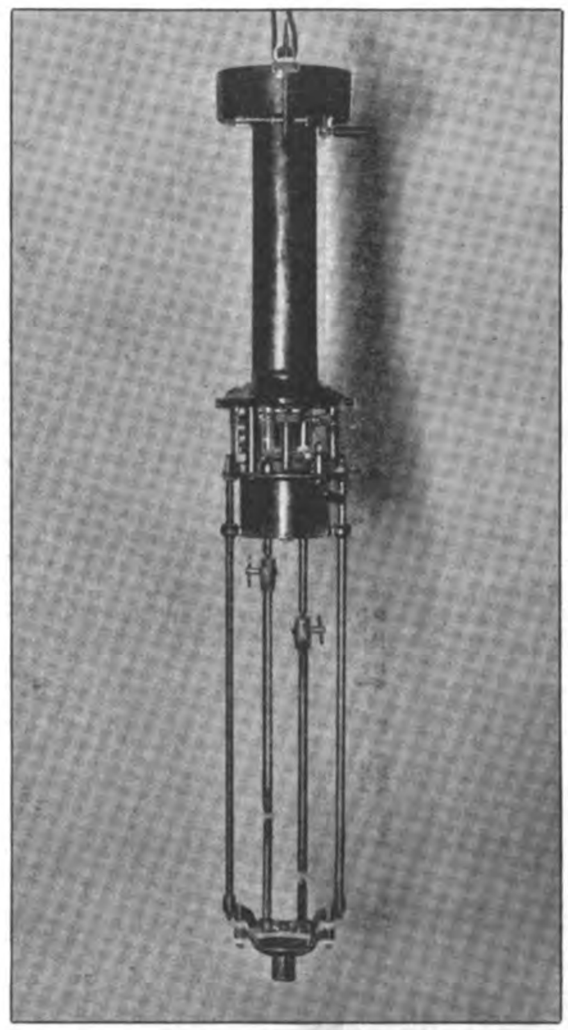
miles, and the same telephone company laid ten miles last year in Baltimore. The system is also coming largely into use in Chicago, St. Paul, Minneapolis, Cleveland, Louisville, San Francisco and Milwaukee.

THE NEW HOCHHAUSEN DOUBLE-CARBON ARC LAMP AND MOTOR-STARTING SWITCH.

The Excelsior Electric Co.'s new arc light machine, which was described in The Electrical Engineer of April 23, 1890, has already gone into operation in a large number of installations, and has sustained Mr. Hochhausen's reputation as a designer of electrical machinery. More recently he has devoted his attention to the construction of a double-carbon arc lamp which embodies a number of features well worthy of attention and which cannot fail to place it among the best of its type. The lamp complete is shown in the accompanying engraving, Fig. 1, and Fig. 2 shows it with the covers removed, exposing the mechanism. A glimpse at the mechanism might, at first sight, make it appear that no magnet spools were employed, but a closer inspection reveals the fact that they are all enclosed within iron shells, which have a double function, namely, to protect the spools, while, at the same time, acting in the role of bell magnets.





Figs. 1 and 2.—The Hochhausen Double-Carbon Arc Lamp.

The operation of the lamp will be best understood by reference to the diagram, Fig. 3. The lamp is so constructed that before current is applied, the carbons are drawn apart. The bell-shaped magnet, placed below the exposed mechanism, has two windings; one of these consists of a coarse coil, E, Fig. 3, while the other consists of fine wire, E^2, both these magnet spools being in shunt to the arc, as shown. Thus, when the current is turned on, the coarse coil E exercises sufficient power to draw down the lid-armature L, to which the rod clutches are attached, and allows the carbons to descend. As soon as the carbons have come in contact they complete the circuit of the magnet-spool enclosed in the shell G, which spool is in series with the carbons and consists of coarse wire. The action of this spool is to draw up its armature, G^3, at the other end of which is supported an insulating button, G^4; this button raises the spring contact G^5 from G^6, and opens the coarse shunt E. The arc is now under the sole control of the fine wire shunt E^2 and a retractile spring which opposes its action.

During the burning of the first set of carbons the other set is held up rigidly by a lever on the lid-armature. The top of the first carbon rod is provided with a button, which is so arranged that when the carbons are burned out the button trips the lever holding the second set of carbons, which are thus immediately brought into action. The action here described is exceedingly simple, and the operation of the lamp in service is very smooth.

Mr. Hochhausen has also devoted special attention to the details which facilitate the cleaning of the lamp and also insure the safety of the trimmer. For this purpose the small lever, shown at the side of the lamp mechanism in Figs. 1 and 2, when operated, depresses the lid-armature and releases both carbon rods, which can be freely slid up and down for trimming. At the top of the mechanism there are provided spring terminals which clamp, and thus make good elastic contact with, a set of terminals on the top of the lamp roof. This obviates the necessity for screw connections, which are usually troublesome to get at and frequently work loose or fail to be screwed up tight by the attendants.

The lamp-hanger, it will be noted, consists of an inverted cast-iron hood containing a slate base, which carries all the terminals and a cut-off switch. Unlike the usual cut-out

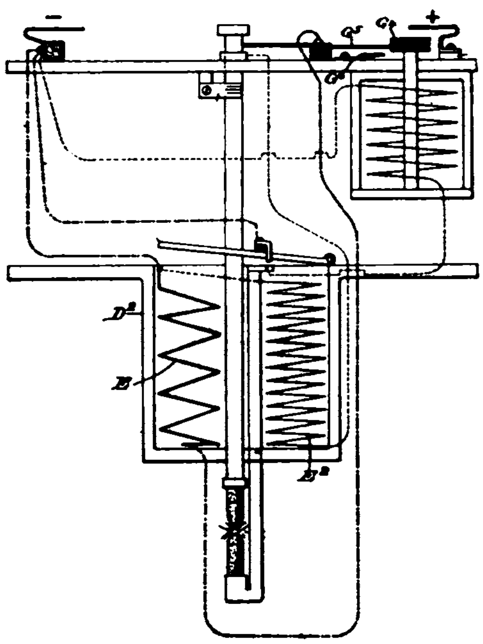


FIG. 3.—HOCHHAUSEN NEW ARC LAMP.

switch, which merely shunts the lamp without putting it out of the circuit, this switch cuts the lamp off entirely from the circuit, so that the attendant is perfectly safe even in the dampest weather. Here, also, the arrangement is such that the mere insertion of the lamp into the hanger effects the contact automatically, so that no screws are required. The arrangement is evidently waterproof, and, besides requiring no hanger-board, obviates the necessity of a hood. Besides the mechanical protection afforded by the magnet-

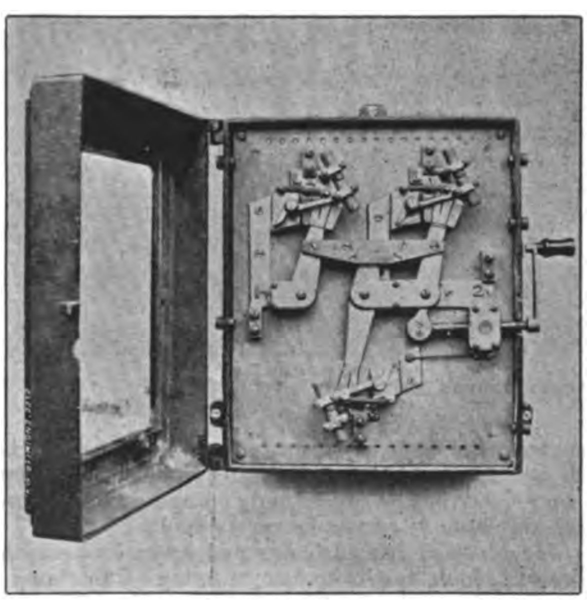

FIG. 4.—HOCHHAUSEN CONSTANT POTENTIAL MOTOR STARTING SWITCH.

spools by surrounding them entirely by iron, Mr. Hochhausen believes that the fine-wire spool will also be largely protected from lightning, and the results already obtained by the lamp in practice appear to bear him out in this regard.

The constant-potential motor-starting switch designed by Mr. Hochhausen is shown in perspective in Fig. 4, and embodies several novel features. A switch of this nature must evidently be so constructed that the field is fully charged before the circuit is closed to the armature in order to avoid the dangerous effects of the heavy current passing through an armature revolving in a weak field and at slow speed. At the same time the arrangement must be such that in shutting down the motor the armature circuit is broken first and followed by that of the field, and for a similar reason. To this it is desirable to add an arrangement which shall avoid excessive sparking at the contacts, and in fact to relieve them of such sparking entirely.

The manner in which this has been carried out by Mr. Hochhausen will be apparent from an inspection of the diagram, Fig. 5. Here, it will be seen, the generator or line is connected to the terminals L L, below which are three other contacts, marked 1, 2, and 3. The contacts 1 and 3 are connected to the armature ends, while 1 and 2 are connected to the field ends. It will now be readily understood that when the attendant begins to turn the crank H the levers A and A′ are gradually drawn over until they come under the spring clips attached to the terminals, marked L

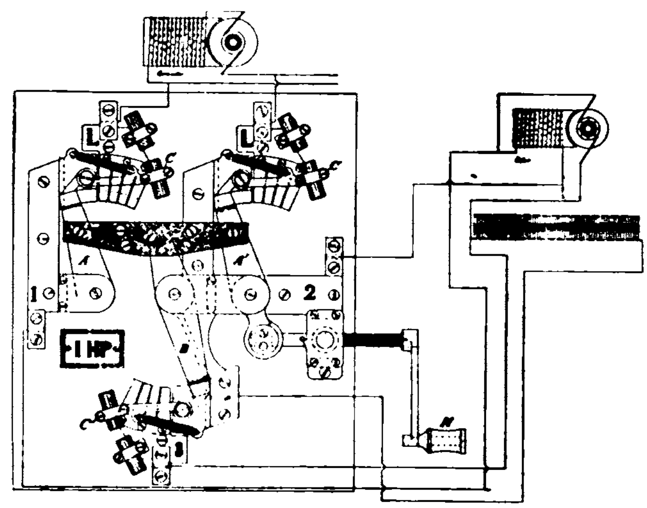

FIG. 5.—HOCHHAUSEN NEW ARC LAMP.

L. After this contact is made, but before the levers have come to the end of their throw, the lever B is started in motion by the cross-piece E, connecting the levers A A′, and at the end of the stroke the lever B has made firm contact with the clips attached to the terminal 3, thus cutting the resistance coils out of circuit and throwing the full armature in circuit. When the motor is to be stopped the handle H is turned in the opposite direction, and by reversing the movement of the various levers the armature has the resistances thrown in circuit with it, is then cut out of circuit and this is followed by the cutting out of the field magnets from the line.

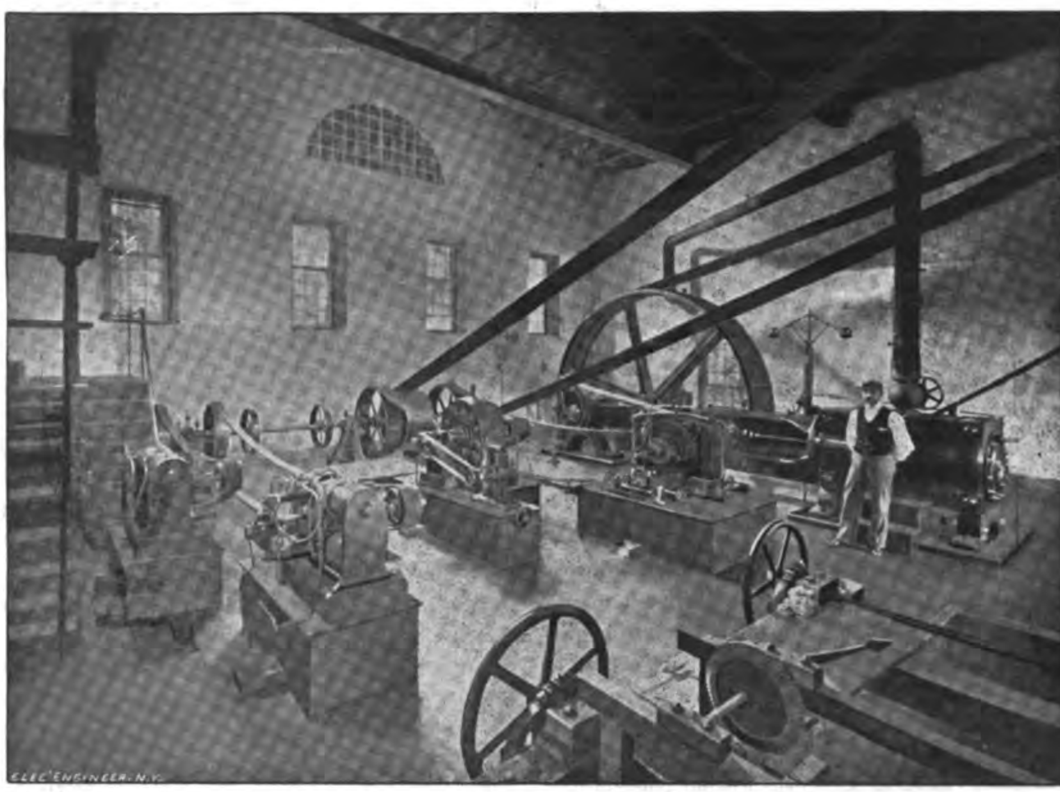
The motion of the crank H is limited in both directions by stops, so that when the handle can no longer be turned the proper contacts have been effected. It will also be noted that the levers A, A′ and B act upon a second set of levers, C C C, which carry carbons at their ends, and which make contacts with corresponding carbons attached to each of the terminals L L and 3. It will readily be seen that as the levers A, A′ and B are withdrawn by the action of the crank, the springs pull the levers over and bring the carbons in contact, the arrangement being such that these carbons come in contact before the levers A, A′ and B meet their corresponding contacts L, L and 3. Similarly, when the motor is shut down the levers A, A′ and B first break contact at L, L and 3 and are followed by the breaking of the contacts C, C, C. The result is that any sparking which occurs is confined to the carbons alone, thus leaving the brass clips and the contact levers entirely clean and bright.

The entire operation will thus be seen to be automatic, and from its nature such that by no possible circumstance could the attendant cause an abnormal rush of current through the motor, the screw of the crank H being so designed that several seconds must elapse between the energizing of the field magnets and the turning on of the current to the armature.

The contacts and levers are all mounted on a slate base and the resistance coils are mounted at the back of the box, which is of cast iron. The resistance is such that the motor starts with good power without endangering the armature.

THE LA ROCHE PLANT AT THE DU PONT POWDER WORKS, WILMINGTON, DEL.

The accompanying illustration shows a plant recently installed by the La Roche Electric Works, of Philadelphia, for Messrs. E. D. Du Pont, de Nemours & Co., powder manufacturers, at Wilmington, Del. The plant consists of one 50 arc light dynamo, one 500 light alternating dynamo, and two 200 light direct-current dynamos, all driven by a 300 h. p. Corliss engine, built by Messrs. Robert Wetherill & Co., of Chester, Pa.



La Roche Electric Light Plant, Wilmington, Del.

The arc light covers an area of five miles, while the alternator has a circuit six miles long, giving light through the Du Pont mansions and some of the mills.

The direct-current machine furnishes light and power for three of the Du Pont mansions. The Schieren link belts and Grimshaw wires are used throughout. The line construction is excellent, showing only a two per cent. drop at the distance of six miles.

A part of the plant has been in operation for some time, and is said to require less attention, and to give better service, than any system tried heretofore by the company.

The La Roche Electric Works placed two 150 light incandescent dynamos at one of these powder mills about three years ago under the most severe conditions; that is, the dynamos were started up in the evening and left to take care of themselves until the next morning. It was largely due to the extremely satisfactory results accomplished by the La Roche machines that the firm were led to adopt the La Roche system throughout. During the recent heavy electric storm the La Roche machines ran steadily throughout the night.

The dynamos are insulated at their bases, and the general system of insulation is so perfect that no accidents have occurred causing injury to persons or property at any time since this system has been installed. It is the general opinion of experts who have inspected this plant that no more complete and perfect a one has been installed in that part of the country.

TELEPHONIC COMMUNICATION BETWEEN STOCKHOLM AND CHRISTIANIA.

The last Swedish Parliament granted a sum of 60,000 crowns for the purpose of extending the telephone to the Norwegian frontier, on the condition that Norway should bring her telephone wires to the Swedish border. According to Norwegian papers the Storthing has acceded to this condition, so that direct telephonic communication between Stockholm and Christiania will shortly be established.

TELEGRAPHY IN HAYTI.

A special cable dispatch from Port-au-Prince of Aug. 15 says: The resignation of the Cabinet yesterday was owing to the failure of the Chambers to grant a concession for the construction of a telegraph line. The Cabinet had made this a government question, and as the Chambers rejected the proposition by a decisive majority, they at once placed their resignations in the hands of the president.

Hippolyte has not yet decided whom he will select for the vacant places, but is canvassing the situation carefully. He does not think the resignations will have much political effect.

There are certain arts in which perfection depends upon the genius and skill of the individual rather than on the condition of the race.—Joseph Henry.

ELECTRIC LIGHT AND POWER IN CANADA.

WHILE we do not expect that American manufacturers of electrical goods and apparatus will derive much direct benefit from the visit of the National Electric Light Association to Montreal, though there will doubtless be a little, we are decidedly of the opinion that the convention should have as one result a stimulus to electrical interests in the Dominion itself. The fact that there are duties, and that manufacturers have already established themselves on a large scale, is enough to prove that Canadians propose to look after supplying their home market themselves. It is true that a good deal of the apparatus now in use bears American names, but even then it has largely been made on Canadian soil, and there are indications that the proportion of home product will be larger as time goes by. So long as we in America are willing to handicap ourselves by heavy taxation on raw materials, we must expect to lose no small amount of trade that is legitimately ours; and the wonder is that this country has been able to compete at all beyond its own borders, even in articles distinctively the outcome of American genius and skill.

Be that as it may, however, it is gratifying to see many signs of electrical activity in Canada, and to believe that this Autumnal picnic will help enlarge the opportunities of our Canadian brethren. It is noteworthy that in Canada much has been done in the utilization of water powers, but that there is still plenty of room for such work is evidenced by the fact that right at the doors of Montreal the Lachine power still goes to waste when it would light the whole city, run all the street cars and drive every piece of machinery. As might be expected from the conditions, the alternating system enjoys considerable vogue in the Dominion, and in the power transmission of the near future it will undoubtedly be relied upon for the performance of some very heavy work. It may be expected also that in Canada, with its cheap water powers and bitter winters, we shall soon see some very interesting and successful plants for electric heating, for heaters have now reached the stage of commercial usefulness, and may be applied in almost as many ways as motors are. There are at the present time in Canada not far short of 150 central station plants in operation, with about 12,000 arc lights and 60,000 incandescents; and of these plants about 25 per cent. are operated by water power. This is a much larger proportion than is found in the United States, and though the water power stations are not among the largest, their rapidly increasing number shows that our Canadian friends are fully aroused to the desirability of turning this store of energy into electric current for all the varied purposes it is now put to. In electric motor and electric railway work, Canada, so far, has not done much, but a promising start has been made, and while we need not look for the headlong American rush in their development, these departments will, without question, grow steadily and surely.

THE CURE OF DYNAMO AND MOTOR TROUBLES.

ALTHOUGH the modern text books on electricity aim more and more at presenting the subjects treated in their practical bearing, it is none the less true that they must necessarily fall short of the ideal in this direction; for, however much an author may seek to treat the subject as it presents itself in actual practice, the limits of his work necessarily compel him to curtail this side of the subject in order to preserve the continuity of the work. If to this we add that comparatively few writers have enjoyed comprehensive "practical" experience, which alone can make their work of genuine value to the student, the reason for the complaint that the text books are not "practical" enough will be apparent. The literature of the steam-engine affords many excellent works of this practical character, but up to the present time no work has so far been forthcoming which will enable one, by direct application, to install and care for a dynamo or motor. It is true that numerous rules and directions intended for this purpose have been issued by various companies, and a very good digest of the "Diseases of Dynamos" was once made by Prof. Silvanus P. Thompson, but none of these afford the engineers in charge of dynamo electric machinery that sufficiency of information which makes them independent of the "expert," who may be a thousand miles off. To place the average dynamo and motor attendant in possession of such information will therefore be acknowledged to be a work not only of immediate benefit to a large class of station employees, but will also prove of especial benefit to those in charge of isolated plants and who are usually entirely at sea when the slightest mishap occurs in the operation of the electrical plant. It is with the object just mentioned in view that Prof. F. B. Crocker and Dr. S. S. Wheeler have taken up the subject of the care of dynamos and motors, and have, we believe, for the first time, subjected to systematic treatment a subject which may well claim the attention of the ablest minds. In the publication of their work, which we begin in this issue, the authors first take up that part of the subject which will at once appeal to the dynamo or motor attendant, and which above all others he will most likely have occasion to refer to on future occasions, namely, the localization and remedy of "troubles." The method adopted in presenting this subject will recommend itself by its logical and effective character. The authors first group the various troubles under eight general heads, which are subsequently taken up in detail. Thus the search for a remedy is at once narrowed down and application can be effected with the shortest possible delay. Many of our readers will without doubt be able to recall instances of "trouble" which required days and weeks to localize and to remedy, but which would have been disposed of in a fraction of an hour with the aid of a guide such as that of Messrs. Crocker and Wheeler. The long experience of the authors both in designing and in the practical operation of dynamos and motors gives to their work that character of "practicality" which will cause it to be welcomed by all engaged in the operation of dynamo electric machines.

GOVERNMENT TELEGRAPHS IN ENGLAND.

The subject of government telegraphs is likely to be actively discussed in this country for a long time to come, and every valuable contribution to the data on the question deserves note. Mr. E. Rosewater, editor of the *Omaha Bee*, an old telegrapher, who was recently elected president of the Old Timers' Association, has an interesting article in his paper on the English and French services, based on his personal observations and notes. Mr. Rosewater makes out a strong case, it is true, and it will readily be admitted that there are many things to admire in those services, though perhaps not much in any of the others, except the German. But the things that win Mr. Rosewater's praise are not necessarily the results of government control; on the contrary, they seem to us, at least, in England, results of the national characteristics, asserting themselves despite unfavorable conditions. But at the end of his letter, Mr. Rosewater touches on the political aspects of the matter, and states significantly, that while the employees are not interfered with politically, "they are not permitted to act as political agitators, or to take part in public meetings." He adds that in France M. Magne, the director general of telegraphs, said he would go further and divorce the service entirely from politics by placing it on the same footing as the army, which, it is stated, does not vote. Now we would like to know if any considerable body of men in America, and if the telegraph operators themselves, wish to see telegraph employees in any such muzzled condition. If they do, the future of America is not a particularly bright one. American freedom is based on a passionate attachment to the idea of personal liberty of conscience and action, and the bare idea that any man, to hold a government position, would sacrifice his right to agitate against wrong, or abandon his influence in removing evils, is abhorrent to every principle upon which this government is founded.

MR. FERRANTI AND THE DEPTFORD STATION.

The work accomplished by Mr. Ferranti in connection with the Deptford station in London, and the prominence which has been given to it owing to the gigantic nature of the enterprise, makes the rumor that Mr. Ferranti has severed his connection with the company of more than ordinary interest. It is safe to say that in no other enterprise of like nature has the individuality of one man been given freer play than in the Deptford station, Mr. Ferranti not only designing all the electrical, but the mechanical equipment as well. The difficulties which had to be surmounted in carrying to a successful completion the task which Mr. Ferranti had set himself would have deterred any one not endowed with a will of iron. In addition, they called for the exercise of the highest skill and ingenuity. True, mishaps have not been wanting in the course of this work, but what great undertaking which required the application of new and untried forces has ever been free from them? While it is yet hardly time to judge Mr. Ferranti's work, no one will, we believe, deny him the credit due to a pioneer in the generation and distribution of current at higher tensions than had been deemed practicable before the inauguration of his work. Now that Mr. Ferranti finds himself freed from the cares which have absorbed his attention abroad so long, it is not improbable that he may find time to pay a visit to these shores, where possibly he may find further opportunities for the exercise of his enterprise and skill.

ELECTRIC LIGHTING FIGURES.

Last week, in commenting on Mr. Tiffany's census figures of electric lighting, we called attention to the absurdity of one statement, which credited San Francisco with paying $440.67 for one arc light. It is just such figures as these that are seized upon by ignorant critics as a weapon of offense against local lighting companies, and hence we already find the following in the Kansas City, Mo., *Journal:* "San Francisco *is robbed* by its electric light company, which collects $440.67 per arc light, while Denver pays only $58.46. It certainly does not cost eight times as much to run an arc light in San Francisco as it does in Denver." Then alluding to the fact that in New Orleans each gas lamp apparently costs $50, while in Indianapolis it only costs $15, the *Journal* adds: "The strong probability is that a ring has been getting in its work in New Orleans and San Francisco, and that the boys had to be fixed generously when these contracts were made." Now this is all wrong, but one cannot blame the *Journal* writer, who simply finds these figures in a public document that has presumably been issued with care. We all know that no single arc light in San Francisco costs such a sum as $440. On the contrary, it is common knowledge also that the rates there are about the average for city lighting. A gross injustice has been done the local San Francisco company, but of course there is no redress. If we are to have any figures on electric lighting, let them be correct.

SIEMENS & HALSKE'S EXHIBIT AT THE FRANKFORT EXHIBITION.

In order to show how they can adapt themselves to every kind of electrical work, Messrs. Siemens & Halske have made up a sort of complex electric light and power exhibit, containing combinations of direct and alternate current generator, motors and transformers, all coupled up together, and transforming from one system to the other and back again, and to all sorts of different pressures and currents. The station works incandescent lamps, direct-current arc lamps, tramways, search lights and motors, and these are scattered about over the whole exhibition.

The electrical power is generated by two dynamos, which are the largest in the exhibition. One is an alternator, the commutator. The outside winding is made of solid copper strips, 1.2 in. high by 0.24 in. broad, insulated from one another by fibre. The whole of the winding is turned up true on the outside, and ten sets of brushes, corresponding to the ten poles of the machine, collect in parallel. These are mounted on a star-shaped casting mounted on the outside bearing of the engine proper. This arrangement is exceedingly simple and very accessible. The brush-holders are so constructed that every brush can be independently adjusted during work without disturbing the others, and at the same time the position of all the brushes may be altered at once by an ingenious and simple device, and all the brushes can be lifted off or put on the armature simultaneously by moving the controlling lever. All the posi-

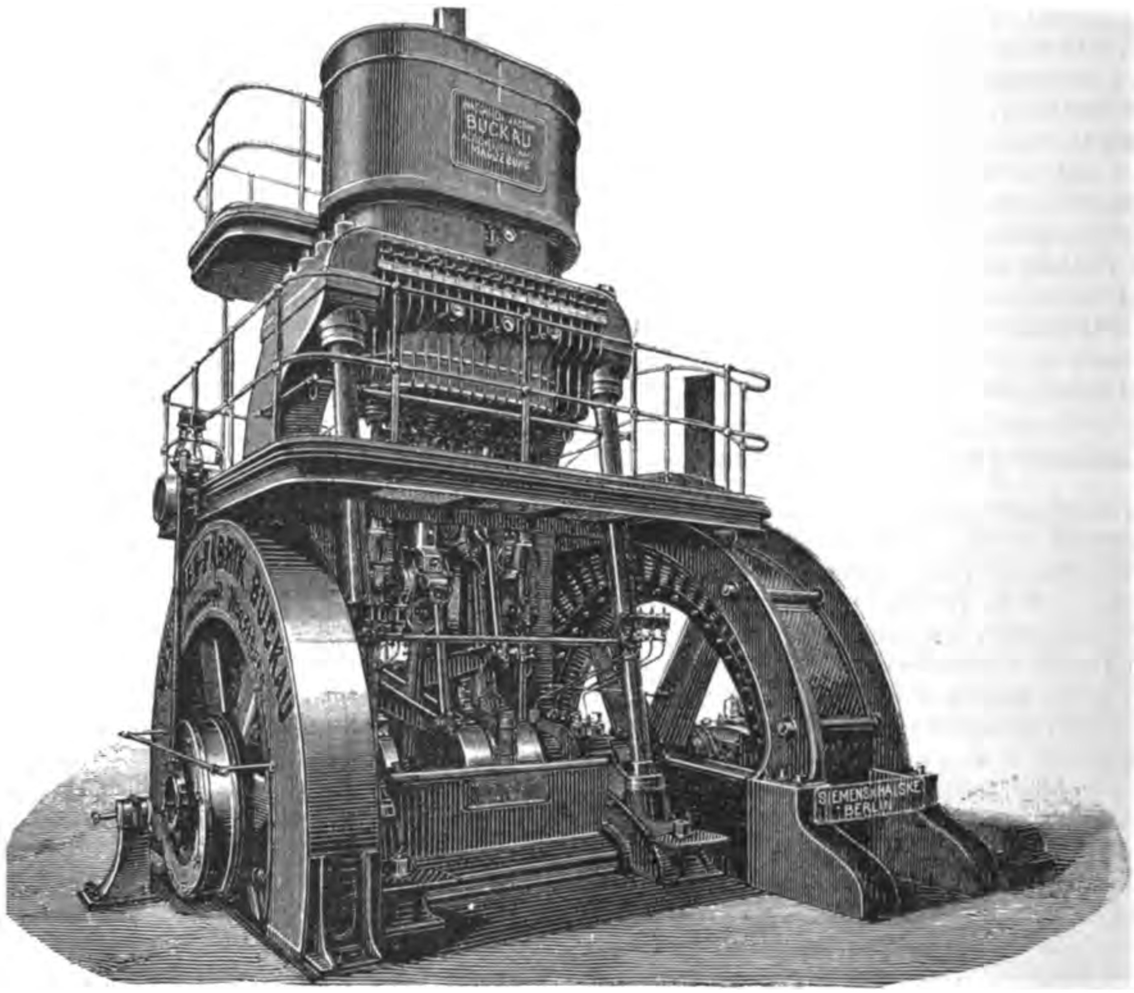

Fig. 1.—Siemens & Halske Alternator Driven by Triple Expansion Condensing Engine.

other a continuous-current machine, and either of them can alone supply the whole distributing system.

The engines are both of the vertical marine type, as shown in the illustrations, Figs. 1 and 2. The continuous-current machine is driven by a triple-expansion condensing engine, by Messrs. G. Kuhn, of Stuttgart-Berg. It has three cylinders, of 20 in., 28 in., and 47 in. diameter, respectively, and 2 ft. stroke. It develops 400 h. p., 500 h. p., and 600 h. p. when run at 80, 100 or 120 revolutions per minute.

The dynamo, made according to Messrs. Siemens' latest design, is coupled direct to the engine shaft. It is a ten-pole machine, radial electromagnets placed inside a Gramme armature of 10 ft. diameter, giving a normal output of 330,000 watts at 65 revolutions per minute, or of above 600,000 watts at 100 revolutions. An interesting feature of these machines is the total want of a special tive and all the negative brushes are connected in parallel, and the current is carried off by two thick but flexible cables visible above the bearing in Fig. 2. This dynamo runs at 150 volts.

The alternate-current dynamo and engine are shown in Fig. 1. The vertical engine is built by the Maschinen Fabrik Buckau, of Magdeburg. It is a two-cylinder condensing engine of the Colman type. The high-pressure cylinder is arranged below the low-pressure and as close as possible to the low-pressure piston rod. The moving systems of the two engines—that is to say, the pistons, piston rods, connecting rods, and cranks—are made of exactly the same weight, so as to balance each other perfectly in all positions, while both cranks are placed as close as possible so that the various thrusts on the bearings are all but compensated. Thus, for a given size, comparatively high speeds are admissible. The engine exhibited, for instance, can easily run at 150 revolutions per minute. At 100 revolutions, which is the normal speed of the alternator, this engine indicates 450 h. p., while the alternator is originally designed for an output of 500 h. p. at the speed named. This discrepancy arises from arrangements with the builder having been made after the dynamo was begun.

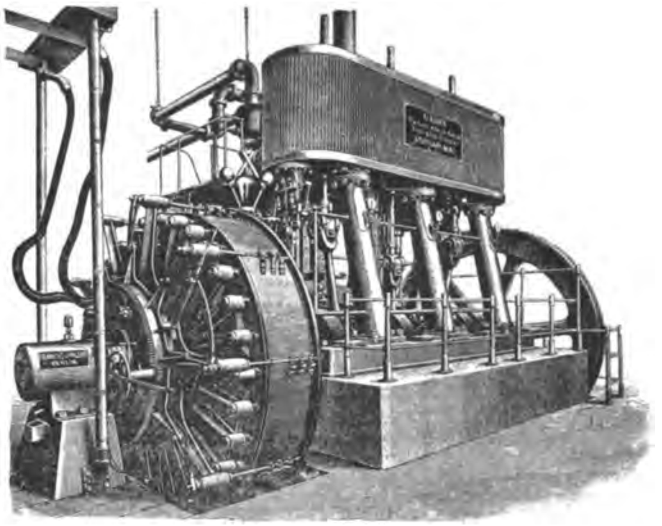

FIG. 2.—SIEMENS & HALSKE CONTINUOUS CURRENT GENERATOR.

The alternator itself consists of a star-shaped field magnet and a fixed external armature, both field magnet and armature being made of laminated wrought iron. Each contains 60 coils of 56 and 20 turns respectively. The conductors are made of twisted copper rope pressed into a square shape, and soaked with varnish in order to avoid eddy currents, the cross-section of copper amounting to about 0.125 square inch. The cross-section of the iron in each core is 20 in. by 3½ in. The rotating field magnets are excited by a separate generator of the same type as the large continuous-current machine already described, and coupled directly on the shaft of a small 60 h. p. vertical engine, by Messrs. Daevel, of Kiel. The stationary armature of the large alternator contains the same number of coils as the rotating field magnet. The cores are **U**-shaped stampings, with the free ends turned inward. When wound and put together they form a sort of laminated Pacinotti armature turned inside out. Any coil can easily be disconnected and taken out without dismounting the rest. The alternating pressure generated at the terminals of the machine is 2,000 volts.

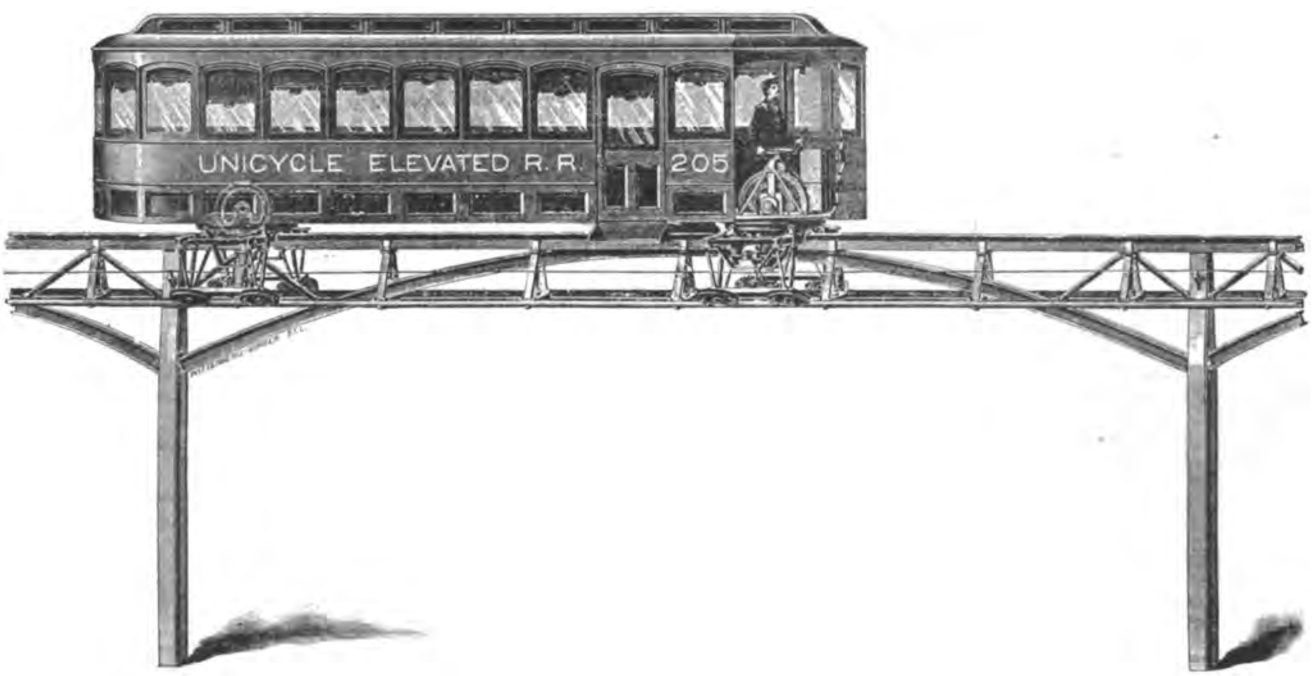
THE UNICYCLE ELEVATED ELECTRIC RAILWAY, ST. LOUIS.

DURING the past four months the Unicycle Elevated Railway Co. have had on exhibition at their headquarters, Nos. 14 and 16 North Seventh street, St. Louis, one of their improved unicycle motor cars in practical operation on a short line of continuous track. The track has loop ends with curves of ten feet radius and also compound curves of eight feet radius. The straight-line portion of the structure is built of steel and iron and the curved portions of wood, so as to illustrate the two different methods of construction.

The, car which is illustrated in the accompanying engraving, is sixteen feet in length and is mounted on two unicycle trucks, which are swiveled to the car by means of flanged segments and anti-friction rollers, thus permitting the car to turn short curves with the greatest freedom.

The trucks and car are locked together by Z-shaped safety hooks. Each truck has a double-flanged main wheel and four double-flanged guide wheels. The flanged guide wheels serve the purpose of locking the truck thoroughly to the track. Two electric motors of three h. p. each are mounted in the lower part of the truck frame, one on each side of the track, and both geared directly to the main driving wheel. Two trolley wheels are attached to the inner ends of the motors and make contact with two trolley wires, which are strung along on both sides of the track. A hand brake, operated by a hand wheel and screw, is located at the top of the main driving wheel.

During the past few months the company have made many improvements in the details of their system; an arch beam has been added to the track structure, as shown in the illustration. Another improvement consists in slightly elevating the track at stations, so as to always have the advantage of a down grade at the start and also to aid in braking the train when stopping. Among other advantages claimed for this system are reduced cost of structure, being about three-quarters of the cost of double-rail elevated roads, higher speed, reduced operating expenses and the ability to turn a shorter curve than any other system. The company are now prepared to make bids for the complete construction and equipment on their system of railway.



THE UNICYCLE ELEVATED ELECTRIC RAILWAY, ST. LOUIS.

THE "S. C. P." MINER'S LAMP.

A PAPER lately read by Mr. Smith before the Federated Institution of Mining Engineers describes the S. C. P. Miner's Safety Lamp. It is claimed for this lamp, writes our London correspondent, that it more nearly resembles in size and form the ordinary oil safety lamps in general use than any other yet invented. By unscrewing the bottom, the lamp or bulb can be replaced by a new one in a few seconds; and in the same way the lamp glass, which is of the ordinary or standard size now in general use, can also be replaced the same as in the oil form of safety lamp. Another feature is that each of the cells composing the battery is separate and independent, and should any accident or fault require one or more of these cells to be replaced, it can (unlike those now in use) be done in a few minutes at the colliery, spare cells being supplied and kept in stock. This fact is of great importance, for in the older forms, if one cell failed the light became dull, and there was no means of telling which identical cell it was; but in these lamps, if any irregularity is observed, such cell can be tested in a few minutes with the voltmeter, and the bad cell taken out, a new one put in, and the lamp sent in as usual, thus obviating the necessity of many extra lamps, whereas in the ordinary forms the lamp has to be returned to the maker, causing much delay and expense. This advantage is said to avoid many of the irregularities found in other electric safety lamps.

The cells are made with a special plate, which gives greater electric capacity for a given weight than any other. It has a high charge-retaining power, is free from local action and sulphating, and there is little or no deterioration of the plate. A plate taken from a battery which has been two and a half years in use shows the truth of this statement.

The battery is of the secondary or storage type, and is contained in a circular metal case, avoiding the use of wood, which has hitherto been too prominent a feature in electric miners' lamps. There are two small studs, marked + and —, at which the dynamo machine is connected to recharge the lamp, and from a third similar stud a small strap of metal switches on the lamp. A nut screws on + and can be so shaped that it can only be removed by a special key, thus (if necessary) forming a lock, as in the old safety lamp. Should the miner succeed in taking out the bulb the light goes out, and if he replaces the bulb the lamp immediately relights itself. The lamp is furnished with the usual "S" hook handle in place of the leather handle too often used in new forms of electric lamps. The smaller lamp is said to burn 7 or 8 hours, the larger one 10 hours. The smaller lamp weighs about 3¾ pounds and is reported to give 15 per cent. more light than an ordinary safety lamp. The larger lamp is double the size of the smaller one; it contains double the number of cells, and gives double the light, and is, of course, heavier in weight. The lamp obtained a silver medal at the recent Falmouth Exhibition of the Royal Cornwall Polytechnic Society. It is made by Messrs. Cathcart and Peto, of London, from designs furnished by Mr. Smith, and is of very recent manufacture. So early has it been brought before the institution that the price has not yet been decided upon, but the makers hope to be able to produce it at a price within the reach of colliery proprietors and engineers.

A MORAL ASPECT OF ELECTRIC LIGHTING.

INSPECTOR MARSH has suggested to Chief of Police McClaughry, of Chicago, the advisability of placing gas or electric lights at alley entrances to all streets. "I believe," said the inspector, "that one of the chief aids to crime in this city is the darkness of the alleys. Our streets are lighted, but most of our alleys are left in utter darkness. When a burglar desires to effect an entrance to a building he works in an alley, where he cannot be detected, and the same advantage is naturally used by the footpad, the assassin and other desperate criminals. The flash-light carried by an officer is of little use to him either in investigating an alley or in searching for fugitives who may have sought refuge there. I believe that if the alleys were properly lighted we should soon notice a remarkable decrease in the percentage of crime." The chief was favorably impressed with the idea, and Commissioner Aldrich will be asked to take some steps to put it into practice.

"THE TRAMWAY AND RAILWAY WORLD."

A PAPER of the above title is to be published in London, under the management of Mr. Frank X. Cicott, of Chicago. It will be a monthly review and will be under competent editorial direction. A very good field appears to exist in England for a journal of this kind, and we have no doubt that by enterprise and ability it will be made a distinct success. It already has the promise of excellent support. The publication offices are at 16 St. Helen's Place, London, E. C. The American offices are at 11 Adams street, Chicago.

College Notes.

ELECTRICAL ENGINEERING AT THE UNIVERSITY OF WISCONSIN.

A special circular of information has been issued relative to the College of Mechanics and Engineering at the University of Wisconsin, Madison, Wis. One of the new professorships there is that of electrical engineering, and Mr. Dugald C. Jackson, as recently announced, will fill that chair. The course in electrical engineering is nearly identical with the mechanical engineering course during the first two years, since a large part of what is required in mechanical engineering is necessary to a thoroughly equipped electrical engineer. In the last two years those subjects given in the mechanical engineering course which are not important to the electrical engineer are omitted and electrical studies substituted therefor. As now arranged, the special features of the course begin with physics in the second year and followed by two consecutive years of electrical study. There is given first a thorough grounding in the science and theory of electricity and magnetism and in electro-dynamics. This is accompanied and followed by electrical measurements and tests of all kinds, standardizing, methods of determining electrical units, economics of electrical distribution, electric transmission of power and electric motors, electric locomotives, electric lighting, dynamos, lamps, etc., photometry, management and care of batteries, telegraphy, telephony, electrolysis and electro-metallurgy. Important additions to the course are contemplated.

A large suite of rooms in Science Hall is devoted to laboratory work in electricity, in immediate connection with the physical laboratories and lecture-room. The laboratory is well supplied with instruments and apparatus.

Reports of Companies.

EUROPEAN ELECTRIC WELDING CO.

THE late rise in European Electric Welding stock was probably due to the advance payment Aug. 25 of £5,000 of the purchase price of the English rights by the City of London Contract Company. The payment was not due until Sept. 1. There remains £20,000 to be paid, and it is due by Nov. 1. It may be paid by Oct. 1. The English company has brought out its prospectus, and subscriptions close to-morrow. Its capital stock is $2,300,000, par $50. It comprises 45,000 ordinary shares and 10,000 founders' shares, of which the European Electric Welding Company received 8,333 ordinary and 400 founders' shares, beside $527,795 cash. One million dollars in capital stock and $242,695 cash are to be put in the treasury for working capital. Options maturing Sept. 1 have been extended to Oct. 1 for electric welding rights in Germany, Austria-Hungary, Russia, Scandinavia, Denmark, Belgium and Switzerland on terms similar to the English terms.

Society and Club Notes.

STREET RAILWAY ASSOCIATION, OF NEW YORK.

THE ninth regular (annual) meeting of the Street Railway Association, of the State of New York, will be held at the Hotel Metropole, Broadway and Forty-second street, New York City, on Tuesday, September 15th, 1891, at 10.30 o'clock A. M.

A special committee has been appointed to present a report at this meeting on the subject of "Electric Motive Power for Street Surface Railways," electricity being the leading topic of interest in the street railway community. It is expected that the discussion following the report will develop the very latest information obtainable on the subject. Entertainment will be provided for the delegates, and every company in the State is urged to be represented.

Obituary.

MR. C. G. MERIWETHER, the superintendent of the Southern division of the Western Union Telegraph Co., with headquarters at Mobile, Ala., died on Aug. 29. He had held the position for several years and was well known in the telegraphic field.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED SEPTEMBER 1, 1891.

Alarms and Signals :—

Annunciator, W. C. Dillman, 458,947. Filed May 6, 1891.

Clocks :—

Synchronizing Mechanism for the Second Hands of Clocks, H. Munson, 458,716. Filed March 3. 1891.

Conductors, Conduits and Insulators :—

Electric Subway, J. C. Reilly, 458,778. Filed May 19, 1891.
Provides a method for leading wires or cables into a slotted conduit.

Distribution :—

Electro-Chemical Transformer, T. D. Bottome, 458,652. Filed Jan. 28, 1890.
Designed for the production of direct continuous currents from alternating currents without the use of magnetic devices or mechanically moving apparatus.

Dynamos and Motors :—

Regulator for Constant Current Dynamos, E. P. Clark, 458,617. Filed Oct. 4, 1890.
Employs a ring-shaped electromagnet having consequent poles, and journaled at its centre, for actuating the regulating device.

Constant-Current Dynamo, E. P. Clark, 458,618. Filed Oct. 4, 1890.
Rotates the diameter of commutation instead of rotating the brushes. Employs deflecting magnets acting upon the armature to vary the position of the diameter of commutation.

Electric Motor, E. Thomson, 458,646. Filed Feb. 2, 1887.
Designed to secure self-regulation or constant speed in constant-potential motors. Employs supplemental coils of low resistance upon the pole-pieces of the field-magnets.

Automatic Cut-Out for Dynamo-Electric Machines, S. H. Short, 458,666. Filed Oct. 29, 1889.
With a compound-wound dynamo employs a cut-out electromagnet in the external circuit and a circuit making and breaking device in the shunt circuit of the dynamo controlled by the electromagnet.

Electric Generator, J. C. Henderson & F. Sargent, 458,702. Filed June 21, 1890.
Combines upon a common supporting base, built up in sections, a steam engine and two dynamos, one on each side of the engine, and having their rotating portions directly attached to the engine shaft.

Armature for Electric Motors or Generators, J. F. McLaughlin, 458,856. Filed May 26, 1891.
Comprises a laminated iron body having a circular series of channels near its outer edge and an armature coil section housed in each channel.

Circuit-Controller for Electro-Magnetic Engines, C. J. Van Depoele, 458,869. Filed Feb. 3, 1891.
For use upon reciprocating motors.

System of Supplying Current to Reciprocating Electric Engines, C. J. Van Depoele, 458,870. Filed Feb. 26, 1891.
Motor has sets of coils energized by currents of different character. It is supplied from a source of continuous current. Means are provided in the vicinity of the motor for dividing such continuous current into alternating currents and intermittent currents of continuous direction and of supplying them to the different sets of coils in the motor.

Electro-Magnetic Reciprocating Engine, C. J. Van Depoele, 458,872. Filed Mar. 19, 1891.
In a reciprocating motor having a number of coils and an iron envelope surrounding them, employs a magnetic shield or shields interposed between a portion of the coils and the surrounding envelope.

Combined Electric Engine and Pump, C. J. Van Depoele, 458,873. Filed March 27, 1891.
A reciprocating motor combined directly with a pump.

Reciprocating Electric Engine, C. J. Van Depoele, 458,874. Filed April 7, 1891.
Combines the employment of an intermittent continuous current and an alternating current in the same motor, a separate coil being provided for each current.

System of reciprocating Electric Engines, C. J. Van Depoele, 458,954. Filed Sept. 19, 1890.
Improvement upon the invention patented to the same inventor November 11, 1884, No. 307,884.

Electire Motor, N. P. Otis & R. C. Smith, 458,976. Filed July 31, 1890.
Especially adapted for the service of elevators and relating specially to the method of starting and operating; which consists in passing the current through all the coils of the armature to render them effective on starting, and subsequently short-circuiting a portion of the coils when the motor is under normal speed.

Lamps and Appurtenances :—

Incandescent-Lamp Cut-Out, T. D. Bottome, 458,653. Filed March 16, 1891.

Carbon-Clamp for Electric Arc Lamps, A. P. Seymour, 458,718. Filed Jan. 3, 1889.
Clamp has a rigid V-shaped part on one side and a loose perforated V-shaped part on the opposite and a clamp screw passing loosely through the perforation of the loose part and seated in an extension from the opposite side of the clamp body.

Duplex Arc Lamp, B. B. Ward, 458,719. Filed Dec. 31, 1890.
A double-carbon lamp especially adapted for use on constant-potential circuits.

Electric-Light Fixture, F. H. Aldrich, 458,769. Filed April 17, 1890.

Electric Arc Lamp, B. B. Ward, 458,876. Filed Jan. 30, 1890.
Relates to focussing lamps.

Electric Arc Lamp, W. A. Turbayne, 458,987. Filed April 14, 1891.
Relates to devices for striking the arc and regulating the feed.

Measurement :—

Electric Meter, M. Koechlin, 458,755. Filed Oct. 16, 1890,
Employs the principle of the Wheatstone bridge and a resistance integrating apparatus.

Medical and Surgical :—

Electro-Therapeutic Apparatus, W. J. Herdman, 458,695. Filed Dec. 27, 1880.

Miscellaneous :

Fusible Cut-Out, C. S. Van Nuis & J. H. Vail, 458,608. Filed Oct. 16, 1890.
Employs a number of fusible wires arranged to be put in circuit successively and automatically upon the rupture of one of them. Includes a revolving drum and electric motor.

Lightning Arrester, J. P. Freeman, 458,656. Filed April 23, 1891.

Protective Fuse, H. V. Hayes & A. C. White, 458,753. Filed May 25, 1891.

Method of and Apparatus for Determining the Temper of Steel, C. A. Casperson, 458,784. Filed Oct. 7, 1890.

Electric Coal-Mining Machine, C. J. Van Depoele, 458,868. Filed Oct. 3, 1890.
A gang drilling or cutting machine actuated by an electric motor.

Electric Switch, A. Wissler, 458,879. Filed June 22, 1891.

Casing for Electric Switches, A. Wissler, 458,880. Filed June 22, 1891.

Phonograph, E. Oxley, 458,916. Filed Nov. 12, 1890.

Electric Comb, J. M. Riley, 458,952. Filed May 1, 1891.

Electric Comb, J. M. Riley, 458,953. Filed June 22, 1891.

Testing-Switch for Electric Circuits, R. C. Smith, 458,961. Filed Dec. 10, 1890.

Cleat for Electric Wires, H. P. Ball, 458,964. Filed Apr. 17, 1891.

Safety Device for Electric Elevators, N. P. Otis & R. C. Smith, 458,977. Filed Dec. 31, 1890.
Devices by which the operator in an elevator car or cage can arrest, reverse or vary the speed of the motor.

Railways and Appliances :—

Electric Railway System, W. H. Knight, 458,582. Filed May 11, 1886.
Employs a number of generators connected respectively to successive sections of an electric railway; provides means for reducing the current of any generator at the instant when a locomotive is leaving the corresponding section of road.

Electric Railway, W. H. Knight, 458,583. Filed Mar. 18, 1886.
Employs a slotted conduit on one side of a track; in a double-track line both conduits are between the two tracks; upon curves arranges the conduit somewhat eccentric to the curve of the track for convenience with respect to the contact device at the end of the car.

Electric Motor Truck, W. H. Knight, 458,584. Filed Mar. 5, 1889.
Motor is fulcrumed upon the axle and extends down between the wheels outside of the axle; frame bars counterbalance the motor upon the opposite side of the axle; includes a compression brake sliding on the frame bars.

Electric Brake, J. C. Lincoln, 458,587. Filed Feb. 24, 1891.
For electric railways. The motor is employed as a brake by using it as a dynamo.

Conduit for Electric Railways, F. E. Degenhardt, 458,619. Filed Nov. 21, 1890.
Designed to provide for security of insulation and for adequate drainage. Conductor carrying boxes are supported within a drainage conduit.

Electric Trolley or Contact Wheel, F. E. Degenhardt, 458,620. Filed Nov. 21, 1890.
Especially adapted for use with a fixed underground conductor.

Conduit for Electric Railways, E. E. Keller, 458,680. Filed Nov. 21, 1890.
Improvements upon the conduit patented to F. E. Degenhardt, No. 458.619. See above.

Electric Railway, H. A. Seymour, 458,665. Filed May 5, 1891.
Employs but one conductor for a two-track line. The overhead conductor is placed between the two tracks; the trolley poles are arranged to incline laterally to the conducting wire from a car on either track.

Electric Locomotor, H. F. & G. P. Shaw, 458,729. Filed Oct. 27, 1888.
Motor is mounted with its armature shaft longitudinally of the car; motion is transmitted to the car axle through a pair of rollers and friction gear.

Electric Railway Conduit and Contact Device, W. H. Knight, 458,747. Filed May 10, 1888.

Self-Lubricating Electric Trolley, T. Driscoll, 458,785. Filed Dec. 12, 1890.

Electric Car Mechanism, W. E. Badger, 458,800. Filed Oct. 17, 1890.
Consists of gear and clutch mechanism; armature shaft mounted longitudinally of the car.

Electric Railway, L. O. Dion, 458,844. Filed Nov. 24, 1890.
Discards continuous longitudinal overhead conductor. Substitutes a series of rigid supports at intervals along the side of the track and extending laterally over the track and carrying branch conductors from a main conductor underground; the rigid supports present points of contact to a conducting attachment on a car, made of such length that when it has separated from one of the fixed branches its forward end will have engaged with the next one.

Method of and Apparatus for Operating Electric Railways by Dynamic Induction, E. E. Ries, 458,859. Filed May 17, 1887.
Claim 1 follows:
The method of propelling vehicles by the agency of electricity by causing alternating or intermittent currents on a line or lines of conductors extending along a railway to induce alternating currents in a circuit or circuits feeding one or more propelling electric motors.

Closed Conduit for Electric Railways, C. J. Van Depoele, 458,866. Filed Feb. 8, 1887.
Contact devices connected to the car effect contact with the insulated conductor in the conduit at intervals by means of electro-magnetic devices and pins extending through the wall of the conduit.

System of Electric-Railway Conductors, C. J. Van Depoele, 458,867. Filed July 19, 1889.
Employs an exposed working conductor or conductors, a conductor insulated from the working conductor or conductors; the insulated conductors forming closed circuits in inductive relation to the working conductors; grounded connections extend from such closed circuits. Designed to prevent inductive disturbance upon other electrical conductors in the vicinity of an electric railway.

Telpher System, C. J. Van Depoele, 458,871. Filed Feb. 28, 1891.
The track has a lower supporting or traction rail, an upper grooved guide rail, lateral guide rails, and frames surrounding and sustaining all the rails in fixed relation. The car body is cylindrical and spring supported within a wheeled frame.

Electric Railway, W. C. Wright, 458,931. Filed Nov. 25, 1889.
Relates to the construction of a conduit and to the contact carriage.

Electric Railway, W. C. Wright, 458,932. Filed Nov. 29, 1889.
Relates to improvements in the contact carriage.

Controlling Dynamo-Electric Machines for Electric Railways, S. H. Short, 458,956. Filed April 30, 1890.
To prevent the overloading of the dynamo and the production of an excessive current.

Telegraphs:—

Telegraphy, D. Kunhardt, 458,585. Filed Mar. 26, 1891.
An arrangement of apparatus and of circuits permitting the use of either direct or alternating currents.

Appointments, Etc.

MR. DAVID N. COOK, of the Essex, Mass., electric street railroad, has resigned for the purpose of taking a position in a railroad equipment company.

MR. S. A. SOUTHWICK, formerly of the Sprague and Thomson-Houston Companies, has been appointed electrician of the Essex Electric Co., of Salem, Mass.

MR. PAUL RUSTLING has been appointed general superintendent of the electric railway at West Bay City, Mich., to succeed Mr. H. H. Applin, resigned.

MR. P. A. SMITH has been appointed manager of the Ellsworth, Me., Electric Illuminating Co., to succeed Mr. F. S. Palmer, resigned.

MR. G. N. BLOSE, lately the manager at Newcastle, has been appointed manager of the Postal Telegraph Co. at Youngstown, Ohio.

SUCCESS OF ELECTRIC LAUNCHES ON THE THAMES.

FROM information furnished by Messrs. Woodhouse & Rawson, the number of launches on the upper reaches of the river is constantly on the increase. They are now almost as familiar to those who use the river as steamboats, and certainly regarded with less of loathing. Woodhouse & Rawson, to meet the requirements for these boats at regattas, have built a floating charging station. In appearance it is very similar to a house boat. The charging station consists of a river barge, 80 feet long and 14 feet beam. The machinery is placed in a compartment at one end, and consists of a semi-portable steam engine plant and dynamo of sufficient output to charge the accumulators on six launches simultaneously. The remaining portion of the boat contains a storeroom, an office, sleeping apartments for the attendants, and an engineer's room, where a lathe is fixed, and attendants are kept constantly in readiness to effect any repairs to launches which may be required, a convenience boat owners know how to appreciate.

THE STANDARD ELECTRIC CO.

THE above-named company, of Detroit, Mich., are engaged in the manufacture of a perfected storage battery, constructed upon different principles from those made heretofore and which possesses, in a high degree, all the points of durability so much to be desired in a commercial battery. It is so constructed as to be entirely free from active material falling out, short-circuiting and buckling, and can be charged and discharged at any required rate without depreciation or injury of the plates or loss in efficiency; this especially adapts it for street railway work, in which capacity it is in practical use with very satisfactory results. The battery is manufactured under the Logan patents, which, it is stated, are entirely fundamental and do not conflict in any point with those of other manufacturers. This battery is causing a great deal of interest, particularly from the fact that expert care is unnecessary with it, as it practically takes care of itself.

OKONITE.

THE International Okonite Co. has just issued a new price list, No. 5, of its insulated wires and cables for all classes of service. It is well classified and full of useful information and data. We notice a page devoted to railway span wire, and a line of Okonite soft tubing made from the regular Okonite compound.

THE WOOD ARC LIGHT SYSTEM.

THE Fort Wayne Electric Co. has just issued a list of sales of the Wood arc light apparatus made from November 1, 1889, to August 1, 1891. The total reaches no less a figure than 20,180 lights, and the list is a remarkable exemplification of the popularity of the Wood dynamo and lamp.

THE KEYSTONE ELECTRIC CO. have just sold a five h. p. motor to the Erie Piano Co., and a two h. p. motor to a pattern shop in Erie, Pa.

RIES ELECTRIC SPECIALTY CO.

THE Ries Electric Specialty Company have recently secured the handsome and commodious building on the northeast corner of Baltimore and Eutaw streets, directly opposite the Eutaw House, and have just fitted it up with the necessary machinery and appliances for manufacturing some of their electrical specialties. One of the first surprises this company has in store for its electrical friends has been in course of active preparation for some time past and will shortly be introduced to the trade and the public at large. It is asserted that the device referred to will create something of a revolution in incandescent electric lighting. A number of other appliances will also be placed on the market.

A STEAM APPLIANCES DIRECTORY.

WE are in receipt of a copy of "Hewling's Directory of Steam Specialties and Engineering Appliances," giving a complete classified list of all manufacturers of articles in this line. It will be found a very handy book of reference. It is published by A. J. Hewlings, 218 Lake street, Chicago, at $1.

RAW HIDE PINIONS.

THE New Process Raw Hide Co., of Syracuse, N. Y., have the following from the Wilkesbarre and West Side Railway Co.: "We have been using your raw hide armature pinions for over a year, and find them the best and most durable pinion that we can buy."

A "UNIQUE SPECIAL SUPPLEMENT."

THE Boston *Herald* of August 16 has the following: "THE ELECTRICAL ENGINEER of August 12 prints a most unique special supplement of about 20 pages, illustrative of the extensive Edison light and power industries as existing to-day, and as compared with their humble beginnings 10 years ago. It is splendidly illustrated, and makes suggestive reading. It is apropos, too, in view of the fact that the Association of Edison Illuminating Companies held its annual meeting in New York City during the week."

THE COBB INSULATING PATENTS have been sold in Philadelphia at auction by M. Thomas & Sons. The patents were granted to Henry B. Cobb, numbered 288,310, 288,311, 293,632, 294,365, 330,-873, 330,874, 396,548, 408,374, 408,375, 406,376, 406,377, 429,304, 429,-305, 429,306, 429,307, 429,292, 440,395, 451,614, 452,517; also a certain invention and patent to be obtained therefor as follows, to wit: "A method of and machine for manufacturing insulated electric conducting wire," as described in an application filed in the United States Patent Office by Henry B. Cobb, May 29, 1890, serial No. 353,561; also foreign patents that were granted to Henry B. Cobb by Austria, Italy, Belgium, England, France, Germany and Canada. The above patents were bought by James C. Stillwell, attorney, No. 727 Walnut street, for $100 each.

A PRETTY TOUGH FILAMENT.—During a recent visit to the New York and Ohio Company's incandescent lamp factory, at Warren, O., some very remarkable tests of the durability of the Packard lamps were witnessed. A 50 volt lamp picked up hap-hazard from a barrel of lamps was taken and run first at 90 volts, measuring on the photometer 200 c. p., and absorbing 2 amperes for a period of 15 minutes; at the end of this time there was absolutely no perceptible discoloration. The voltage was then raised to 120 volts, the candle power being probably 600 and the current 2½ amperes. But the end was not yet, as the filament would not break, and it was only when the connecting wire to the platinum leading-in wire melted apart at the soldered joint that the current was turned off and the lamp taken down somewhat blackened, but still in the ring, and the filament perfectly intact. The lamp was then broken and the filament removed and bent double once or twice with the fingers, and seemed to be tougher than ever. Mr. Packard says that such tests with his lamps are frequently made, and, in fact, the lamps seem to like them. The sceptic may be inclined to regard these statements as mendacious; if so, let him go there and see it done and he will come away an astonished believer; or let him take a Packard lamp and make the experiment himself.

THE NEW ELECTRIC LIGHT PLANT for the Pawtucket Gas Co., at Pawtucket, R. I. will be very substantial. The dynamo-room will be 60x150, the engine-room 58x78 ft., and the boiler room 60x60 ft. The side walls will be of brick, with iron roof-covered with corrugated iron. The whole plant will be built by The Berlin Iron Bridge Co., of East Berlin, Conn., after the plans and specifications of Remington & Henthorn, engineers and architects, of Providence, R. I.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

Advertising is to business what steam and electricity are to machinery.

THE ACME LEAD CABLE.

THIS is one of the latest products of the International Okonite Company (Limited), New York and London. It is a lead-covered cable and designed for extra heavy work and high voltage under extremes of temperature, being especially adapted for underground work. A special feature of the new cable is its thorough insulation, which consists of a combination of two or more distinct insulating materials, possessing different valuable qualities; one, of the high electrical resistance of Okonite; the other, an improved rubber compound especially adapted to resist the effects of high temperature. The high insulating properties of Okonite are well known to the trade. The special rubber compound, which also possesses high insulating and waterproofing qualities, has the additional quality of not being sensitive to heat. Its application serves as a protection to the high grade Okonite insulating material beneath, and insures centralization of the conductor at high temperature. In other words, it does not soften, neither does it allow the conductor by its weight to sag down through the insulating materials. After this second layer is applied, the cable, thus far made, is run through a bath under high heat until the insulation becomes impregnated with a material which protects it thoroughly from the effects of gas and moisture.

Over these two layers of special insulating material is superimposed a braid which in its turn is saturated with the same material to prevent capillary attraction to the exposed ends of the cable and protect it from the rotting effects of gas, and to increase lasting qualities, making it a most durable braid.

Though more expensive, the manufacturers use a braid in preference to a tape, on account of its superiority. Being elastic, it does not break on bending, as the tape is sure to do, but gives readily.

The now practically finished cable is then lead-covered by the most improved hydraulic processes that have yet been introduced, insuring freedom from blow holes and air bubbles, and an even thickness and quality of lead. The lead is alloyed with tin, to secure sufficient hardness, and to resist abrasion in drawing through ducts, yet assuring sufficient ductility to enable the cable to be easily handled without rupture.

THE HANSON PRIMARY BATTERY.

A NOVEL form of primary battery intended for use in supplying light and power in private dwellings has recently been devised by Mr. Walter Hanson, of Washington, D. C., and is shown in the accompanying illustrations. Here, Fig. 1 shows a vertical sectional view of the battery, while Fig. 2 is a plan of two cells, showing Mr. Hanson's method of connecting them.

The earthenware jar A has suspended in it a porous cup, C, by means of a wooden frame, B, so that the solution in the jar may come into close contact with both the bottom and sides of the cup. The carbon plates D are suspended in this cup, and are separated at their upper ends by a wooden strip, E. The sides and tops of these carbons are electroplated with copper, and are connected by the copper band F bent to form a triangular loop with the sides of the carbons and the end of the wooden strip between them.

The zinc plates G have secured to their upper ends the bent wires *g* and *h*, by means of which they are suspended in the jar.

Two solutions of different strength are used in the battery, the stronger being placed in the porous cup C, while the jar A is filled with the weaker solution, which surrounds the bottom and sides of the cups.

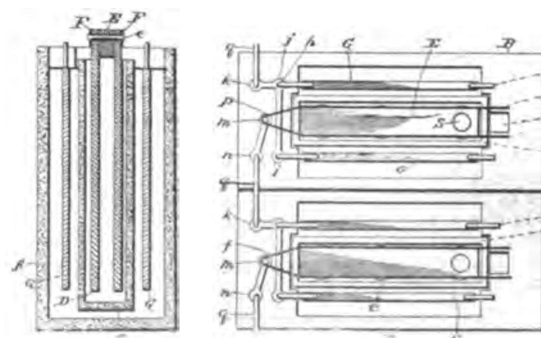
The two solutions are not, therefore, united, but the porous cup acts as a conductor between them, and thus increases the action of the battery.

In one end of the frame B, beneath the cap *b*, there is set into the frame a series of mercury-cups for concentrating the currents and providing attachment for the poles when a single battery is used, or for attachment of the electrodes when it is desired to use a series of batteries.

The frame B is cut out to receive these mercury-cups and their connecting-bars, and they are driven into the frame and covered by the cap *b*, which keeps them securely in place. This cap is provided with holes, *c*, which register with the mercury-cups. The wires *h* are bent in the form of a staple, one end being attached to the zinc plate and the other end passing through the cap and entering one of the mercury-cups. In the apex of the triangle *f* of the copper band F there is a copper pin, *p*, which is soldered to the band, and enters one of the mercury-cups. It will be seen that the wire *h* of one of the zinc plates enters the mercury-cup *i*, and that the wire of the other zinc plate enters the mercury-cup *j*, thus connecting the two zinc plates, while the pin *p* of the negative electrode enters the mercury-cup *m*.

Two holes are shown at R and S respectively. These are for the purpose of filling the jar and cup without removing the electrodes.

The Hanson Battery, Light & Power Co., of 514 8th street, N. W., Washington, D. C., has been placing these batteries with Elektron motors in houses, restaurants, saloons, etc., since the middle of May with great success, having now over 100 such installations out. It not only installs, but maintains, for a fair consideration. Some idea of the quality of its work may be found from a letter to Mr. Frank Aldrich the manager, from Major W. F. Tucker, of the U. S. A. Pay Department, as follows: "Last week the motor was given a pretty good test, and, I wish to say, was satisfactory in every way. You should be able to place a great many of them as they become better known." Mr. Aldrich has a set of 33 cells at his private residence, running 18 lamps of 50 volts. At an average, 10 of these lamps are run every night for three hours. The batteries are charged once in



FIGS. 1 AND 2.—HANSON PRIMARY BATTERY.

four weeks. Eight of the batteries are also connected up to run a pump, which lifts 150 gallons an hour a distance of 60 feet. This pump is also connected with a fountain in the front lawn, and thus a steady circulation is kept up. Mr. Aldrich is now getting up an equipment ordered for a boat on the Potomac, 18 feet long, to be driven by a two h. p. motor; and he is also getting ready for a trial of the batteries in street car traction.

THE LEFFEL WATER WHEEL PAMPHLET.

THE new pamphlet published by James Leffel & Co., Springfield, O., hydraulic and mechanical engineers, and makers of the James Leffel water wheel, is elegantly printed on finely finished paper, is handsomely illustrated throughout, and contains a large amount of useful and practical matter for those improving water power. A great number of plans for placing wheels are shown, both upon upright and horizontal shafts. Entirely new tables of wheels are published, containing features never before published.

This firm has been making the James Leffel water wheel for 30 years continuously, and its business is conducted by the same persons and managers that have been with it since its early history. They make 110 different sizes and styles, have shops, tools and patterns designed exclusively for this business, and are turning out more and better work to-day than at any time heretofore. The new pamphlet will be sent free to any one applying to the above address.

GREAT WESTERN ELECTRIC SUPPLY CO.

MR. THOMAS C. RAFFERTY, who for some time past has been in charge of the railway department of the Great Western Electrical Supply Co., has now been appointed assistant general manager of the company, which is doing a good share of the supply business of the West and enjoying a growing trade. Mr. Rafferty assumed his new duties September 1st.

MR. G. M. ANGIER, who has been connected for about a year with the Great Western Electric Supply Co. and has had charge of the lighting and other special departments, and who, previous to this, was with the Thomson-Houston Co., at St. Paul, has resigned his present position and accepted the assistant managership of the Knapp Electrical Works, Chicago. Mr. Angier is a young man, active and energetic, and has a host of warm friends among the electrical fraternity, who will be interested to learn of his new connection and wish him the success he will undoubtedly achieve.

THE WARD ARC LAMP.

THE Electric Construction & Supply Co., of 18 Cortlandt street, manufacturers of the Ward arc lamp for incandescent circuits, have just issued a very fine and well-written catalogue on their apparatus. As our readers are no doubt well aware, the practice of combining arc lamps with incandescent circuits has now become quite general. In fact the day is not far distant when an incandescent circuit without such lamps on it will be a rarity. There are a great many places where only the incandescent service exists yet where arc lamps are badly needed, and it is for just such places that the Ward lamp has been specially designed. It has now been perfected in many details, and includes various forms, the principal of which are the regular circuit lamp for ordinary work; the search lamp, the railway lamp, the theatrical lamp, the alternating lamp and the photo-engraving lamp. As to the street lights, some interesting quotations are made from the proceedings of the Edison Convention in 1890, when New York reported the use of 250 of them, Brooklyn 360, and Boston an equally large number, while since that time there has been a great growth. The railway lamp is provided with an automatic cut-out to throw into the circuit a resistance equal to that of the lamp. The alternating lamp is now furnished of the same general appearance as the continuous for use on circuits of low potential, running on 50 volts from the secondary. The engraving and theatrical lamps are of neat design and of simple construction. The search light is of easy manipulation, and made to stow away when not needed. One type for river and inland use can be mounted on top of the pilot house, with a shaft extending through to the interior, by means of which a wheel is fastened to it for revolving, raising or lowering the light, and the connections are such that the light can be revolved any number of times independently of the wires carrying the current.

The company supplies also resistance coils, lamp hoods, etc. The pamphlet, which is well illustrated, is supplemented by a number of testimonials. One from Brooklyn states that there are now in use in that city no fewer than 740 Ward lamps on the Edison circuits, giving great satisfaction. The Holland, Mich., Co. write that all their customers were wanting to change their incandescent lamps and get the arcs.

THE INTERIOR CONDUIT CO. AT MONTREAL.

THE Interior Conduit & Insulation Co., of New York, will be ably represented at Montreal by its general manager, E. W. Little, and E. T. Greenfield, electrician. As usual the company will present a complete exhibit of their admirable and now generally adopted system of electric wiring. This being the first opportunity presented since they have embarked in the general electrical manufacturing business to make an exhibit of their new appliances and apparatus, it is expected and promised that many new and novel devices will be shown, including several that have been exclusively described in THE ELECTRICAL ENGINEER.

The Johnson ampere meter, an absolutely "dead beat" instrument, and the Johnson vice lock switch will be found to be worthy of attention.

The company also promise to show the new "California" arc lamp, which they are about to place upon the market. This lamp is only fifteen inches in length, has no obstruction underneath, consequently casting no shadows, and will burn over 90 hours without trimming or change of carbons. For economical and other recognized advantages this new departure in arc lamps will be worthy of special attention from those visiting the exhibition.

The Garland carbon protector is another device that is promised to be shown. This device will be found specially useful in enabling the users of the single-carbon type of lamp to enjoy all the advantages of long life of carbons, hitherto only accomplished by the use of double-carbon lamps. It is claimed for the Garland carbon protector that it is effective in decreasing the consumption of the carbons from one inch and a half to one-half inch per hour.

Other useful and novel appliances especially applicable to the conduit system will be shown.

A PIECE OF WRAPPING PAPER.

"ONLY a piece of wrapping paper, but there's a thought wrapped in it for you," is the legend printed on a bit of coarse paper. Opening this as one does naturally, we find the announcement of the Jenney Electric Motor Co., of Indianapolis, Ind., together with the statement that the Jenney motor is the best made. It is an ingenious little scheme of advertising, and likely to prove effective.

CABLE RATES.

THERE has been a good deal of talk in the newspapers as to an advance in cable rates, the overtures having come from the Anglo-American Co. to the Mackay-Bennett (Commercial) Co. This is denied, and Mr. W. H. Mountford says that the Anglo Co. has made no such proposition, while the Commercial people say that they are quite satisfied with the money they are making at 25 cents a word.

WESTON ELECTRICAL INSTRUMENT CO.

IN the way of voltmeters and ammeters it would be difficult to find more popular goods than those manufactured by the Weston Electrical Instrument Company, of Newark, N. J. They have been adopted as standards by nearly every large company engaged in the manufacture and sale of electrical instruments in the United States. The demand for them continues brisk.

NEW YORK NOTES.

CHAS. A. SCHIEREN & Co., manufacturers of the famous patent perforated leather belting for dynamos and other swift-running machinery, are making extensive alterations in the appearance and appurtenances of their offices and salesrooms, 47 Ferry street, New York. Their quarters will be very inviting as well as convenient when the changes being made are completed.

THE FISHKILL LANDING MACHINE CO., Fishkill-on-the-Hudson, N. Y., manufacturers of the Fishkill-Corliss engines, horizontal and upright, are experiencing a steady demand for their specialty. With their latest styles of valve-gear and noiseless dash-pots, these engines are bound to enjoy a high degree of popularity. They are very attractive in appearance, and are efficient and durable.

ABENDROTH & ROOT MANUFACTURING CO., 28 Cliff street, New York, manufacturers of Root's improved steam boiler, find the demand for it steadily increasing. They are very busy at present and the outlook for the balance of the year is exceedingly promising.

THE INTERNATIONAL OKONITE COMPANY, LIMITED, New York and London, find business brisk, especially in their cable department. The Acme lead cable for underground purposes, recently brought out by this firm, promises to become very popular.

WESTERN TRADE NOTES.

THE FOREST CITY ELECTRIC WORKS, of Geneva, O., are shipping large numbers of the well-known Cleveland Arc Cut-Outs and constantly receiving new orders. The satisfaction they are giving is well shown.

Some quotations from recent correspondence: "We have been using the Cleveland Arc Cut-Out during the past six years with great success. We consider them safe and reliable in every respect." (From Brush Electric Light and Power Co., Cleveland, O.) "We have used your Arc Cut-Out for a number of years almost exclusively. We have found it very satisfactory in every respect." (From Detroit, Mich., Electric Light & Power Co.) "We have over seven hundred (700) of your Arc Cut-Outs in service and are pleased with them." (From Brush Electric Light Co., Rochester, N. Y.) "We are pleased to say that we have used your Arc Cut-Outs for the past two years and with good results." (The Toledo Electric Co., Toledo, O.)

THE JAMES LEFFEL & Co. have just sold the Niles Electric Light & Power Co. three 4½ feet Leffel wheels with all of the shafting, gearing and transmitting machinery for operating their plant there. They are also building a 400 h. p. wheel for the Edison Illuminating Co., in Rochester, N. Y. The Rochester Power Co. have just started a 500 h. p. wheel 30 inches in diameter, with new patented gate arrangement which is working very satisfactorily. A 5½ foot wheel is almost ready for shipment to Goshen, Ind., for electric lighting service. C. P. Poole, Lynchburg, Va., has bought a 5 foot wheel for electric lighting.

THE BUCKEYE ELECTRIC CO., of Cleveland, O., manufacturers of incandescent lamps, have issued a very handsome little catalogue of their lamps. It is beautifully illustrated, and the frontispiece, showing the various sources of artificial light from Father Time with a torch, through the era of candle, oil and gas, to the incandescent lamp, is exceeingly pretty and appropriate.

THE SIOUX CITY GAS LIGHT CO., of Sioux City, Iowa, are making some extensive changes in their power plant, and will put in two large Armington & Sims engines. This company has been using a 400 h. p. engine of this make for some time past. The Pond Engineering Company, of St. Louis, have the order for this additional work.

E. F. VAN NESS & Co., of Valparaiso, Ind., have arranged to install an electric lighting plant, and have purchased their machinery, including two steel boilers and an Armington & Sims engine. This order was placed with the Chicago office of the Pond Engineering Company.

WARRELL FUSE-BLOCK.

Warrell Fuse-Block.

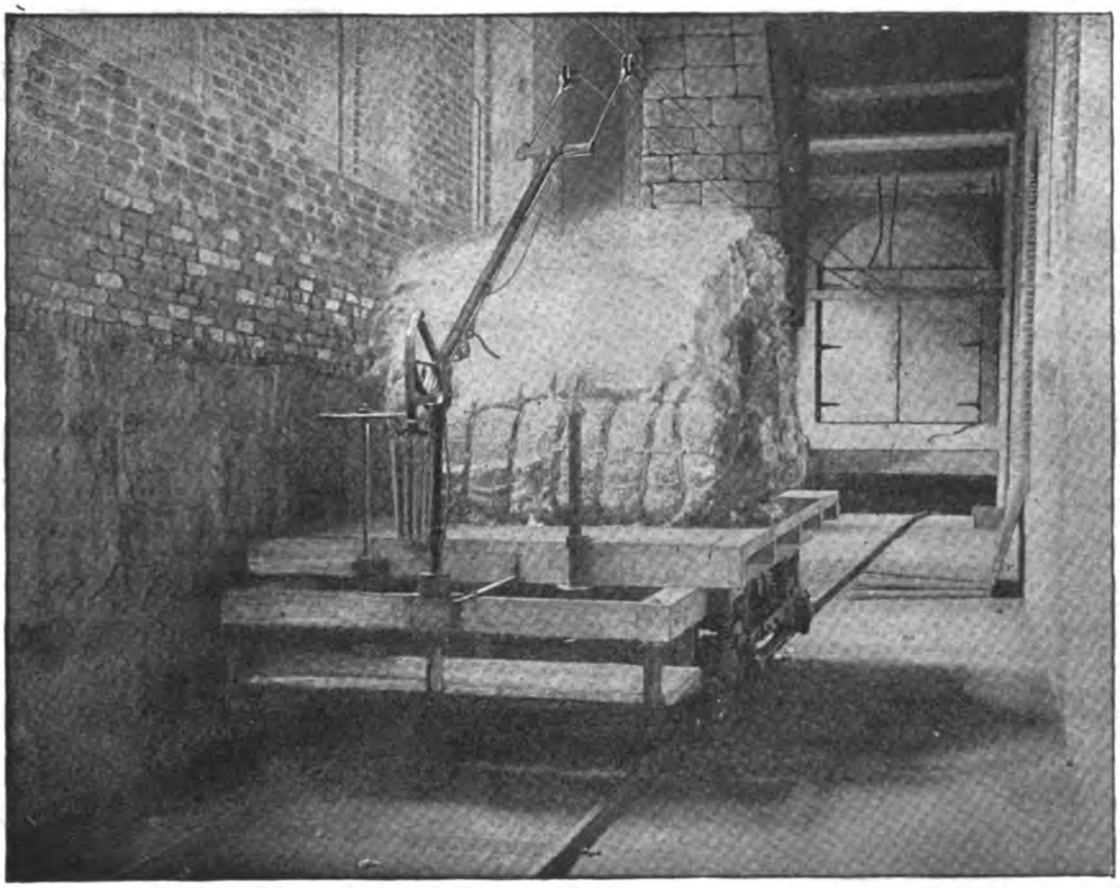
THE illustration herewith shows a single-pole fuse-block recently invented by Mr. Fred. G. Warrell, of Philadelphia. These fuse-blocks are constructed of the best vitrified porcelain encased in a glass shell, thus rendering them moisture-proof. The shell, being transparent, gives the wireman a full view of the interior without taking it apart. They are very compact, being less than an inch long.

Mr. Warrell has also invented a double-pole fuse-block of the same character, possessing the same advantages as the single-pole block, and only slightly larger.

ELECTRIC TRAMWAY, JACKSON MILLS, NASHUA, NEW HAMPSHIRE.

AN interesting example of the saving in time and money made by the use of electricity as a motive power for the handling of heavy materials in manufactories is shown in the plant recently installed by the Thomson-Houston Motor Co., of Boston, Mass., at the mills of the Jackson Manufacturing Co., of Nashua, N. H. The Jackson Company has for a number of years transported its cotton from the cotton house to the picker room by means of platform trucks running on rails, which were loaded with cotton and pushed along by men. When the motive power was changed to electricity the same rails were used and the road was equipped with a three horse power motor car. Instead of the six men formerly employed, two men do the entire work, thus accomplishing a great saving both in time and money. A wooden tunnel, the full length of the cotton house (300 feet), about eight feet wide by ten feet high, contains the track. About every fifty feet openings are made in the tunnel, from which the cotton is taken and loaded on the car.

The illustration shows the motor car with a load of cotton, near the end of the route. The iron doors seen at the end of the tunnel open into the picker room. The motor car is also employed as a locomotive for hauling coal from the coal sheds to the boiler room, which is situated at the right of the tunnel next the picker house. As will be seen by reference to the cut, the double-trolley system of wiring is used, thereby avoiding the use of the rails for the return circuit. The total length of the track is about 300 feet with a gauge of four feet. The road has a grade of 3 per cent., notwithstanding which loads of 4,000 pounds weight are easily handled by the motor car. The current is furnished by a 220 volt Thomson-Houston generator of the type known as D 7½, which also furnishes current for lighting the tunnel.



THOMSON-HOUSTON FREIGHT CAR AT NASHUA, N. H.

THE AKRON ELECTRICAL MFG. CO.

THE above-named company was organized in January, 1891, by prominent capitalists of Akron, O., for the purpose of forming a strong and pushing corporation for the manufacture of general electrical supplies, generating and power apparatus. The company has a paid-up capital of $100,000, and is well backed financially. Located as it is in the heart of one of the best manufacturing districts in the country, amply provided with the best railroad facilities, there is no limit to the extent and magnitude of its operations. The well-known Loomis Fire-Alarm System is manufactured by it. It is also placing on the market a complete line of stationary motors and generators, for both power and light uses, of perfected form and slow speed, with full power, high efficiency and unsurpassed mechanical construction. It will make a specialty with the stationary machine of the application of electricity to mining operations, and is prepared to take contracts for the complete mechanical and electrical equipment of mines of all kinds.

Mr. W. D. Chapman, general manager of the company, has had an extended experience in electrical street railway construction work, being one of the earliest contractors in that part of the country to equip street railways with electricity, and also has had about 15 years' experience in mining engineering, which eminently adapts him for the management of the company. The company will also build electric motors of improved type for street railway work and take contracts for the complete building and equipment of street railways, from the laying of the track to all of the details which comprise a first-class street railway plant. In this connection it will manufacture numerous specialties for overhead street railway construction.

The president of the company is Mr. F. A. Wilcox, who is also well known in street railway circles, in which he has large interests. The vice-president, Mr. E. B. Miller, is a prominent business man of Akron, where he is connected with the large reaper works of the Buckeye Mower and Reaper Co. Mr. Wm. B. Doyle, secretary and treasurer, is a capitalist of Akron. The field of operations of the company is large, but its adequate facilities will be handled in the most thorough manner, and it is the intention to do a large and general electrical manufacturing business for the installation of plants of any magnitude.

NEW STYLE ANDERSON TROLLEY WIRE HANGERS.

We illustrate two new forms of trolley wire hangers recently brought out by Messrs. A. & J. M. Anderson, and now being sold

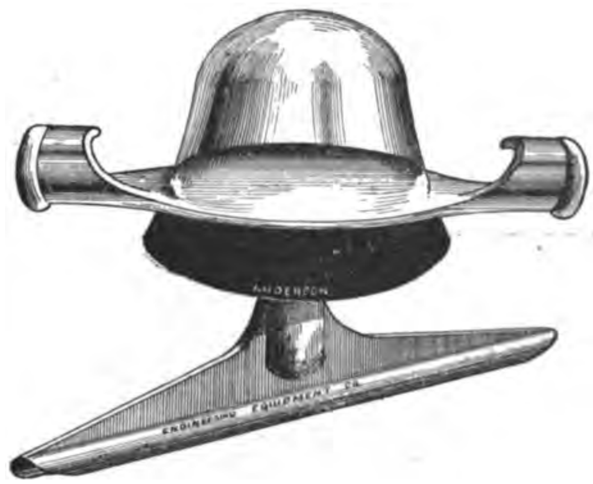


Fig. 1.—Anderson Trolley Hanger.

by the Engineering Equipment Company, of New York and Boston.

Fig. 1 shows a hanger which has met with a very favorable reception from constructing engineers and has the merit of bringing the trolley wire as near to the span wire as possible. Fig. 2 illustrates the second form, which has the much-used high support and permits the hanger to be readily sprung into place upon a tightly drawn span wire. We note a decided tendency, however, among many constructing engineers to bring the strain as much in line with the trolley wire as possible. The form shown in Fig. 2 was designed, therefore, to accomplish this aim and has been adopted by several engineers in their present work, as possessing advantages not to be found in other forms of hangers, in addition to being uncommonly compact and strong, and thoroughly reliable as regards durability.

Both these designs of hangers have the form of an inverted cup, with side arms for attachment to the span wire. The cup is filled with the standard Anderson compound, known as the Ætna insulating material, with a long petticoat extending beyond the metal, and a threaded brass fixture embedded therein, to which

Fig. 3.—Anderson Ætna Railway Bell Insulator.

any one of the numerous trolley clips or ears on the market can be readily attached. Brass alone is used for the metallic portion of the hanger, which effectually prevents the creeping over the insulation of the rusty film which sooner or later by oxidation occurs in hangers containing iron, thereby seriously impairing the insulation of the trolley wire. Altogether the new hangers are light, exceedingly strong and made to last, and several orders have already been placed. They have met with a cordial reception among constructing engineers who believe they will stand the test of time and fill the want of substantial materials for permanent overhead construction.

In Fig. 3 is illustrated the standard Anderson Ætna railway bell insulator, well known through the thousands now in use. The Ætna material is an exceptional insulating compound. It is moulded under a pressure of several tons to the square inch, does not crack or split when struck, is entirely unaffected by water, has stood boiling for hours without damage and will stand any amount of ill-treatment on account of its toughness and strength. It is especially adapted, therefore, for use as a reliable bell insulator, or in a similar form, wherein the weight of line and any strains must be borne by the material itself.

The Engineering Equipment Co., 143 Liberty St., New York, and 126 Pearl St., Boston, are the selling agents for the line

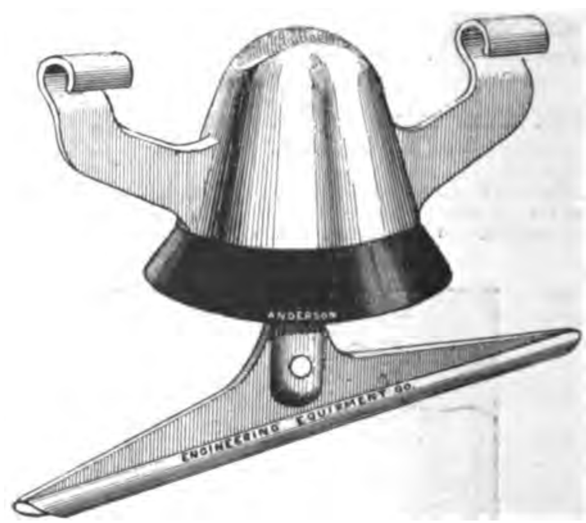

Fig. 2.—Anderson Trolley Hanger.

materials and the Boston trolley manufactured by the Messrs. Anderson.

THE GERMANIA SHADE-HOLDER.

Among recent electrical specialties, the shade-holder manufactured by the Germania Electric Co., of Boston, deserves more than a passing notice. The patent covering this simple device was issued in February, 1890, but with characteristic conservatism the Germania Co. has not pushed its sale before thoroughly testing it by extensive use. A large number of these shade-holders were put into use about two years ago, and they have given such uni-

Germania Shade Holder.

versal satisfaction that the company has determined to push them, and has made every endeavor within the last few months to place them on the market at the lowest possible price.

The shade-holder, as seen by the accompanying engraving, consists of two parts. Projecting from the under side of a main ring are three ears, through which screw-nuts are passed for holding the shade or globe in position. The upper part of the main ring is bent over and has three inwardly-projecting arms, which are hooked at the end in order to hold the second smaller ring in position. This small ring is simply a plain band of thin metal having two ears through which a screw passes, and is used for clamping the shade-holder to the socket or fixture.

A simpler or more efficient device could hardly be imagined. In making these shade-holders nothing but first-class metal is used, and the whole is highly finished, making a very light, stiff shade-holder, beautiful in design, and cheap. It will be noticed that there are no joints and no weak points, so that there is absolutely nothing to break and no part to work loose. It is in every respect a model shade-holder.

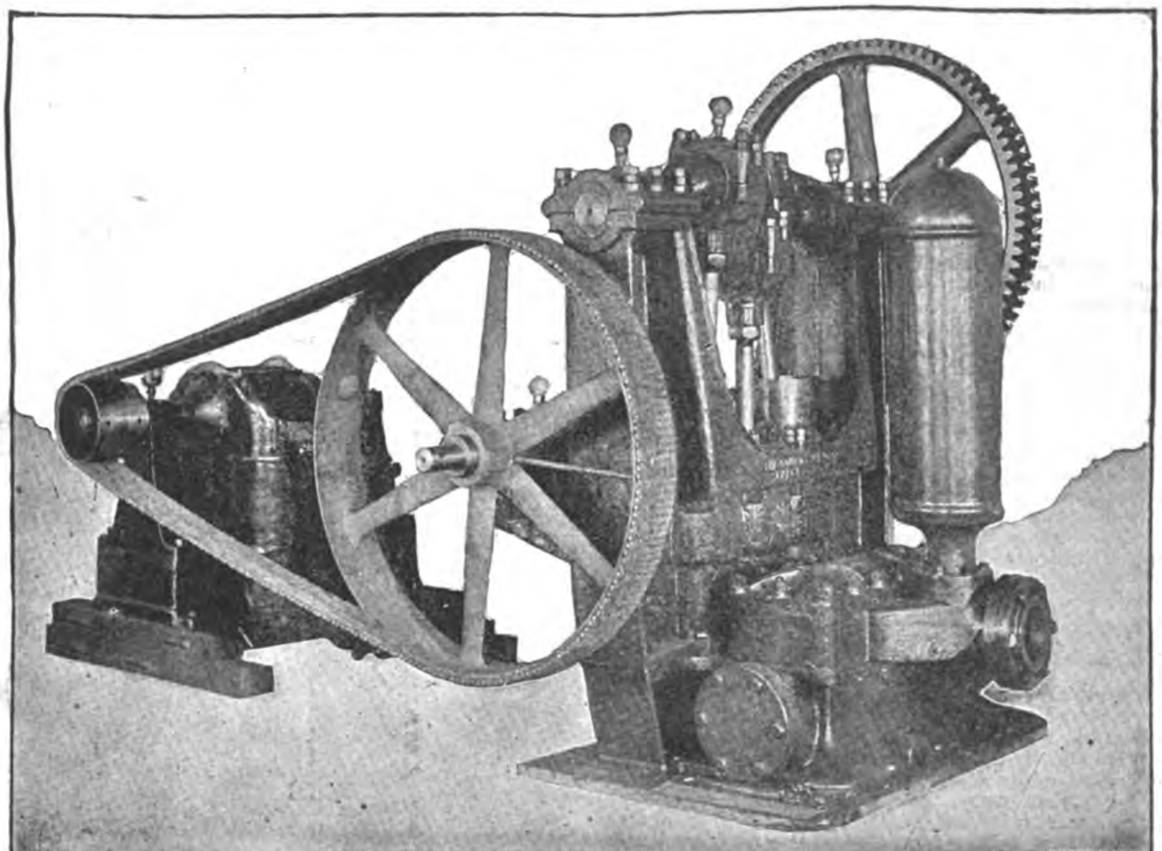
THE GOULDS "TRIPLEX" ELECTRIC PUMP.

THE general application of electricity for mine operation in lighting, operating fans, haulage locomotives, coal cutters, drills, etc., makes electric pumps only a part of the general system—nor should this item of pumping be under-estimated when the best authorities concur that on an average seven tons of water are pumped for every ton of coal mined. Heretofore, as is well known, this pumping has been generally performed with steam pumps, steam being generated at the surface and transmitted below for operating the pumps. With the electrical transmission pumping can be done at places where it has been impossible to operate the steam pump from the long distances which the steam must necessarily be conveyed, and because of the small space required by the electric pump in comparison with the large, cumbersome steam pumps generally used.

The Goulds Mfg. Co., of Seneca Falls, N. Y., has designed an electric pump especially for this class of work. One type of this pump, known as the "Triplex," is built with phosphor bronze bushed cylinders, glands and solid plungers of the same metal to resist action of sulphuric acid, usually encountered in mine pumping. The connecting rods are tied to the crank shaft by solid bronze bushed strap ends having adjustment for wear. The bronze suction and discharge valves on either side of cylinder are of a simple, yet heavy substantial pattern, best adapted for severe and continuous service. The construction of the pump admits of its being taken apart, which may be necessary, to carry it into a mine, and as readily put together for service. The pump is designed to operate against any pressure up to 800 feet lift.

Another form of "Triplex" pump is shown in the accompanying illustration, which has raw hide pinion and pulley for belt. This combination of pump and motor connected by a belt can be brought within surprisingly small limits, and is practically noiseless in operation. It readily commends itself also for house or office building service, where any noise is objectionable.

As will be noted, these pumps are operated by Thomson-Houston motors, and the results of an elaborate series of tetss made at the Thomson-Houston Works, at Lynn, Mass., showed that the 4 in. x 4 in. pump operated by a three h. p. motor developed an efficiency of 59.5 per cent., when operating under a pressure of 150 lbs. per square inch, that is, equal to a lift of 350 feet; while the 4 in. x 6 in. pump, driven by a five h. p. motor, developed an efficiency of 60 per cent. under like conditions.



THE GOULDS "TRIPLEX" ELECTRIC PUMP.

TESTS ON THE SHORT "GEARLESS" MOTOR.

DURING the past month the Short "Gearless" motor has been very thoroughly tested in Cleveland, being put to the hardest kind of work in regular commercial operation. Among some of the noteworthy tests are mentioned the following:

In order to prove the power of the motor, it was attached to two other motor cars and drew them without difficulty along a rough and dirty track, attaining a very fair rate of speed. The car was stopped at the commencement of a 40-foot curve, at the other end of which was a 8 per cent. grade. It was then started up, and without difficulty drew the three cars around the curve and up the grade. This was one of the severest tests which could be put upon the motor under all the conditions. A prominent electric railway manager who was present stated that not a single motor on his line could do the same work.

The car was put into regular service on three of the Cleveland street railway lines, hauling trail cars and drawing heavy loads without the slightest difficulty, and at speeds far in advance of the ordinary schedule of the road. Current and voltmeter readings were taken in each case, showing that the power consumed was even less than had been anticipated by the Short people themselves.

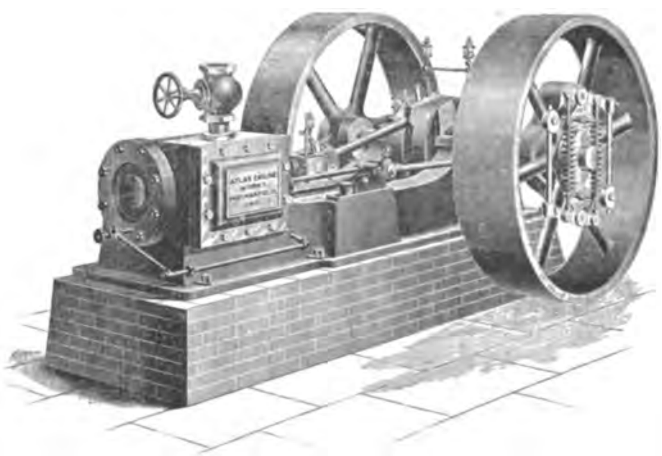
A comparative test was made on Tom Johnson's line between the "Gearless" motor, drawing a trail car, and one of the best-known of the "Single Reduction" motors now in the market, also drawing a trail car. The cars were run ten minutes apart over the same line for a distance of 22 miles, covering one round trip. This distance was made in two hours by both cars, stopping to take on and let off passengers. The fare register showed 80 passengers carried by the Short motor and 47 by the "Single Reduction." Ampere and volt readings were taken at intervals of one-half minute for a long distance, the general averages showing that the Short "Gearless" motor required about 25 per cent. less power than the S. R. G. motor. This was a complete surprise to all concerned, as the Short Company had hardly hoped to show any material advantage over other motors in the matter of current, its chief claim being for the "Gearless" a large reduction in the repair account, owing to the extreme simplicity of the machine.

In one of the tests the trail car ran off the track at a curve. Its brakes were set and it was drawn on to and around the curve with full load on both cars without the slightest difficulty.

ATLAS ENGINE WORKS.

THE accompanying illustration shows an automatic self-contained engine built by the Atlas Engine Works, of Indianapolis, Ind. This engine is designed especially for electric light and other work, where perfect regulation is necessary and high speed desirable; and is solidly built with long bearings and large pins.

A special feature of this engine is its governor, which, with few parts, combines the best points of governors of its type, and



THE ATLAS HIGH SPEED AUTOMATIC ENGINE.

has this additional feature, namely, that the weights being hung from the centre, the inertia of the whole is made to contribute in a very effective manner to the fineness of the regulation of speed. The eccentric is hung rigidly, is not liable to wear out of line, and is yet under perfect control of the weights and springs. The main steam valve is perfectly balanced, the only friction being due to its own very light weight. The balancing hood is loose on the seat and yields promptly to water or excess steam in the cylinder, while springs return the hood to its place, and studs guide it to its correct seat.

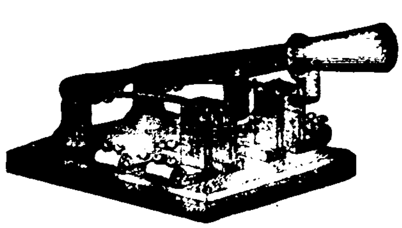
Altogether, the engine with its governor and valve forms a most attractive piece of machinery, perfect in regulation, economical of fuel, and reasonable in price.

The Atlas Engine Works have recently published a very handsome catalogue of their engines and boilers and accessories, together with complete specifications and directions for setting up.

THE WESTON QUICK-BREAK SWITCH.

THE illustration herewith shows a new "quick-break" switch recently invented by Messrs. W. H. Weston & Co., of Philadelphia. These switches are constructed of yellow or red brass, dipped or polished, and mounted on slate bases. The wearing parts are strong, durable, and easily replaced. The contacts are of ample proportion, capable of carrying a current in excess of rated amount. All arcing is prevented, as the breaking of the contact is done very quickly, no matter how slowly the handle may be raised.

The quick breaking is accomplished by means of a tempered steel spring. On raising the handle, tension is placed on the



WESTON QUICK BREAK SWITCH.

spring, and when the contacts are about leaving the clips the tension causes them to fly out, when there is no opportunity for the formation of an arc.

MR. T. T. ROBINSON, of Dedham, Mass., has been chosen treasurer of the Worcester, Leicester, and Spencer Electric Railway Company.

MR. HARRY WILLARD has been appointed superintendent of the Leicester, Mass., Electric Co.

THE STANDARD UNDERGROUND CABLE CO.

THE Standard Underground Cable Company will have an unusually handsome exhibit at the Montreal Electric Light Convention. Among other things it will consist of a double set of the company's initials done in brass, supporting samples of underground cables for all classes of electric service.

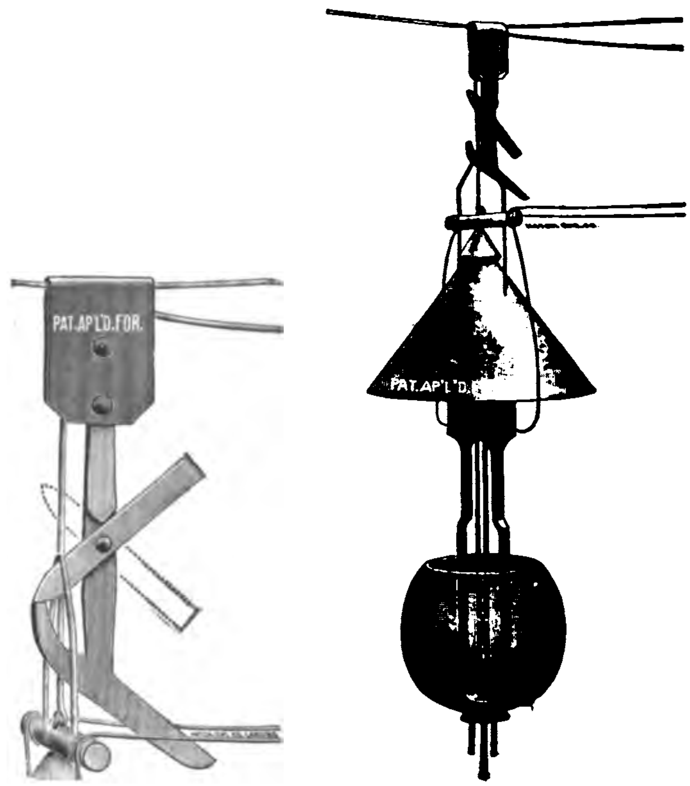
It will contain, also, a special sample board of samples of all the kinds and sizes of cables to be used in the contract of the Minnesota Brush Electric Light and Power Company, of Minneapolis, just awarded the Standard Company, and which covers over 400,000 feet of underground cable, making it the largest single contract of its kind ever given in the United States.

Vice-President J. W. Marsh, of Pittsburgh, and Manager G. L. Wiley, of New York, will represent the company at the Convention.

THE PADDOCK ARC LAMP HANGER.

THE cuts represent the action of the Paddock "Safety Arc Lamp Hanger" just being placed upon the market by the Central Electric Company, of Chicago.

This hanger is very simple in its construction, and is so well illustrated in the cuts that it hardly needs any further description.



PADDOCK ARC LAMP HANGER.

The hanger affords safety from the falling of lamps, and all attendant dangers and expenses by reason of insecure fastening or the breaking of ropes. Combined with the hanger is a sleet-proof pulley, which is always indispensable in this sort of device. The hanger is being placed upon the market at an extremely low price.

THE WILLIAM POWELL CO.

THE new catalogue of the Union Brass Works of 50, 52, and 54 Plum street, Cincinnati, O., is one of the most complete, substantial, and business-like trade publications that has lately come under our notice. It contains 104 pages of well-printed and profusely illustrated matter, is strongly bound in cloth, and contains descriptions of all the improvements up to date of the lubricators, signal oilers, valves, etc., manufactured by this enterprising company. The catalogue ought to be in the hands of every electric light station superintendent.

CROCKER-WHEELER MOTOR CO.

THE Crocker-Wheeler Electric Motor Company are full of business. They have just furnished a ½ h. p. motor for the new Chilian cruiser being fitted out in England. Their orders on hand are very heavy.

NEW PULLEY CLUTCH AND CUT-OFF COUPLING.

THE accompanying engraving, Fig. 1, shows the new pulley-clutch designed by Mr. W. J. Woodcock, and now being built by the Allentown Foundry and Machine Co., of Allentown, Pa., and which embodies a number of ingenious and valuable features. The clutch is shown in transverse and longitudinal sections, respectively in Figs 2 and 3. As will be seen, the long hub I cast

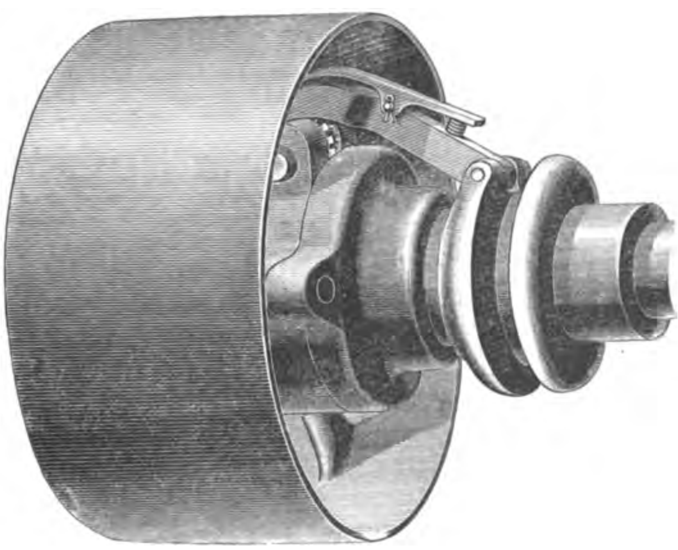


FIG. 1.—WOODCOCK PULLEY CLUTCH AND CUT-OFF COUPLING.

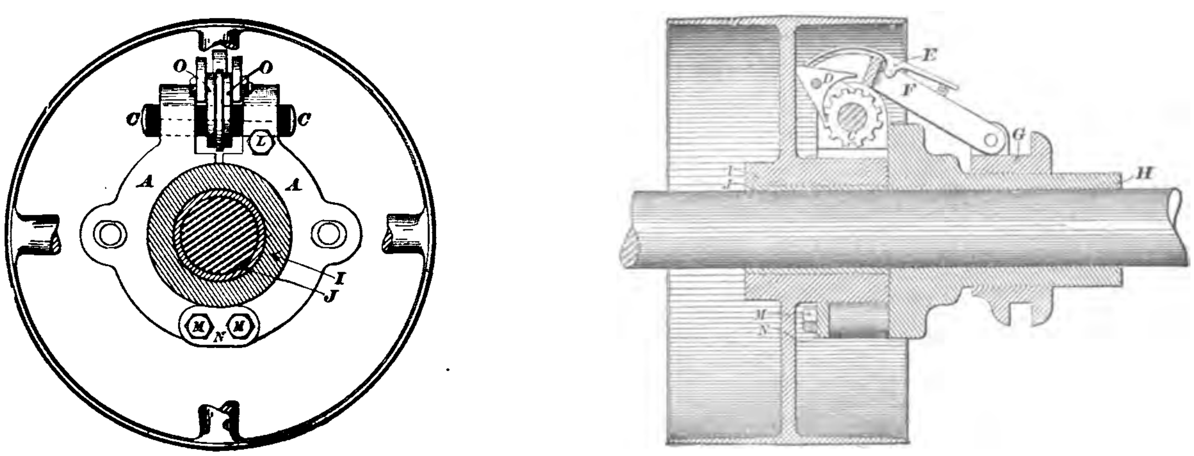
to the pulley is bored out and lined with a brass bushing, J. This pulley runs loosely on the shaft, and the long hub of the flanged coupling H is keyed on the shaft. The hub of this coupling is turned off to allow the sleeve G to move longitudinally on it. Each clamp is pivoted on a bolt, M; these bolts are fitted into the flange of the coupling H, so as to cause the clamps to revolve with the coupling. For further security a plate, N is placed under the heads of the bolts M M to tie the two together. The right and left-handed screw C C works in brass nuts, which are fitted in the clamps A A, and by turning this screw in one or the other direction the clamps A A are either tightened or loosened on the hub I of



FIGS. 2 AND 3.—WOODCOCK PULLEY CLUTCH AND CUT-OFF COUPLING.

the pulley. For the purpose of turning the screw C C in either direction a ratchet wheel is fastened to its centre, which engages with the pawl D; the pin on which this pawl works passes through two links, O O, which are free to rotate on the screw C C; this pin also passes through the forked end of the lever F. The other end of this lever is attached to the sleeve G, as shown.

From the foregoing it will be seen that the links O O form a connection between the screw C C, the ratchet wheel, pawl, and lever F. A finger E is fulcrumed on the back of the lever F, and the spring acting at one end, causes the other end of the finger to press on the pawl D, keeping the latter engaged with the wheel. Now, by means of a suitable fork and collar in the groove of the sleeve G a longitudinal movement can be given to the sleeve while the shaft is in motion. When the movement of G is towards the pulley, the lever F is carried forward, and the pawl and ratchet act to tighten the clamps A A, thereby transmitting motion to the pulley; when a loosening of the clamps is required the sleeve G is moved back sufficiently to reverse the pawl D; the finger E in this case will bear on the other side of the pawl, causing the ratchet wheel to loosen the screws.

By this simple means the position of the pawl is quickly changed, thereby producing an action either for tightening or loosening the screw C C, according to which side of the pawl is engaged with the ratchet wheel, the whole arrangement requiring but a small space on the shaft. A marked advantage is claimed for this clutch, namely, the tightening may be gradual, thereby starting the machinery slowly, and by further tightening, all slipping on the pulley is prevented. For dynamos, and other machinery requiring caution in starting, this clutch is said to be well adapted.

For cut-off couplings the pulley part is not required; one section of the shaft extends into the hub I sufficiently far to support it while running loose, and the hub I is keyed on the other section of the shaft.

At L a screw is provided when soft metal or a wooden plug is to be brought in contact with screw C. By tightening the screw L the plug is brought in contact with C, and makes it tighter in the thread, so as to stand without loosening when in use.

STANDARD ELECTRIC TIME CO.

THE above company, of New Haven, Conn., are to have quite an exhibit at the Montreal convention. They will furnish three large dials, 24 inch, on the main gallery, besides numerous smaller dials in the other departments of the building. These will be operated by one of their self-winding regulators at the headquarters in the exhibition building, where they will have an exhibit of their secondary dials, self-winding clocks, and electric gauges.

E. G. BERNARD & CO.

MR. E. G. BERNARD reports having closed contracts during the past week for four plants, one for a knitting mill in Cohoes; one for a woolen mill in Marcellus; one for a silk mill in Argusville, and one for a hotel in Albany. This makes Mr. Bernard's sixty-ninth knitting mill plant.

WIRE FOR THE MASONIC TEMPLE, CHICAGO.

THE new Masonic Temple building, at Chicago, requires one of the largest isolated plants in the country, and over 65 miles of Simplex wire will be used for the circuits. The competition was quite severe, but the merits of the Simplex Co.'s make counted, and George Cutter will supply all the wire used for the lighting circuits.

BISHOP GUTTA-PERCHA CO.

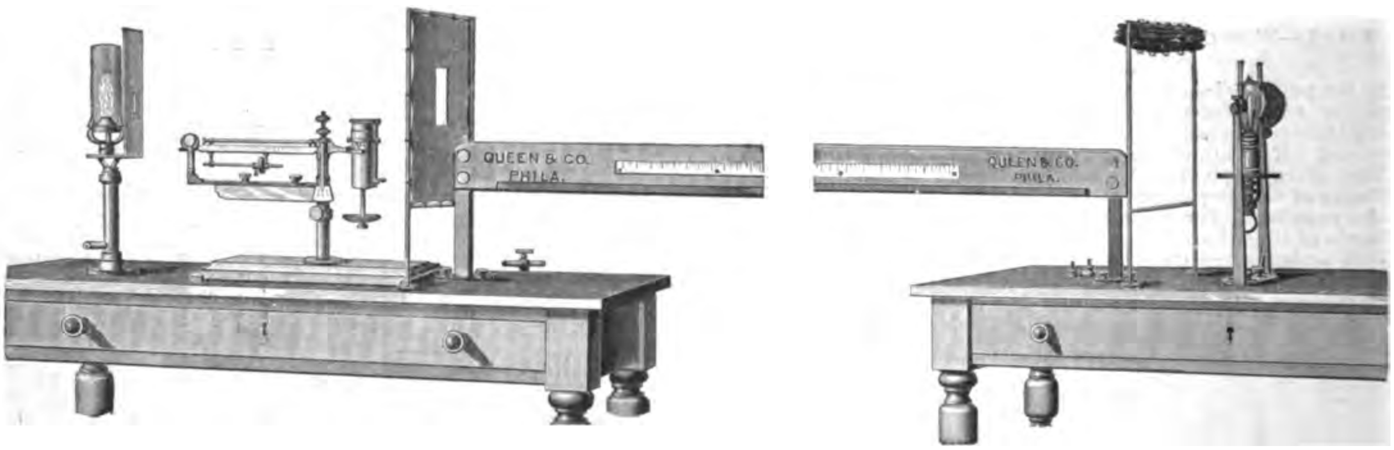
THE above company, of 420–426 East Twenty-fifth street, this city, report business as good and improving. This concern is not only one of the very oldest in its field, with a large number of early and interesting installations to point to, but it has been quite active in supplying wires and cables for all the later developments of electricity, including underground work in the great cities, submarine work in New York Harbor, and the transmission of alternating currents of high potential. The company's catalogues and sample cards will be found useful.

NEW LABORATORY PHOTOMETER.

MANY photometers are catalogued by instrument manufacturers and sold as suitable for electrical work, but these photometers are primarily gas photometers made to do duty as electric light photometers. Recognizing this fact and appreciating the demand for an instrument especially adapted to electrical measurements and provided with accessories to this end, Messrs. Queen & Co., of Philadelphia, last spring took up the problem and have brought out the photometer illustrated in the accompanying engravings. The instrument and accessories were designed by Mr. Elmer G. Willyoung, of Messrs. Queen & Co., and the first one built was recently sold to the Standard Lamp Co., of Appleton, Wis., where it is giving great satisfaction.

The photometer is of the usual Bunsen type. Two tables, each four feet long by 20 inches wide, support the graduated bar and accessory pieces. These tables are of white wood with ebonized top and can be firmly screwed to the floor; the table legs unscrew so that the whole apparatus can be packed in comparatively small compass for transportation or storage. The tables stand at such a height that observations may be taken by a man of medium height without bending. The bar is of metal supported by a larger bar of wood; the graduated bar is made in several different lengths and either graduated directly in candle-power or else, in the metric system, to half centimetres. The wooden bar is made with a cross-rail along the bottom, along which rides the carriage containing the Bunsen disc or "grease spot"; this carriage is arranged so as to rotate through 180 degrees about a vertical axis, thus allowing measurements to be made with each eye alternately toward each light and, hence, taking the mean of observations, eliminating largely the errors due to differences of vision between the two eyes.

As a standard may be used a candle-balance, a Methven screen,



NEW QUEEN LABORATORY PHOTOMETER.

or an incandescent lamp, as may be preferred. The left-hand table is provided with cross-rails parallel with the width of the table. The candle-balance is mounted upon a base fitted to these rails, and when drawn forward to the limit of the rails is in correct position for use as a standard. Pushing the balance back out of the way, brass bed plates are disclosed, upon which the Methven screen or standard incandescent lamp (held by a special socket) may be placed and firmly fixed by means of two milled-head screws. The right-hand table is also provided with bed plates in such a way that the universal socket, the Methven, or the standard incandescent lamp may be placed in position and their light measured by comparison with any of the other standards; hence the checking of the standards among themselves or the standardizing of the standard incandescent lamp can be very easily and quickly done.

The candle-balance has been arranged for weighing candles while burning. The bar of the balance is graduated in half-grain divisions and differences of weight can be read off by means of the rider up to 50 grains. Equilibrium is secured by means of a counterpoise weight sliding along a rod beneath the balance beam; the rod itself is threaded at one end so as to be used as a micrometer adjustment when the counterpoise weight is fastened by means of the check-screw. Either one or two candles may be used as desired. The balance also has an adjustment in its own length for bringing the line passing through the centres of the candle flames exactly at the zero of the scale.

For holding the incandescent lamp to be measured, the universal socket shown on the right-hand table has been devised. By means of this socket any lamp of any make may be presented to the sight box at any angle whatsoever. This socket consists, essentially, of a lamp socket with its central axis perpendicular to a graduated circle. This socket can be rotated about this vertical axis and clamped in any position; the amount of rotation is measured by means of an index attached to the socket. A small set-screw allows the index to be set at zero when the plane of the carbon filament is at right angles to the table length. The socket as a whole can also be rotated about a horizontal axis cutting the line passing through the center of sight box and center of illumination of the standard; the amount of rotation is read here also by means of an index and graduated circle. In order to bring the axis of greatest illumination of the lamp into the axis passing through the centre of the sight box, the frame supporting the socket proper may be raised or lowered to whatever point desirable and there fastened. With the universal socket, as with the candle-balance, there is a small adjustment in the length of the table, thus allowing the axis of greatest illumination to be placed exactly at the end of the scale. Both circles are graduated to every five degrees.

The standard incandescent socket, not shown in the engravings, is designed to hold an incandescent lamp to be used as a standard; as stated before, this lamp socket may be placed upon the right-hand table and its candle-power measured by comparison with either the candle-balance or the Methven screen; it may then be placed upon the left-hand table and used as a standard, thus making both the standard and lights measured of the same color, and hence greatly facilitating observations.

Curtains are provided for excluding extraneous light. All metal parts are finished dead black.

It is intended, as time permits, to adapt to this photometer several different accessories for use in taking measurements according to different methods, as, for example, Prof. Nichols' spectro-photometric method, the method of Lommer and Prudhun, recently described, etc. It is contemplated also to adapt the photometer to arc light measurements by adding certain accessory pieces.

THOMPSON & ROBERTSON.

THE above firm, of 258 Broadway, have notified the trade that they have secured the sole right to manufacture and sell the celebrated "Fibrous" dry battery and Fibrous Disc Leclanché porous cup, heretofore made by Taylor & Walsh, of this city. These will be manufactured under the personal supervision of the inventor and well-known electrician, Mr. J. Hart Robertson, and Mr. Louis Walsh, the latter of whom, it may be added, will represent the firm at the Montreal Convention. These Fibrous batteries are said to be superior in their durability, constancy, and great recuperative powers, and are specially recommended for all classes of open circuit work.

ELECTRICAL SUPPLY CO., CHICAGO.

CATALOGUE No. 44, just issued by the above concern, of 104 Michigan avenue, Chicago, is devoted to electrical house goods, and includes telegraph, fire-alarm, district messenger systems, and school supplies. It is a very handsome and complete publication, and gives all the needed information in regard to a very large variety of apparatus of the classes named. The catalogue, moreover, is not less ornamental than it is useful.

☞ ***Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Miscellaneous, etc., will be found in the advertising pages.***

THE

Electrical Engineer.

VOL. XII. SEPTEMBER 16, 1891. No. 176.

A CENTRAL STATION COMBINING THE ADVANTAGES OF BOTH THE CONTINUOUS AND ALTERNATING CURRENT SYSTEMS.[1]

BY H. WARD LEONARD.

WE are all well aware of the fact that the greatest strength of the three-wire system is due to features, the lack of which constitutes the greatest weakness of the alternating system, and that the reverse of this statement is equally true.

The high efficiency, reliability, safety and adaptability to supply almost any requirements for electric energy, which are the features of strength of the three-wire system, are the very points upon which the alternating system suffers by comparison, for its efficiency is much lower, its reliability is less, due to the fact that its machines are not practically operated in multiple arc, its safety is necessarily less, due to the existence of the high primary pressure, and its current is not adaptable to commercial use for motors, charging storage batteries, electro deposition, and so forth.

On the other hand, the low first cost of an alternating system, the simplicity of its circuits and of the operation of the central station, and its ability to reach with moderate expenditure of capital, lighting at any practical distance, make it the only possible pioneer in new and untried territory, without great risk, and almost the certainty, of expending capital which will never be remunerative.

Hence, it is that we find the three-wire system in possession of the densely settled centres of cities and towns, and not extending to the outskirts because of the uncertainty of a sufficient return upon the necessary capital, and both the central station manager and the distant would-be consumers anxiously awaiting the development of improvements which will enable the three-wire central station to supply such distant consumers. And hence it is, that the manager and consumers of an alternating system anxiously await the day when motors can be operated, and a more economical, safe and reliable current than the present alternating current can be furnished, by such a station to supply the imperative wants of the heart of a busy city.

If the above statement of the present existing conditions be a fair one, it will be evident that if we could only in some way secure the advantages of both systems in a common distribution, we should greatly improve matters. The object of this paper is to point out what appears to the writer to be a step forward in that direction.

The following conditions seem to be necessary:

1. We must supply a continuous current for the central portion of a town during the daytime when power is required.
2. We must supply the outlying districts with an alternating current during the night-time when lighting is required.
3. We must not operate the alternating system under conditions of light load when its efficiency is very low.
4. We must be able to supply current for lighting continuously throughout the 24 hours of the day.
5. We must have but one set of conductors in any consumer's place.

In order to meet the above conditions I propose the following:

1. Wire all consumers upon the standard three-wire systems.
2. Connect all consumers upon standard three-wire mains.
3. Arrange the network of mains so that the central section of the network can be disconnected from the outlying sections through the agency of switches.
4. Install three-wire feeders to supply the central portion of the systems at full load, and install 1,000-volt primary wires and alternating current converters with a three-wire secondary circuit to supply the outlying section at full load.

Let us see how we will operate the station. Suppose it is eight o'clock in the evening. The switches which serve to connect the central and outlying sections are open, and our three-wire plant is supplying the full load of the central portion of the city. The alternating plant in the same central station is supplying the converters of the outlying section, which convert from 1,000 volts primary to 220 volts in the secondary, and the secondary coil has a connection at the center which is led off to supply the central wire of the three-wire system of the outlying section, the outside terminals of the secondary being connected to the outside wires of the three-wire system. It will be noticed that both plants are being operated at full load.

Now, suppose it to be eleven o'clock. The load has gone off rapidly so that the alternating plant is now operating under the worst possible conditions, and these conditions will continue for the outlying district until dusk the next day—that is, for probably 18 hours. An operator is now sent out who goes to each section supplied by a converter, and, by throwing a switch, transfers the secondary wiring from the alternating system to the three-wire mains. In this way the small remaining load is gradually transferred to the three-wire plant, and then the alternating plant is shut down. The three-wire plant continues in operation all night and all the next day, supplying all devices with a continuous current. Motors can be operated in all portions of the system, even for domestic purposes in the distant residences, and all consumers get the opportunity of the use of the continuous current for any purpose desired for 18 hours out of the 24.

Dusk now arrives and soon the heavy lighting load will rapidly come on, and in such case the outlying section could not be supplied by the small wires feeding the distant three-wire section during the day, which are only about one-tenth the size which would be necessary to supply the full load.

The operator again goes round the circuit, and now transfers the load of the outlying section from the three-wire plant to the alternating plant, and this condition prevails again until eleven o'clock arrives, when the operation is repeated, as before described.

The switches for transferring the load of the outlying section from one system to the other, can readily be controlled by simple means from the central station itself, if desired.

Now, let us look at some of the advantages we have gained.

All of our inside wiring is done on the three-wire systems for use of a lamp of 110 volts. This means that for the same distances and loss in conductors we will save eleven-twelfths of the cost of copper which would be required by a secondary using 55-volt lamps upon a two-wire system; or, to put it another way, we can supply 110-volt lamps upon a three-wire system with the same cost of copper and the same percentage of loss in conductors at three and a half times the distance which would be permissible for 55-volt lamps on a two-wire circuit.

We all know the great desirability of using large converters, on account of their cheaper first cost per lamp and their higher efficiency, and also because a far more perfect regulation of pressure can be obtained upon a lot of lamps scattered in different kinds of stores throughout a block, if they be supplied from one converter, than can ever be obtained by supplying these lamps by a lot of small converters loaded differently in almost every case, and consequently supplying a different pressure at the secondary terminals of each converter.

Under the system proposed by me one converter would ordinarily supply the entire lighting of a block, resulting in less first cost, higher efficiency of conversion, longer life of lamps, greater reliability and greater simplicity of plant.

A point worthy of notice is that for 18 hours out of the 24 an absolutely safe pressure is in use throughout the entire system, and that during all day-light hours, when the greatest liability to accident from contact with high pressure wire exists, no high pressure is in use.

With such a system no consumer need be turned away.

The consumer who wants to charge storage batteries, and also make electric welds by electricity, can do so upon the same day and from the same wires that supply his incandescent lamps.

The factory upon the outskirts of a town, which runs its isolated plant, and must to-day either use storage batteries or run machinery all night to supply a few watchman's lights, can now switch on to the central station at six o'clock, and operate the few lamps it may need until dusk next day, when heretofore the alternating system, which was the only one which could reach it, did not run after midnight, or possibly after daybreak, because of the loss of money in so doing.

1.—Read before the National Electric Light Association, Montreal, P. Q.

With this system the outlying districts can be pioneered with the least first cost and least risk. Any outlying section in which, from any cause, the demand increases greatly beyond that originally anticipated, can be supplied permanently by the three-wire system by merely running the necessary feeders to supply the already existing mains, and in such case the switches and converters would be moved out further, or transferred to some new section ready for pioneer work.

The combination of a storage battery system and an alternating system also presents peculiar advantages. The storage battery is at its best when supplying a small steady load, such as we have for at least 16 hours out of the 24. The alternating is at its best when supplying the full load possible only during the remaining eight hours. The average electrical load on a general system is only about 12 per cent. of the maximum, consequently we are entirely safe in the statement that the greatest load during the 16 hours of light load is not more than 10 per cent. of the maximum load for the 24 hours.

If we are to attempt to operate the heavy load by storage batteries, we must either make an enormous investment, or, what is even worse, operate storage batteries at a disastrous overload. On the other hand, if we try to operate the 16 hours' light load with converters, our efficiency, when operating at 10 per cent. of our converter capacity, would be unmentionably low. But reverse the case and everything works at its maximum efficiency. During the eight hours of possible heavy load, we operate all devices by the alternating system. At the same time a continuous current dynamo charges our storage batteries located either in the central station, or, if more desirable, at different centres in the system of distribution. At the end of the eight hours' run we shut down the plant, lock up the station, and leave it for 16 hours, the storage batteries meantime supplying all devices.

If, for extraordinary reasons, we have not capacity sufficient in the storage batteries to supply the demand, we run the continuous current plant to assist it; and if that should fail or prove insufficient, we start up our alternating, and supply all, or a disconnected part, of the system with it.

With this plant distances are of no consequence; we can use 1,000 volts for the continuous current plant as well as for the alternating, and the single two-wire distribution is all that is necessary for perfect results.

The weak spot of this latter arrangement will, no doubt, be thought to be the storage battery, but my experience with this device is that if you use it properly under suitable conditions, and do not attempt to squeeze impossible results out of it, economical and satisfactory service can be obtained from it, and certainly no better conditions could be obtained for it than those described above.

Up to this time a bitter fight has waged between those believing that the alternating, the direct, or the storage battery, system, respectively, was the only suitable one.

I believe in them all, each operated so as to be used under the best conditions for its use, and I trust that the suggestions given above may lead to our being better able to meet and overcome our common enemies: High First Cost, Low Efficiency, Danger, Unreliability and the Inflexible Conditions of the existing demand.

CENTRAL STATIONS OPERATED BY WATER POWER.[1]

BY GEO. A. REDMAN, SUPERINTENDENT BRUSH ELECTRIC LIGHT COMPANY, ROCHESTER, N. Y.

THE purpose of my paper is more to give a description of what is being done with water for electrical purposes in the city of Rochester by the three different electric light companies doing business in that city, and some of my own experience with water power, than to take up your valuable time with the technical description of turbines, which can be gleaned from any of the numerous catalogues of turbine manufacturers, which contain full descriptions of turbines and their construction.

The adaptation of water power to electrical purposes has grown very rapidly within the past few years; there are several causes operating to enhance the value of water power, none more so than that of electricity.

Streams that have had no pecuniary value heretofore are now being utilized for the purpose of running electrical machinery, yet, at the same time, the supply of water is diminishing, caused by the destruction of forests, and water right owners in various parts of the country are devising means of storing water during the rainy seasons to furnish a supply during the dry season; also storing it in the daytime for night use. One large water right owner in Western New York, during the month of July and August, places flash boards two and one-half feet high on top of his dam, at an expense of $100, and stores up for night use the water which is not necessary for him to use in the daytime, thereby saving in the two months equivalent to a coal bill of $2,100.

1.—Read before the National Electric Light Association, Montreal, P. Q., Sept. 10, 1891.

The Johnstown, N. Y., Electric Light Company have improved their water power at the Cuyadota Falls by erecting a dam 34 feet high on top of the falls, giving them a total head of 75 feet and nearly doubling the amount of power.

A survey of the upper Genesee River, between Mount Morris, N. Y., and the celebrated Portage Falls, has been made during the past year for the purpose of establishing a reservoir that will furnish the city of Rochester 30,000 horse-power more, daily, during the entire year than they have at present.

The earliest forms of water wheels were the paddle and flutter wheels that only utilized the impulsive action of the water; these were followed by simpler wheels of the reaction type and others.

We now have the improved forms of the Leffel, Victor, Lesner, Success, and many others. There is a demand for the best and most economical turbine that can be manufactured.
