Turbines should be built to secure the delivery of the water upon the turbine without checking the velocity of the water more than one-third, and permit the free discharge of same after passing through the turbine, and to work with as good efficiency under part gate as under full gate, and to be made of the best phosphor bronze, to stand the wear and tear under high heads.

It is essential to locate central stations to be run by water power, where there is no great danger of a flood, or so protected by a breakwater as to make it perfectly safe, and also to avoid trouble with back water upon the turbines.

Where a station is situated on the bank of a river, it is best to take the water from the river by means of a raceway, with the headgate parallel with the flow of the water, and at times of a freshet or running of anchor ice, it will more than pay any expense incurred by so doing.

The raceway should be of a sufficient depth and width to permit the water to flow not more than 90 feet per minute, and a waste gate should be placed in the side or end of the race to use in case of emergency; and when cleaning out the raceway a rack should be built across the race to prevent driftwood and other rubbish from passing into the turbines.

For that purpose I would recommend a rack built of iron slats two inches wide, one-eighth of an inch thick, and placed five-eighths of an inch apart on seven-eighths inch iron rods, at an angle of 45 degrees. Particular attention should be given to keep the rack clear by raking. A trough or platform should be placed over, and immediately back of, the rack to rake the rubbish and anchor ice into, and so arranged that a current of water from the race will pass through the trough and carry off all the rubbish, etc. For any one who is using 100 h. p. or over, it will be a great saving in labor and pay well for the extra expense incurred. For winter service a boom should be placed in front of the headgate, and the current will carry off a large portion of the anchor ice and other floating objects.

The headgates should be built to work with a rack and pinion; also a roller should be placed back of each gate stem to facilitate the handling of the gate.

The gates should have a protection built over them to protect the gearing from the storm. In cold climates, where the gates are apt to be frozen in, salt is essential in freeing them from ice; all headgates and timbers should be of the best quality of oak, and should be well bolted, and not less than two gates to one raceway. The tail race should have not less than two to three feet of dead water when the wheels are not in motion.

Where the tail race runs under the station, cement floors should be laid to prevent moisture in the station; a floor of that material will soon pay for itself.

Vertical turbines should be placed so that the steps are covered with water at all times. In adapting turbines to very high heads, or to conform to location, it becomes necessary to set the turbines above tail water, and conduct the water away from the turbines, through a draft tube; the same depth of pit and area of discharge is required where a draft tube is used, as would be when the turbines are set at the bottom of the fall; the mouth of the draft tube should always be submerged about six inches in standing tail water. It is claimed that draft tubes can be used 30 feet in length. I do not think a draft tube more than 18 feet in length should be used on account of the difficulty in keeping the tube air tight, for, if the tube leaks, the vacuum is imperfect and there will be a great loss of power, and where steps are used they will be apt to be burned out.

When possible, I would advise horizontal turbines to be used, as they are more easily taken care of, and are often used without any steps. The burning out of steps is an expense and annoyance. One of the greatest advantages in the horizontal turbine is that the dynamo can be belted direct to the turbine shafting, and is in some cases coupled direct to the turbine, making a good percentage in economy in power, and avoiding the use of gearing, and I deem it advisable to put in a number of small turbines, instead of one large one; in case of a break down they are more easily repaired, and cause less delay to customers.

In the old station of the Brush Electric Light Company, of Rochester, the vertical turbines cause considerable annoyance in the burning out of steps and stripping of the gears; so much so that it became necessary to support the vertical shafting with water cushions. For wooden steps we have had the best success with lignum vitæ.

In my opinion, governors for the turbines are necessary, and will govern any slight variation of load under high head, but where one-third or more of the load is thown off or on suddenly, it is necessary to handle the gate by hand, as under the above circumstances the turbine is apt to slack down or run far above the normal speed, as the case may be; in the latter case causing the burning out of lamps and armatures. The governors should be placed as near the turbines as possible to save lost motion in the gate shafting and avoid the use of gearing as much as possible.

We have two governors in use in our office building under a low head of 16 feet, and they govern the turbines under all circumstances in quite a satisfactory manner.

The decided advantage of a water power station over one run by steam power is not only one of economy in the saving of the expense of coal, but the station and apparatus can be kept cleaner and cooler, thereby saving considerable in expense of repairs. It is also far more pleasant for the employees.

The Brush Electric Light Company, of Rochester, purchased the entire lower falls of the Genesee River (which is about two miles from the business centre of the city) some nine years ago. At that time it was looked upon by many as a piece of folly, to think of running dynamos there, on account of the distance from the business centre of the city and the dampness around the falls. Notwithstanding the adverse opinions, they erected two buildings on the west side of the river above and near the brink of the falls, and put in two 30½ inch Leffel, two 20 inch Victors and one 40 inch Leffel turbine, the first four mentioned turbines, under 94 feet head, and the last under 28 feet head, with a total of 2,500 h. p. After running this power for five years they built a new station and leased their old power to different parties for pulp and flour mill purposes.

The new station is a three-story stone building, 45 feet wide and 90 feet long, with a two-story brick addition 42 feet wide and 80 feet long, and located at the foot of the falls on the east side of the river. The turbine capacity consists of 15 double 15 inch horizontal Lesner turbines under 90 feet head, with 14 foot draft tubes, a total of 3,360 h. p., using 6.95 cubic feet of water per minute per horse-power. But one turbine has been damaged to any extent in four years. The turbine casings are placed on iron girders with the ends of the girders resting on solid rock.

The amount of floor space occupied by all of the turbines is 4 feet by 38 feet; the weight of each turbine is 196 pounds, less than one pound to a horse-power; each turbine is placed in a separate division of the casings and the shaftings extend through the shafting room, upon iron bridgetrees, with 7 feet and 6 inches between journals, and the dynamos are belted direct to the turbine shafting; the shafting runs at 800 revolutions per minute, with 25 inch pulleys on the turbine shafting and 24 inch on the dynamos; we use untried beef tallow for lubricating, and are well satisfied with its results. The turbine gate shafts and governors are placed in the dynamo room at an average distance of 14 feet from the turbines, where they are easily handled by the attendants. We have in use four different styles of governors: the Walsh, Snow, Pritchard—electric, and one friction. With the latter we have done some experimenting. A tell-tale is placed in the shafting room, connected to a float in the race above the falls, which shows the height of water in the race at all times.

The water is taken into the raceway, about 80 feet above the falls; the race is 32 feet wide, and five feet six inches deep, and cut through the solid rock; there are four headgates with a house built over them; a wooden diagonal rack is placed in the race near the spillway to assist in freeing the race from anchor ice; the spillway is six inches deep and 32 feet long. The waste gates are placed next to the spillway, and are three feet six inches wide; there are two of them. In front and near the top of the penstocks an iron rack is built according to dimensions given; also a rubbish trough.

There are three iron penstocks, six feet in diameter and 80 feet high, built of three-eighths inch boiler iron, with a gate to each penstock.

There are five elbows to each penstock leading to as many turbines, with an iron slide gate to each elbow; in addition, each turbine has a register gate, thereby permitting the repairing of any one turbine without interfering with the running of the others. A turbine can be taken out and another put in its place in 25 minutes.

Cement floors are laid in the shafting and turbine rooms.

There are three tail races, extending under the entire length of the main building; each race is nine feet wide and six feet and six inches deep.

As a reserve power, when making repairs and cleaning the raceway, we have a 600 h. p. Cooper-Corliss engine; in the past year it has been necessary to use it but a few days.

For fire protection, two-inch iron pipes are run from the penstocks through both buildings, with four lines of hose attached at all times; the hose is tested once a week. In addition to the hose, a dozen fire pails filled with water and placed in different parts of the station are kept in readiness, and are not permitted to be used for any other purpose.

A record is kept of the time of starting and stopping of each turbine, also the speed and load on same, and any variation in height of water, and all repairs that are made. In addition to the above records, the day and night wheelmen report the condition of the power at the time they are relieved.

There are nine men employed at the station, five of them in the dynamo department and four in the water power department.

We have in service 30 dynamos; three of them are run without any stoppage, and the balance of them on an average of 13 hours per diem.

A record book is kept in the dynamo room, in which entries are made of the time of starting, stopping, speed and load of each dynamo, also all repairs of every description, all accidents to either machinery or circuits, nature, time and cause of same.

All the circuits are tested five times daily, and the tests and time of same entered in record book.

By means of the water power the company is enabled to furnish cheap and satisfactory light and power at the following rates, viz:

City arc lights, all night and every night, 27 cents per night; commercial arc lights, all night and every night, 40 cents per night; commercial arc lights, evening, 25 cents per night; commercial arc lights, evening and all day, 40 cents; ⅛ horse-power motor, $18 per annum; ½ horse-power motor, $48 per annum; 1 horse-power motor current, $72 per annum; 2, 4 and 6 horse-power motor current, $50 per annum, per horse-power; 8, 10 and 15 horse-power motor current, $40 per annum, per horse-power; ⅛ horse-power fan motors, $15 per season, from June 1st to Oct. 1st; 16 candle-power incandescent lamps, $5 to $12 per annum; 25 candle-power Bernstein lamps, $12 per annum; 50 candle-power Bernstein lamps, $24 per annum; 100 candle-power Bernstein lamps, $48 per annum.

The rates I have mentioned are for arc circuits; our rates for current on 500 volt constant potential circuits are as follows, viz:

One horse-power, $48 per annum; 2 horse-power, $96 per annum; 5 horse-power, $180 per annum; 8 horse-power, $240 per annum; 10 horse-power, $300 per annum; 15 horse-power, $450 per annum; 20 horse-power, $600 per annum.

We operate a total of 832 motors, of which 196 are fan motors, 1,896 arc, 135 Bernstein and 200 Swan incandescent lamps. One motor circuit contains 26 miles of outside wire and one 2 horse-power and one 4 horse-power Brush and 394 ⅛ horse-power "C & C.," motors, and is run with a No. 8 Brush arc dynamo. We have one 40 K. W. 500 volt "C. & C." generator in service on an eight mile circuit, with 48 horse-power in motors in use; the ammeter averages 29 amperes. We experience no difficulty in running same with our power.

The 26 mile motor circuit is the most popular circuit we have, and is run through the north-east suburban portion of the city. All the motors on this circuit, with a few exceptions, are placed in tailor shops that are either in the dwellings or in shops built in the rear of the dwellings.

The rebate for poor service during the year ending December 31, 1890, was one one-hundreth of one per cent. of the gross receipts, and the uncollected accounts for the same period was one tenth of one per cent. of the gross receipts.

The Edison Electric Light Company have recently erected a three-story stone station at the foot of the upper Genesee Falls, on the west side of the river, and have at present two double discharge Leffel mining wheels under about 90 feet head, giving 600 h. p., and are placing two more of 400 h. p. each. In addition, they have a fine steam station in the centre of the business district. Incandescent 16 candle-power lamps are furnished at one cent per lamp hour; arc lamps for city use, 28½ cents per night; municipal incandescents at six cents per night. The latter they are partially replacing with arc lamps. They have in circuit 105 arc, 805 municipal and about 13,500 16 candle-power incandescent lamps.

The Rochester Electric Light Company's plant is situated at the upper Genesee Falls, on the east side of the Genesee River, near the business centre of the city.

The station is three stories in height from the top of the falls, with the wheel pit underneath, blasted out of solid rock 95 feet in depth. They have five Leffel horizontal turbines; four are 23 inches, and the other 30½ inches in diameter, with a total of 1,500 h. p., under a head of 86 feet 8 inches.

The penstock is a steel pipe seven feet in diameter; the power is transmitted to five shafts, 80 feet above, by belts 173 feet in length, running at a speed of 7,200 feet per minute.

The dynamo room is directly over the shafting, from which all of the dynamos are belted through the floor. The dynamos are those of the United States system.

They have in service 325 city arc, and 140 commercial arc, lamps; also 1,500 incandescent lamps and two 10 h. p. motors. They have just placed one 85 h. p. generator and one 1,500 light Westinghouse alternating dynamo.

As a reserve power, they are putting in a 400 h. p. engine. The city lights are being furnished at 27 cents per light.

In addition to those I have mentioned, there are five incandescent plants and one arc isolated plant run by water power in Rochester, some 500 incandescent, and 25 arc, lamps, making a grand total of 1,991 arc, and 16,640 incandescent. The population of Rochester is 135,000, making a very high average per capita.

UNIFORMITY IN METHODS OF KEEPING CENTRAL STATION ACCOUNTS.[1]

BY J. J. BURLEIGH, CAMDEN LIGHTING AND HEATING CO.

THE National Electric Light Association partially fills its mission by bringing together, twice a year, central station managers and others interested in the production of light and power, but notwithstanding the very valuable paper of Mr. A. R. Foote, read at the Niagara Falls meeting, and the papers of Messrs. Smith and De Camp, read at the Kansas City meeting, absolutely nothing has been accomplished towards a uniform system of accounts or a classification of expenses.

All, I am sure, feel the very great necessity for a more comprehensive and uniform system of accounts.

A system that will show the exact cost per unit of their output.

A system that, being kept uniformly by all, will give managers an opportunity of comparison with each other.

This knowledge of cost per unit of output is particularly felt at this time, since nearly all central stations are in direct and active competition with other illuminating companies and with other means of supplying power.

At present no two keep their accounts alike; hence, comparison with each other is out of the question.

The principal function of accounting is to bring out the fact that the average cost of certain items of expense per unit of output in one station exceeds the average cost per unit of the same items of expense in another station, and the accuracy of these averages depends entirely on the uniformity of accounting. Great differences in these averages would prompt an inquiry as to the cause, and if the circumstances did not warrant higher averages, steps could be taken to reduce the cost of these particular items.

To make these comparisons of any value to those desiring to make use of them, a uniform classification of accounts should be adopted, and, to insure accuracy, the different items of expense, chargeable to the different accounts, should be specified.

The operating accounts proper embrace the current working expenses and the cost of keeping in good order the original plant.

The company with which I am connected have classified their accounts as follows:

CHARGEABLE TO	Arc Lighting.	Incandescent Lighting.	POWER.		TOTAL.
			St. Cars	Stationary	
Boilers, repairs of					
Belting, "					
Boiler House and Stack, repairs of					
Carbons					
Clerks					
Converters, repairs of					
Dynamos "					
Dynamo Attendants					
Enginemen and Firemen					
Engines, repairs of					
Fuel					
General Officers' Salaries					
Horses, Wagons and Harness					
Insurance					
Int. on Notes, Bonds and Mortgages					
Incidentals					
Instruments of all kinds					
Lamps, repairs of					
Lamp Supports and Fixtures					
Lamp Globes					
Lamps, Incandescent					
Linemen					
Labor at Stations					
Labor on Street Cars					
Loss and Damage					
Legal Expenses					
Meters, repairs of					
Motors "					
Oil					
Office expenses, repairs and furnit. for					
Poles and Lines, main. and renewals of					
Right of way					
Station, repairs of					
Stationery and Printing					
Superintendent and Foremen					
Steam Piping, repairs of					
Shafting "					
Taxes, City					
Taxes, State					
Tools, repairs and renewals					
Trimmers and Inspectors					
Water					
Waste					

All expenses that are naturally or entirely charged to either arc lighting, incandescent lighting or power are entered in their respective columns; expenses that are not entirely charged to any one service are apportioned on horse-power output basis, making the division as between arc, incandescent or power, in the proportion which the horse-power used for each bears to the total horse-power output.

1.—Read before the National Electric Light Association, Montreal, P. Q., Sept. 10, 1891.

For the proper division of those accounts not chargeable entirely to any one of the principal departments; for example, the total output of the station being 1,000 h. p., the company operating 500 arc lights, 2,500 incandescent lights and 250 h. p. for power, the division of a bill for boiler repairs, engine repairs, fuel and similar divisible accounts, would be one-half arc lighting, one-quarter incandescent lighting, one-quarter power.

The division ought to be accurately determined each month.

No intelligent economy can be practised without a thorough knowledge of the cost in the past and a comparison of the same with the present outlay. Constant comparison of accounts tends to economy. The experience of other companies is a good guide and would be found of great utility.

I would like to urge upon the convention the importance of the adoption of some uniform classification of expenses that they can recommend to central station managers for their adoption.

It does not follow that central station managers are to expose their books in detail, but to so prepare their accounts that they can give the secretary of the National Association replies to such questions of cost per unit as would be proper to exhibit to the other members.

Such statistics would be of the greatest interest and value; indeed, it would be of more value than all the other papers combined.

I have a station producing arc and incandescent light and power, earning a moderate dividend for its shareholders, but I have nothing to guide me as to how my expenses per unit compare with other central stations. I would give much for such information.

Therefore, I conclude that this is one of the most important subjects that can engage the attention of the Association.

ELECTRIC RAILROAD CONSTRUCTION AND OPERATION AND A CONSIDERATION OF THEIR CONNECTION WITH CENTRAL STATION INTERESTS.[1]

BY C. J. FIELD, OF THE FIELD ENGINEERING CO., NEW YORK.

INTRODUCTION.

THE advantages of the electric railway have passed beyond the age of experiment or question. They are proved by their development in the past four years, and any argument as to their advantage in the general development of street railway practice or suburban rapid transit is antedated. It took several years to convince old staid financiers and directors of the larger street railway properties that it was to their financial advantage to throw in the scrap heap several million dollars, more or less, in equipment and spend that amount in addition and still make it pay; but they have seen this advantage in the development and increase of traffic and returns to their company. These returns have been brought about principally by the development of rapid transit, in the introduction of electricity and the flexibility of the system in adapting itself to all and any conditions of commercial practice.

In looking over the past four years of practice in electric railway work, we have much to commend and considerable to condemn. The boldness of the achievements, the problems that have been solved, the rapidity of development and the perfection of the apparatus, seem almost beyond comprehension. That this apparatus, in less than four years, should reach the high state of perfection, economy and efficiency that it has, as compared to the long years of development of other mechanical appliances, is remarkable. The natural consequence of this large amount of work and development in this short time is that there has been much work done that would have been better left undone, in the way of poor engineering, cheap work, and not a proper appreciation of the problem to be solved. These, in some few instances, have retarded the development and progress of electric railway work in their vicinity, but street railway companies have now come to a proper appreciation of the necessity of good work well done, and that the wisest and best method is to consider carefully what will bring the best return for the money invested—not necessarily on the blind basis of the highest cost being the cheapest, for money can be wasted in this way as well as in others. We have examples now in several directions of large equipments being installed on a sound engineering basis and with careful consideration of the best interests of the electrical fraternity, street railway owners and public combined, and we can safely add that there is no problem in this line which cannot to-day be taken up with a full assurance of practical solution and successful development in electric railway traction.

The future outlook of electricity in the development of rapid transit, inter-suburban, and even express service, is assured. We are coming now to the solving of the larger problems in this work and bringing the public to a proper appreciation of the resources and possible achievements in this line and its superiority over the old fogy systems of the past. We even see a considerable number of our friends from cable engineering lines of street railroad work coming over into the electrical fold, fully appreciating that the cable system has a very limited field for successful development and that electric traction is very broad gauge in the field of engineering work. Therefore, with this outlook, better construction work, better engineering, better mechanics, the solving of these larger problems is assured, and we see even to-day, in a number of cases, electric suburban traffic supplanting steam on a cheaper, better and more successful basis. The favorable report of the New York Rapid Transit Commissioners has done much to add to public confidence in this direction. Electric manufacturing companies are assisting the development of the work by making their apparatus more substantial, better in construction and more satisfactory in its mechanical design and operation. The reduction in the speed of the motors, the development of single reduction and even of direct connected motors, is doing much to add to the confidence in this line.

We hear asked sometimes, by laymen, the question: "What speed can electricity obtain in railway work?" The able consideration of this subject in several papers and practical experiments as well, enables us to reply very briefly but confidently to this inquiry, that speed and power in electric railway traction are only limited by road-bed construction; in other words, any speed is obtainable within the range of possibility, with the maintenance of proper track. We do not intend, however, to generally review electric railway work, but more particularly to give some details of the practical problems in their construction and operation, and, therefore, we will leave the consideration of other parts of the subject to papers which will, no doubt, treat it more fully.

STEAM PLANT.

The consideration of the best development in the power generation of electric railway work has been one that has received considerable attention in past years from the best engineers in this line. We reach here a part of the problem which requires much more careful consideration than has been given steam power in electric lighting generally in the past. The work to be successfully done by the steam engine in the generation of electricity for the operation of railroads is of the severest kind, and can be compared only to that of the engine operating rolling mill trains. It is owing to not fully appreciating this fact that we hear in some parts of the country of failures of steam plant on this kind of work. Electrical manufacturers are assisting the solution of this problem by the building of larger generators in units of 200 to 400 or 500 horse-power. What we want in the generating station for electricity is the smallest division of units consistent with the safe and economical operation of the station. Following the problem out on this line, we can build a successful station; and we would add to this that each unit should be entirely independent and separate from all other units, thereby increasing the reliability. This cannot be obtained in a safe and economical way by the use of our old friend, the countershaft. Undoubtedly, the countershaft has been of much use in electric lighting service, and particularly in arc lighting, but in railway work, with large generators, we can see no excuse at the present time for its use. Generators should be belted direct to the engines, whether Corliss or high speed, or else coupled direct to the engine shaft. With a Corliss engine of 500 horse-power, operating at 80 or 90 turns, with a fly-wheel 18 to 20 feet in diameter, we can belt with belt centres of, say, 40 feet, generators of several different commercial types; this gives us advantages which we have heretofore had only in high speed engines with direct connection. The engines should, in any event, as heretofore stated, be extra heavily built for the work to be done, with ample fly-wheel capacity. On engines of this size and speed a fly-wheel capacity of approximately 60,000 lbs. is about right. On engines operating about 150 turns, say, 30,000 to 40,000 lbs.

While laying particular stress on the rapid and sudden changes of load, we do not know how to illustrate it more forcibly than in Figs. 1 and 2. Fig. 1 will show a practical case of changes in the indicator diagram within one minute, placed on the cylinder of an engine running on railway work, which shows a variation within that time of from full load to no load and back again several times. Fig. 2 illustrates a load diagram from an ordinary case which has not been particularly selected for its maximum and severe conditions. These impress on the mind more forcibly than words can the requirements of this work. High speed engines in the development of railway work have received in some cases a set-back, owing to the engine manufacturers not appreciating fully the conditions and necessity of the work undertaken. So-called high speed automatic engines can be as successfully operated on this class of work as any other, if they are specially built for it. This means larger parts, bearings of more ample size and length and ample fly-wheel capacity. On a cross-compound engine of, say, 300 horse-power, there should be about six to eight tons in the fly-wheels, the bearings seven or eight inches in diameter and 15 or 18 inches in length. (Such a type of engine is being furnished by the manufacturers of the Ball Engine.) In the case of engines built in this manner, there can be no fault found with their operation. A type of engine, which we believe is going to be largely used on this class of work, as well as lighting work, is one that will come in between the high speed engine and the Corliss and which will combine many of the advantages of both. Such an engine has been sought for by many engineers and has been attempted by a number of builders. To-day, however, we cannot find it on the commercial market. This engine in units of 500 horse power would run at a rotative speed of about 140 or 150 revolutions and with a piston speed of about 650 to 700.

The question which has troubled most engine men in regard to the high speed engine, with a single valve covering this kind of practice, has been a question of valves and clearances. Beyond any question, when it comes to this size, we have got to come to the Corliss practice of double valve, thereby reducing the clearances and bringing it down to the extent of the Corliss practice. The writer's company is having built, for the electric railroad at Buffalo, two engines of this class, by the Lake Erie Engineering Works, which we believe will do much to develop this line of work, and, also, will be particularly adapted for coupling direct to the engine shaft. The trouble in this line has been to get electric manufacturing companies to take up the building of large multipolar generators adapted for direct coupling at a speed of from 100 to 200 revolutions. This problem was developed on a much smaller scale in this country, for marine plants, several years ago. We find that in Europe, where their work has been more special, they have successfully developed this type of engine and generator, and, beyond any question, it is going to be both for lighting work and for railway work the type of unit for central station practice in the future. It means, where the vertical engine is used, the installation of the steam and electric plant in the space formerly used for engines alone. This means reduction in the cost of building, operation and maintenance.

In concluding this part of our subject on steam generation, we trust that our experience in the past in lighting will show us the fallacy of poor steam engineering, and that we will build our sta-

1.—Read before the National Electric Light Association, Montreal, P. Q., Sept. 10, 1891.

tions for the future, and not have the problems before us that nine-tenths of the electric lighting stations have to-day, which mean, that in order to get down to commercial economy and competition, they have got to rebuild their whole outfit. We will merely append to the consideration of the steam plant part of our problem a few interesting figures and data which the writer collected for presenting to street railway companies, in order to give them some useful information in this respect. We believe that they may be well introduced here. The figures given on the tables, etc., are not ones that the manufacturer of an engine would tell you were those of the best economy for his engine or plant, but they are figures which will be appreciated by station owners and railway companies as those which are obtained in every-day commercial tests.

The relative commercial economy of engines and costs are as follows:

Type.	Lbs. of Coal per H. P. hour.	Cost per H. P. Sizes over 100 H. P.	
High speed single	4 to 5	$11 to $13	This is based on an evaporation of 9 lbs. of water per lb. of coal.
" " compound	3 to 3½	14 to 16	
" " " cond	2¼ to 2½		
" " " triple	1¾ to 2	18 to 22	
Corliss single	3½ to 4	16 to 18	
" compound condensing	1¾ to 2	22 to 25	
Corliss triple	1½ to 1¾	27 to 30

Steam pressure, 100 lbs.

The cost of steam plant complete is about $50 to $60 per horse-power for high speed, and $65 to $75 per horse-power for Corliss.

ELECTRIC PLANT.

The question of the best electrical generating plant for railway work is one which is allied closely to that of steam plant, particularly in the relation of the generators to that of the engines. In some respects, in treating of the steam plant, we have intimated what our idea was in connection with the generators. All large generators of from 200 to 500 horse-power should be connected as directly as possible, either by direct belting or shaft coupling, with the engines operating the same. It is only by this development that the safest and best solution of electric railway station practice—in fact, station practice in general—can be reached. Manufacturers of railway generators have had an experience extending back many years, that experience in the development of direct current incandescent machinery; although not of quite the same voltage, has led the way up to the safe, economical and commercial development of railway generators; and we find the railway generator of to-day one of the most perfect and reliable factors in the electric railway system. The only problem remaining to be solved in this connection is to build them in larger types and have slower speed for direct shaft coupling. Generators on this work are subjected to the severest and most excessive strain, particularly where of small type, but the building of them in large units is going to remove, to a great extent, the question of the overloading of the machine. Railway machines are often

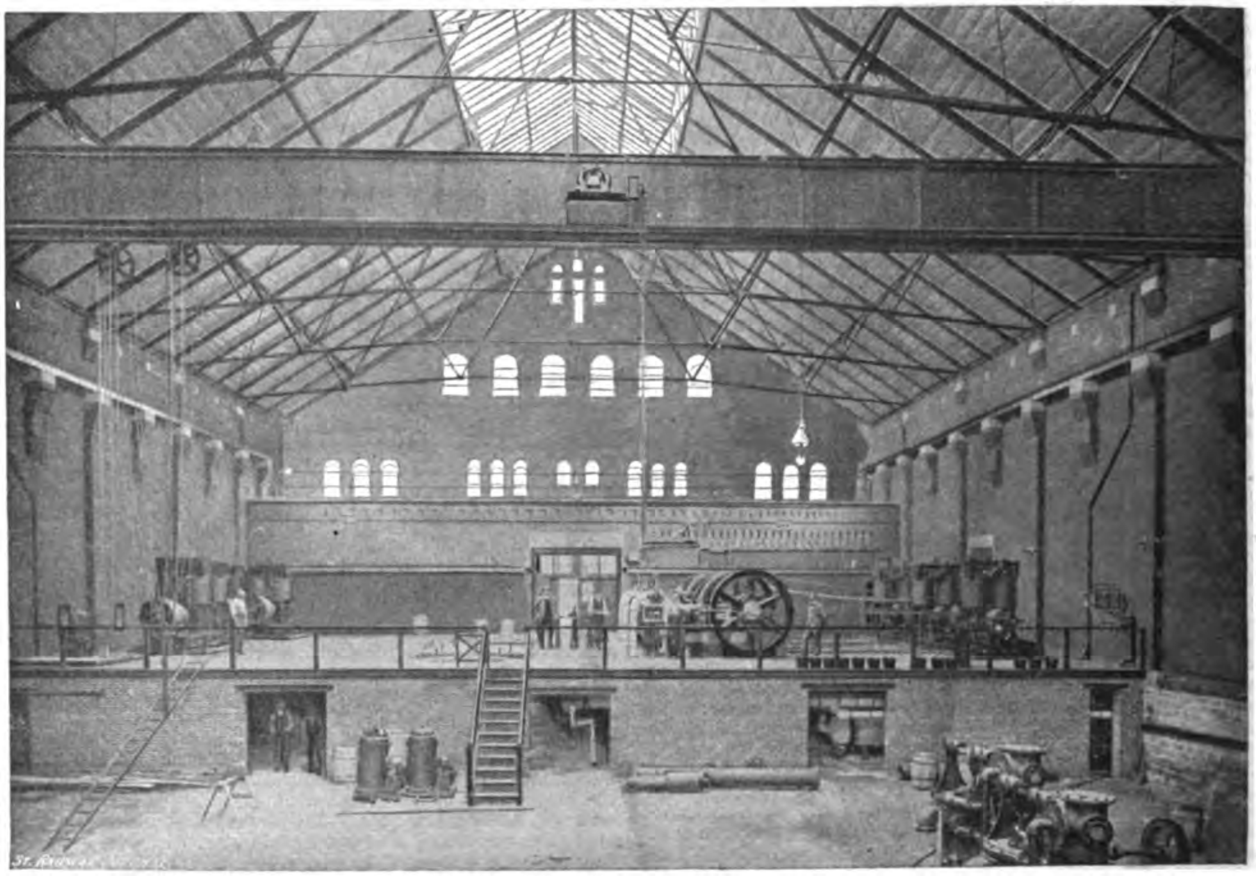

FIG. 4.—INTERIOR OF POWER STATION—BUFFALO RAILWAY.

There are four classes of boilers:

1. Horizontal return tubular, which is the most general in use, and costs $9 to $10 per horse-power.

2. Vertical tubular (Corliss or Manning), which is a vertical tubular boiler with water leg, giving an internal fire-box, economical in floor space, largely used throughout New England. Cost $10 to $12 per horse-power.

3. Sectional or water-tube boiler, of which Babcock & Wilcox is the best known, especially adapted for higher pressures and safety. Cost $17 to $19 per horse-power.

4. Scotch type of marine boiler—one that has not been used to any extent as yet in station work—but we believe it will be as an offset to the sectional type; and fulfilling the requirements for higher pressure and economy of space.

Capacity of engine requisite for different generators:

subjected to an overload of from 25 to 50 per cent. In general these are only momentary, and we find most of them able to stand up to the work to be done.

The question which puzzles many of the railway companies, as well as the electric companies, is, What amount of generating capacity is necessary for the operation of a given number of cars? This question, of course, has got to be carefully considered in connection with each case, but there can in a general way be laid down an approximate basis for this work. Some railway companies, in order to show a higher economy than their competitors, are unwisely claiming the requirement of a smaller amount of power than others; but the wisest manufacturer is the one who urges his client to install a larger amount of power than is barely required for the successful operation of the road under any and all conditions. For if any one thing will lead the public to condemn the electric railway traction it is a lack of power, thereby causing the cars to move slowly, and in case of any accident, disabling part of the power. A fair basis on general conditions for 16 to 18-foot car bodies is 20 to 25 h. p. per car, which, with a properly designed and constructed plant, will give the desired power. The cost of generating this power for railway work for 16 and 18-foot cars is three to five cents per car mile for all expenses of the generating station. In some roads we find that cars of a larger size than these do not necessarily take a proportionately larger amount of power. We find from practical experience that a car 32 or 33 feet long, double the size of the 16-foot car, takes under general conditions about 50 per cent. more power, and we find by the same experience that a trail car adds about 50 per cent. to the amount of work to be done on the motor car for the same size. As to the minimum and maximum amount of power taken on an electric car, we find that a general average for a 16-foot car, under ordinary commercial conditions, without excessive grades, is one horse-power per car mile per hour; or, a car operating at an average 10 miles per hour means an average of 10 horse-power per car. The same car will give, however, on a load diagram, taking all its conditions, from maximum to minimum, a variation of from nothing to 50, 60 or even 80 h. p. This gives us an idea of the severe strains and conditions to which an electric motor is subjected.

ELECTRIC CARS AND THEIR EQUIPMENT.

One of the questions on which we find more variety of opinion than any other is, What is the best size, type and style of car for given case and conditions. The old standard 16-foot car body we find is now being widely departed from, and the problem is, How large a car can we get on a single truck with four wheels without excessive destructive effect on the roadbed? and, What is the longest car we can operate on street car service economically on an eight wheel base? We believe the limit is reached with a single truck in a 20-foot car body; we know that the truck manufacturers claim in some cases to operate a longer body, but we do not believe it wise. An 18 or 20-foot car running under close headway we believe to fulfill best the conditions of city traffic in the larger cities. Such a car, with a wheel base of seven feet, and in some cases seven feet six inches, where curves are not too sharp, will give satisfaction, and not be too severe on the roadbed where the same is properly constructed. As to the difference in effect on the road-bed between the electric car and the horse car, it is, briefly, that the horse car is pulled by horses, from which it receives a balancing power and a steady pull, whereas an electric car is operating itself by a power moving the wheels against the track, having no steadying or balancing power from the pull of the horses, and transmitting all its power and moving itself through the wheels. We find, therefore, that it subjects the track to a very severe pounding, necessitating a much better construction of roadbed, practically equaling that of a steam railroad.

Some companies have favored the use of a vestibule on street cars. We believe, though, that any vestibule is a failure and a misnomer. It accomplishes no good and causes much trouble; a shield over the dashboard for the motor man in winter weather would give all that would be required. What is wanted on a street car is that which will allow the freest ingress and egress from the car for the passengers, and anything that retards this—and a vestibule most certainly does—is a detriment and an obstacle to rapid transit. On some roads we have tried the introduction of even larger cars, say, 28-foot body, or 36 feet over all. Such a car, of course, has to be put on a double truck. These cars have found favor with some companies when first considering the problem; the difficulty with them is in getting the passengers in and out of the cars as quickly as possible, and making too many stops, due to the larger number of passengers carried. For inter-suburban heavy traffic, with few stops, we believe such a car would fulfill the requirements, but only in such a case.

Thus, having gone over the question of the cars, we come to the consideration of the electric equipment for the same. To-day we find the double reduction motor discarded, as far as any new equipments are concerned. All the large electric manufacturing companies are placing single reduction motors on the market, and they are in successful commercial operation. One company is placing in the field a motor directly connected to the shaft and without any gearing—in other words, there is no reduction in speed, the speed of the armature being the same as that of the wheels—the same being accomplished by a very ingenious arrangement. We have heard asked in the past the question, Why was it necessary to place 30 h. p. to operate an electric car to do the work that two horses had done formerly? The answer is: The two horses did not do the work in a proper manner and give rapid transit. The life of a street car horse is very short, and we

FIG. 3.—CARS, POLES, AND OVERHEAD CONSTRUCTION—BUFFALO RAILWAY.

find under general conditions that 30 h. p. with two 15 h. p. motors has been found about right; in fact, we even find the companies tending towards a larger installation of power, particularly when using larger than a sixteen foot car body, and we find to-day, being installed for rapid transit in inter-suburban work, 40 and 50 horse-power electric equipments per car, many of them operating at a speed of 30, and even 40, miles per hour. As the amount of power is directly proportionate to the speed, we can readily see the requirement for such an amount of power. The cost of a single car equipped, including the car body, truck and motors, is from $3,000 to $3,500, and the cost of the electric part of the power generating plant is from $35 to $45 per horse-power.

LINE CONSTRUCTION.

We find in the past about as great a development in overhead and line construction for electric work as in any other part of the subject. While formerly this was one of the greatest sources of unreliability in the operation of the plant, to-day it has reached a very practical development. Formerly the trolley wires were too light, the feed wires were insufficient to furnish power, and the line was giving trouble, grounding and breaking continually. In the insulation of a single trolley system, with one side of the system grounded, we have the most severe requirements that it is possible to obtain in any electric insulation, in that any grounding on the other side of the system means trouble in the operation of the road. This has led to the introduction of double and even triple insulation into our line material to properly protect the trolley wire from grounding. Where streets are wide enough to spread the tracks to six feet and six feet six inches within the near rails we see introduced in many places centre iron poles, which make a considerably stronger style of construction than cross-suspension. There are not many streets, however, where street cars are in operation that are wide enough, or where the city will allow the spreading of the tracks to this distance, and in closer proximity it is not safe to operate with centre poles. On the work installed by the Field Engineering Co., in Buffalo, we find the most extensive system of overhead and underground construction in operation anywhere. Here all the feed wires, with a few exceptions, are placed in underground conduits, thus removing all cause for objection to the unsightliness of a large number of feed wires overhead. These underground feed wires are connected to the overhead wires from junction boxes upon the poles. Thus, in Fig. 3 is shown one of the lines on the Buffalo Railway system, which gives an idea of this style of construction, as well as the use of the large cars, which are 36 feet over all.

The cost of overhead construction may be summarized about as follows:

Line construction per mile, complete, including track bonding. plain pole work, cross suspension or bracket with feed wire	$2,000 to $2,500
With sawed and painted poles	2,500 to 3,000
Iron poles, cross suspension, concrete setting, double track, feed and guard wires	6,500 to 7,500
Same with centre poles	4,500 to 5,500

We also append a table which will give a general summary of the cost of electric equipment of street railway systems, omitting the track construction, which, of course, varies with the number of miles to be equipped.

COST OF ELECTRIC EQUIPMENTS FOR STREET RAILROADS.

No. of Cars.	Steam Plant. H. P.	Capacity of Generators, K. W.	Steam Plant.[1]	Station Electrical Equipment.	Car Equipments, Car Trucks and Motors.	Line Construction ½ mile of Double track per car.	Total Equipment (omitting track).
6	120	80	$7,000	$6,400	$19,500	$7,500	$40,400
10	225	150	11,000	10,500	32,500	12,500	66,500
15	375	240	17,500	15,000	48,750	80,000	111,250
20	450	300	22,000	17,500	65,000	40,000	144,500
30	675	450	28,000	22,000	97,500	90,000	237,500
50	1,125	750	50,000	33,000	162,500	187,500	433,000
100	2,025	1,350	90,000	60,000	325,000	375,000	850,000

The above figures are approximate only and based on the best City R. R. practice.

1. Add 25 per cent. to these figures for Corliss.

TRACK.

The track of street railway companies before the introduction of electricity was more behind the times than any other part of their equipment. The old flat rail is antiquated and antedated, and in a few years its use will be obsolete. The necessities of electric railway traction—in fact, of any traction—have impressed upon the street railway companies in their equipments the requirement of a good road-bed for the successful operation of a road, and we find this part of the problem receiving as much attention as any with companies who appreciate fully the work before them The general construction to-day is girder rails of from 60 to 80 lbs. per yard, placed on chairs where block paving is in use, with ties 2½ to 3 feet between centres. We find in some cases even 90 and 100 lb. rails used, but we believe in more moderate weight for the rails and the ties placed closer on centres. We believe this has been the general experience in railway work. Such a style of construction costs from $9,000 to $10,000 per mile. In suburban roads, on streets where there is no paving, we find the T rail being used; the road bed can be properly constructed on this basis with 45 to 50 lb. rail, for $6,000 to $6,500 per mile, the rail being spiked directly to the ties.

In order to make a summary of the data and figures, I will summarize them in a practical example.

AN ILLUSTRATIVE EXAMPLE.

I propose to take, as the best means of illustrating practically, the purchase, equipment and operation of a street railway system with electricity, a city with a population of, say 100,000—with a dilapidated street railway system, earning a gross income of $125,000, to purchase same for $500,000—property rights, franchises, etc., and equip it with 40 miles of single track and 65 electric cars.

COST OF EQUIPMENT.

Steam Plant (1,500 h.p. steam plant):		
Five engines, 250 h. p. each, compound condensing, size, 16 inches x 32 inches x 42 inches, with wheels weighing 30,000 lbs.	$32,500	
Eight R T. boilers, 72 inches x 16 feet	9,600	
Jet condensers	8,000	
Two boiler feed pumps	900	
Steam and exhaust piping	12,000	
Five engine foundations	8,500	
Eight boiler settings	3,200	
Five 30-inch belts	2,000	
Erecting and starting	3,500	
Freight and miscellaneous	2,500	
		$72,700
Electrical plant:		
Five generators, 200 kilowatts	$37,500	
Switchboard installation, foundations, etc.	4,000	
		41,500
Building:		
Power station, including stack, traveling crane, etc.	$25,000	
Car house and repair shop, including tools, etc.,	15,000	
		40,000
Track construction:		
40 miles girder rail construction, ties 2½ feet centres, 63 lb. rail, etc., $1.15 per foot	$244,880	
Relaying, including paving, etc., at 60 cents per foot	126,720	
Trucking, hauling, etc	24,000	
Ties, including 10 per cent. of joint ties, 130,000 at 40 cents	52,000	
Ties, including 10 per cent. of joint ties, 15,000 at 70 cents	10,500	
		456,100
Line construction:		
Ten miles iron poles, etc.	$75,000	
Ten miles wooden poles, etc.	40,000	
		115,000
Car equipment:		
65 electrical equipments at $2,000	$130,000	
65 car bodies, 18-foot body, with open ends	65,000	
65 trucks at $250	16,250	
		211,250

Summary:		
Steam plant	$72,700	
Electrical plant	41,500	
Building	40,000	
Track	456,100	
Line construction	115,000	
Car equipment	211,250	
		$936,550
Superintendent's and Engineers's work	$50,000	
General and miscellaneous	50,000	
		100,000
		$1,035,550
Original purchase		500,000
Total cost re-equipped		$1,535,550
Gross income, say, $350,000.		

Net income, say 35 per cent., equal to 8 per cent. on cost, on the basis of an investment of about one million and a half of dollars, and from a property which in many instances was hardly earning its fixed charges formerly.

We have here illustrated a practical example of what is being done every day in this country at the present time in the purchase

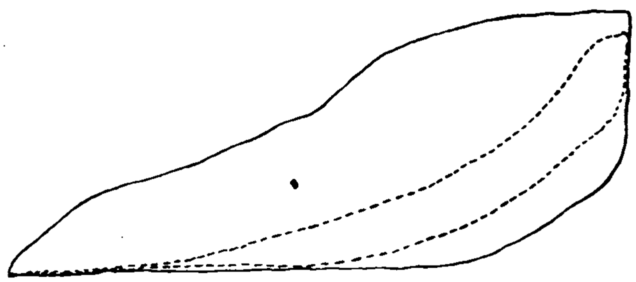

FIG. 1.

and equipment of street railway systems. In fact, we find a large number of bankers and capitalists giving it their earnest attention as one of the best fields for investment at the present time.

CENTRAL STATION IN CONNECTION WITH ELECTRIC RAILWAY WORK.

We desire to call the attention of central station owners to the profit to be made from the furnishing of power in street railway operation, and also by the combining in smaller towns of the street railray companies and electric light companies. The trouble in most cases in central stations obtaining contracts for power, outside of small roads, has been to convince the railway companies that the electric light station can economically and reliably furnish this power, and we must say, that in many cases their fears are well founded. Therefore, it behooves the central station companies to place their generating plants and station, not only for their own busiuess, but for this added business, in such a shape as to remove this objection. There is no reason why electric light stations should not do a large and profitable business in this line, as well as in stationary motor work, for the same factor is introduced here, and the same reasons hold, why they can safely and profitably furnish this power; if they have a station properly built, and large enough to add this power, that factor is established. If they have a proper station operating force, in many cases this force need not be added to at all. As to what basis this work can be profitably done on, we hesitate to state figures, except in specific cases, but will try to give a general idea of some of them. For many small roads power contracts have been taken at so much per day, assuming a basis of 100 to 125 miles operated. Such contracts have been at from $3 to $5 per car. The regular basis, in accordance with which most street railway companies make their contracts and desire to base their cost of operation, is the unit of car mile operated; therefore, most contracts are on this basis. This comes down, therefore, to a basis of from three to five cents per car mile; the latter figure we consider excessive, and one which would be only made by any company for temporary necessities. We know of cases where the matter has been carefully considered, and the plant properly installed for it, where contracts have been made for between 2¼ and 2¾ cents per car mile for 16-foot cars, on roads with grades not exceeding 1½ to 2 per cent. In this case, and, in fact, in most cases where the closer figures prevail, the railway company furnishes the generators, and the station owner furnishes the steam power and all expenses of both steam and electric power due to ordinary wear and tear. A profitable source of investment has been found in the more moderate sized towns of, say, up to 30,000 or 40,000 inhabitants, in the installation of combined electric railway and lighting stations; the companies either equipping new ones or purchasing old street railway systems and dilapidated lighting plants running on an unproductive basis, but which have a good franchise and field for business. Such companies have proved very profitable, as the combining of the operating expenses for railway and lighting station has done much to reduce expenses, and in many cases one manager or superintendent has proved sufficient for the entire system.

What we have tried to prepare here has been, not a paper which will be so attractive to merely read, but in which will be combined a certain amount of data and information which will be of use in the further consideration of the problems herein outlined, and trusting that, if we have accomplished nothing else, we have led you to a profitable line of thought, it is respectfully submitted.

FIG. 2.—DIAGRAM SHOWING FLUCTUATIONS IN LOAD.

ELECTRICAL STANDARDS.

At the last meeting of the British Association the report of the committee on electrical standards was read, in the absence of the secretary, Mr. R. T. Glazebrook, by Professor Carey Foster. The committee have made repeated measurements of the electrical resistance of several B. A. coils, and the result shows that the coils have remained practically constant since 1885. The report stated that notices have been sent out giving directions for setting up standard Clark cells, and asking that cells set up according to these directions should be sent to them. The object of this is to ascertain to what extent of accuracy different cells may be expected to agree with each other.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, *150 Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XII. NEW YORK, SEPTEMBER 16, 1891. No. 176.

It is doubtful if any great truth has ever been lost; though some may have apparently lain dormant for a time, yet they have continually produced results.—Joseph Henry.

CONVENTION ECHOES.

Of one thing we may be certain, namely, that none of the attendants at the Montreal Convention have any cause to regret spending a week in the beautiful Canadian city as recipients of a hospitality perfectly overwhelming in its heartiness and cordiality. When the Association determined to visit Montreal, it expected a repetition of such welcomes as it had enjoyed in Chicago, New York, Boston and elsewhere, but it never anticipated the fraternal greeting that awaited it in the commercial capital of the Dominion and that was to take so many forms of expression.

It might even be said that owing to the outflow of this hospitality, the social side was unduly prominent in the exercises of the week, but we at least cannot find fault with our host, who was willing to give us everything save Canada itself. One would like to make some return, but as every effort would be inadequate, it is allowable to hope that in the fixing of popular interest on electrical matters by this meeting and in the display of what electricity can do to promote the advance of Canada in prosperity and civilization, our friends in the Dominion will be rewarded.

In spite of the pressure of social functions on the time of the Convention, a great deal of good, solid work was done, and it was interesting to note that the attendance at the successive daily sessions was even above the average. The fact is, half the value of a Convention lies not in what is debated on the floor, but in what is chatted over in chance interviews and quiet corners by those who have notes to compare or are in search of special information. Many station managers are anxious to talk about their work with their fellows, or to ascertain private opinion as to the drift of things, but they are averse to making a parade of their desire for knowledge, and would much rather buttonhole a man on the subject than submit him to a very public *viva voce* examination.

Many of the utterances in the Convention were unusually significant, and their consequences may be very important. Take, for instance, the philippics of Mr. Weeks. If he has rightly voiced the sentiment of central station men as to the invasion of their territory from time to time, and as to the resolve to band against it, it is well to know that such a state of mind exists. The movement he has set on foot will need close watching, and it will undoubtedly have large sympathy so long as moderate measures are followed and so long as the result is to give permanence, stability and prosperity to electrical investment. The remarks also by Mr. Leonard and Mr. Huntley as to "composite" stations were most timely, and deepened the conviction as to the prospects of a very general development along that line of work. Seconding these were the eminently practical station papers of Messrs. Ayer and Burleigh; the discussion of Mr. T. C. Smith's paper of six months ago, and the debate on the new rules for wiring submitted by a special committee that had evidently been hard at work and had reached some very definite conclusions. It was fortunate also that two such admirable papers on electric railway work were offered by Capt. Griffin and Mr. Field. Central station men ought to be foremost in the promotion of electric railway enterprises, as one of the most profitable new fields into which they can carry their experience without making any sacrifice of existing opportunities in light and power.

Of the Exhibition it will suffice to say that it was the best commercial display ever given, and that in many respects it compared favorably with the International Exhibition at Philadelphia in 1884. It is hardly to be expected that another such exhibition will be made until the holding of the Chicago World's Fair in 1893.

THE CENTRAL STATION PROBLEM OF TO-DAY.

The presidential addresses delivered in the past before the National Electric Light Association have for the most part dwelt upon the past and present state of the industry which the Association is intended to foster, and in more than one instance pointed out the lessons to be drawn from the experience gained. In this respect, however, we believe none has surpassed in suggestiveness the admirable address of President Huntley delivered at Montreal. Being himself an eminently practical man, and addressing those whose chief business aim is to make money for their stockholders, rather than to discuss the abstract scientific principles of the apparatus which they handle, President Huntley very properly pointed out what seemed to him likely to be the future course to be pursued by central station managers. One striking point alluded to was, that it was not wise for the central station manager to look too far ahead in laying plans for the future, and we are certain that all will be impressed with the comparatively short-time limit which Mr. Huntley sets, and beyond which he deems preparations for the future should not be made. It is well, indeed, that Mr. Huntley has given prominence to this point, for the work which is now in progress, and other work which is bound to develop, may so greatly increase the capacity of our central stations, so far as lighting is concerned, as to certainly warrant some conservatism in this respect. In utilizing the means at command at the present time, Mr. Huntley also expresses undoubtedly sound views on the mode of distribution which will lead to the highest economy of operation. Without restricting himself to any particular style of current, he points out the great utility of the "zone system," an excellent idea as applied to electric distribution, and which, we think, will be carried out in practice in one form or another as its merits become better understood. We believe the opinion expressed by Mr. Huntley as to the relative merits for general distribution and utility of the continuous and alternating current, will probably find some opposition from the friends of the latter, but Mr. Huntley states, distinctly, that he views the subject entirely from the standpoint of the station manager who has to use apparatus furnished to him by the electrician. If, as it would seem according to Mr. Huntley, the alternating current is not yet able to give us all the service rendered by the low tension continuous current, it ought to be the aim of those interested in the progress of the latter to supply this want without delay, and we are certain that the energies which have been applied in bringing the alternating current to its present state of utility, will be equal to placing the same beside the continuous current in every essential feature. Altogether Mr. Huntley's address proves that he is a keen observer of events, and his views on the subjects treated will be read with interest by everyone interested in the progress of the art.

THE ELECTRICAL CENSUS.

There was, perhaps, no subject brought before the Convention which commanded more immediate attention and, indeed, aroused more energetic action than the announcement that the Superintendent of the Census had ordered the cessation of work on the preparation of the electrical census. It would be needless to repeat the reasons why this work should be prosecuted with the utmost degree of diligence, and the work which Mr. Allen R. Foote had already accomplished in this direction was a sufficient guarantee of the fact that the electrical section of the eleventh census would be a compilation of which America could be proud, and which would be of incalculable benefit to every one engaged in the industry. To stop such a work, now fairly begun, at this time, would be a positive disgrace, not to speak of the waste of money entailed in the expenditures already made upon it up to date. Even if the work should be taken up at some future time, the rapid strides which the industry is making would make the figures obtained a year or even six months from to-day entirely out of accord with those existing at, and gathered up to, the present time, so that the conclusions to be drawn from the census would be warped to that extent. All considerations of economy as well as of accuracy call for the uninterrupted prosecution of the work undertaken by Mr. Foote, and every effort should be made to induce Mr. Porter to rescind his recent order, and, if unavailing, Congress ought to be prevailed upon to appropriate the necessary funds. The committee having this matter in charge cannot act too quickly nor too energetically.

Fuses on Alternating Circuits.

The discussion on Mr. T. Carpenter Smith's paper read at the Providence Convention last February, while it could hardly be called adequate, considering the large number of details treated of by Mr. Smith, nevertheless served to bring out one or two points which ought to receive immediate attention. Perhaps the most important was the nature of the fuses employed in the alternating current systems, and the difficulties which accompany their use, as described by several members. It would thus seem that the action of the alternating current has a disintegrating effect upon the fuses, which causes them to blow after comparatively short use and thus necessitates a constant renewal and supervision of the circuits. This action should, we think, be thoroughly investigated and the proper remedy applied. As Mr. Smith pointed out, the electric light cannot be said to be firmly established in any place until operated so that there is no interruption of the current—not even for an instant. It is doubtful whether every station now operating can refer to a continuous uninterrupted run of all circuits for as short a time probably as a month. It would seem also that not a little difficulty is experienced by the loosening of screws in the converter, no doubt due to the internal vibration caused by the changing magnetism of the transformer core. These and other defects will, in time, be thoroughly eliminated, but it is just as well to have them pointed out now, so that the remedy may be applied as soon as possible.

The Ideal Electric Motor.

While the electric motor of to-day leaves little to be desired in the way of efficiency and regularity of operation when designed for a particular work in a stationary position, it cannot be denied that in some applications involving a change both in speed as well as in power at frequent intervals, such as occur particularly in railway work, difficulties are met with that reduce the economy of operation materially. A motor, therefore, which can operate at any speed, from zero to the maximum, and likewise at any given torque or pull over the same limits, and always at its maximum economy, will be conceded to be an achievement of no little value, and one which must make itself felt wherever electricity is applied to motive purposes. Judging from the demonstration given at the Montreal Exhibition, it would seem that such a motor is now actually available. The details of the principles upon which this motor operates are not yet available for publication, but we await with interest the paper which Mr. H. Ward Leonard, the inventor of the motor, will read before the American Institute of Electrical Engineers at an early date.

THREE YEARS' DEVELOPMENT OF ELECTRIC RAILWAYS.[1]

BY CAPT. EUGENE GRIFFIN.

THE first recorded description of the electric car is found in the fourth verse of the second chapter of Nahum: "The chariots shall rage in the streets; they shall jostle one against another in the broadways; they shall seem like torches, they shall run like the lightnings." Notwithstanding this early mention, it was not until 1888 that the electric railway became a practical commercial success. I fix the date at 1888 as it was in that year that Bentley and Knight opened the Allegheny City road to regular traffic; that the Sprague Company equipped the Richmond road, and the Thomson-Houston Co. installed the Eckington and Soldiers' Home road in Washington. It was in 1888 that railway officials began to realize the possibilities of this new tractive force; that the great West End system of Boston adopted electricity to the exclusion of cable, and that orders began to flow in upon the electric companies for street car motors to such an extent as to soon make the manufacture of such motors one of the leading branches of the electric industry.

The pioneers who devoted their brains and frequently their purses to this work previous to 1888 are deserving of all credit. It was their misfortune, not their fault, that their ideas were not developed and worked commercially. It is difficult for one man to combine the qualities of inventor, manager, superintendent, seller, expert and financier, and yet this is what Van Depoele, Daft, Bentley and Knight and others had to attempt. The record of their efforts is an interesting one, but the chronological record of electric traction has been so frequently given that it would be a waste of your time to repeat it again.

During the Toronto Annual Exhibition, in 1884, an electric railway some 3,000 feet long was operated from the entrance to the grounds to the main building. This was a conduit road and the wires carried a potential of over 1,000 volts without accident. A thirty horse-power electric locomotive was used hauling trains of cars.

The Van Depoele Company subsequently equipped roads at Minneapolis, Minn., Montgomery, Ala., Detroit, Mich., Windsor, Ont., Appleton, Wis., Port Huron, Mich., Scranton, Pa., Lima, O., Binghamton, N. Y., Ansonia, Conn., Dayton, O., Jamaica, N. Y., St. Catherines, Ont., and elsewhere, many of which are still in operation.

In the fall of 1887 Frank J. Sprague contracted for the electrical equipment of the Union Passenger Railway at Richmond, Virginia. This was an important road in a large city and Mr. Sprague's undertaking was the most ambitious effort in this direction up to that date. It is worthy of note that Sprague's original intention was to use motors with but one reduction, but he was forced to abandon this idea as none of the electrical companies at that date were able to produce single reduction motors. The motors used at first were too light for the work; the copper brushes scored the commutators badly and were rapidly consumed. Nevertheless, Mr. Sprague persevered despite all obstacles, and in 1888 the road was running with so much success that it was one of the object lessons which induced Henry M. Whitney and his brother directors of the West End Street Railway of Boston to adopt electricity as a motive power when they were already far advanced in the plans for cabling their system.

As nearly as can now be ascertained the following electric roads were actually in operation on January 1st, 1888:

Roads.		Location.	Miles.	No. of Mtr. cars.
Union Pass. Ry. Co..........	(Daft)............	Baltimore, Md.....	2.00	3
Windsor Electric Ry........	(Van Depoele) opp.	Detroit, Mich......	1.25	2
Appleton do	do.	Appleton, Wis....	5.50	5
Port Huron do	do.	Port Huron, Mich..	2.75	4
Highland Park..............	(Fisher)............	Detroit, Mich......	3.25	4
Scranton Suburban road.....	(Van Depoele).....	Scranton, Pa	5.00	12
Los Angeles Electric Ry. Co.	(Daft).............	Los Angeles, Cal..	5.00	6
Lima Street Ry. and Motor Power Co................	(Van Depoele). ...	Lima, Ohio........	4.00	8
Columbus Consolidated Street Ry......	(Short).	Columbus, O	1.00	2
St. Catherines Street Ry. Co.	(Van Depoele)....	St. Catherines, Ont.	7.00	13
Seashore Electric Ry. Co....	(Daft)..............	Asbury Park, N. J.	4.00	18
San Diego Street Ry. Co.....	(Henry)	San Diego, Cal....	3.00	9
East Harrisburg Pass Ry.Co	(Sprague)....... ..	Harrisburg, Pa....	4.40	10

A total of 13 roads, 48.25 miles of track and 95 cars.

On July 1st, 1891, there were 354 roads in actual operation, with 2,893 miles of traek equipped electrically, and 4,513 motor cars. Such has been the growth of three and a half years.

During the past spring the legislature of the State of Massachusetts was considering a proposition which practically amounted to the imposition of new taxes upon the West End Street Railway Co., and the abrogation or virtual annulment of certain vested rights which the company might claim. In his able and vigorous defense of his corporation, President Whitney was forced to investigate and determine the true relations which existed between his company and the public, and he was surprised himself to see how closely the welfare of the city of Boston and its surrounding suburbs was identified with the welfare of its street transportation system. He at once entered upon a "campaign of education," and his speeches in Somerville, Roxbury, Dorchester and elsewhere (several of which have been published in pamphlet form) are masterly, impressive, straightforward and convincing presentations of the close relations which existed between the rapid transit systems and the health, wealth, morality and prosperity of our large cities. I commend these speeches to the consideration of you all. I have not hesitated to draw from them largely myself.

I consider this growing realization of the true position which transportation companies occupy in respect to the public as one of the most important of recent developments, and it may be well to give it some consideration.

The last census has clearly shown a strongly-marked tendency of our population to gravitate towards the large cities. In every State the percentage of growth in cities is far greater than in towns and villages. Such condensation of population means an increase of the tenement house system in contradistinction to the cottage system, a crowding of people beneath each roof, and increase in vice, immorality, misery, crime and the death rate. How is it to be avoided? The laborer must live near his work, near in time and near in money. He can spare but a fraction of his time, but a fraction of his day's wages in going to and from his work. If the zone fare system exists as in Europe, the area within which he can live is limited by this consideration. Two cents per mile might restrict him to a radius of 2½ miles (5 cents). If the single-fare system prevails, as in this country, time is practically the only restriction. Let us assume that he can allow thirty minutes morning and evening for his car ride, paying five cents for each ride. At the rate of six miles per hour, fast for horses, he has a radius of three miles and an area of 28¼ square miles within which to select a home. At the rate of nine miles per hour, slow for electricity, he has a radius of four and a half miles and an area of 63¼ square miles within which to select a home. This example suffices to illustrate the point. An increase of only three miles per hour in rapidity of transit doubles the available residence area without increasing the time or expense of the laborer in going to and from his work.

The steam road, the elevated road, the underground road and the cable, each and all afford rapid transit; but their application is restricted within very narrow limits because of their great cost, while the electric roads can be profitably extended in all directions.

The objections to overhead wires have been, and in many places still are, very strong; but actual experience has shown that the objections are not well founded. Wires are not an ornament to the street, and objections on this ground will always exist; but lamp-posts, signs, railway tracks, and many other similarly useful objects are not ornaments. Overhead wires will never be condemned on this ground alone. Objections on the score of unsightliness become of less and less importance each year as the methods of construction are improved and the public appreciate more freely the benefits of electric motive power.

One of the early apprehensions in reference to the use of overhead wires was the possible danger to life from the current used. On this point I think the public are now well satisfied. While there are few employés on any of the roads now in operation who have not had the full shock of 500 volts repeatedly, there is not a single instance of any of the patrons of these roads who have been killed or even seriously injured by the 500 volt current from the overhead wire. Electric cars will run over and kill the careless pedestrian or the drunken passenger who falls from the platform in front of the wheels as will the horse car, but no passenger or pedestrian has ever been killed by the trolley wire, and statistics do not show that the electric car is in any respect more dangerous to life than the horse car or cable car. Last year (1890) the West End street railway system of Boston carried 114,853,081 passengers and all the steam railroads of the whole State of Massachusetts only carried 98,843,712. The West End system killed 15 passengers and employés and the steam roads killed 325. Of the 15 fatal accidents on the West End system, 5 were attributable to electric cars and 10 to horse cars. It is only fair to say that the narrow and crooked streets of Boston and the enormous traffic of the West End system are conditions peculiarly conducive to accidents. The fear of the electric current is one born of ignorance and time alone can overcome it.

In the year 1889, nine human beings were killed by the arc light wires in New York City (2,500 volts) and the authorities were roused to such a pitch of frenzy that the poles were chopped down and a large part of the city left in darkness. Yet, with perhaps one exception, all of the victims were employés of the lighting companies and suffered because of failure to observe proper and well-known precautions. In the same year, twelve persons were asphyxiated by gas and over thirty were killed by signs and other objects falling on their heads as they walked peacefully along the streets. In time we are able to estimate every danger relatively,

1. Abstract of a paper read before the N. E. L. A., Montreal, Sept. 10, 1891.

but in the beginning unknown dangers, those to which we are not accustomed, are greatly exaggerated.

The double and single trolley systems have each had ardent advocates, but three years' experience has decided the question in favor of the single trolley and the ground return.

In July, 1888, several roads were using the over-running trolley and it was a question whether the over-running or under-running system was preferable. Three years have decided this question also, and practically all of the electric roads of to-day operate with under-running trolleys. The "fish pole" of 1888 has been supplanted by the neat steel rod of 1891, and the "broom-stick train" can no longer be spoken of with disrespect as regards outward appearances.

Three years have not passed without much litigation and already we have historical cases finally determined, which tend to fix the legal boundaries of the rights of electric railways. Some of these decisions are of great importance.

The telephone companies have quite naturally been ardent advocates of the double trolley, and to avoid suffering from the induced currents of the single trolley, they have sought to induce the courts to compel railway companies to use metallic circuits. The recent decision of the Supreme Court of the State of Ohio is a fair statement of the present legal aspect of this question.

The telephone companies have been beaten in every case, and the fact has been definitely settled that railway companies may use a single overhead trolley wire and a ground return without infringing any rights of the telephone companies.

Many interesting legal questions have arisen in reference to line construction. Objection was made by the summer residents of Newport to the construction of an overhead electric railway, and eminent counsel was employed to place every possible legal obstacle in the way. The case was carried to the Supreme Court of the State of Rhode Island for determination of some of the novel points involved, and its decision was in favor of the electric railway company.

In the purely technical field all obstacles have been overcome. Like Perry, "We have met the enemy and they are ours." The severe strain imposed by railway work on the generating plant has necessitated the development of new types of engines and the fluctuations of the dynamos have been prevented by compound winding and series coils. Self-regulating dynamos are now considered necessary in any well-planned power plant.

The difficulties Mr. Sprague encountered in Richmond in using copper brushes have now been avoided by the introduction of the carbon brush, for which we are indebted to Mr. C. J. Van Depoele. As early as 1883-4 Van Depoele used carbon brushes with his motors. When the Van Depoele Electric Manufacturing Co. was purchased by the Thomson-Houston Co., in 1888, Van Depoele went to the Lynn factory of the latter company. Many did not then consider the carbon brush as practicable, and it was some time before Mr. Van Depoele had an opportunity to demonstrate its possibilities. When the time did come its great value was so apparent that it was at once adopted for motor work and subsequently has been used exclusively with generators.

Since the general adoption of the present method of mounting the motors directly on the axles, double reduction motors have been used. The supposed necessity of high speed of revolution in the armature made this obligatory. In 1890 it was found practicable to make motors in which the armature revolved at a slower rate and a single gear sufficed for the now greatly reduced reduction. From 10 and 12 to 1 with the old motor we come to 4½ to 1 with the new motor. The gears are enclosed in boxes and run in oil so that the noise has been reduced to a minimum, the offensive noise of the gears being practically eliminated. We have also gearless motors with no reduction and no gears.

Generator construction has kept pace with the improvements. As large stations have been built generators have increased in size, and electrical companies are now producing 500 h. p. dynamos as readily as the steam engine builders respond to similar demands.

We have learned what it costs to operate electric railways and the result is gratifying. In 1888 it was prophesied that while electric roads might make good showings so long as the apparatus was new and curiosity riding lasted, in a short time the machinery would begin to wear out and the roads would be swamped by the great repair bills. In reality we find the almost universal testimoney is that the longer the road runs, the less is the cost of repairs. This is, of course, not due to the fact that the apparatus improves in quality with age, but the explanation is to be found in the very simple fact that as small defects are eliminated and the employees become more experienced and the organization is perfected, the apparatus is better cared for and injuries are prevented.

A very conspicuous example of this is the West End Street Railway, which has been under my own immediate observation. In the contract between the Thomson-Houston Electric Company and the Railway Company it was provided that we should keep the overhead line and electrical apparatus on the cars in repair at a given price per car mile. There were many reasons which influenced us to enter such a contract, but the chief reason was that this was the uncertain element in the operation of an electrical railway, and unless this uncertainty could be eliminated, the West End would not make any contract. The cost of these repairs has steadily decreased, and on the 1st of October the West End Company avail themselves of their option and relieve us of this part of our contract, knowing there is now no uncertainty and that they can do the woık themselves for less money than they pay us.

Some months since President Whitney gave to the public the detailed figures showing the receipts and operating expenses of the West End road. These are of very great interest to all, and I give them in full for the purpose of drawing some conclusions from them :

THE ELECTRIC SYSTEM.

	April.	May.	June.	July.
Gross receipts	$134,321	$1446,38	$153,968	$144,552
General expenses	8,193	7,793	7,465	6,955
Track and car expenses	47,447	45,443	39,629	43,891
Motive power	20,194	30,924	26,359	26,398
Total op. expenses	85,834	84,163	73,459	77,249
Net earnings	48,487	60,475	80,529	67,308
Miles run	394,459	376,821	360,567	377,191
Ratio of mileage	26.68	25.58	25 15	25.19
Per cent. op. expenses	63.36	58.18	47.70	53.44
Earnings per mile run	34.05	38.43	42.71	38.32
Expenses per mile run :				
Motive power	07.65	08.22	07.81	07.00
Car repairs	01.39	01 33	01.18	01.17
Damages	00.75	00.89	00.16	00.12
Conductors and drivers	07.33	07.36	07.25	06.92
Other expenses	04.63	04.56	04 47	05.37
Total expenses per mile run	21.75	22.36	20.87	20.48
Net earned per mile run	12.30	16.07	22.34	17.84

HORSE CAR SYSTEM.

	April.	May.	June.	July.
Gross receipts	$344,396	$374,605	$395,555	$409,878
General expenses	22,514	22,682	22,217	20,657
Track and car expenses	136,693	127,902	125,398	135,954
Motive power	117,740	118,972	116,210	116,271
Total op. expenses	276,947	269,556	263,825	272,888
Net earnings	67,449	105,049	131,729	136,990
Miles run	1083,887	1094,683	1073,718	1120,377
Ratio mileage	73.32	74 42	74.85	74.81
Per cent. op. expenses	80.62	71.95	66.70	66.58

THE ENTIRE SYSTEM.

	April.	May.	June.	July.
Gross earnings	$478,717	$519,244	$549,543	$554,431
General expenses	30,707	30,478	29,683	27,613
Track and car expenses	184,141	173,344	165,027	179,853
Motive power	147,933	149,896	142,570	142,670
Total op. expenses	362,781	353,720	337,284	350,137
Net earnings	115 935	165,524	212,250	204,294
Miles run	1478,346	1471,004	1433,785	1497,568
Ratio of mileage	100	100	100	100
Per cent. op. expenses	76.82	68.12	61.37	63.15
Earnings per mile run	32.39	35.29	38.33	37.02
Expenses per mile run :				
Motive power	10.01	10.19	09.94	09.53
Car repairs	01.05	00.79	00.76	00.75
Damages	00.77	00.50	00.15	00.07
Conductors and drivers	08.03	08 01	08.00	07.91
Other expenses	04.68	04.55	04.67	05.12
Total expenses per mile run	24.54	24.04	23.52	23.38
Net earned per mile run	07.85	11.25	14.81	13.64

Taking the June figures, it will be noticed that the net earnings per electric car mile exceed the net earnings per horse car mile by 10.07 cents, while the operating expenses of the horse car lines exceed those of the electric car lines by 4.20 cents per car mile. The difference is 5.86 cents per car mile, which is the gain to the company due solely to the public satisfaction with the electric service. Mr. Arthur Jones of the T. H. International Co. first produced this figure which he calls the "satisfaction figure."

The net earnings per electric car mile exceeded the net earnings per horse car mile by the following amounts :

In April	6.08	cents	per	car mile.
" May	6.47	"	"	"
" June	10.07	"	"	"
Mean	7.54	"	"	"

The net earnings of the horse cars for the three months averaged 9.36 cents per car mile, hence the electric cars showed a gain of 80 per cent. in the net earnings per car mile over the horse cars.

For the three months, we have the following figures for the electric cars :

Total receipts	$432,947
" expenses	243,456
Percentage of expenses to receipts	56 p. c.

In St. Paul and Minneapolis, with a combined population of 350,000, there is to-day not one single horse car. Minneapolis has 120 miles of electric railways, all equipped with the overhead system, and St. Paul has 75 miles of electric railways and 15 miles of cable. Most of the cable mileage is to be abandoned and supplanted by electricity. The last car horse disappeared from the streets of Minneapolis in June of this year. The July report of the Minneapolis system shows:

Gross earnings	$107,571
" expenses	52,585
Net earnings	54,985
Percentage of expenses to receipts	49 p.c.

Cleveland, Buffalo, Rochester, Toledo, Omaha, Cincinnati and many other large cities are now operating their street cars almost exclusively with electric motors, and the universal testimony is favorable to the increased facilities afforded the public and the increased profits to the stockholders.

Not the least important of the developments of the last three years has been the financial development. The fine showings as to earnings, the gradual decrease in operating expenses, where increases were expected, the oft demonstrated ability to run electric cars in all kinds of weather, in ice, snow, sleet, hail or rain has greatly improved the standing of electrical securities. An electric road is no longer an experiment, it is a paying investment and there are not a few instances where the introduction of electricity has been the salvation of a horse road that otherwise would soon have been in the hands of a receiver. The rapidly increasing demand for electrical securities is an evidence of a healthy growth of public sentiment in this direction. To equip electrically means the expenditure of money which must come from an increase of the bond or stock issued. The ability of the public to rapidly absorb these new bonds or stock must be the ultimate limit of the ability of the railway companies to move in this direction.

In August the West End Street Railway Company put out four millions of common stock for additional electrical equipment under a plan of subscription which provided for two deferred payments. When the subscription books were closed on the 5th of August, 33,000 shares had been paid in and only a paltry 245 shares had taken advantage of the option for deferred payments. I know of no more striking object lesson than this, except perhaps the rapid rise of the West End common stock from 63 to 77, which immediately followed.

Electric securities have heretofore been offered at tempting figures, but the day for this is passing. The public are realizing that a good street railway security is better than a Western railroad bond or stock, and the electric roads are better than the horse roads. Electric railways will pay where no one would dream of building a horse road, and when the public taste is whetted for electrical securities, we shall see a marvelous increase in the number of roads and the equipment of existing roads that will mean transportation facilities for thousands who are now unprovided, and many years' work for our electrical factories.

SOME DETAILS OF THE CARE AND MANAGEMENT OF AN ARC LIGHTING SYSTEM AS PRACTICED IN THE "MUNICIPAL," OF ST. LOUIS.[1]

BY J. I. AYER.

As central station men, it seems to me that we should demand of each other as much knowledge of the practice and experience as is practicable to give. In fact, if this Association is to be useful, our meetings should be largely "experience meetings," and the practical experience of those engaged in the development of the lighting and kindred industries, if given liberally at each meeting, would be followed closely by those interested in the production of electrical apparatus and supplies, and would do much to advance the business and improve appliances. Believing that we are here, as central station managers, for mutual improvement and for the free interchange of ideas and experience, I have presumed to present you with a limited, though doubtless dry, outline of the practice which obtains in the central station under the writer's charge.

The station, as designed, has a working capacity of 6,000 arc lights, and is now operating daily 3,500, and about 200 constant current motors; 2,000 of these lights are distributed over an area of 60 square miles, suspended between and from poles 50 and 65 feet in length, at a height of from 35 to 50 feet above the roadway, an average distance apart of about 900 feet, and used for street lighting. The motors and about 1,500 lamps are operated for the usual varied service of private consumers; 69 circuits supply the lamps and motors, containing about 1,200 miles of wire and supported on 12,000 poles.

For generating the current, we have six 600 h.p. Corliss engines, which drive 300 feet of shafting, from which are driven sixty-five 60 light and twelve 80 light, 2,000 c.p. arc dynamos. The arrangement of the dynamos is such that we have ample room for the care of 85 machines on a floor space of about 100 x 45 feet, and are able to operate a large number of dynamos with a very limited amount of help. Four boys and one young man of very limited experience care for all the machines during the night, in an entirely satisfactory manner; while a suitable man, with three assistants, give the necessary care to the dynamos during the day.

Thirty-one trimmers, with horses and carts, travel about 500 miles a day to renew the carbons in the street lamps. The average number of lamps to each of these trimmers is 68. Sixteen trimmers care for the 1,500 commercial lamps. Five inspectors, or trouble-men, with carts and horses, care for the lines night and day, answer fire alarms, locate faults and correct minor troubles on the lines. Two day and two night inspectors care for the commercial arc and 2,500 incandescent lamps. A stable of 20 horses, in addition to the 40 horses owned by the trimmers and inspectors, is required. The maintenance of 60 vehicles justifies a blacksmith and wagon shop, which, with the stable, require the services of eight men. Two men care for the shafting and three engineers and four oilers for the engine room. In the boiler house, where there are nineteen 300 h.p. boilers, there are two pump men, with two assistants, twelve stokers, one boiler cleaner, and six coal shovelers. These, together with an average force of 35 line and ground men, foreman, chief trimmer, chief inspector, superintendent of lines, store keeper, repair shop employees, carpenters, clerks, etc., constitute a force of about 170 men. A very large per cent of these men are called upon to perform duties which are simple, yet, because of their extreme newness, are not thoroughly comprehended by them. To get the best results, each man requires clearly written rules, as few of them as possible, and their rigid enforcement. In all practice this is the wise way to put it; but it is absolutely necessary that it be so with a large force, where many of the men do their work independently, and free from the constant supervision of a foreman.

In the room used as an office at the station by the inspectors and formen are city maps, mounted on boards, where the locations of the lamps are indicated by tacks and the circuits by strings. For the central part of the city, where there are many circuits on the same line of poles, each circuit is shown on a separate map of that section. A number of printed slips, which represent a pole with cross arms, indicate the location of the wires on the poles on the different streets traversed by the different circuits. Any change of circuits is noted on a separate blank when the work is ordered, and when completed the maps are corrected to correspond. It takes but a few days for a man to become quite familiar with the circuits, by keeping them so conspicuously placed. In large stations this method of indicating circuits is almost indispensable, and will prove of great value if used in smaller ones.

For testing purposes we have a portable tachometer for indicating speeds, two Thomson indicators for the engines, a recording steam gauge, two standard ammeters and a voltmeter reading to 5,000 volts for the dynamo room; on each circuit a spring socket for attaching ammeters and a current indicator for indicating the direction the current is flowing through the circuit; near the lightning arresters on the upper floor, a switch-board specially arranged for testing only; a Wheatstone bride, magneto bells, etc. The engines are indicated once each day.

Evaporation boiler tests are made every month to see that the quality of coal is maintained at the standard. All the circuits are tested four times each day. All live circuits during the day are tested for grounds, and all others for apparent open circuits as well. In addition to this, all circuits are tested while alive by taking volt and ammeter readings simultaneously. The number of miles of wire and number of lamps being known, any material increase in the energy consumed gives evidence of a fault not always easily discovered by other methods. In testing for grounds on circuits not alive, a strong magneto bell is used. For all other testing a battery current of from 30 to 50 volts is used, and the circuit is required to pass at least one ampere to operate an ordinary call bell. When this bell is placed in series with a circuit which has more resistance than will pass this current at the pressure, the circuit is at once inspected and the fault located. In locating the trouble, one side of the bell circuit is connected to the line and the other to earth. The inspector or trouble man carries a similar bell with him, which he connects in series with the earth and line at various points, until the fault is located. The value of circuit testing with low voltage is keenly appreciated by those who have practiced it. When the circuits are alive, ammeter readings are recorded every two hours, and all readings are from the same instruments. These instruments are arranged so as to be read singly or in series, and one is used to check the other. The value of first-class instruments in plants of any size cannot be overestimated, and should be in daily use in all stations, rather than the makeshifts generally supplied.

The stopping and starting of engines and boilers, pumps, dynamos, circuits, etc., are all recorded on reports made by those in charge of the different departments. Each inspector, trimmer, line foreman, storekeeper, and all heads of departments make daily reports of work done, and time and material used by them. Each trimmer is charged with a certain number of demerits for

1. A paper read before the N. E. L. A., Montreal, P. Q., Sept. 10, 1891.

each fault on his route, such as defective or dirty lamps, broken or dirty globes, carbons used in excess of the required number, etc., and each month prizes are awarded to those having the best records.

The advantage of using vehicles for trimmers for all street-lighting work is being recognized. Provide a man with proper appliances and your service will improve. He cannot carry all that he should and walk long distances, nor will he take the same care when he is worn out with tramping that he otherwise would. We find it desirable for the trimmer to own and care for his own horse, while the company provides a suitable vehicle and harness, which he turns into the stable once a week for inspection, cleaning and repairs, when needed.

We select from our linemen those whom we class as inspectors or trouble men, who are equipped with a light-running cart, with a suitable place for the storage of all tools necessary to use in an emergency. In addition to the special duty required of them during storms or at fires, these men correct all minor troubles reported to the office from various sources. During the first year's operations the average time lost, due to open circuits at night—that is, the average time lost from the time the circuit was opened until it was closed and the lights restored—was an hour and five minutes, notwithstanding that all circuits are more than ten miles in length. When these troubles occur, it is almost always during a storm, but the conveyances with which they are provided and their thorough knowledge of the circuits enable them to become very expert in locating and correcting troubles. During the past year nearly 15 per cent. of all the calls answered by our trouble men were to correct troubles on the lines of other companies. Because we have wires all over the city, the police, and the public generally, think that all the wires belong to us, and, when they discover any trouble with them, are very apt to report the same by telephone to our station. During the entire twenty-four hours there is always one man on duty, ready to answer just such calls and correct the troubles.

All arc lamps, before leaving the station, are placed in a test rack, where they are supplied with a current maintained absolutely constant. Voltmeter readings are noted soon after the lamps have been lighted, when the carbons are about half consumed, and also when they are burned quite short. During the early part of the burning the lamp is adjusted so that the readings, taken at three different points, give an average reading of 46 volts. In case of double lamps, this work is carried out on both rods. This extreme care in regard to adjustment we regard as absolutely necessary. If a lamp is permitted to consume its carbons, any fault which would not be discovered with a brief test is quite likely to develop. To determine the length of arc by the current and voltage is more likely to result in uniform lamps then where tested by the eye. With ten lamps, adjusted to burn at an average of 46 volts, with $9\frac{5}{10}$ amperes, the average number of watts per lamp was 436. Without changing the adjustment of the lamps, the current was increased to $9\frac{8}{10}$ amperes, and there was an average consumption of 524 watts per lamp, an increase of 20 per cent. of energy; and by increasing the current to ten amperes, the average number of watts per lamp was 550, the average voltage 58, the increase above normal being 33 per cent. That means 33 per cent. more coal, 33 per cent. more work at your dynamo, 33 per cent. less capacity in your dynamo, and probably 33 per cent. less life in your armature. One is apt to think that the difference between $8\frac{5}{10}$ and 10 amperes, when supplied to the lamp, is only a difference of 5 or 10 per cent., which is not very serious. This would be true if the lamp were adjusted each time for the ampere current it was to be operated with. To those who have not made this experiment, perhaps, a portion of the mystery as to where the coal goes will be cleared up. By using the ammeter and voltmeter for adjusting the lamps, and then seeing that the circuits are provided with the same ampere current indicated by the same ammeter, one will be apt to bring about like conditions in all lamps; at least, they are more likely to be uniform than if independent ammeters are used on each circuit. By reference to this statement relative to the amount of energy consumed by change of current, it will be easy to see how expensive one or two low lamps would be on a circuit, where the operator, to correct the trouble, supplies them with current enough to make them bright. Of course it is understood that better service as well is obtained by operating the circuits with no more current than that for which the lamps are adjusted. In this connection, I believe it is proper to again call attention to the well-worn subject of connections. A great deal of time and trouble is spent in soldering joints, and when the lines are led to the lamp they are apt to be poked into the binding posts, held with set screws indifferently tightened, and between these binding posts and the lamp connections proper there are perhaps three or four, if not more, indifferent contacts, all of which look very well in the factory, but are very bad after a few months' service. Hanger-boards should be used which have the line wire soldered to connections which cannot get loose. In our practice we accomplish this by using about 18 inches of flexible insulated cable, which is soldered to the hanger-board binding posts at the station (cut-out boxes are treated in the same manner) leaving the lineman nothing but an ordinary line joint to make, which can be easily done outside. Where lamps are suspended from the hanger-boards by the hooks which conduct the current, we always insist on some character of second connection being made to the lamp besides this. A simple way to do this is to take some small wire and tie the hook to the loop, in much the same manner as you would with a piece of twine. We have no screw connections anywhere in our circuits, and with a little ingenuity and care, they can be avoided always in arc lighting circuits. By the use of a special socket in each circuit for connecting an ammeter, we are able to take the readings with volt and ammeter, and get a correct indication of the actual consumption of energy on a circuit while in operation. With the data relative to the number of lamps in service and the number of miles and size of wire, we are able to discover any excessive consumption of energy and prevent the development of a series of little faults, which, in a short time, grow to be very serious ones if permitted to continue. Usually these readings are taken on each circuit three times a week, and during the time these observations are made, indicator cards are taken from the engines. From these two sources we get the actual consumption of electrical energy per circuit and per engine. We also get the indicated horse power. From a set of eleven observations taken from July 30th to August 28th, at various hours during the night run, the station shows an efficiency, between indicated horse power and electrical horse power at dynamo terminals of 74.9 per cent., ranging from 70.3 per cent., the lowest, to 77.5 per cent., the highest efficiency shown. The circuit readings indicate an average consumption of energy per lamp of about 6-10 of an electrical horse power. The average indicated horse power is about 8-10 per lamp. A good condition of the circuits is maintained constantly, because any neglect in any department is quickly shown by the data obtained from our records. Some months ago, when press of business caused the measurement of circuits to be neglected for a few weeks, the writer discovered an increase of over ten per cent. in the consumption of fuel, when there should have been a slight decrease. An investigation showed that an accident to an ammeter had caused a false reading, which increased the cost of fuel alone about $16 a day. The difference in the appearance of the lamps was not such as to call forth special comments then by those interested, yet, when the fault was discovered, it was remembered that some seemed to have been burning high for a week or two. On suburban circuits on long loops, it is our practice to place cut-out boxes on the pole where the line branches. This saves a great deal of time in locating troubles; but, let me add, that unless a thoroughly water-tight and substantial cut-out is used, it will prove more of an annoyance than an advantage. A log of each circuit and dynamo, as well as of engines and boilers, is a very satisfactory and desirable part of the records, and will frequently assist materially in locating troubles and saving expense.

Throughout the country it is almost the universal practice to wire for arc lights without cost to the customer. There is no valid reason for this custom, and for more than a year it has been our custom to charge for cost of labor, with the result of reducing expenses more than $600 per month. In every case where lamps are discontinued in the spring, we require a contract for fall and winter service, else the wires are removed when the lamp is taken down. We invariably cut down the line between the house and pole where the service is discontinued for the season, though it is to be renewed later. To induce annual contracts, a rebate of five per cent. is given at the expiration of the year, and is found to work to advantage.

There are very many details of construction, as well as of office work, which could be referred to, if it were not that this paper is now too long; but I will be glad to furnish a copy of "general instructions to employees," used in the government of this plant, which refer to and bring out some points of management which are not mentioned here, to those who care for them.

REPORT OF THE N. E. L. A. COMMITTEE ON TABULATING WIRING AND INSURANCE RULES.[1]

CLASS A.—CENTRAL STATIONS.

FOR LIGHT OR POWER.

These Rules also apply to Dynamo Rooms in Isolated Plants, connected with or detached from buildings used for other purposes. Also to all varieties of apparatus, of both high and low potential.

GENERATORS OR MOTORS—Must be:

1. Located in a dry place.
2. Insulated on floors or base-frames which must be kept filled to prevent absorption of moisture, and also kept clean and dry.
3. Not exposed to flying or combustible materials.
4. Each covered with a waterproof cover when not operating.

In no case must a generator be placed in a room where any hazardous process is carried on, such as the working-room of a cotton, jute, flax, woolen or flour mill.

1. Presented and adopted by the National Electric Light Association, Montreal, P. Q., Sept. 10, 1891.

CARE AND ATTENDANCE.—A competent man must be kept on duty in the room where generators are operating.

Oily waste must be kept in metal cans and removed daily.

CONDUCTORS.—From generators, switchboards, rheostats or other instruments, and thence to outside lines, conductors must be:

1. 1. In plain sight.
2. Wholly on non-combustible insulators, such as glass or porcelain.
3. Separated from contact with floors, partitions or walls through which they may pass, by non-combustible insulating tubes.
4. Kept rigidly so far apart that they cannot come in contact.
5. Covered with non-inflammable insulating material sufficient to prevent accidental contact.
6. Ample in carrying capacity to prevent heating. (See Capacity of Wires Table.)
7. Connected by splices or joints equal in carrying capacity to the conductors themselves, soldered if necessary to make them efficient and permanent.
8. When under floors or in distributing towers, placed in spaces ample for inspection and ventilation, and provided with special insulating covering.

SWITCHBOARDS—Must be:

1. So placed as to make it impossible to communicate fire to surrounding combustible material; accessible from all sides when the connections are on the back; or may be placed against a brick or stone wall when the connections are entirely on the face.
2. Kept free from moisture.
3. Made of non-combustible material, or of hard wood, filled to prevent absorption of moisture.
4. Equipped with bars and wires in accordance with rules 1, 2, 4, 5, 6 and 7 for placing interior conductors.

RESISTANCE BOXES AND EQUALIZERS—Must be:

1. Equipped with metal or non-combustible frames.
2. Treated as sources of heat.
3. Placed on the switch or a distance of a foot from combustible material, or separated therefrom by asbestos or cement.

LIGHTNING ARRESTERS—Must be:

1. Attached to each side of every overhead circuit connected with the station.
2. In plain sight.
3. On the switchboard or in an equally accessible place, away from combustible material.
4. Connected with at least two earths by separate wires of large size.
5. So constructed as not to maintain an arc after the discharge is passed.

TESTING.—All series and alternating circuits must be tested every two hours while in operation to discover any leakage to earth, abnormal in view of the potential and method of operation.

All multiple arc low potential systems (300 volts or less) must be provided with an indicating or detecting device, readily attachable, to afford easy means of testing where the station operates perpetually.

Data obtained from all tests must be preserved for examination by insurance inspectors.

CLASS B.—ARC (SERIES) SYSTEMS.

OVERHEAD CONDUCTORS.—All outside overhead conductors (including services) must be:

1. Covered with some insulating material, not easily abraded.
2. Firmly secured to properly insulated and substantially built supports, all the wires having an insulation equal to that of the conductors they confine.
3. So placed that moisture cannot form a cross-connection between them, not less than a foot apart and not in contact with any substance other than proper insulating supports.
4. At least seven feet above the highest point of flat roofs and at least one foot above the ridge of pitched roofs, over which they pass, or to which they are attached.
5. Protected whenever necessary, in view of possible accidents to conductors or supports, from possibility of contact with other conducting wires or substances to which current may leak, by *dead insulated guard irons or wires.* Special precautions of this kind must be taken where sharp angles occur, or where any wires might possibly come in contact with electric light or power wires.
6. Provided with petticoat insulators of glass or porcelain. Porcelain knobs and rubber hooks are prohibited.
7. So spliced or joined as to be both mechanically and electrically secure without solder. They must then be soldered to insure preservation and covered with an insulation equal to that on the conductors.

The following formula for soldering fluid is approved:

Saturated Solution of Zinc..................	5 parts.
Alcohol................................	4 parts.
Glycerine................................	1 part.

Conductors should not be run over, or attached to, buildings other than those in which light or power is being, or is to be, used, but on separate poles or structures, always easily inspected.

SERVICE BLOCKS must be covered over their entire surface with at least two coats of waterproof paint and so maintained.

Telegraph, telephone and similar wires must not be placed on the same arm with electric or power wires and *should not* be placed on the same structure or pole.

INTERIOR CONDUCTORS.

ALL INTERIOR CONDUCTORS—Must be:

1. Where they enter buildings from outside terminal insulators to and through the walls, covered with waterproof insulation, and must have drip loops outside, preferably slanting upward toward the inside and bushed with water-proof and non-combustible insulating tube.
2. Arranged to enter and leave the building through a double contact service switch, which will effectually close the main circuit and disconnect the interior wires when it is turned "off." The switch must be so constructed that it shall be automatic in its action, not stopping between points when started, and prevent an arc between the points under all circumstances; it must indicate on inspection whether the current be "on" or "off," and be mounted on a non-combustible base in a position where it can be kept free from moisture, and easy of access to police or firemen.
3. Always in plain sight, never covered, except in special cases, where an armored tube may be necessary.
4. Covered in all cases with a moisture-proof non-combustible material that will adhere to the wire, not fray by friction, and bear a temperature of 150° F. without softening.
5. In dry places, kept rigidly apart at least ten inches, except when covered (in addition to insulation) by a water-proof, non-conducting and non-inflammable tubing, which must be strong enough to protect the insulation covering from injury. Conductors thus placed may be run not less than three inches apart, and be fastened with staples, under which are placed mechanically rigid insulating strips or saddles of greater width than the metal of the staple, by which possibility of injury to the tube may be prevented.
6. In damp places, attached to glass or porcelain insulators, and separated ten inches or more.
7. When passing through walls, floors, timbers or partitions, treated as in central stations under like conditions.

LAMPS AND OTHER DEVICES.

ARC LAMPS MUST BE IN EVERY CASE:

1. Carefully isolated from inflammable material.
2. Provided at all times with a glass globe surrounding the arc, securely fastened upon a closed base. No broken or cracked globes may be used.
3. Provided with a hand switch, also an automatic switch, that will shunt the current around the carbons should they fail to feed properly.
4. Provided with reliable stops to prevent carbons from falling out in case the clamps become loose.
5. Carefully insulated from the circuit, in all their exposed parts.
6. Where inflammable material is near or under the lamps, provided with a wire netting around the globe and a spark-arrester above, to prevent escape of sparks, melted copper or carbon.

Incandescent lamps on series circuits, having a maximum potential of 350 volts or over, must be governed by the same rules as for arc lights, and each series lamp provided with a hand switch and automatic cut-out switch; when lights are in multiple series, such switches and cut-outs must not control less than a single group of lights. Electro magnetic devices for switches are not approved.

Under no circumstances will incandescent lamps on series circuits be allowed to be attached to gas fixtures.

CLASS C.—INCANDESCENT (LOW PRESSURE) SYSTEMS.

300 VOLTS OR LESS.

OVERHEAD CONDUCTORS.

OUTSIDE OVERHEAD CONDUCTORS—Must be:

1. Erected in accordance with general rules for Arc (Series) Circuit Conductors.
2. Separated not less than six inches, where they enter buildings as ser ice conductors, and be provided with a double pole fusible cut-out, as near as possible to the point of entrance to the building, and outside the walls when practicable.

UNDERGROUND CONDUCTORS.

UNDERGROUND CONDUCTORS—Must be:

1. Provided with suitable protecting devices at the ends of tube or conduit services inside the walls of buildings, as a guard against moisture and injury.
2. Terminated at a properly placed double pole house cut-out.

3. Of specially insulated conductors after leaving the tube or conduit, and separated by at least ten inches, until the double pole cut-out is reached.

INSIDE WIRING.

Wire should be so placed that in the event of the failure or deterioration of their insulating covering, the conductors will still remain insulated.

At the entrance of every building there shall be a double pole switch placed in the service conductors, whereby the current may be entirely cut off.

CONDUCTORS MUST NOT BE:

1. Of sizes smaller than No. 16 B. & S., No. 18 B. W. G., or No. 3 E. S. G.
2. Lead or paraffine covered.
3. Covered with soft rubber tube.
4. Laid in mouldings of any kind in damp places.
5. Laid in mouldings with open grooves against the wall or ceiling.
6. Laid in mouldings where less than half an inch of solid insulation is between parallel wires, and between wires and walls or ceilings.

Mouldings, where admissible, must have at least two coatings of water-proof paint or be impregnated with a moisture repellent.

CLEATWORK is not desirable, and cleats must *not* be used unless:

1. In a very dry place.
2. In a place perfectly open for inspection at any time.
3. They are of porcelain, or well-seasoned wood, filled, to prevent absorption of moisture.
4. They are so arranged that wires of opposite polarity, with a difference of potential of 150 volts or less, will be kept at least two and one-half inches apart, and that where a higher voltage is used, this distance be increased proportionately.
5. There is a backing provided, of wood at least half an inch thick, well-seasoned and filled, to prevent absorption of moisture.

METAL STAPLES must never be used to fasten conductors unless

1. Provided with an insulating sleeve or saddle rigidly attached to the metal of the staple, and having such strength and surface as to prevent mechanical injury to the insulation of the conductor.
2. Under conditions in which cleatwork would be acceptable, or where driven into a moulding specially adapted for open work.

SPECIAL WIRING.

Wherever conductors cross gas, water, or other metallic pipes, or any other conductors or conducting material (except arc light wires), they should be separated therefrom by some continuous non-conductor at least one inch. In crossing arc light wires the low tension conductors must be placed at a distance of at least six inches. In wet places an air space must be left between conductors and pipes in crossing, and the former must be run in such a way that they cannot come in contact with the pipe accidentally. Wires should be run *over* all pipes upon which condensed moisture is likely to gather, or which by leakage might cause trouble on a circuit.

In breweries, dye-houses, paper and pulp mills, or other buildings specially liable to moisture, all conductors, except where used for pendants, must be:

1. Separated at least six inches.
2. Carefully put up.
3. Supported by porcelain or glass insulators.

Moisture proof and non-inflammable tubing may be accepted in lieu of such construction.

No switches or fusible cut-outs will be allowed in such places.

INTERIOR CONDUITS MUST NOT BE:

1. Combustible,
2. Of such material as will be injured or destroyed by plaster or cement, or of such material as will injure the insulation of the conductor.
3. So constructed or placed that difficulty will be experienced in removing or replacing the conductors.
4. Subject to mechanical injury by saws, chisels or nails.
5. Supplied with a twin conductor in a single tube where a current of more than 10 amperes is expected.
6. Depended upon for insulation. The conductors must be covered with moisture-proof material.

The object of a tube or conduit is to facilitate the insertion or extraction of the conductors, to protect them from mechanical injury, and, as far as possible, from moisture.

Twin tube conductors must not be separated from each other by rubber or similar material, but by cotton or other readily carbonizable substance.

Conductors passing through walls or ceilings must be encased in a suitable tubing, which must extend at least one inch beyond the finished surface until the mortar or other similar material be entirely dry, when the projection may be reduced to half an inch.

DOUBLE POLE SAFETY CUT-OUTS MUSE BE:

1. Placed where the overhead or underground conductors enter a building and join the inside wires.
2. Placed at every point where a change is made in the size of the wire (unless the cut-out in the larger wire will protect the smaller). This includes all the flexible conductors. All such junctions must be in plain sight.
3. Constructed with bases of non-conbustible and moisture proof material.
4. So constructed and placed that an arc cannot be maintained between the terminals by the fusing of the metal.
5. So placed that on any combination fixture, no group of lamps requiring a current of six amperes or more shall be ultimately dependent upon one cut-out.
6. Wherever used for more than six amperes, or where the plug or equivalent device is not used, equipped with fusible strips or wires provided with contact surfaces or tips of harder metal, soldered or otherwise having perfect electrical connection with the fusible part of the strip.

SAFETY FUSES must be so proportioned to the conductors they are intended to protect, that they will melt before the maximum safe carrying capacity of the wire is exceeded.

All fuses, where possible, must be stamped or otherwise marked with the number of amperes equal to the safe carrying capacity of the wire they protect.

All cut-out blocks when installed must be similarly marked.

The safe carrying capacity of a wire changes under different circumstances, being about forty per cent. less when the wire is closed in a tube or piece of moulding, than when bare and exposed to the air, when the heat is rapidly radiated. It must be clearly understood that the size of the fuse depends upon the size of the smallest conductor it protects, and not upon the amount of current to be used on the circuit. Below is a table showing the safe carrying capacity of conductors of different sizes in Birmingham, Brown & Sharpe, and Edison gauges, which must be followed in the placing of interior conductors.

BROWN & SHARPE.		BIRMINGHAM.		EDISON STANDARD.	
Gauge No.	Amperes.	Gauge No.	Amperes.	Gauge No.	Amperes.
0000	175	0000	175	200	175
000	145	000	150	180	160
00	120	00	130	140	135
0	100	0	100	110	110
1	95	1	95	90	95
2	70	2	85	80	85
3	60	3	75	65	75
4	50	4	65	55	65
5	45	5	60	50	60
6	35	6	50	40	50
7	30	7	45	30	40
8	25	8	35	25	35
10	20	10	30	20	30
12	15	12	20	12	20
14	10	14	15	8	15
16	5	16	10	5	10
		18	5	3	5

SWITCHES—Must:

1. Be mounted on moisture proof and incombustible bases, such as slate or porcelain.
2. Be double pole when the circuits which they control are connected to fixtures attached to gas pipes, and when six amperes or more are to pass through them.
3. Have a firm and secure contact, must make and break readily, and not stick when motion has once been imparted by the handle.
4. Have carrying capacity sufficient to prevent heating above the surrounding atmosphere.
5. Be placed in dry, accessible places, and grouped as far as possible, being mounted, when practicable, upon slate or equally indestructible back boards.

MOTORS.—In wiring for motive power, the same precautions must be taken as with the current of the same volume and potential for lighting. The motor and resistance box must be protected by a double-pole cut-out, and controlled by a double-pole switch.

ARC LIGHTS ON LOW POTENTIAL CIRCUITS—Must be:

1. Supplied by branch conductors not smaller than No. 12 B. & S. gauge.
2. Connected with main conductors only through double-pole cut-outs.
3. Only furnished with such resistances or regulators as are enclosed in non-combustible material, such resistances being treated as sources of heat.
4. Supplied with globes protected as in the case of arc lights on high potential circuits.

FIXTURE WORK.

1. In all cases where conductors are concealed within, or attached to fixtures, the latter must be insulated from the gas pipe system of the building.

2. When wired outside, the conductors must be so secured as not to be cut or abraded by the pressure of the fastenings, or motion of the fixtures.

3. All conductors for fixture work must have a water-proof insulation that is durable and not easily abraded, and must not in any case be smaller than No. 16 B. & S., No. 18 B. W. G., or No. 3 E. S. G.

4. All burrs or fins must be removed before the conductors are drawn into a fixture.

5. The tendency to condensation within the pipes must be guarded against by sealing the upper end of the fixture.

6. No combination fixture in which the conductors are concealed in a space less than one-fourth inch between the inside pipe and the outside casing will be approved.

7. Each fixture must be tested for possible "contacts" between conductors and fixture, and for "short circuits," before the fixture is connected to its supply conductors.

8. The ceiling blocks of fixtures should be made of insulating material.

ELECTRIC GAS LIGHTING.

Where electric gas lighting is to be used on the same fixture with the electric light:

1. No part of the gas piping or fixture shall be in electrical connection with the gas lighting circuit.

2. The wires used with the fixture must have a non-inflammable insulation, or, where concealed between the pipe and shell of the fixture, the insulation must be such as is required for fixture wiring for the electric light.

3. The whole installation must test free from "grounds."

4. The two installations must test perfectly free of connection with each other.

PENDANTS AND SOCKETS.

No portion of the lamp socket exposed to contact with outside objects must be allowed to come into electrical contact with either of the conductors.

CORD PENDANTS—Must be:

1. Made of conductors, each of which is composed of several strands insulated from the other conductor by a mechanical separator of carbonizable material, and both surrounded in damp places with a moisture-proof and a non-inflammable layer.

2. Protected by insulating bushings where the cord enters the socket.

3. So suspended that the entire weight of the socket and lamp will be borne by knots, above the point where the cord comes through the ceiling block or rosette, in order that the strain may be taken from the joints and binding screws. All sockets used for wire or cord pendants should have openings at least equal to one-quarter inch gas pipe size.

4. Allowed to sustain nothing heavier than a four-light cluster, and in such a case special provision should be made by an extra heavy cord or wire, as a mechanical reinforcement.

5. Equipped with keyless sockets as far as practicable, controlled by wall switches. In no case may a lamp giving more than fifty (50) candle power be placed in a key-socket on a flexible pendant.

CLASS D.—ALTERNATING SYSTEMS.

CONVERTERS OR TRANSFORMERS.

CONVERTERS—Must not:

1. Be placed inside of any building except the central station, unless as hereinafter provided.

2. Be placed in any but metallic or non-combustible cases.

3. Be attached to the outside walls of buildings, unless separated therefrom by substantial insulating supports.

4. Be placed in any other than a dry and convenient location (which can be secured from opening into the interior of the building, such as a vault) when an underground service is used.

5. Be placed without safety fuses at the junction between main and service conductors and safety fuses in the secondary circuits where they will not be affected by the heat of the converter.

PRIMARY CONDUCTORS.

In those cases where it may not be possible to exclude the transformers and primary wires entirely from the building, the following precautions must be strictly observed:

1. The transformer must be located at a point as near as possible to that at which the primary wires enter the building.

2. Between these points the conductors must be heavily insulated with a coating of moisture-proof material, and in addition, must be so covered and protected that mechanical injury to them or contact with them shall be practically impossible.

3. The primary conductors, if within a building, must be furnished with a double-pole switch, and also with an automatic double-pole cut-out where the wires enter the building, or where they leave the main line. on the pole or in the conduit. These switches should, if possible, be enclosed in secure and fireproof boxes outside the building.

4. The primary conductors, when inside a building, must be kept apart at least ten inches, and the same distance from all other conducting bodies.

SECONDARY CONDUCTORS.

The conductors from the secondary coil of the transformer to the lamps or other translating devices must be installed according to the rules for "inside wiring" for "Low Potential Systems."

CLASS E.—ELECTRIC RAILWAYS.

POWER STATIONS.

All rules pertaining to arc light wires and stations shall apply (so far as practicable) to street railway power stations and their conductors.

RAILWAY SYSTEMS WITH GROUND RETURN.

Electric railway systems in which the motor cars are driven by a current from a single wire, with ground or floor return circuit, are prohibited *except* as hereinafter provided:

1. When there is no liability of other conductors coming in contact with the trolley wire.

2. When the location of the generator is such that the ground circuit will not create a fire hazard to the property.

3. When an approved automatic circuit breaker or other device that will immediately cut off the current in case the trolley wires become grounded, is introduced in each circuit as it leaves the power station. This device must be mounted on a fireproof base and be in full view of the attendant.

TROLLEY WIRES.

TROLLEY WIRES—Must be:

1. No smaller than No. 0 B. & S., copper, or No. 4 B. & S., silicon bronze, and must readily stand the strain put upon them when in use.

2. Well insulated from their supports, and in case of the side or double-pole construction, the supports shall also be insulated from the poles immediately outside the trolley wire.

3. Capable of being disconnected at the power house, or of being divided into sections, so that in case of fire on the railway route, the current may be shut off from the particular section and not interfere with the work of the firemen in extinguishing the flames. This rule also applies to feeders.

4. Safely protected against contact with all other conductors.

CAR WIRING.

All wires in cars must be run out of reach of the passengers and shall be insulated with a waterproof insulation.

LIGHTING AND RAILWAY POWER WIRES.

Lighting and power wires must not be permitted in the same circuit with trolley wires with a ground return, except in street railway cars, car houses, and power stations. The same dynamo may be used for both purposes, provided the connection from the dynamo for each circuit shall be a double-pole switch so arranged that only one of the circuits can be in use at the same time.

CLASS F.—BATTERIES.

When current for light and power is taken from primary or secondary batteries, the same general regulations must be observed as apply to such wires fed from dynamo generators, developing the same difference of potential.

CLASS G.—MISCELLANEOUS.

1. The wiring in any building must test free from "grounds" before the current is turned on. This test may be made with a magneto that will ring through a resistance of 20,000 ohms, where currents of less than 250 volts are used.

2. No ground wires for lightning arresters may be attached to gas pipes within the building.

3. All conductors connecting with telephone, district messenger, burglar alarm, watch clock, electric time and other similar instruments must, if in any portion of their length they are liable to become crossed with circuits carrying currents for light or power, be provided near the point of entrance to the building with some protective device which will operate to shunt the instruments in case of a dangerous rise of potential, and will open the circuit and arrest an abnormal current flow. Any conductor normally forming an innocuous circuit may become a source of

fire hazard if crossed with another conductor through which it may become charged with a relatively high pressure.

(Signed)

A. J. DeCamp, Chairman; M. D. Law, Stephen E. Barton Wm. Brophy, T. Carpenter Smith.

Certain questions have come before the committee, which they considered of too great importance to be decided at this stage. Among these are the subjects of the grounding of the neutral wire in compensating or three-wire systems—the grounding, either permanently or through automatic cut-outs, of the secondary wires in transformer systems—the adoption of a uniform alloy for fusible cut-outs—and the adoption of better methods for testing circuits.

From the nature of the electrical business and the rapid advance it is making, there must, of necessity, questions continually arise which can only be decided by a later and larger experience, therefore the object of the Association would be best served by the appointment of a permanent committee to whom should be referred all such questions, which they shall consider and report upon at the next succeeding meeting of the Association.

Your committee, therefore, offer the following:

Resolved: That a committee of five be appointed by the President, to be a permanent committee on safe methods of construction and operation—any vacancies that may occur on the committee from time to time to be filled by the President.

(Signed) (Committee,)

Wm. McDevitt, T. Carpenter Smith, Wm. Brophy, M. D. Law.

LIST OF ATTENDANTS AT THE MONTREAL CONVENTION.

New York.—Ackerman, P. C., Adams, M. F., Aidall, John E., Alexander, P. H., Babcock, W. R., Barberie, E. T., Barney, Genl. C. H., Bartlett, E. E., Beane, John W., Beardsley, W. H., Bell, Dr. Louis, Bowman, F. A., Burdick, J. R., Caldwell, E., Candee, Capt. Willard H., Cavell, E. N., Chase, S. A., Cheever, H. Durant, Chenowith, A. C., Churchill, H. H., Coles, S. L., Colvin, F. R., Corey, R. B., Crane, W. F. D., Cullen, W. F., Davis, A. E., Davis, C. J., Davis, E. T., Dillont, Col. J. Frank, Dunham, S. E., De Ronde, Frank S., Dreyfuss, T. FOURTEENTH CONVENTION OF THE NATIONAL ELECTRIC LIGHT ASSOCIATION, MONTREAL, SEPT. 7-11, 1891.

THE Association began its Fourteenth Convention at the Windsor Hall, Montreal, Sept. 7, at 3 p. m.

PROF. BOVEY, as chairman of the Citizens' Committee, welcomed the Association, and introduced
MAYOR JAMES MCSHANE, who bade the delegates welcome also. He was followed in a similar strain by Sir Donald A Smith, Sir J. W. Dawson, principal of McGill University; Aldermen Clendenning and Cunningham, Mr. Justice Wurtele, ex-Mayor Beaugrand, Mr. Richard White.
PRESIDENT HUNTLEY then said:

Mr. Chairman, Ladies and Gentlemen:

For the first time in its history the National Electric Light Association meets on other than its native soil. Yet, even in so doing, it but adds new evidence to the feeling in the breast of every electrician that his art is foremost among the influences tending to promote human intercourse and break down the walls of separation. Coming, as do our members from every State in the Union and the Dominion of Canada and representative as they are of all the varied agencies and methods for the distribution of the electric light and power, it affords me the greatest pleasure to acknowledge in their name the fraternal welcome with which we have all been received, and the lavish hospitality that makes us at home in this noble Dominion and in its magnificent city of Montreal (applause).

From the fact that the invitation was so cordial, and that the reception has been so warm, I can but infer that the Association enjoys here an intelligent appreciation of its work, its object and its aims. Permit me to say, therefore, that the Association asks for itself, during the coming week, a kindly tolerance of its technical papers and discussions, hoping that the large exhibit of electrical apparatus of the latest and most perfected character may make amends for the somewhat abstruse nature of its proceedings. If the earnest and practical quality of our dealing with the great questions of electricity shall in anywise stimulate electrical work in Canada, and lead to the electrical utilization of its great water powers and coal beds in light, locomotion, power and heating, we trust it will be accepted as at least some slight acknowledgement of the manner in which we have been so generously greeted (applause).

UNITED STATES COUNSUL GENERAL KNAPP then said a few words in behalf of the United States.

JUDGE ARMSTRONG, of Camden, N. J., then made a very felicitous response on behalf of the Association, and he was supported by

MR. ERASTUS WIMAN, who while claiming for Canada a greater development than other countries in the telegraph and telephone, and a very healthy growth in electric lighting, invited the attention of his fellow Canadians to the possibilities of electric power especially in the domain of electric railway work, instancing the great Thomson-Houston road of the West End Co. in Boston as an example. He said that nothing had so appreciated the values real estate in America as the electric roads now started and running successfully in 400 towns and cities; and he wanted Canada to enjoy the advantages of the same methods. Certainly, Montreal, of all cities, would be greatly benefited by it.

PRESIDENT HUNTLEY then read the following address:

OPENING ADDRESS OF PRESIDENT HUNTLEY.

My predecessors in this chair have seen the Association advance in strength and worth, outliving trials and vicissitudes, to emerge on a wider, larger field of usefulness and opportunity. I do not believe that there is another industry in the world which has passed through such quick stages of evolution as ours, and become so soon established in popular favor and general prosperity. But we must not assume that because electric lighting has set its feet upon the rock, and laid its deep foundations, nothing more remains to be done save to pursue the policy and practice of the past. On the contrary, I deem it necessary to say here, that my own responsibilities, as a central station manager, compel me, as never before, to be watchful of the tendency of conditions and inventions in the art, so that I may, in any degree, profit from my own hard-won experience. If, as central station men, we are to secure adequate return on the investment committed to our care, it becomes us in every way to study closely all the ideas that will give higher efficiency of plant, and higher economy in operation. There was a time when some of us expected to grow rich out of abnormal prices, paid willingly for a novelty. To-day there is not one of us who does not know that his hopes of dividend lie wholly in the skill with which the best business ability and the soundest engineering are applied to the work in hand.

It is now pretty well recognized among intelligent station managers that the day has passed when they can limit themselves to one class of service or apparatus, to the exclusion of all others. To obtain the fullest measure of success, and the largest return from the capital invested, they must be ready to supply any demand made upon them, and, as a result, the successful station, even to-day, is gradually assuming a composite character. This compositeness is manifesting itself first in the variety of apparatus, as a result of the selection of the machines best adapted to a given class of work, and independent of any particular system. One cannot help seeing in this change from early practice, a step towards increased efficiency of station operation, as well as a good reactive effect upon the manufacturers of apparatus, who are thus all placed on a common basis of competition. But besides a compositeness in detail, signs are not wanting that no one method of distribution from a central station can, in the large majority of cases, be adequate to the demands that are made upon us, and that to meet them in a manner to insure a profitable business requires a flexibility and variety in methods of distribution, the full extent of which is to-day hardly recognized. To reach the full limit of its usefulness the central station should avail itself of methods which, I believe, will finally resolve themselves into what may be called the "Zone System" of distribution.

The idea embodied in the zone system can best be explained, perhaps, by taking a concrete, practical example, and for this purpose the present occasion makes the selection of the city of Montreal an interesting one. Setting aside for the moment the possibility, and even the probability, of the transmission of electrical energy to the city from the power obtained at the Lachine Rapids, we will assume a station erected at the water-front of the Harbor, as indicated on my diagram. It will, I believe, be granted that up to within a distance of one-third of a mile radius the three-wire low-tension direct-current system of distribution answers fully every requirement of simplicity and economy, and hence, if, with the station as a centre, we draw a circle having a radius of one-third of a mile, we shall have a "zone" supplied in the most economical manner for every class of light and power apparatus now familiar to us.

Coming to the districts beyond the first zone, we are necessarily obliged to have recourse to higher potentials for the feeders, and the selection of the proper potential is a matter of simple calculation. We may, for the sake of this argument, call it 500 volts. Continuing on in this way, in steps of 500 volts, successive zones, half a mile across, might extend in the aggregate to several miles without reaching the limit of [illegible] which have been found to be perfectly feasible in practi[illegible]

In the example no reference has been [illegible] of the current employed or to the method of local [illegible] Evidently we may readily resort to the alterna[illegible] employing converters to reduce or raise the potenti[illegible] rect current reduced from high to low by motor-dy[illegible] one is perfectly practicable. Perhaps some of [illegible] of electrical engineers will show us how to use [illegible] for both alternating and direct currents.

[illegible] system [illegible] per to record [illegible] ay to distribute [illegible], is by low-pres- [illegible] plan now generally in [illegible] of his own; or, in the direct system, a separate motor-dynamo. I need not here enlarge upon the train of reasoning which has led me to this conclusion, but I may remark that I am strengthened therein by my own experience in Buffalo, where we are now introducing gradually 200-light converters, and replacing the smaller ones heretofore employed. Nor do we propose to stop there, but expect to install converters of still higher capacity, distributing the current to a number of customers by low-pressure mains centering at the large converters. As addressing myself to practical men, I need not refer to the fact that it costs practically no more for labor, etc., to put up a 200-light converter than it does a 10-lighter, while the initial cost per light is less in the case of the larger converter. In these conclusions I am only recommending for large American areas what I believe is now recognized abroad by Ferranti and others, whose work, like our own, will eventually lead to the establishment of large converter sub-stations from which low-tension wires will supply the surrounding districts.

The allusion made to the motor-dynamo system for converting the direct current from high to low potential may to some appear nothing more than the citing of a possible method in view of the existence of the alternating system, well tried and ready at hand. But, without wishing in the least to detract from the merits of this system, which has probably done more to popularize electricity than any other, I cannot, as a practical man, conceal from myself the fact that, taking everything into consideration, the low-tension direct-current system of distribution is the most flexible within its area, and serves the greatest variety of purposes. I do not think that any one can successfully contradict the assertion that to-day no other system can, with equal efficiency, take care of arc and incandescent lamps, motors, large and small, storage batteries, electric heaters, etc.

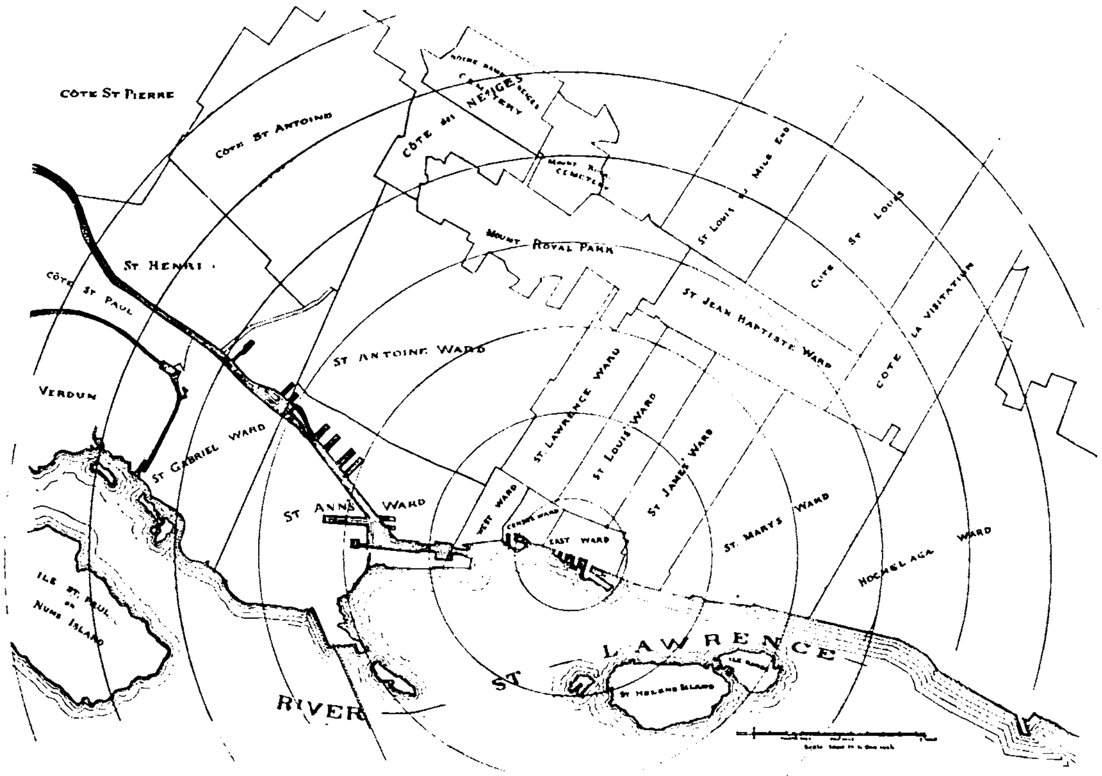
In making this statement, I desire to be understood as referring to the *present condition* of the art, the only condition which, as practical men, we ought to consider in matters of this kind; but I hope the time will soon come when the same can be said of the alternating system.

There are still o[illegible]thods which suggest themselves, by which the "zone" [illegible]ould be effectually carried out, but those indicated are [illegible] to demonstrate the idea I have endeavored to conv[illegible]

After the intell[illegible] manager has decided upon the nature of his appar[illegible] the initial capacity of his station, his most important co[illegible] is the allowance to be made for [illegible] growth. Lo[illegible]ome of you, and recall the mistakes [illegible] but which w[illegible] about by the enormously rapid [illegible] of the indu[illegible] not go outside of my own experi[illegible] such an [illegible] Less than two and a half years ago [illegible] in Buffa[illegible]tion considered far too large for [illegible] most ext[illegible] growth. Some of my colleagues shook their heads. Yet even to-day it is being worked to its fullest capacity, and provision will soon have to be made for more facilities.

What, then, may be asked, shall we determine upon as the unit time limit of growth for which provision should be made? Shall we build our stations sufficiently large to take care of the demands of five, or ten, or twenty years hence? This is a most serious question, and one to my mind as important as the selection of the proper station apparatus itself. I note the erection of several stations abroad, and some here, designed to supply the demands of 15 or 20 years hence. Without wishing in any way to detract from the laudable enterprise and faith exhibited by the promoters of these stations, a calm survey of the past, present, and probable future condition of the art leads me to believe that the setting of so long a time limit as 15 or 20 years is inadvisable. I need not remind you in detail of the changes in methods and apparatus which have been effected during the last five years, by which the efficiency and output of our stations has been increased; and if to this we add the fact that already new methods, such as those recently pointed out by Mr. Tesla, may at any time increase the present lamp capacity of our stations five and ten fold, I think we may be justified in placing five years as the limit of time, to make provisions beyond which may involve expenditures, the benefits of which may not be realized.

These are matters we are endeavoring to settle for ourselves. It is to our interest to settle them. So, too, with the underground question, but there we have gratuitous advice, assistance and abuse, to such an extent that less progress is made than in any other part of the work. We all want to put our wires underground where the number is so great as to make them unsightly or unwieldy, and not a few of us have been parties to experiments now written off to profit and loss. As soon as the time arrives when every house has its wiring as a matter of course, just as now it has its piping for water and gas, it will be a comparatively easy matter lay down comprehensive underground systems. But at the present time the customers for current are scattered, and not continuous. The man with enterprise enough to take electric light and power soon moves into a larger store. His successor does not want the service, but gropes along with kerosene, or spoils his goods with gas. Cutting out disused underground services is an added risk and expense, and ten lights could be installed on overhead circuits for ten dollars, where with underground the cost would be fifty. It follows that in any city, Buffalo, for example, we shall not make one underground connection where with overhead wires we should have made twenty. Now, are the public or are we the greatest losers? The public, I think. It is as unreasonable in most instances to demand underground wires as it is to expect every railroad to make every crossing above or below grade. But for our overhead wires, America would not be to-day the great



Pres. Huntley's "Zone System" of Electrical Distribution.

land that it is of electrical triumphs; and, while I hail with delight every advance in the solution of the underground problem, I hope long to gladden my eyes with the sight of a pole well set and a wire well strung.

Another stirring question of the hour is that of municipal ownership. Now, it has been taken for granted that electric light men are against this plan, tooth and nail. How absurd that notion is! Because we represent the latest development of invention and industry, we certainly do not forfeit our pride as citizens, nor lose our interest in the advance of social science. It would, in fact, be difficult to find a more progressive, well-known body of men in America to-day than they who have put their money and energies into electric lighting. They are neither crusted nor cranky, but when any movement has been started for the betterment of the communities in which they live, some of them have been at its head. Now, is it strange that such men should object to the confiscation of the properties they have built up and that are beginning to pay? Is it strange that they should ask for these new theories in social economy to be tried on something else first? Many of us have grave doubts as to the accuracy of the figures that are supposed to prove that municipal plants pay. Others of us have great objection to any taxation, the proceeds of which are to set the municipality up in a commercial business. Others, again, believe that the best results are reached in any industry when it is freest from political influences, and is left to the uplifting and perfecting impulses of individual enterprise.

I believe that the most conclusive answer we can make to the sophisticated arguments of an ill-disguised socialism, presenting itself in this muncipal ownership scheme, is to give the very best service possible at the lowest rates compatible with fair profit. Some of the prices we now obtain seem so low as to exclude any profit at all, especially when repairs and reconstruction are considered. But here again we may help ourselves out by native wit. Every company in the ranks of this Association ought to ascertain for itself at regular intervals just how it stands as an industry. A good deal of apparatus in use is decidedly inefficient. Overhaul it. If necessary, throw it out and put in better. Above all, adopt a good system of bookkeeeping. It has been a source of much gratification to me to see in the pages of one of the leading electrical journals, recently, a most valuable series of articles on central station management and finance by Mr. H. A. Foster. I trust that every electric light man will read those articles, if indeed he has not done so already. The subject is admirably treated from the practical standpoint, and it is impossible not to derive good from the many hints and suggestions; while the various forms and blanks shown may be adopted with much benefit. Electric light securities are to-day far from enjoying the esteem in financial circles that they deserve. This is due in a measure to speculative investment and to over-capitalization in the past, but is also attributable very often to the poor system of accounts employed, and I am glad to see the subject thus receiving attention. If we know what our current costs, we know what we can sell it for, and unless that information is obtainable from our office books, engineering will go for naught, and capital required for new work will stand aloof.

In conclusion, I would urge that the Association determine upon meeting only once a year. Even if it were not impossible to recover in six months from such overwhelming hospitality as we are now the recipients of, I believe that the time has gone by when half-yearly meetings were necessary. Once in twelve months is often enough for us to come together for the comparison of our experiences, and the report of further refinements in the detail of the industry. The mere fact that frequent reunions are no longer necessary is in itself a hopeful sign, for it tells of stable and settled conditions, and of activities that now require our presence at home pretty well the year around.

Various invitations were then read and accepted, and the meeting was adjourned till 10 a. m., Tuesday.

TUESDAY MORNING SESSION (SEPT. 8).

Upon the opening of the Convention, a report was read from Messrs. G. B. Shaw and E. A. Armstrong, recommending, as a committee on revision of the constitution, that no change be made, as the present form should be given a fair trial. Committee discharged.

The committee on relations between parent and sub-companies having made a formal report,

MR. E. R. WEEKS said—I think the time has come for some plain talk on this subject. You will remember that the early history of electric lighting was phenomenal in that the people were so ready to believe everything that was promised for the new industry, and so confident in its value as an investment. The wonderful achievements of Bell, Edison, and others in telegraphy and telephony did much to pave the way for the introduction of the electric light. Such was the attitude of the public mind that companies were readily organized for central station work, and the extravagant statement of parent companies as to the performance of machinery, of their apparatus and of their manufacture were received with a cordiality not very complimentary to the wits of investors. Manufacturers of apparatus claimed for it a high efficiency, in one case even as high as 105 per cent. Declarations were made, that with the exception of brushes and commutators, which might need renewing every two years, it was practically indestructible, nay, it was even held that it would improve with use, and they set their price so high on that, that these qualities seemed assured. They guaranteed to purchasers, first, high efficiency; second, patent protection, and third, exclusive rights in their respective territories. They assured investors that the new light could be produced cheaper than gas, and, in order to compete with gas, and increase the demand for the apparatus, they advised continual reductions in rates of service. Companies speedily organized in the larger cities, and capital smiled on electric light investments. It was soon found, however, that various so-called systems of electric lighting were extremely crowded, and the apparatus was so short-lived that investments must be increased to meet the demands for improvement and for renewals, for which the parent companies made little if any discounts. Still, so confident were the local companies of success during future years, and so blindly credulous in the good faith of manufacturers, that the additional capital flowed in, and the parent companies were enabled to enlarge their producing powers and to increase their dividends. In the course of time it began to appear that the second claim of the parent companies, in consideration of which local companies had paid such high prices, could not be maintained. Patent protection was not given. The pioneer enterprises saw their field invaded by apparatus employing the very devices for which they had paid so liberally upon the assurance that those devices were controlled by the granters. Meantime capital was beginning to discover that electric light investments were often bottomless abysses. The crude and imperfect apparatus, itself short-lived, necessitated constant renewals; its extreme delicacy necessitated frequent costly repairs, and the cut-throat competition, instigated and supported by rival manufacturers using practically the identical apparatus, affected public confidence. Most of the profitable fields had been occupied, and although the electric light had demonstrated its desirability and its superiority over gas, the rate of service was necessarily much higher, owing to the greater cost of plant, operation and maintenance. As the parent companies found themselves with immense producing powers, and without sufficient demand to employ them, the very powerful ones began to purchase the business and factories of the weaker, presumably to clear the field of competitors, and the temptation to violate their contracts with pioneer local companies proved to be strong. It was observed with a few of these systems that their purchasers had placed them in charge of their most experienced men, and after fortifying the weak points by the use of their own special devices, intending to sell this apparatus at greatly reduced prices in fields already fully occupied by their own apparatus, which had been bought at high prices by companies to whom they had promised protection of all kinds. What treachery could be more abominable for those who had borne the brunt of the new industry struggling for a foothold, who had literally enriched the parent companies by their own pleading, who had created the demand for apparatus that parent companies had to sell, and who, through their own experience, had shown inventors and manufacturers wherein their apparatus could be improved and cheapened. But worse treachery followed. The most outspoken enemy of the electric light has always been gas. The gas companies were heavy corporations who had fully occupied the field of lighting for many years, and had fattened upon the profits yielded by the industry of which they had a monopoly, and which required a plant comparatively simple in construction, easily and cheaply operated and maintained, and employing raw material, the residual products of which were made to yield a handsome revenue. When the electric light entered the field it labored under the enormous disadvantages of costly, complicated and imperfect apparatus, unknown operating expenses and depreciation, and no bye-products. Yet the gas interests, recognizing the new light as a formidable rival, fought it in every way available to a long established, powerful and wealthy monopoly. The parent electric companies were bitter in their denunciation of the methods employed by the gas interests in their efforts to prevent the establishment of the new industry, and until their revenues from local companies began to fail, assisted the latter in the struggle in every way which did not seriously affect their pockets. At the present time, Mr. President, the condition of affairs is changed. The gas interests are still opposed to the electric light. But as this has shown that it has come to stay, gas companies all over the world are preparing for a new effort. They will wage war with our weapons—with cheap apparatus furnished them by our parent companies. They will endeavor to so demoralize the field of electric lighting, that legitimate business cannot stand the strain. Parent companies are selling to the gas interests, and they have the effrontery in their advertisements to boast of their success, apparatus that employs the very devices whose exclusive control had been guaranteed to the interests that the new purchasers are straining every nerve to kill. And this is being done at a most critical period, when depreciation is becoming known at its full value, when, owing to the general depression, market values of service are at their lowest, and when there is a strong tendency on the part of municipalities to demand of the electric industries expensive, doubtful changes, and to curtail their privileges and reduce their rights. The manufacturing companies are indirectly and directly promoting this tendency, and are inciting municipalities to purchase plants, thus depriving local companies of that profitable service which they themselves have created. To the one hundred thousand stockholders in the local companies of America is chiefly due the establishment of the new industry. They have produced the sinews of war and by them the battle has been fought and won. From them parent companies have derived support which has made them what they are. For this veteran service and this timely support what return do parent companies make? Having possessed themselves of many millions of our hard-earned money, they are now violating their most sacred obligation and betraying us to the enemy. You, Mr. President, like Agricola Senex in the fable, have nurtured a viper in your bosom. You have created a Frankenstein monster who now turns his hand against you, and I warn you, central station men fo America, that, if you would save your millions, you must prepare to carry the war into 'Africa with respect both to the gas and to the parent companies. These two interests with their pronounced porcine proclivities in common must both be considered in this connection. The gas companies have, not without a certain assurance, fought well to concede to us the period of experimentation, believing that through the treachery of the parent companies they could easily step in and capture the business when its permanent value became known. After we have paid the score and quaff the froth, they, like the thirsty soul in Virgil, intend to seize the bowl and drain it to the dregs. But, Mr. President, if to them we seem vulnerable on account of the prices which we have paid for apparatus, let us not forget that they too have their undipped heel. Their plants also can be duplicated at much less than their original cost, and by improved processes their rates can generally be greatly reduced and still leave a large and a most attractive profit. For while gas is fast losing its place as the leading illuminant, it is certain to be the fuel of the future, and fuel will always be more generally and largely used than light. Fuel is everywhere a necessity, while light is largely a luxury. I therefore advise everyone interested in electrical central stations to investigate the gas business, subscribe for the gas journals, and let slip no opportunity to gather information regarding this great industry.

With regard to the parent companies, I will say that you central station men who have created these companies have the power to check their rapacity, and if need be to destroy it. Your interests are identical. You have a peculiar element of strength in that you do not seek to serve the same customers, and can therefore never be brought into conflict one with another. Your investments now aggregate upwards of one hundred millions and with stockholders among the best business men, the leading men of affairs in America. You have the power to inaugurate a movement and carry it forward which will be irresistible. Why should this army of producers with their one hundred millions of active and productive property, and their inexhaustible resources submit to the extortions and treacherous attacks of a few syndicates who are little more than brokers in material, whose *bona fide* investments aggregate twenty-five millions, and whose factories can be duplicated, yes, and greatly improved upon, for one half that sum? Let us enter into a compact whereby we will pledge ourselves to purchase apparatus only of those companies who will treat us fairly, and in case we cannot get such fair treatment, in case we are met by a combination, a trust or a pool on the other side, let us pledge our united support to a new manufacturing enterprise which will enter the field with this guaranteed business to rest upon, and Mr. President, if as a last resource, if the worst come to the worst, let us with our upwards of one hundred millions of investment call into a common fund from one to five, ten or even twenty per cent. on our investments and standardize our apparatus and do our own manufacturing. You, Mr. President, well know that there are already upwards of twelve millions pledged in writing to this movement. Your committee should push this work forward with all possible vigor, as it cannot fail to result in the greatest good to the greatest number. (Applause.)

JUDGE ARMSTRONG said that it resolved itself down to the principle that they would not deal with, or give business encouragement to, those who were thus against them. Mr. Wilmerding and Mr. Francisco both spoke in support of concerted action, the latter stating that he had had to furnish light at about one-third of the cost owing to this kind of guerilla warfare against him.

MR. T. C. SMITH urged that as controlling patents on nearly every one of the main essentials in arc lighting had run out, the remedy was in the hands of every local company to manufacture for itself. What the central station needed was information enabling it to use its old stuff already bought and paid for. He believed there was enough apparatus lying around central stations to do all the business for ten years to come.

MR. NICHOLLS remarked that, after all, they must admire an aggressive business policy, but in this instance he doubted the wisdom of the procedure of some of the manufacturing companies.

MR. WEEKS then offered the following resolution :

Resolved, That the Committee on Relations between parent and sub-companies be instructed to formulate a definite plan of procedure for the protection of the central station companies, and prepare the necessary articles of agreement and report the same to the Association in executive session at its next Convention.

This was adopted, as also a motion to print and distribute the whole discussion of the subject, at the earliest possible moment.

MR. H. W. SWETLAND, in the name of the Committee on Data, then presented a report upon the Comparison of Economy in the Generation of Power.

There being no report from the Committee on the World's Fair.

MR. J. A. HORNSBY, the secretary of the Electrical Department of the World's Fair, made the following remarks:

Gentlemen of the National Electric Light Association:

The World's Columbian Exposition was very much pleased a the action taken some time ago by your Association in th appointment of a Committee on World's Fair. That courtesy is responsible for my presence here to-day as the commissioned officer of the World's Fair, representing especially the electrical department. I had intended reading a paper on the subject of the World's Fair as a whole. You are, however, technical people, and I will try to explain to you practically, instead of reading a paper. The machinery building, which will be 500 feet long by 900 feet, is to be in every way a modern structure. It is impossible just at this time to tell how far the machinery department will go and where the electrical department will end. In the discussions of the classification committee of the World's Fair a year ago, the electrical department was given a group under the department of machinery and assigned to a corner of Machinery Hall. Its part was inconsiderable and very little was thought of it. The two learned gentlemen who assisted the commission to make the classification insisted that electricity was a branch of machinery and as such was entitled only to the consideration of being grouped with machinery. That has been changed; it is not so now. The electricity building is 700 feet long by 350 feet wide, having 240,000 square feet of floor space. It has a 100-foot gallery around the entire extent at an elvevation of 38 feet. The roof is 160 feet high, dome shape. It is in the Italian Renaissance archtecture, under contract to cost $650,000. That is to be purely for the electrical exhibits. The building for the service of the exposition with electricity occupies a larger scope than it did. Electric launches will be there. An electric intramural railway will traverse the entire length of the ground. The road will be three miles, or thereabouts, long. Electrically propelled elevators will be in all of the buildings. Everything that is done in the shape of power will be by electrical transmission (applause). This will be an expensive plant. The various companies engaged in the supply of power and light will be contracted with to build modern, model lighting and power stations of their own, after their own plans, to be approved only by the exposition management. This will be a 24,000 horse power plant—a large one, as you gentlemen, well know. The distribution will be in three directions. There will be a tunnel passing down through the Mines Building, the Transportation Building and its annex, the Horticultural Building and the Women's Building—these will be supplied from one source. Another tunnel will be built across, striking the coner of the Mines Building and passing through over to the Electricity Building, and thence through the Manufacturers' Building, the Government Building, the Fisheries Building, to the pier on which will be casinos, statues, fountains, etc. A short tunnel will be built also from this power-house, going first through Machinery Hall, down through the Agricultural Building, the Agricultural annex (the saw mills will be run entirely by electrically transmitted power) the Forestry Building and the Dairy. From this plant will be served 8,000 arc lamps, 85,000 incandescent lamps and 4,000 horse power for the operation of the machinery belonging to exhibitors.

There is a wooded island 30 acres in extent which it is contemplated to use for an aboriginal preserve, if you please—the Indians will probably be there. This island, the lagoons, canals—all of the grounds will be lighted by electricity. All of the buildings will be lighted by electricity. In our own building I have recently finished the plan. We will require in that building, and have arranged for, 800 horse power for the running of exhibits, aside from the operation of exhibits from the exhibitors' own plants which will be located here as well. In there we will have light proportioned, one 2,000 candle power lamp to 1,000 square feet of space. In addition to that, in the centre of the building we will have some spectacular effects, and in all of the corners; 700 arc lamps, I believe, are destined to that building.

So far as we are concerned ourselves, the electrical department has been divided, the "service" being absolutely separated from the "exhibition" department. All of the exhibition will be under the superintendence of the chief of the department of electricity. Everything electrical in the exposition will be on exhibition. But this other plant here will be purely a service plant, the exhibition feature to be a secondary consideration. It was contemplated originally to install a service plant proportioned to the good will of the electrical people—free lunch, as some one has been pleased to call it. The management of the exposition thought it would be possible on account of the general interest taken in the exposition to have the electrical people donate for the use of the exposition enough apparatus and enough talent to serve the purposes contemplated. By the hardest work and closest application of the electrical department we have made it appear advantageously, and certainly for the benefit of the electrical people, that that course would not be in accord with their wishes. Their interest would be dampened if such a procedure were to be inaugurated. Therefore we have been successful in having this plant installed purely as a business proposition, the idea being to demomstrate unequivocally and in practice the economy of an electrical service over that which was contemplated before—steam and gas. In that far we have been successful, and after the Columbian Exposition I think we will be able to demonstrate fully all that has been claimed for electricity on the score of economy, comfort, and luxury.

There is one other matter. I have been in correspondence for six months, or thereabouts, with electrical people in all parts of the world relative to the holding in Chicago in 1893 of an International Electrical Congress. I have arrived at a point in our correspondence and negotiation at which I can say the project is in the way of being successful beyond our highest hopes. We look for the presence in Chicago at that time of the ablest men in the greatest profession now in existence. The Europeans have promised to have their very highest authorities with us. The best of the electrical people of this country are heart and soul with us. The representatives of the societies in this country and in Europe have signified their intention of taking active hold of the matter of holding this International Electrical Congress. A good many of these congresses have been held heretofore, largely in Europe. A good deal of satisfactory work has been done in the settlement of standards, the unification of methods, the revision of nomenclature. Very little, however, of that work has been done in this country. The question has come up whether this should be done through and by the World's Columbian Exposition, or whether it should be done by the various societies. The question should be answered in the affirmative in both instances. It should be done by the societies. They have largely contributed already. It should be done under the auspices of the United States Government, which is the authority for holding the World's Columbian Exposition. As the representative of the electrical department, as its accredited commissioner to this Convention, I will say that the exposition management stands ready now, and at all times, to aid such a movement in any way. A provision has been made in the report of the presiding officer of the exposition management, which will be read before Congress next winter with a view to having the Government of the United States take official notice of the contemplated Electrical Congress. The management of the exposition have already acquiesced in the proposition to build a hall for the holding of this congress on the exhibition grounds. All of the adjuncts of debate will be present. No money will be spared by the management to make the congress in every way a successful one, and I do hope that at this meeting of this Association, strong, powerful, prominent, representative as it is—that some action should be inaugurated looking to the starting of the ball which shall roll to be a gigantic one. Something should be developed at this time that would give us a nucleus around which to work. In the course of time the other societies will take their part. The Electrical Engineers, I understand, have gone far already, and with the help of such societies as these, we have no question about farthering a proposition to hold an International Electrical Congress. (Applause).

MR. T. C. MARTIN—Mr. Hornsby in his remark has made reference to the work of the American Institute of Electrical Engineers in connection with this congress, and I think I may briefly state what has been done, and then if you will allow me, suggest that this Association act upon somewhat similar lines. Two and a half years ago, at least, at any rate before it was known that the World's Fair would go to Chicago, and when some of us still fondly hoped that it would not, the American Institute of Electrical Engineers, taking time by the forelock, appointed a committee to secure the holding of an Electrical Congress or conference in this country. A congress was then about to be held in France, at Paris, at the Exposition, and we sent delegates to that congress. Those delegates—some of our most prominent electrical engineers and inventors, among them being Mr. Edison, Prof. Elihu Thompson, and others of that rank—extended in the name of the Institute to the delegates to that Electrical Congress an invitation to attend such a congress in this country during the Columbian Fair year. The invitation was received and accepted. During the present year another congress of like nature is being held at Frankfort, in Germany. That congress in France was held under the auspices first, of the French Government and of the exposition authorities, and secondly, under the auspices of the French society. A similar procedure prevails at the present time in Germany with regard to the conference there, and it is being held under the auspices of the Government, and with the direct support and aid of the German society. Now I think that Mr. Hornsby has outlined to us just such a line of action for work in this country. It is proposed on the part of the Institute—and when I say that, I speak as secretary of the committee which has the work in hand—to work as far as lies in our power with the World's Fair authorities, and we think that, with the assistance and co-operation of such powerful bodies as this, the congress that is held in Chicago in 1893 will not only be the most memorable, but the most useful of all the congresses that have been held up to date. As a member of this Association I think it would be well in supporting Mr. Seely's motion to have a committee appointed that will work; that will commit this association unreservedly to the support of the World's Fair, and will aim to make the movement in Chicago, and the congress, a success. (Applause).

THE SECRETARY—The following is the motion of Mr. Seely: That the Committee on World's Fair be discharged, and that the Chair appoint a new committee.

The motion was seconded by Mr. Martin, and carried.

THE PRESIDENT—The Chair will appoint as such committee, Mr. B. Sunny, of Chicago; Mr. Coleman, of Milwaukee; Mr. Hart, of New Orleans; Mr. Royce, of Washington, and Mr. Price, of New York.

MR. PECK—As the report of the electrical section of the Committee on Data, I wish to present this form by which to record data concerning street lights.

JUDGE ARMSTRONG—I move that it be received and adopted.

MR. BURLEIGH—And that the Secretary of our Association refer it to the Census Department at Washington, with the request that they so arrange their statistics as to conform to that form. Agreed.

MR. WEEKS—My attention has been called to a clipping from one of the Kansas City papers which I find noticed editorially in THE ELECTRICAL ENGINEER of September 9th, regarding the price of street lighting in various cities of the country, and I take it that if data are to have any value whatever, they should be accurate, and I am very sorry to see that the data that are given by the Census Department in Census Bulletin No. 100, referred to in this article, are not accurate. For instance, the statement is quoted that in San Francisco the price is $440.67 for one arc lamp for one year, and in Denver $58.46. Those statements are made simply without any qualification whatever. I happened to be familiar with the facts in both cases, and I know that there is no foundation—absolutely no foundation for those statements, and I think that it is but just to our good friends Rollins, of Denver, and Roe, of San Francisco—than whom there are no fairer-minded and just men in the fraternity—that that statement be corrected. The facts are, that in San Francisco, where it should be remembered coal is $7.00 a ton, the highest price paid for any one lamp per year is $361.90, and that is a four thousand candle power lamp maintained at a point remote from the central station with a considerable mileage of circuit in order to reach that point. And instead of being so generous as one would infer brother Rollins has been in Denver to give them an arc lamp for $58.46; his good business sense has led him to do quite otherwise. The rate that he gets there is $160 within a certain radius and $216 outside, and for tower lighting—two very different propositions.

In this connection I want to call attention to the amendment that was suggested by the committee to the scheme proposed by Mr. Foote, that a very important factor in this whole matter one of the most important factors is the question of distribution. I have had occasion to look into this matter quite extensively of late, and I find that the distribution of municipal lights ranges all the way from eight and six-tenths lamps per mile of line, down to one lamp per mile of line. Any electrical engineer will at once appreciate the importance of this, and that element should always be included if a comparison of prices is made. Of course there are other elements that occur to almost every one—the system used, the watts consumed, the period of contract, the price of coal, whether it be water power or natural gas, but the mileage of circuit per lamp seems to have been generally overlooked. It is important in two ways—first, it determines the amount of investment. I find in the cities that I have looked up, that the investment per lamp in street systems ranges from $35.87 to $190.40. You can readily see that when it comes to operation it will be still more important, as not only has the resistance of the line to be overcome, but it has to be controlled and maintained, and your trimmers have to traverse all of this distance. I want to say that I think that Mr. Foote, in the schedule proposed, has covered the ground very thoroughly with the amendment suggested by the committee. I hope that he will find that it will be readily filled out by the central station men.

MR. FRANCISCO emphasized these remarks as to the present uncertainty of data alleged to be correct.

MR. FOOTE, as census agent, took the opportunity to ask that the information required in the census schedules be fully supplied, so that when they got the figures for tabulation, they would have something which was true.

JUDGE ARMSTRONG stated, from the Committee on Legislation, that it had no formal report to make. His own State of New Jersey had been comparatively free from antagonistic legislation.

MR. WILMERDING said that in Illinois there had been several bills introduced with a view of knocking out their interests, but none had gone through. He characterized these efforts as "sand-bagging."

MR. FRANCISCO was happy to report that in Vermont the legislature was not sitting this year.

THE PRESIDENT reported that little had been done in New York owing to the fact that the gentlemen who benefited by such measures were just at present fighting among themselves.

DR. BELL said it would be interesting to know just what the nigger in the fence was in all these "strikes."

MR. SCOTT—I just want to speak in relation to this matter that the gentlemen have spoken about, so far as to suggest that sometimes legislation is produced by the indiscretion of electric light companies themselves. In Pennsylvania, we have carefully watched the legislation and have tried to have everything avoided that was inimical to our interests, but there has been a bill passed at the last session which directly strikes at and affects their interests and which should not have been passed at all, and could not have been passed (for there was no money in it) but for the determined efforts upon the part of its promoters. That was a bill in relation to the cutting of trees. It is a most iniquitous piece of legislation. It provides that any person who has knowledge of the cutting or trimming of any tree along or upon any public highway, or the branches of trees upon private property, which protrude over the highway, by any telegraph, telephone or electric light company, and who shall lodge proper information, that thereupon the Court of Common Pleas shall appoint a jury of view, and that jury of view shall proceed to assess damages and costs upon such telegraph, telephone or electric light company. There was an influence brought to bear in favor of that bill which could not be overcome. Some of us took the trouble to contest it and found that the Suburban Electric Light Company of Philadelphia had asked the land association along their route for the privilege of cutting trees. They went to the secretary's office and asked for this privilege, and he said: "Yes, you can cut all that you want to"—meaning just to cover the right of way outside of their fence. But that company went to work and cut trees down that were inside of the fences. Any one traveling from Philadelphia to New York can see for over half a mile the fine trees lying right there on the road alongside the railroad track, along the State road from Philadelphia to Trenton. Well, it was a bad thing to do (laughter). And the land association, which is composed of politicians of Philadelphia, who can carry any measure through the legislature, decided at once that they would stop that business and so they put this bill through. So that it is not merely the aggrieved property owner, or anybody who may have any particular interest in the matter, but any tramp who comes along the road may lodge an information before the Court of Common Pleas, and then the damages have got to be assessed, even if it is only ten cents for that tramp. There is another matter of legislation that we have tried to accomplish in Pennsylvania. It is understood by every one who has had interest enough to look the matter up, that gas and water companies have an exclusive right—such an exclusive right that electric light companies cannot get. Now, there is no more reason why an electric light company starting in a small town, like our own town of Bristol, of eight thousand inhabitants, against a gas company which has been running since 1856, and has been paying eight or ten per cent. dividend right along—there is no reason why that gas company should have an exclusive franchise, whereas an electric light company, after having invested twenty or thirty thousand dollars in their plant, and have finally got the thing running, should be compelled to buck against any one who may choose to come in and make a competition. Those matters can be arranged in time, but of course it may take a long time, and it will require a great deal of trouble and effort on the part of somebody. We can do a thing of that kind in a better way than by the use of money. We can accomplish what we wish by argument. If you will just show the people who are interested in the corporation—your own stockholders, the men who have put their stamps down for the purpose of carrying on that business—that there is something that they have got to look out for, that just as soon as you begin to make eight or ten per cent. and to accumulate a surplus, the gas company or the water company in their own town, using the power which they can apply to that purpose, can run a pole line right along the side of us, and can take our customers right away by cutting our rates—that they can do this because they have an exclusive charter, whereas we cannot go in and manufacture gas or put water through the streets as they can do. I say that if you make your stockholders understand this, you may accomplish much. There are a great many of those questions that come up, and that ought to be looked after, not only by the Committee on Legislation, but it ought also to be the business of every man connected with a central station company, from officers to stockholders, to look out in this way for their pocketbooks (applause).

DR. BELL thought that something ought to be done with the "fake" electric light companies or organizations, chiefly composed of gas officials, which existed simply to keep a real, live operative company out of the field.

The committee was continued.

The Committee on Underground Work reported progress. It is now preparing an exhaustive report on the subject.

MR. T. C. SMITH then presented

THE REPORT OF THE COMMITTEE ON SAFE WIRING.

It was decided, on motion, to print the report at this Convention, and take it up as soon as practicable.

MR. WEEKS criticised the departure from the constitution in holding the meeting in September instead of during August.

MR. SEELY and the President explained that it had been done reluctantly, and of necessity, as the hotel accommodation could not be secured before.

The meeting then adjourned until 10 A. M. Wednesday.

THIRD SESSION, WEDNESDAY, SEPT. 9.

The Convention was called to order at 10:20 a. m.

THE PRESIDENT read a letter from the Canadian Pacific Railway Company offering the members of the Convention free telegraph privileges for social messages during your stay in Canada, over the Canadian Pacific Railway Company's telegraph; through Mr. A. B. Chandler, the president of the Postal Telegraph Company of New York, similar privileges over that telegraph system. An invitation was also read from Sir Donald A. Smith to the members of the Association and their friends to visit him.

The discussion of Mr. T. Carpenter Smith's paper on "The Distribution and Care of Alternating Currents"[1] was then taken up.

MR. LAW—I find that Mr. Smith has so thoroughly treated this subject of the distribution and care of alternating currents that he leaves but little to say. I most heartily endorse what he says of the short sighted policy of the majority of electric light managers in putting up cheap insulation; in other words, the principal point of success in alternating work may be stated in one word, "insulation," for on alternating wires a short circuit or ground means, as a rule, a burned-out armature. For I find that in most cases the dynamo man gets tired of renewing the fuses at the generator and will put in a 160 or 200 ampere fuse on a machine that is only adapted to carry 130 amperes. I find that the better plan is on a 130 ampere machine to put in a 135 to 140 ampere fuse and then change it often, not waiting for it to burn out, but change it and put in a new one. By doing this you keep the machine fused very close to its carrying capacity and the fuse will then go before the armature will become overheated. Not only should alternating lines be of good insulation, but the primary should in all cases be fused where they branch from the main lines to the converters. In other words, if you follow the insurance rules that have been presented to you for discussion, in primary construction the same as in secondary work, you will find, perhaps, an advantage in it. It is a very common practice to bring these branches directly from the mains to the converters without any protection whatever (other than the insulation on the wire) to prevent contact where one of these wires must cross the primary wires. I have seen a No. 8 wire burn off a No. 0 wire at the point where the primary loops cross the main lines, and a No. 0 wire, charged with a 1,000 volt alternating current, is not a nice thing to have down in the street, especially should the primary loops leading from the main lines to the converters be well insulated, for as a rule they are of small wire, because a large wire is not necessary; these wires are many times quite long, and being small, they soon get slack so that a good, stiff breeze will twist them together, and unless they are all well insulated, they will burn in two the first time that they are wet and they are not pleasant things to meet on a dark night. If proper fuses are placed where the branch joins the main line, it is not only a protection to your machines and converters, but to life also.

When taking charge of a very large station, a year and a half ago, I found a great many of, I am almost safe in saying all, the primary fuses were removed from the converters and No. 14 copper substituted, simply because they sometimes blew out. Now a properly placed fuse does not blow out unless there is a cause for it. There is the greatest danger in not having the primary wire fused before reaching the converter, although there is a remarkably small number of burn-outs in converters, yet when it does occur there is a danger of the primary wires becoming connected with the secondary and you have a 1,000 volt current at your lamps. All converters are so built that a contact between primary and secondary coils is almost impossible; but if by a short circuit in your primary, it receives a current of from 50 to 100 amperes, when it is only adapted to carry from one to five amperes, thus causing it to overheat to such an extent that it will burn any insulation which may be used. This is very liable to cross the primary and secondary wires and you have all the dangers of a high E. M. F. clear to your lamp socket. Properly fusing the primary wires will effectually prevent all this danger.

One weak point I find in alternating central station construction is the double-throw switches; they are never large enough to break the arc which they are sometimes required to do, for it has not only to break the usual load of from 50 to 75 amperes on

1. See THE ELECTRICAL ENGINEER, Feb. 25, 1891.

each circuit, but in case of a short circuit or ground it may reach three or four times that amount, and the fire and noise produced in a break of that kind is only realized by those who actually perform the operation. Likewise the fuses are not one-half large enough to break readily. These fuses are generally placed on the back of a wooden switchboard and are a great source of danger from fire. (Applause.)

MR. FRANCISCO remarked that in his experience one-half of the trouble met with in underground and overhead work had been due to the loose, miserable manner in which the overhead wires were put up. If the electric light companies themselves had thoroughly installed their system and run their wires in a proper manner, spending perhaps what they have for underground work, they would not have had one-half of the trouble they have at the present time. He was satisfied that if the electric light companies would even now—of course, in certain large cities there is no question in regard to what should be done, as the companies have got to go underground anyway, whether it be practical or not; but in a large proportion of the cities it would be found that if the companies would properly construct their lines and keep them so, they would have no difficulty with the city authorities. He said this after having interviewed a large number of the city officials of different places. Mr. Francisco was also decidedly in favor of operating for all kinds of service on the meter basis, where it is possible, as it permits of a thorough control of the business.

MR. LAW related a "trouble" with a meter which he traced down and found that the customer had actually pried up the cover and introduced a couple of spiders.

To avoid this action on the part of customers MR. FRANCISCO applied a small wire, so that when the customer pried open the meter he formed a short circuit, and he would never repeat the operation.

MR. AYER brought up the question as to the location of the cut-out on the fuse. Some manufacturers take the position that they should be separate and indepependent of the converter and left on the outside and should not be incorporated in the converter box, while with others it is the practice inside the box.

MR. T. CARPENTER SMITH, in reply, stated his experience had been that, as a rule, there is little trouble with the primary fuse in the converter except when it has to be replaced. He had for some time past left the secondary fuses out, and had always followed the practice of putting a cut-out immediately at the converter but on the outside of the converter, and found that he had a great deal of trouble with the secondary fuses from the fact that it is a heavy fuse and the contacts are not large enough. It is difficult to get contacts that will last three or four months without being corroded. He therefore put copper in those fuses and depended entirely on the cut-out which is immediately outside the converter. On the primary, in some cases, for large buildings, he puts cuts-outs on the pole and still keeps tbe fuses in the primary end. But he had had very little trouble with the primary fuse except in the case of short circuits, in which case the primary fuse always went. He never had any trouble with a short circuit from the blowing of the primary fuse, but believed others had had trouble with the primary terminals being so close together when the fuse blew that the lead vapor crosses and continues the arc. There were converters now made in which the primary fuses are put on a separate plug, and that plug is pushed in and can be taken out and the fuses replaced without touching any high tension wires or connections with the current on. That had another value, and that is, that the fuses, if required, could be soldered into the plug and spare plugs can be kept on band, while a lineman can go around once a week, or as often as is thought necessary, and by working the plugs keep the contacts clean.

MR. SMITH also pointed out the absolute necessity of maintaining the current on the wires without interruption even of a few seconds.

CAPT. BROPHY said that he frequently found wires in the primary and secondary side of the transformer instead of the fuse—not in one case but in hundreds of cases. The cause of this was the electrolytic action that takes place in the transformer which causes the fuses to give way. The transformer, when placed on a pole or on the outside of a building, is subject to the condensation of moisture on the inside, which is liable to lead to an accident to the lineman, who, to avoid the replacing of fuses, substitutes copper wire. For that reason he believed that the fuses should be placed in the transformer so that they are not subject to these cbanges. (Applause.)

MR. SCOTT remarked that there were troubles in converter fuses even when they were carefully watched all the time. About two years ago he had one converter that was persistently blowing its fuse. On examination, the base under the screw-head of the fuse connection showed a mark indicating that the fuse had melted there. The screw had become loose eitber by the swaying of the pole or the magnetic vibration of the converter and the screw had formed an arc which had melted the fuse. The brass had become red hot and the switchboard below it was completely charred for about half an inch behind it, so that the screw and its base were ready to fall through. After that he made his linemen go every thirty days and examine the fuses.

MR. SCOTT traced much of the trouble from lightning in small converters to the lineman's using a ten ampere fuse where a five ampere was required. The lightning thus passed through the fuse and burnt out the converters. Such troubles with the coil are generally six inches or a foot from the beginning of the coil, and he had never found an instance where the lightning had traversed the complete circuit. By just taking off the tape and paper the fault can be taken out and the converter will work just as well. But by sending a man around at least once a month to tighten up the screws under the fuses or to replace those that show any oxidation they can be kept in good order.

Regarding the meter question, MR. BLAXTER had adopted the method of demanding a guaranteed usage, and if the actual usage is under that guarantee they charge it according to that guarantee; if the usage is over that amount they charge it in the same way.

MR. T. CARPENTER SMITH stated that if the customer were impressed with the fact that he had to pay for the leakage on the large converters he would not install more lamps or converter capacity than he actually needed, and he cited an instance where a house wired up for 127 lamps with three 40-light converters, rarely had more than 10 lamps, and for a few hours only, so that finally two converters were taken out.

MR. REDMAN then read his paper on "Central Stations Operated by Water Power"[1] and introduced it by calling the attention of the members to the prices in Rochester, as given by him. They varied undoubtedly with the prices in some other cities, but it had to be born in mind that water power was used entirely. It had only been necessary during the past year to shovel coal for half a day, and that necessity was occasioned by the cleaning out of the race-way. Another thing that he called particular attention to was the development of the motor service. They had two motor services; with very few exceptions the motors are placed in dwellings or in small shops built in the rear of dwellings. Heretofore the small manufacturers resident had done business in the centre of the city, and on the fifth or sixth floors of buildings, but they now do their manufacturing at home, either in their dwellings or in small shops. As a boss tailor remarked, when he did his work down in the city, he only worked himself, but now, said he, "Mein frau and all the children work."

JUDGE ARMSTRONG drew attention to the fact that in making comparison of prices charged for lighting and power, account ought to be taken of the fact that in Rochester water power was used, a fact which city authorities are apt to overlook.

MR. REDMAN stated that where a motor is used for ventilating purposes they get $120 per annum, for constant service. No meter is used. He also referred to the heavy consumption of power by planers in machine shops, which was also confirmed by Mr. Francisco.

MR. FRANCISCO stated that if a consumer has a meter on, the charge is 25 cents per thousand watts, in Rutland Vt. They charged the same rate for light and power—25 cents per thousand watt hours. He also referred to an instance in which a customer made a contract in order to avoid the meter, but after a run it was shown that if he had paid by meter his bill would have been one-third of that paid under the contract.

MR. WILMERDING stated that if they could get at the rate of 25 cents per thousand watt hours they should prefer the meter, but he bad found the meter system unsatisfactory because the character of the service varies so much. Their charge for elevator service is from $5 per montb to $15. That is on the basis of ten cents per thousand watt hours. On their contract prices they make three rates: A rate for continuous power, a rate for intermittent power, and a rate for elevator service. For the elevator service they charge $5 per month per horse power, or $60 per year for any kind of elevator service. But he had never found that any of those elevators when run on the meter showed more than one-third of what the contract price would give. He had also found that customers are more surprised than he was at the small price that they have to pay for the service. For that reason he had concluded recently that he would not furnish any elevator service on the meter. (Laughter.) His coal cost $2.65 per ton, but they are using compound condensing engines, and their indicated coal consumption is not more than two pounds per horse power per hour.

MR. AYER: There has been nothing said here with reference to constant current rates and it may perhaps be of some value to some of us to know what the charges are in St. Louis. We are running in excess of two hundred constant current motors on arc circuits, and we make a charge of $10.50 for a single horse power for ten hours' service, regardless of the character of the service. Wherever we happen to have a variable load, we indicate the load on those motors, and we insist on their making a contract based on the maximum load. If we find them bringing in additional machines later, our motor inspector is very apt to get track of the fact, and we soon know just what they are doing. We find no

1. See page 300, this issue.

difficulty in making satisfactory arrangements on that basis. We find that on constant current motors the price has been satisfactory, and we have had no difficulty in making our contracts on motors at $10.50 per month per horse power. For three horse power and upwards we make the rate $8.50.

MR. WILMERDING did not want to be understood as saying that he made a $5 per month rate straight through, but that was on elevator service. Their lowest contract price for the intermittent service is $6.25, and the lowest price on constant power is $9 per month.

MR. T. CARPENTER SMITH stated that there was one advantage that a constant current motor had over a constant potential motor, and that was, that it would slow down if it was overloaded.

MR. H. WARD LEONARD remarked that the cost of water power, although it is apparently cheaper than steam, is frequently higher than it would have been for a first-class steam plant. He thought, further, that water power is really not sufficiently constant to entirely eliminate the steam plant. With the exception of a few plants where the water power is peculiarly favorable, the water power has to be assisted by a steam plant, and the ultimate expense is frequently higher than it would have been than if they had entirely disregarded the water power and built the steam plant at the best possible location. In his own experience he finds that the best use to make of water power is not that of operating a full load, but of taking care of that portion of the load which is quite light, and which operates between, say, 11 o'clock at night and dawn of the next day, for the load is fairly constant during those hours, and the economy of the water power is then more marked because it enables the services of an engineer to be dispensed with. The use of the water power had proved to be very economical in certain places where a not very reliable water power existed, but where perhaps fifty or one hundred horse power could be obtained at almost any period of the year, and which would answer to carry a light load during certain hours of the day and late at night.

MR. T. CARPENTER SMITH stated that the question of the relative cost of steam power and water power had been very fully considered in some papers which were read before the American Society of Mechanical Engineers, and notably in a paper read last year by Mr. Manning, of the Amoskeag Mills, at Manchester. The latter states that his experience has led him to the conclusion that, all things considered, steam will, under almost any conditions, if properly handled, be produced as cheaply as water power. Mr. Smith thought that in most central light stations the best use to make of the water power was to use it in condensing. Steam has an enormous advantage over water power in that with steam one can state almost to a certainty just what one's power will cost. If a steam engine has really to be installed anyhow as a relay to the water power, one might as well run with steam all the time, for one has got to keep the engineer there, and fires ready for lighting. And further, a steam engine possesses the ability to be driven beyond its rated capacity, whereas the water wheel is absolutely limited to the power contained in the head. Another paper, which was read some years ago by Mr. Lewis F. Lyne, on the use of headlight oil for keeping boilers clean, was also worthy the attention of the members. He had tried that oil, and had such success with it that he had used it ever since.

MR. H. WARD LEONARD then read a paper entitled "A Central Station Combining the Advantages of both the Continuous and Alternating Current Systems."[1]

In the discussion which followed,

MR. T. CARPENTER SMITH took issue with Mr. Leonard on his statement that the alternating system suffers by comparison with the three-wire system, "for its efficiency is much lower, its reliability is less due to the fact that its machines are not practically operated in multiple arc, its safety is necessarily less due to the existence of the high primary pressure, and its current is not adaptable to commercial use for motors, charging storage batteries, electro-deposition, and so forth." As to its efficiency, the converter system, as at present installed, may be lower than that of the three-wire system. But with regard to the satisfaction of the public, he thought that the efficiency of the alternating system was considerably higher, and he instanced a case of customers lost by irregularity in regulation of the three-wire system. Mr. Leonard had said that "its (the alternating system's) reliability is less, due to the fact that its machines are not practically operated in multiple arc." He did not think that that amounted to anything, and for this reason: that, while the machines are not generally operated in multiple arc, still they can be, and if there were any necessity for it they would be so operated. He preferred not to do it, because he thought that in case of accident to any one machine there is far less danger of accident to others. Another advantage and one in which safety is also concerned lies in the fact that the alternating system has its road divided up into small units. That is to say, no matter how badly the wiring may have been done in any one building it does not affect any other building, and one customer cannot threaten the safety of every other customer of that station by having his apparatus or the wiring in bad condition. A very serious question which was brought before the Committee on Safe Wiring is one that we have got to face before very long and to consider seriously, and that is the grounding of the neutral wire. There have been several arguments brought forward why this should be allowed. It practically came down to this, that the insurance agents and inspectors have preferred to ground the neutral wire, and practically make a return to the one-wire system of installing electric lights, to avoid the much greater danger of the 220 volt arc between outside wires, and the consequent damage in buildings where combination fixtures are used. He did not know whether it was not a good thing to go back to the one-wire system of wiring. If the grounding of the neutral wire is permitted they must also permit the grounding of the transformer. He denied the statement that the safety of the alternating current is necessarily less, due to the existence of the high primary pressure. Personally, he had never known of a case of contact between the primary and secondary coils of the converter. He knew that such have occurred, but he did not think that there had ever been one worth considering when we considered the enormous number of converters that have been put into service. The statement as to the alternating current not being adaptable to commercial use for motors so far would seem to be proved; but four years ago that same argument was brought forward—that the current could never be used for meters. He therefore thought that in a few years we shall see the motor in the same way. He thought that when one sums up the disadvantages of the alternating system it could be brought practically down to one, and that is poor efficiency on low loads. To meet that a system must be devised which will have all the advantages of the alternating system, and which will have an efficiency practically the same at high load as at low load. At high load he believed that the efficiency of the advanced transformer system was as nearly perfect as we are likely to get it.

MR. LEONARD, in reply, stated that Mr. Smith seemed to have made the error of assuming that he (Mr. Leonard) was appearing in the role of an advocate of the three-wire system. If such an impression existed he wished to correct it as promptly as possible. His remarks with reference to the three-wire systems and the alternating were such, he thought, that they would be admitted by almost every one to-day. He presumed that any one familiar with the facts would admit that the average efficiency of the three-wire system was higher, that it was conspicuously higher at light loads, and in speaking of the possibilities and advantages of the system which he had proposed he was only giving consideration to the existing conditions of to-day. Regarding the placing of machines in multiple one would almost nowhere find to-day an isolated plant where there are a large number of machines supplying a constant potential distribution, in which each machine is supplying a separate circuit. The possibilities of regulating and the economies are so much higher when machines are in multiple arc that, entirely outside of any consideration of central station supply or of the three-wire system, it seems as though the result of experience has been that where machines can be operated perfectly, simply and reliably with multiple arc it is better to do so. With reference to the question of grounding the neutral wire, Mr. Leonard agreed thoroughly with Mr. Smith that the grounding of the neutral wire is extremely bad practice, and that there is no argument for grounding the neutral except, perhaps, that of laziness. As to high pressure primary, the paper which he had read, of course, bore evidence in itself that he was a thorough believer in the necessity of high pressure primaries for reaching any great distance, and there certainly appeared to be an advantage in having those high pressure wires as few in number as possible. And instead of having a complete network through the city of high pressure wires, if we can by any means obtain a few of the high pressure wires to centres there would be less liability to any trouble due to the existence of high pressures. All of his remarks had been on the basis of the three-wire systems merely because of the saving in the cost of conductors which is attained thereby. Were we able to have a two hundred volt lamp instead 110 volts it would be of course infinitely preferable to have the two-wire system and use a 200 volt lamp than to have three wires for a lamp of 110 volts on each side, and furthermore the cost would be reduced even beyond that of the three-wire system. As to the sub-station method of operating on the outskirts of the town, that was unquestionably, when the alternating current motor is at hand, a very desirable way of operating. And yet it seemed that even there, until we have our two hundred volt lamp, it will be extremely advantageous to use for distribution something which will enable us to reduce the cost of our conductors on the consumers' premises to a point far below that with 50 volt lamps.

MR. SMITH stated that he had apparently made it clear that the 200-volt direct current in the building was what the insurance people are afraid of now, and that consequently we must abandon that pressure in any new system which is to be an improvement upon that. The use of an alternating current of 2.0 volts he did not believe would have that disadvantage, and in that case Mr. Leonard's plan would be all right.

MR. LEONARD, referring to the method of sub-stations as adopted by Mr. Ferranti mentioned by Mr. Smith, remarked that

1. See page 299, this issue.

Mr. Smith had not yet pointed out how he gets rid of the losses that will occur upon the final converters. He had put an intermediate set of converters in, and had taken means to take out converters as the load diminished, but his final converters in his distribution throughout the city were still connected, and were the same as we had before.

MR. SMITH replied that he would use the same plan as Mr. Leonard proposed in his system. He would have them grouped and switched in and out by the operator, just as he did in the sub-stations. He was only comparing one system as against the other. He still held to his proposition that multiple arcing was not used because it is a great advantage, but to allow of two machines being connected together. It is a good thing simply because in an isolated plant the conditions are different from what they are in a central station.

DR. LOUIS BELL doubted the advisability of constructing very large dynamos. With three or four smaller machines one may be able to crowd on a load and thus keep going. He had heard grave doubts suggested by those who know Mr. Ferranti personally as to whether he would ever complete his large machines. There was such a thing as getting an alternating current so big that you cannot handle it efficiently, and he thought that those units of Ferranti come very near that.

MR. SMITH, while not contending for 220 volts of alternating current in dwellings, desired only to point to the fact that as compared one with the other, if 220 volts of direct had not been found dangerous or objectionable, the 220 volts of alternating would not be found so.

MR. ORFORD stated that in Bridgeport he had been running the three-wire system, and had 3,000 lights in operation, on the direct plan, but he knew nothing of the danger refered to by Mr. Smith. He was also able to regulate the system perfectly and to throw machines in or out with no visible effect on the lamps in circuit. He had, on inquiry, decided not to install the alternating system.

CAPTAIN BROPHY said that, having to deal with people who use both systems, he did not wish, under any circumstances, to take sides in this discussion. He had probably had as much experience in watching the good and bad points of both systems as any one, owing to his position. They both had their good qualities. Regarding the matter of fuses, he had studiously insisted on increasing the size of fuses. The system of using a certain sized fuse for a given number of lamps had caused a great deal of trouble and annoyance. As a rule, in the central stations the fuses are altogether too small; they should never be below the safe carrying capacity of the wire, and in 95 cases out of a 100 they are, except, perhaps, in his own territory, where he had insisted on their being increased. He believed that if high potential or dangerous currents were used people should be told they are so. The losses from fire by the introduction of the electric light system had been too insignificant to take notice of. It was true that it is said that one of the largest fires in Boston for years was caused by the electric light. There were certain officials all through the country to-day, some of whom are more ornamental than useful, whose duty it sometimes is to determine the cause of a fire and they very often know very little about it. In years gone by the standard cause of a fire, when no other cause could be assigned, was matches, rats, acts of Providence, etc. Now it is electric light wires. He trusted that all would see that their wires were installed as carefully in the future as they had been in the past, and indeed improve on them. (Applause).

MR. BURLEIGH read his paper on "Central Station Accounts."[1]

MR. BURLEIGH said he was aware of the many difficulties that stood in the way of a uniform classification of accounts. To change the present systems would be embarrassing to many, but great good would follow a uniform classification. It was not necessary that all should keep their accounts exactly alike, but that they should agree on certain headings for expense charges, and what items are to go to those expense headings; so that when one hears his neighbor say that his arc light cost him so many cents per arc light hour one would know exactly what that includes.

MR. NICHOLLS drew attention to two points which he had adopted in his practice and which he finds of incalculable value. He had two private abstract books bound, with a lock and key on them, so that while they are kept in the regular vault they are not accessible. In the first book he has the charter under which he operates. He has his agreement with the city, the franchise, etc., copied in this book; also the different agreements with the companies with which he does business. In addition to having all those put down in this book he has them indexed and cross-indexed. If he has to refer to any particular clause or agreement as to powers of any kind he can, by looking at this index, find it at very short notice. He reads over these agreements periodically, because there may be a clause in an agreement that has been pigeon-holed which appears of no earthly use to one to-day, but a year from now it may be found to give you certain advantages, or under that agreement certain rights accrue which have been forgotten and which one may wishimmediatley to take advantage of.

1. See p. 302, this issue.

In the second book Mr. Nicholls keeps a monthly abstract of earnings and expenses. This he brings right up to the end of the month, and insists on having it before or not later than the 12th or 15th of the month following. In addition to having that copied out into his private abstract book, he has the cost of power as compared with the variable expense of the station made up. The power is estimated at the engine, the bus bar and at the service, allowing for the average drop. He also has the cost of his total power turned out compared with his total earnings. Thus he can tell what it has cost to produce power at the engine, at the bus bar and at the service for every month since he has been in operation, and consequently he is in a position to know exactly what he is doing.

MR. FRANCISCO, referring to a paragraph in Mr. Burleigh's paper, inquired how one could know how much power he is furnishing for arc lights where both are furnished from the same circuit, and where lights were being turned off and on.

MR. BURLEIGH, in reply, stated that that would have to be determined approximately.

MR. NICHOLLS added that he took ampere readings every fifteen minutes and recorded them in a book kept for that purpose. He also indicated the engines frequently.

MR. SCOTT—The principle of bookkeeping is like a tree branching out in every direction. Every one of those branches tends to the central trunk. The ledger is the reservoir of all accounts, and the only true way of keeping books is by a ledger, which ought to contain all the accounts. He employed a series of vouchers for construction, operating, merchandise, etc. accounts. A simple blotter would then do for a journal. On the cash book he subdivided by alloting 100 pages to construction, 100 pages to merchandise and 100 pages to operating. The journal entries show:

Cash, Dr., To Sundries:
By Capital Account.
By Merchandise.
By Lamp Rentals.

Sundries, Dr., To Cash:
To Construction Vouchers.
To Operating Vouchers.
To Merchandise Vouchers.

The posting is direct from those vouchers which have the signature of the foreman who receipted for the bill at the bottom and also the signature of the president and secretary, showing that the voucher has been passed at a regular meeting of the board and is signed by the secretary and treasurer. Then the ledger accounts will show capital, surplus, profit and loss, real estate, station, engine No. 1, 2, 3, 4, boiler No. 1, 2, etc., engine connections, converters, meters, poles, wire, labor and expenses on line, pins and insulators, etc., merchandise, coal, oil and waste, insurance, taxes, operating expenses. Then in addition he has a lamp record which is taken from the blotter in the storeroom. Each customer's account shows a debit for the lamp issued with a credit for the lamp returned. Those lamps are all numbered consecutively and the numbers are entered on the record. The numbers are retained in that record. At the end of a year, or six months, or three months, the lamp record is examined and the renewals are charged in the proper account in the ledger. The board of directors have submitted to them monthly a balance sheet from the ledger, and the board, as a committee of the whole, audit these accounts before each meeting of the stockholders and strike off for depreciation whatever they think is necessary; thus, poles at 28 per cent.; tools from 25 to 50 per cent., etc. The whole shows just exactly what it has cost to run the station, to supply the number of lamps that is shown by the lamp record. For instance, last year he produced 1,919,000 amperes of current at a cost of 1,110,000 net pounds of coal.

THE PRESIDENT described in brief the system of bookkeeping employed in connection with his company in Buffalo. This had been modeled after the methods in use in the gas interests of the Standard Oil Co., and had given good results. He had already furnished several members with the blank forms employed by him and referred also to the articles of Mr. H. A. Foster on "Station Management and Finance," which appeared recently in THE ELECTRICAL ENGINEER, as affording an excellent basis for station accounts.

The Convention adjourned until the following day.

FOURTH SESSION. THURSDAY, SEPTEMBER 10.

The Association met at 10 A.M. THE PRESIDENT read an invitation from the Business Men's Association of Norfolk, Virginia, to hold the next meeting of the Association in that city. Also an invitation from Robert M. May, Mayor of Augusta, Ga., and from the Cotton Exchange, Exposition Company, and the Commercial Club, of Augusta, to hold the next meeting of the Association in that city. On motion, the invitations were received and referred to the Executive Committee.

CAPT. EUGENE GRIFFIN then read a paper, entitled "Three Years' Development of Electric Railways."[1]

1. See p. 310, this issue.

In the discussion which followed MR. W. J. HAMMER referred to the fact that Capt. Griffin had not mentioned some of the experiments of Dr. Siemens, whose railroad is still running in Berlin, and which dated beyond any that Capt. Griffin had referred to, and he also mentioned several other experiments, among them those at Menlo Park in 1880 and 1881.

CAPT. GRIFFIN replied that he did not intend that the list should be taken as complete, but had confined it simply to the United States, and to electric cars which had been actually operated on existing roads.

JUDGE ARMSTRONG stated that so far as the experience of the railroad company which he represented was concerned, the very fact of operating the lines by electricity had brought them large additional travel. Not because they make better time (because they run exactly on the same schedules as they did with horses), not that their cars were any more comfortable, but seemingly from the very fact that there is a motive power there which requires the expenditure of no life energy whatever. Judge Armstrong did not agree with Capt. Griffin that it will pay to put down an electric road where a horse road would not pay, because one could surely, he thought, operate a horse railroad at less expense by running fewer cars than one could possibly operate an electric road where the steam plant and power for producing electricity has to be kept ready all the time. If the road is operated on a fifteen minutes or half hour schedule on street cars, that is not necessary. But under given conditions, where the travel can reasonably be kept at a fair schedule, Capt. Griffin might be, and perhaps was, right. His experience was that it paid only because they carried so many more people than they did when they were operating by horses.

DR. BELL stated that as the result of inquiries made by him he had found that there had been great increase in traffic, varying from 20 per cent. to 300 per cent., following the change from horses to electricity, whereas the actual expenses (although greater with electricity than with horses) were much less in proportion to the traffic with electricity than with horses, and that furthermore very frequently a real decrease in the running expenses was observed. He thought that there were certain classes of roads which are operated every day by electricity that never could be profitably operated by horses, that is, roads on grades which are far too severe for successful regular operation with horses, and which at the same time run through regions too sparsely settled to permit of surmounting grades by cables.

THE PRESIDENT then read the following despatch :

Mr. Allen S. Foote :

All investigations in charge of expert special agents have been postposed until after the meeting of Congress. All agents have been dropped, including yourself. Letter by mail.

Signed, ROBERT P. PORTER.

The reading of this despatch called forth a storm of indignation, and Dr. A. F. Mason offered the following resolution :

Whereas, the Hon. Robert P. Porter, Superintendent of the Eleventh Census, has authorized the collection of the statistics of the electrical industries and has appointed Mr. Allen R. Foote special expert agent for that purpose; and

Whereas, Mr. Foote has prepared schedules for the collection of such statistics covering nearly every known practical use of electrical energy; and

Whereas, these schedules provide for information of great public value that is imperatively demanded for the intelligent discussion and settlement of questions of grave public importance; and

Whereas, this Association is advised that the work undertaken is in danger of being delayed, if not altogether abandoned, by reason of insufficient appropriation, thus utterly wasting the $12,000 or $15,000 already expended, and what is of far more serious moment, depriving the people of the benefits derivable from a report that there is reason to believe would be a thorough and reliable authority on the subjects of which it treats:

Therefore be it resolved,

1. That this Association respectfully request the Hon. Robert P. Porter Superintendent of Census, or, if he is not sufficiently empowered, the Hon. John W. Noble, Secretary of the Interior, to provide for the carrying to the earliest possible completion of the work so well begun.

2. That immediately upon the convening of the 52d Congress, the Executive Committee of this Association be directed to secure the reintroduction of Senate Bill No. 4,329, of the 51st Congress, appropriating $50,000 for the special work under Mr. Foote's direction and to use all proper means to secure its passage at the earliest possible date.

3. That this Association hereby expresses its approval and high appreciation of the work Mr. Foote has done in his official capacity as special agent of the Eleventh Census for the Collection of the Statistics of the Electrical Industries and its belief that the reports he may prepare, if enabled fully to carry out his plans therefor as shown by the schedules submitted by him for examination, will have a value equal to that of the most valuable reports ever issued by the United States Government.

4. That the President and Secretary of the Association be directed to at once forward a certified copy of these preambles and resolutions to the Hon. John W. Noble, Secretary of the Interior; the Hon. Robert P. Porter, Superintendent of Census, and Allen R. Foote, special agent for the Eleventh Census, at Washington, D. C.

DR. MASON concluded by stating that he had carefully gone over the census schedule prepared by Mr. Foote, and had found them to be by far the most complete of their kind which had ever come under his notice.

The resolutions were unanimously adopted.

DR. MASON then moved "That a committee of five members of the National Electric Light Association be appointed who shall carry to Washington the preamble and resolutions just adopted, present the same to the Hon. the Superintendent of Census, the Hon. the Secretary of the Interior, and, if desirable, to the President of the United States, and urge the necessity of the continuance without a day's delay of the work of Special Agent Foote." The resolution was unanimously adopted.

DR. MASON then offered the following resolution :

Resolved, That the Association request the co-operation of other electrical associations and societies, also all associations or societies directly or indirectly interested in the subject, in measures to secure the carrying to completion of the census work commenced by Special Agent Allen R. Foote for the collection o statistics of the electrical industries.

The resolution was unanimously adopted.

THE CONVENTION then took up the Report of the Committee on Safe Wiring Rules, and Dr. Mason offered the following resolution :

Resolved, That a committee of five be appointed by the President, to be a permanent Committee on Safe Methods of Construction and Operation, any vacancies that may occur on the committee from time to time to be filled by the President.

The resolution was adopted.

The Convention then went into Committee of the Whole, which reported the rules in the form as printed on p. 313, which were adopted by the Convention.

MR. C. J. FIELD then read a paper on Electric Railway Construction and Operation.[1]

MR. BURLEIGH inquired what service was rendered by the local lighting company for the three cents per car mile.

Mr. FIELD answered that the actual service was to operate the generators which the street railway companies should install. He believed that the street railway company should install their own generators, because questions will arise about accidents happening to their own generators, and the station should only be responsible for ordinary wear and tear—not accidents due to short-circuiting, lightning or other causes.

MR. BURLEIGH inquired if Mr. Field advised central station men to attempt the care of overhead lines, the electrical part of the car equipment, etc.

MR. FIELD—In general I would say, No. I think that is the street companies' own business.

The Convention then adjourned until September 11, at 10 A. M.

FIFTH SESSION—FRIDAY, SEPT., 11.

The Association met at 10 A. M.

THE PRESIDENT—We will first take up the paper of Mr. J. I. Ayer, entitled : "Some Details of the Care and Management of an Arc Light System as Practiced in the 'Municipal,' of St. Louis."[2]

MR. AYER remarked that the paper being in print in the hands of the members, he would forego reading it but would add certain details not contained therein : In referring to the station, and in giving you this paper I have done so with the idea of bringing out, developing and inviting other papers of this nature. I want to say with reference to our station that the problem which I had there was different from that of almost any central station that I know of to-day. It was to start in and build a plant of large capacity, to spend money far in excess of the requirements of the business in sight, and to build a station which still had a very large business to start with. We already had a contract with the city of St. Louis for 3,000 lights, and the prospect was, when the station was first laid out, that it would ultimately absorb other companies and take in a number of smaller stations, as was afterwards done; and so my instructions were to build as large a station on a given piece of ground, which they handed over to me, as I could, and regardless of what it cost. I was confronted by a problem in that particular which will explain some of the peculiarities of construction which we adopted. I built a station with a working capacity for 6,000 lights, but when the station was put into operation it commenced with with 2,000 lamps. All the stations throughout the country which are in the hands of our members have, as a rule, grown up from small affairs. They started up in some junk shop or other, with a few dynamos, and grew as the necessities required ; and the result is that there has been an enormous amount of patchwork all the way through. But in our station there is nothing of the kind. We had to start off and build something which would be complete in itself, and which was comprehensive enough to take all the work in the near future that was likely to be drawn in it. Since putting the station in operation we have absorbed the other companies, and brought up the output of the station to the number of lights mentioned in the paper. At the time of building this station there was nothing of its character, size or magnitude in this country. The problem which confronted me, aside from the designing and construction of the station, was the system of management to be adopted, the methods to be applied, the details relative to the management of the men, and it all had to be worked out and put in motion with the wheels at the beginning. The plan that I outlined, the blanks that I made for the government of my men, are the ones that I am using to-day. I had made but few minor changes in the original blanks that were laid out beforetwe had done any work at all in the way of operating. And while, undoubtedly, we have followed

1. See page 303, this issue.
2. See page 312, this issue.

in detail many of the practices that have obtained in other central stations in the management of our men and in the division of the work, I want to say that I was unable, on applying to a number of cities, to get anything to assist me in arranging our blanks or system. It was a thing that could not be found. I have since found, in conversation with central station men who have large plants, that we have thought out the same ways, independently, of managing our stations—that we are working on similar lines. In some instances it is peculiar that it is so. One object of the paper in outlining the details of practice at our station is that that has not been done very much, and because I realized what difficulty I had in endeavoring to obtain information. In fact, I did not obtain any that was of value to me. That is my excuse in a measure for going into details of our plan of working to such an extent in this paper.

First, I will refer to our method of caring for the street lamps. We have got a number of street lamps distributed over a very large area. The city required that our lamps should be supported very high above the street. The minimum altitude of the lamps is thirty-five feet above the roadway. The city also required that we should suspend them between the poles. They were arbitrary in the matter. In order to get our lamps at that elevation the shortest pole that we could use was fifty feet in length. In suburban lighting they required the lamps to be fifty feet above the roadway, and they had to be suspended from sixty-five to seventy foot poles, according to the length of the space. The average distance apart is about 900 feet. I think that we have about 1,500 lamps where the average distance apart is 825 feet. The balance of them, 500 or more, have an average distance of 1,300 feet between the lamps. These are long distances.

In lighting the suburbs and, in fact, the whole city, we have found the use of a cart and horse very desirable. As stated in the paper, the average number of lamps per trimmer with a vehicle is sixty-eight. When one stops and thinks about the work, where lamps are located close together, of easy access, supported by methods which enable the trimmer to get quickly at the lamp, or even supported as mine are when they are placed so high above the streets, that looks like a small number; because we have, as doubtless many others have, some trimmers who care for more than one hundred commercial lamps per day. But we have got our lamps at this high altitude, and it takes a long time to raise and lower them. We are compelled to use a device for raising and lowering, a device which has to be lowered and locked in order to prevent its being meddled with, and that necessitates, each time, the unlocking of the device by the trimmer, applying the crank, lowering and raising the lamp; and, as the poles are set on the curb line of the streets, and passing vehicles could knock the device off easily, the hoisting device has to be placed up high out of the reach of the sides of the wagon, and that necessitated the use of a ladder by the men to get up to the hoisting device. It seemed to me, before we went into operation, that it would be essential that we should have something of that sort. We have a cart, modified to suit the requirements, and enabling our trimmers to carry extra globes, extra lamps, rubber clothing, means for keeping the carbons dry, and any number of tools that they wish (and we require them always to carry a few) and to carry the means to enable the trimmer to make any temporary repairs for the purpose of removing any defect or trouble which he may find. We have found that by furnishing our men with cart and horse (requiring them to furnish the horses) we have been able to employ men for $65 per month who are in every way equal to the men whom we employ for trimming commercial lamps, where they carry a step ladder around the town, at two dollars per day. For $65 per month we find them seeking the positions as trimmers. They furnish their own horses, feeding, shoeing and caring for them in every particular—leaving us only to supply them with vehicles and harness. The cost of maintenance for vehicles and harness is not very great. The cost of outfit was about $75 per trimmer. The cost of repairs and depreciation of harness and vehicle is about forty per cent. annually as we calculate it. That thing has been discussed somewhat, and in some other places they have tried the use of carts, and are not altogether pleased with them, but where the conditions are satisfactory I must say that we find much better results in the care of our lamps in that way than we have ever experienced with the same class of help. With $40 trimmers, such as we have, I doubt if we could get the results that we do in any other manner.

We have got a very useful little blank which I presume may be advantageously used in many other places. We have printed on it a form of telegraph pole with fifteen cross-arms on it, and ten pins. Although we use no more than eight pins for our work, yet we use other pole lines in carrying our wires over the city, and we keep a record of every pole and wire on those blanks. The location of the pole and the positions of the wires on the pole are indicated on the blank. From the corner of First to Tenth street, Circuit No. 5 will occupy the two outside pins on the top cross-bar, and the side of the street and the name of the street is given, so that by reference to that diagram at any time we know the exact location of our own and of other people's wires. In laying out new circuits and in doing additional work it is a very convenient thing to refer to, and it saves lots of work. It is very convenient where you have many poles, and especially where you have to run a mixed line, and interchange with other companies, to have some such arrangement.

In the care of a station it is rarely the practice in the smaller stations to have anything in the way of instruments except those furnished by the parent company, and possibly, sometimes, one outside instrument. We all know the utter unreliability of the ordinary commercial device furnished to us as an ammeter by these parent companies; and unless you do accurately know the amount of current, leaks will creep into the plant which I am sure would astonish any one if they were to go at the matter carefully and measure them. I do not think that there is a station in a town of 20,000 inhabitants and over, that can afford not to be provided with a high reading voltmeter (I am now speaking exclusively of, and referring only to, arc light circuits) that will measure the whole difference of potential on your circuits during the operation of them, so that you may know the amount of energy being consumed, and accurate ammeters are essential in order to know what that energy is. In the paper I have made a point of that. I will give you a statement of a little test. Until I had made the test and made the comparison I could not realize that the difference or the opportunity for difference was so great. With ten lamps adjusted to burn an average of 46 volts with 9.5 amperes of current, the average number of watts of the ten lamps was 436 per lamp. Now, without changing the adjustment of the lamps in any manner, but simply increasing the current so that the ammeter needle read 9.8 amperes, an increase of .3 ampere, you will find that the indicator furnished by our parent companies will not agree within half an ampere. With an increase of current of only .3 ampere the average consumption of watts was 534, or an increase of 20 per cent. in the watts consumed. That was the result of a change of only .3 ampere. When the current was increased so as to give the lamps ten amperes we had an average voltage of 58 volts per lamp instead of 46, an average of 550 watts per lamp, or an increase of 33 per cent. in the energy consumed. There is a saving equivalent to a very handsome profit on your lamps. We all know that often in a moderate-sized station some one will often come in and think the lamps are not in good order, and ask, "What is the matter with the lamps? Push them up." The ammeter is found to be all right, but still we give them more energy. Many of our superintendents want to have good lamps, and they want to make a good show with them, and so they keep their lamps bright in this manner. Now they will get just as satisfactory a light, and a more even light, by having the lamps properly adjusted and running them on a normal current, than they can possibly get in this manner, and be able to save from thirty-three to fifty per cent. of the energy consumed in those lamps. This is a point that I know a good many of you have already looked into, and you have discovered in practice that it is an opportunity for very serious leaks, but I have never heard any one bring it out before. This shows you the necessity of having a good and accurate instrument adapted to your work. Our practice is to take the commercial instruments furnished by the company whose apparatus we use, and then standardize them, regardless of their scale indicating where the needle should stand to indicate the currents that our lamps are adjusted for. We use two Weston ammeters as standard instruments. I find it desirable to have two, rather than one. Those we use almost entirely for standardizing these other instruments which we use in practice. There is something very peculiar about an ammeter. I find that they will run along perfectly accurate, and that two or three instruments will agree exactly for a week or ten days, and then, without any apparent cause, and when working under identically the same conditions, and connected together in series so as to take the same amount of current, the needle will vary sometimes as much as 0.2 or 0.3 on one instrument. Then we bring in our standard instrument and put it in the series in order to find out which one of those has changed its adjustment. It is something that we do not attempt to account for, grouped as they are, for this occurs in cases where we have them fastened to a board against a post, and where all the influences surrounding them are the same under all conditions and at all times, and they are not in close proximity to any wires carrying heavy currents, and there is no opportunity that I know of for change either in condition or position. And yet the change does occur. I think that money expended for good instruments to be used in adjusting lamps and in maintaining the current constant is money well expended. In operating the large number of lamps that we do, if we had an ammeter on every circuit (as some do) we would have a very variable condition of affairs. Of course these variations in ammeters would exist. We keep continually two ammeters in series. We have a very convenient plug and socket made for inserting the ammeter quickly in the circuit, so as to get it right in circuit. It is placed on the switchboard by simply inserting a single plug. Thus we connect the ammeter in series with the circuit. Our practice is in starting up, as soon as the dynamo is in operation, to insert the plug, and see that the current is what we desire to show by this instrument. We go through the whole series in that way, and that thing is repeated in our station every two hours during the night, and during the daytime once an hour we find it desirable to do this. While we have not much change in load we have changes in circuit conditions during the night, and the governors are not always responsive to a moderate change of load. You can easily build up your current 0.1, 0.2, or 0.3 of an ampere, and the governor will not always respond. We burn more carbon, and of course more coal, during that time.

This matter of circuit connection is often a fruitful source of trouble as well as one of the causes of an immense loss of energy, and is a thing that we all ought to pay close attention to. I know that all central station men now make it a practice to make a solid circuit making good line joints, but when we let out a lamp we are apt to have a binding post there, and we are apt to insert the wire in, either in the hanger board or on the lamp proper, and the man sets up the set-screw and leaves the lamp hanging there; then the wire will corrode and a condition will be brought about which will soon so disarrange things that a 50-light dynamo will run only 40 lights. We use hanger boards for suspending all our lamps, whether inside in commercial use, or outside in city use. The hanger boards are all provided with cutoffs. We took our boards as they came from the manufacturer, but shortly subsequent to that we soldered a short section of flexible insulated cable to the binding post of each hanger board, and then when the man cames along to make a line connection after the hanger board is put in place, he makes an ordinary line joint. Thus they get a good, solid, strong connection. The soldering that is done is done in our repair shop, or done at the station, where they have time to have it done well. Of course, a man cannot do a good job out in the wind, and under all the conditions usually existing, when he has to solder up a connection of that nature, and when an iron is obliged to be used to solder a wire to a binding post. We have all seen cases where cutouts on a line have soldered joints which had better have been left alone, and even with the solder left off. There is often a lot of acid left on so that the wire is corroded in a very brief time, or they get a little lump of solder piled up in one corner. The same practice obtains as to all the devices that we put in circuit. In cutout boxes we use the best flexible insulated cable, so that it may be put in and out many times, and leaves the connection unimpaired. We have those soldered to the hanger board binding post at the station. This leaves the lineman nothing but an ordinary line joint to make, which he can do outside easily and well. I cannot say that is done on all our circuits, because of the hurried way in which the plant was put in operation, and because we put in 1,200 lights at the very outset, and so there is more or less of the old construction which has not been overhauled. But generally we have no connections in our station except solid soldered connections, except where a lamp is connected to the hanger board. We have a hook hanger, and we also have a binding post on this hook on the lamp. We hook the lamp into the hanger board hook, and solder a short piece of cable which we put in a binding post, and bind it with a screw. Thus we get a double connection where we cannot have a solid connection. There is no hanger board that I have seen, and no method of hanging lamps by hook, or connecting them by a single connection to the hanger board, that will not develop trouble in ordinary practice, but by using the double connection you get very good protection.

I have mentioned in the paper that it is our practice to charge the customer for arc light installations. I am aware that this practice does not generally obtain throughout the country. One of my employees who came to me from an older company once told me that I was wrong in attempting this; that the thing could not be carried out; that it would make trouble and give us bother in endeavoring to collect from, or compel customers to pay for, arc light installations. I maintain that there is no more reason why we should do wiring free than there would be for a gas man to charge nothing for piping a house. There is no more reason why a gas man should pipe a customer's house than there is for our wiring a house free for incandescent lamps. Of course in the early days, when arc lights were still an experiment we were anxious to get the thing in a man's house so that he would try it, hoping that if he liked it he would keep it; and so we did not charge for wiring. And later on the same thing prevailed, and to get a customer started we were willing to do the wiring for the sake of getting him converted from the present method of lighting by gas to the new method by electricity. And so that practice has been followed up because the precedent has been established. We have effected a saving, or decreased our expenses, more than $600 per month by refusing to put in the lamps free. We make a charge of 35 cents per hour for all labor except that of the foreman, and we charge 40 cents per hour for his time. We also charge for the horse and wagon at the same rate, and we charge from the time the men leave the station until they return. That charge will usually cover the time of connecting it in circuit, and the cost of the minor things which we never take out—in the way of screws, insulators, and other such little things—and perhaps also the cost of removing the wires. We have another shrinkage there in the scrap wire which comes in, and which may, or may not, be recovered. But in a measure this charge covers largely the expense. We make a point with our customer that we want to own those appliances, that we bear the cost of them, but that we want to charge him for the labor, and we charge for the labor in that way. We do not pay those prices, you well understand, to our linemen. We own our own teams. The horse and wagon is worth $4 a day to us. Charging at that rate, they do not cost us anything. I know that there is a good deal of objection made to this plan, and in fact the president of our company said that I was taking a wrong stand, but it did not make any difference to me, and after the first few months all objections were gone. Many of our customers require only short service lamps, as from October to the 1st of January, or perhaps through the winter, taking them out in the spring, and we have customers who take lamps for six months in the year only, their business being of such a nature that they do not require them longer. These people want the lamps every year, but not for all the year, but still they do not want their wires taken out, and so, to save increased expense to them, and to avoid the taking out and putting in of wires, we require them to sign a contract when the period of service expires for the succeeding season. Then we leave the wires in, and agree to connect them without cost. But for our own protection we disconnect them entirely from the circuit. We always cut the wires out of the building, close the circuit at the pole, and take down the loop leading to it. I am satisfied that it is well worth the cost to do this, for then we are in no danger of burning them up, and by cutting them off, closing up and making a solid circuit we do not have to look for trouble from cut-out boxes, or other bad contacts, nor do we have trouble. The place where men never think to look for trouble is in those dead wires. They forget them. While this costs a little money, I think it saves a little in the end.

MR. NICHOLLS agreed with Mr. Ayer that wiring should be paid for by the consumer, and he followed that practice in his work with good results.

MR. FRANCISCO also concurred with Mr. Ayer, but showed how difficult it was to carry out this rule where there were competing companies in the same territory. He also bestowed high praise on Mr. Ayer's station, which he had visited. He always charged free wiring to expense and not construction account, as he considered it a dead loss.

MR. NICHOLLS—I am glad Mr. Francisco referred to the question of competition. I think it is better to sell your product at a lower price—to give a discount rather than to give something for nothing. You then know exactly what you are doing and exactly what you can afford to do. If you do free wiring I maintain that you have no right to charge it up to the capital account. You ought to charge it to the expense account. When once you wire a customer's premises he has you at his mercy. He can tell you to take your wires out. Whereas, if you meet competition by saying we will give you ten, fifteen or twenty per cent. discount, then if you have a row with your customer you simply lose his custom, but you are at no financial loss in the matter as regards the actual expenditure of capital, and I think that is a far more reasonable way of meeting competition—to sell the product at a lower price.

MR. FRANCISCO—I would say that I always charge free wiring to expense and not to construction or anything else. It is a dead loss.

MR. SEELY drew attention to the fact that three of the largest companies in New York city started to do free wiring. They spent half a million dollars before they realized the fact that it was an expensive luxury. It cost them on an average about three dollars to put in. They finally reached a combination whereby they agreed to charge the customer actual cost. Some en-enterprising gentlemen put the actual cost down to $1.50 a light. His opponent kept his price stiff at $3. The three-dollar man did not get the business. Finally the wiring got down again to about $1 a light. But he did not agree with the gentleman about the account to which wiring should be charged. In some large buildings there is $10,000 worth of wire alone. If you make a contract with a man to wire a building you make a contract with him to either buy that wire at the expiration of the contract or to remove it. It would be found that companies have spent thousands of dollars in wiring large buildings, and it would be nonsense to charge that to expense. Mr. Seely doubted the possibility of adjusting accurately all the arc lamps in a large station such as that of Mr. Ayer.

MR. AYER replied that he kept men specially on that work who with practice had become very expert at it. It could be carried out more easily in a large station than in a small one. Mr. Ayer tested all his lamps as they came from the manufacturer, employing boys in this work eighteen or nineteen years old. They are paid $35 or $40 a month for that character of work.

Mr. Orford thought that an arc lamp required only one adjustment. He had arc lamps in operation in stores for six years and they have never been touched for the purpose of readjustment. All that was necessary was a uniform current strength.

Regarding the question of renewals the only advantage which he saw in the customer buying his incandescent lamps would be that they could sell them in a bunch and have done with it, whereas they now supply them one or two at a time as required. The disadvantage of the customer buying his lamps had appeared to be that some of them might burn the lamps as long as they would burn, and in that way it would not be very creditable, as they have to compete with very good gas. If the Convention could help him in any way to kill competition in his town from a fellow member of the Association he would like to get some assistance.

MR. SCOTT had found considerable trouble with inaccurate measuring instruments furnished by parent companies.

He had done free wiring because the gas company had lowered its rates from $2 to $1.60 in order to compete with them, and had offered to pipe all large stores and residences free. But after firmly establishing the company he thought that wiring should be charged for.

DR. LOUIS BELL, referring to dynamo governors, stated that the best results could hardly be expected in actual practice when the best laboratory instruments will get out of adjustment with the most skillful use, and when they are subjected to a degree of care which could not be even approximated in the most refined commercial work. He thought that the cause of error that is so frequently made in ascribing exceedingly fine regulation to commercial apparatus was due to the fact that it is not sensitive enough to show more variation, and instanced examples.

MR. ORFORD replied, with the Weston instruments and Howell indicator he managed to keep his circuits at the proper voltage. He did not think it necessary to maintain the highest regulation on arc circuits, as a small difference could not be recognized.

MR. W. C. WARNER'S Paper on "Different Forms of Carbons Used in Arc Lighting" was then taken as read.

On motion it was resolved that the Rules for Safe Wiring, adopted by the Convention, be at once printed and a copy sent to each central station and insurance association in the United States.

On motion of Mr. FRANCISCO, Sir William Dawson, Mr. Frank R. Redpath and Prof. Henry T. Bovey were elected honorary members of the National Electric Light Association on the recommendation of the Executive Committee.

On motion of Mr. SEELY and by the recommendation of the Executive Committee, Mr. Thomas D. Lockwood was also elected an honorary member.

The Convention then went into executive session.

The Secretary presented the following report:

SECRETARY'S REPORT.

The condition of the Association, so far as its membership goes, is much stronger and more encouraging than it was at the opening of the year. Many individual memberships have been dropped since the adoption of the present constitution, owing to the fact that memberships are, under it, very largely represented by corporations and firms instead of individuals. Notwithstanding this fact, a quite large addition has been made. New members, since the last report of your Secretary, and the general interest in the affairs and work of the Association, have very largely increased, owing to the active agitation concerning the very important benefits arising from membership and the representative character of the Society.

According to the last Secretary's report, the number of member's who had paid dues for 1891 was as follows: Active members, 65; associate members, 107. Total, 172. The present membership stands as follows: Active members, 78; associate members, 142. Total, 220.

I beg to say, in connection with the total membership of this Association, that it is far from what it should be, and far from what it might possibly be made, in view of the immense possibilities for the diffusion of valuable information within its grasp. Our active membership list, especially, should be very largely increased, and could be by making an active membership a valuable consideration and worth more than the annual dues amount to, in the way of practical information furnished during the year. I would suggest that the Committee on Data be increased in its membership and that the collection and distribution among our members of important facts, figures and details relating to the furnishing of light, heat and power be carried out systematically, persistently, throughout the year. There is a vast field here for good, and I consider it as important a work as the Association has to do. Respectfully submitted.

On motion, the report was received and filed. The Treasurer's report was then presented by Mr. Beane, as follows:

TREASURER'S REPORT.

This report is made from April 1, dating from the beginning of office, until July 1, our fiscal year dating from January to July and July to January of each year. This report is based on the books of the Association and on the trial balance of the Auditor on April 17, and on my trial balance of July 1.

The operations of the Treasurer, as regards receipts, is indicated by Schedule "A," the total receipts being $1,265 Total disbursements amount to $1,387.62, making the disbursements $122.62 over the receipts for that period. The proof of this is contained in the following: Balance in the bank April 17, indicated by the auditor's trial balance, was $1,373.15. Balance in bank July 1, indicated by trial balance, $1,122.02. Cash on hand July 1, $128.51. Total of cash on hand July 1, $1,250.53. Which total is $122.62 less than the amount on hand April 17, proving the difference between the receipts and disbursements as indicated by the report. The assets of the Association on July 1st consist of cash in bank, $1,122.02, and the value of furniture account charged with $214.15. The assets were further increased by the payment of the Committee on Exhibits of moneys disbursed, and their account is Schedule "B." Respectfully submitted.

The report was, on motion of Mr. Seely, referred to the Finance Committee.

DR. MASON offered the following resolutions, which were unanimously adopted by a rising vote:

The National Electric Light Association, assembled in Montreal, at the close of its session desires to put upon record its appreciation of the distinguished honor shown it by the Dominion of Canada in the presence of His Excellency Lord Stanley of Preston, Governor-General of the Dominion—

Of the large-hearted hospitality of the city of Montreal, evidenced by many grateful acts, official and individual—

Of the tireless industry of the Citizens' Executive Committee, whose efforts have carried to completion the most successful meeting in the history of this body—

Of the grand work done by the Committee on Exhibits, issuing in an exhibition of rare educational value, calculated to develop a larger appreciation of the flexibility of electricity and its wide adaptation to human needs—

Of the gracious liberality of McGill University, which has lent the dignity of its great name and the personal influence and labor of its officials to the success of our meetings—

To the Press of this city, whose extensive and fair reports of our meetings have extended our influence—

To the railway companies for their liberal reduction in fares, and to the Windsor Hotel management, where as guests we have found a home.

Resolved, That the above minutes be placed on the records of the Association and a certified copy thereof be sent to the various bodies mentioned.

On motion of MR. SEELY, seconded by JUDGE ARMSTRONG, the following resolution was adopted:

Resolved, That a vote of thanks be tendered Mr. J. I. Gulick for the efficient and successful management of the exhibition now being held under the auspices of this Association, the largest ever held on this continent; and that the Secretary be directed to have this resolution engrossed and presented to Mr. Gulick.

On motion of MR. SEELY, seconded by DR. MASON, a like vote of thanks was extended to Mr. Luther Stieringer.

MR. FREDERICK NICHOLLS, MR. M. D. LAW and MR. A. M. YOUNG were elected as members of the Executive Committee of the third class.

DR. MASON gave notice of the following amendment to the constitution: "That in the first article the word 'International' be substituted for the word 'National,' so that the title of the Association would be, 'The International Electric Light Association.'"

Buffalo was selected as the place for holding the February meeting of the Association.

On motion of MR. SEELY, a vote of thanks was extended to Mr. Allen R. Foote for his services.

The Convention then adjourned *sine die*.

INCIDENTS AND ENTERTAINMENTS.

A LARGE number of the delegates with the ladies of their party reached Montreal by the special trains on Sunday, Sept. 6, from Bostona nd New York, the latter being under the special direction of Mr. C. O. Baker, and the former under that of Mr. A. C. Shaw. The trains were united at Rutland, Vt., and by the process of gathering up other delegates en route, the special when it pulled into Montreal had at least 200 passengers on board. It was also accompanied by a number of local friends and members who, with bagpipes to the fore, boarded it some distance from the city. The party arrived about midnight. It deserves mention also that many of the delegates made their way to Montreal by the pleasant route of the Lakes.

On Tuesday the entertainments began at 2.30 P. M. with a fire department display on the Champ de Mars. Owing to the adjournment of the Convention daily at 2 o'clock, it was easy to combine work with play, and many members with their ladies attended. Thence they adjourned to Terrace Bank, the residence of Mrs. F. R. Redpath, who gave a garden party in their honor. The same evening a conversazione was given at the Redpath Museum and Molson Hall, McGill College, where the gathering was very large. The committee who received were Sir Donald A. Smith, Mr. and Mrs. F. R. Redpath, Mr. Peter Redpath, ex-Mayor and Madame Beaugraud, and Prof. and Mrs. H. T. Bovey. Not only were the permanent buildings open, but a large tent was erected specially to serve as a refreshment hall.

After luncheon on Wednesday, about 150 carriages were drawn up in front of the Windsor, and the delegates and a large number of their friends entered and went for a drive around the heights of Mount Royal. The visitors enjoyed the trip very much, especially the magnificent view from the look-out. In the party were Mayor McShane, Ald. Clendenning, Ald. Cunningham, Ald. Stevenson and a number of prominent citizens. They arrived back in the city in time to attend the garden party at Belmont Hall, 537 Sherbrooke street, the residence of Mrs. John Molson, where a delightful hour was spent in social intercourse.

Sir Donald A. Smith, who throughout took great interest in the Convention, giving his countenance at the opening and extending his hospitality to many of the members, entertained a party of gentlemen, consisting of citizens of prominence and members of the Association. Among the party were President Huntley, vice-presidents James I. Ayer and John A. Seely, J. W. Beane, secretary; Cap. Eugene Griffin; Samuel Insull; G. W. Davenport, Frank R. Redpath, T. C. Martin, Judge Armstrong, S. Dana Greene, C. W. Price, Gen. C. H. Barney, Peter Redpath, W. C. McDonald, Sir J. William Dawson and others. There were about fifty at table. After dinner an hour of keen pleasure was spent in inspecting Sir Donald's picture gallery, rich both in old masters and in modern art, containing a magnificent Turner, Jules Breton's "Communicants," a Tissot, a Constant and many others of equal merit.

An impromptu ball was given in the Windsor the same evening and proved a decided success. The credit of this is mainly due to the indefatigable efforts of Mr. John Carroll, the genial secretary of the Reception Committee. The Ladies' ordinary of the Windsor was tastefully fitted up for the occasion, and proved very suitable for the purpose. Quite a number of Montrealers were present, among them being Mayor, Mrs. and Miss McShane, Mr. and Mrs. Hagar, Miss Christie, Mr. and Mrs. David Starr, Ald. Stevenson, Consul-General Knapp, Miss White, of Ottawa; Mr. John Carroll, and many others. The officers, all of the delegates and the ladies of the Association were present and enjoyed the affair very much. Dancing was indulged in until after midnight to the music of a full orchestra. Light refreshments were served during the evening in the new club rooms.

The morning session was so fully occupied on Thursday that many had scarcely time to catch the steamer Filgate for the Lachine Rapids trip at 2.30 o'clock. Among the city men present were Messrs. Henry Bulmer, the chairman of the harbor commissioners; John Kennedy, harbor engineer; Ald. Stevenson, Ald. Villeneuve and Prof. McLeod. On passing the Eugene Phillips' electrical works the party found it handsomely decorated with flags and streamers in their honor, and nearly every operative, male and female, was at the windows waving flags. Lachine was reached in due course and a short stop was made at Caughnawaga. The party did not leave the boat, but amused themselves by tossing coppers and aluminum medals to the boys and watching the scramble. The run down the rapids was thoroughly enjoyed by all. The water was comparatively low and gave a good idea of the dangers of the narrow passage, as the boat tossed about here and there in close juxtaposition to the rocks. The visitors were loud in their praises of the outing and everyone enjoyed it. The city was reached about six o'clock.

The evening of Thursday was devoted to the banquet tendered the Association by the citizens of Montreal, and given in the fine Windsor Hall. The room was beautifully decorated with flags, plants, flowers, etc., and the tables were laid for about 500 covers. The arrangements had been made and carried out by Messrs. John Carroll, chairman; W. E. Christie, John Kennedy, S. C. Stevenson, A. J. Corriveau and G. B. McFarlane, and were admirable. Sir Donald A. Smith presided, and among those present were the Governor-General, Lord Stanley of Preston, Lord Kilcoursie, A. D. C., Sir William Dawson, Sir Henry Edwards, Mayor McShane, ex-Mayor Beaugrand, U. S. Consul General Knapp, Justice Baby, Justice Cross, Prof. Bovey, Justice Doherty. Before the regular proceedings began, Mr. T. C. Martin, in the name of his fellow-members, presented Prof. H. T. Bovey with a phonograph as a little souvenir and in recognition of his work as chairman of the Citizens Committee. After the toast of the Queen, that of that of the President of the United States was given, and responded to by Consul General Knapp. The toast of the Governor-General was responded to by Lord Stanley in a most happy manner. Ex-Mayor Beaugrand then proposed the health of the N. E. L. A., and President Huntley responded in an excellent speech, which he concluded with a pressing invitation to the Chicago meeting in 1893, when the countersign would be "Montreal, 1891." At this point Sir Donald Smith presented Mr. Huntley with a beautiful ebony mallet mounted in gold and bearing his name engraved upon it. Judge Armstrong then proposed "The City of Montreal," to which Mayor McShane, Mr. Justice Cross, Mr. Hugh McLennan, Ald. Rolland (in French) and Ald. Clendenning responded. Gen. Barney then proposed the toast of "McGill University," to which Sir William Dawson made an admirable response. The toast of "The Citizens Committee," proposed by Mr. J. I. Ayer, was responded to by Mr. John Kennedy, Mr. A. J. Corriveau, Mr. J. Carroll and others. After the toast of the ladies, the "Electrical Press" was responded to by Mr. G. M. Phelps, and "Electrical Science" by Mr. T. D. Lockwood. The banquet then concluded, as it began, to the stirring strains of the bagpipe, played by kilted Highlanders.

The festivities of the week may be said to have closed on Friday, when a large party watched an exciting lacrosse game between the Montrealers and the Cornwall Island Indians, at the grounds of the Montreal Amateur Athletic Association. In the evening At Homes were given by Mrs. Frank Redpath at Inglenook and by Mrs. Bovey at Sunnandene.

An interesting episode of the Convention was the visit paid to the Exhibition by the Governor-General on Thursday. Lord Stanley spent the morning in a close and careful examination of the exhibits, and soon betrayed an intimate acquaintance with mechanics and with the various ideas embodied in the electrical appliances for the distribution of light and power.

A more perfect day could not have been conceived than that which dawned on Saturday morning on a party of about 75 who responded to the invitation of Madame Louis Givernaud, Mr. Alex. Macdonald, and Mr. J. B. Tresidder to join them on a cruise up the Richelieu River as far as Fort Lennox, known as the Isle au Noix. Special cars had been provided on the 9 o'clock train on the Canadian Pacific Railroad to Iberville, whence the start was made. At the wharf, where the three private steam yachts laid waiting, the guests were received by Madame Givernaud, Mr. Macdonald and Mr. Tressider, with Mr. Corriveau as introducer of the party. The guests were then divided among the three yachts which were all gaily decked with flags, the Stars and Stripes occupying a prominent position in honor to the American guests. After a loud tooting of whistles a start was made, and the three yachts got fairly on their way, and by a little dexterous manœuvering, were kept almost side by side where the width of the channel permitted it. The weather was beautiful, the sun shining brightly, and a refreshing breeze blowing, which seemed to infuse new life into the most of whom were fatigued by a week's hard work and late hours. In a few minutes all were comfortably settled in settees or chairs, while others lounged on the deck and gave themselves up to the full enjoyment of the hour. After an hour's sail up the river, the scenery on which is extremely beautiful in a quiet, restful way, a landing was made at the Island, and the whole party soon distributed themselves over the fortifications and barracks, speedily gathering together again, however, at the call of lunch, which was served on impromptu tables set out in the shade of one of the buildings, the guests seating themselves on the banks of the fortifications. Here an excellent repast was made, and the walls soon resounded thereafter with three times and a tiger for the lady and gentleman who had provided so royal an entertainment. Other toasts followed, after which the party reluctantly returned to the yachts, a number of them having to hurry off to catch the 3.30 train to Montreal. Quite a number, however, lingered behind, and as they were too late for the train, Madame Givernaud, with true Canadian hospitality, took half them to her house and entertained them to dinner, while Mr. Macdonald divided the courtesies with her by entertaining the others in his home. A quiet stroll through the quaint old town, a visit to the large China factory owned by Mr. Macdonald, and a peep at the old church whiled away the hours in a thoroughly pleasant manner. At 7.30 the train was taken for return to the city, the guests, even with all American fluency, being quite unable to express their thanks for such a perfect day's enjoyment. There has been much, very much, to be enjoyed in Montreal by the kind hospitality of Montreal's citizens, but those who were fortunate enough to go on the yacht party will never, it is safe to assert, forget the beauties, the hospitality, the perfect enjoyment and rest of that day on the Richelieu River.

EXHIBITION NOTES.

THE ELECTRIC MERCHANDISE COMPANY, of Chicago, had one of the most interesting exhibits at the Convention, though they confined themselves to a parlor of the hotel, in the shape of several Burton electric heaters, in charge of Mr. D. B. Dean and Mr. W. R. B. Willcox. Current could not be secured till evening, but every evening they made an interesting exhibition of the Burton heater in operation, and attracted a great many people by its novelty. The heaters exhibited were designed for street car work, and are installed in cars two on each side, all four being in series. The heaters exhibited were operated by a 110 volt circuit, taking from 3 to 4 amperes, and become too hot to touch with the hand 5 minutes after the current is turned on. The heating is accomplished by about 70 feet of German silver wire, which is prevented from oxidizing by being imbedded in fine brick-dust. They exhibited a very complete assortment of electric railway supplies, consisting of pole ratchets for tightening the span wires, and also trolley hangers, Chicago clamps, trolley wheels, and raw hide pinions, which are made from plain raw hide, and have no glue or paste between the layers, being formed with 25,000 pounds pressure, and cold-riveted. A novel and useful headlight for electric cars was also shown, having a triple silver-plated reflector with an incandescent lamp of any desired candle power, the connections with the car being made by a flexible conductor in rubber tubing.

HOLLAND BROTHERS & YOUNG, of Montreal, exhibited to the great delight of all Montrealers a number of Edison phonographs in active operation. The neat room which they had fitted up with various cabinets was crowded all the time, and the expressions of wonder and delight which these little instruments elicited were alike interesting and instructive—instructive of how little the general public yet understands of the many wonders of electricity.

THE INTERIOR CONDUIT AND INSULATION COMPANY, of New York, made a very handsome display of their regular line of interior conduit, mounted on a large panelled board. The tubes of the conduit are also covered with steel or brass, making them extremely durable and serviceable. Connection boxes and junction boxes were shown in their proper place, and well displayed the many good qualities of the system. Attached to the exhibit, and forming a part of it, was displayed the Johnson vise-lock switch for currents from 50 to 100 amperes. These switches form the most compact and smallest ever shown for such large currents. The vise-lock switch does not depend upon springs for contact, but the contacts fit firmly into jaws. A sample of the Johnson underground conduit was also shown, for carrying all kinds of cables, either of high or low voltage. Another interesting feature of this exhibit was the California arc lamp, which burns 90 hours without change of carbon and which throws no shadows underneath. The lamp measures only 14 inches over all, and the carbons are shaped like horizontal quadrants, about six inches wide, the arc playing between them, and feeding across the whole extent of the edge surface. The Interior Company are sole agents and manufacturers for the United States and Canada, east of the Rocky Mountains. The Garland carbon protector also formed part of the exhibit. Mr. E. W. Little, general manager, and Mr. Paul Oscanyon, assistant electrician, were in charge of the exhibition.

THE MCGILL UNIVERSITY, of Montreal, had secured for themselves a neatly arranged kiosque in the exact centre of the hall, and kindly exhibited several pieces of interesting apparatus. They showed a chronograph, connected to a brake circuit chronometer for determining the clock error by the transit of stars; a Thomson composite electric balance, a Thomson voltmeter, ranging from 500 to 10,000 volts, a multicellular voltmeter, instruments for the determination of longitude, and a few very interesting samples of the kinematic models for the study of motion. The kiosque was under the superintendence of Prof. McLeod and Prof. Nicholson, and Prof. Bovey also gave considerable attention to the exhibit, in the midst of his arduous duties as President of the Citizens' Executive Committee, for the entertainment of the members of the National Electric Light Association. Mr. Carroll was fortunate enough to secure a good photograph here of the vice-regal party, consisting of the Governor General, Lord Stanley, his aide-de-camp, Lord Kilcoursie, and Sir Wm. Dawson, while resting in the exhibit of the Eugene Phillips Company, during their visit to the exhibition hall.

THE EUGENE F. PHILLIPS MANUFACTURING COMPANY, of Montreal, were represented at the Convention by Mr. Eugene F. Phillips, president; Mr. John Carroll, secretary and treasurer, and Mr. Frank S. Mead, general manager. Mr. P. C. Ackerman, of the New York office of the American Electrical Works, was also present. The Phillips Company had a very tastefully arranged exhibit in the centre of the hall, capped by a broad sign board with electric lamps forming the word "Phillips." They exhibited handsome samples of all kinds of magnet wire, office and annunciator wire, flexible cords, telephone cords, switch cords, telegraph and telephone cables, rubber insulated wires for electric light and power, and numerous reels of nicely finished weatherproof line wire. Mr. Carroll, who is now located in Montreal, has endeared himself to all the members of the Convention by his unvarying good nature and attention, and his phenomenal efforts to entertain one and all.

THE CONSOLIDATED ELECTRIC MANUFACTURING COMPANY, of Boston, represented by Mr. C. E. Bibber, exhibited a neat sample board on which were displayed samples of the new C. E. M. socket, C. E. M. jack knife switches, cut-outs, Davis arc cut-outs, and other supplies. The most interesting feature of the exhibit, however, was the Wade dynamo register, which automatically records the working of every arc light circuit in a station. This instrument, which is manufactured exclusively by the Consolidated Company, is intended to be installed in the superintendent's room, and has a clock attachment, carrying a revolving disc of paper upon which a pencil attached to an electromagnet bears. The electromagnet is in series with the dynamos and lamps, and every flash of the dynamo is thus accurately recorded on the dial, so that the superintendent in the morning has a perfect record of the running of the dynamos during the night, and the time to a second when the lights were turned on and off. Should the circuit be broken, the armature of the electromagnet is released, and makes contact with a local circuit which rings a bell and alarms the attendant.

ALEXANDER, BARNEY & CHAPIN, of New York, were represented by Mr. P. H. Alexander—what would a convention be without him?—and Mr. Henry G. Issertel. They had no exhibit of their own in the hall, but showed, in one of the parlors of the hotel, a complete set of samples, consisting of A. B. C. incandescent lamps, the Bernstein series incandescent lamps, French yachting horns, and a very neat display of all kinds of push buttons and electric bells, of all sizes and descriptions. They also showed A. B. C. sockets, tapes, switches of all makes, Alexite cut-outs and rosettes, and A. B. C. splicing torches.

THE HEISLER ELECTRIC LIGHT COMPANY, of Philadelphia, were represented by Mr. Oscar Hermann, who exhibited a 200 light 32 candle power incandescent dynamo for series long distance incandescent lighting, and an automatic regulator which is belted to the dynamo. The armature of this dynamo is stationary, with a rotating internal field, and is divided into two circuits, so that should one coil burn out, one-half of the machine could still be operated, and keep half the lamps burning. The exciter is on the same shaft, and is part of the machine. Between the exciter and the armature is a fan revolving on the main shaft for ventilating and also for the expulsion of dust. The Heisler Company also exhibited their series incancescent lamps and sockets which run on a 5 ampere circuit, and range from 5 to 100 candle power. These lamps were shown mounted on street fixtures, and also on decorated fixtures for house use.

THE ELECTRIC ENGINEERING AND SUPPLY COMPANY, of Syracuse, N. Y., were represented by Mr. F. H. Leonard, Mr. L. C. Hinds, Mr. J. D. McIntyre, and Mr. F. Hawkins. They exhibited a large sample board on which were the initials E. E. S. in Packard frosted lamps, for which they are the agents for Canada and the Eastern States. On the top of the board they showed a distinct novelty in the shape of clusters of various colored lamps which were made to revolve by an electric motor behind the scenes. They also showed a very handsome assortment of large and small knife switches and electric railway supplies, trolley hangers, various E. E. & S. sockets, rosettes, cut-outs, branch blocks, &c., 5 to 10 ampere switches, and a new double pole 5 ampere switch just got out.

CHARLES A. SCHIEREN & COMPANY were represented at the Convention by Mr. Charles A. Schieren, Jr., of New York, and Mr. G. H. Hamblett, of Boston, who were probably the two most disappointed men in the hall. With their usual energy they had prepared a very attractive and tastefully designed booth for the reception of their goods, but, alas! "the samples that they looked for never came." Mr. Schieren stated that they had a very interesting, complete set of samples, but they had been delayed on the Canadian Pacific Railway, and could not be found. Nothing daunted, however, Messrs. Schieren and Hamblett stuck to their post, and drew word pictures of the peculiar excellency of their dynamo belts to their numerous friends.

THE PHOENIX GLASS COMPANY, of New York and Pittsburgh, as usual, had one of the most beautiful displays in the hall, attracting special attention among the ladies, as their goods lend themselves easily to decorative purposes. Mounted on red cloth, they showed in great profusion, and artistically arranged, samples of glass shades for gas and electric fixtures, plain, richly cut, tinted and etched, making a very beautiful effect. They also showed a number of round balls of the Star and Hobb cut, and had suspended in front of their stand a large ball 12 inches in diameter. Mr. A. H. Patterson and Mr. E. H. Peck looked well after the interests of the Phœnix Company.

THE ECONOMIC ELECTRIC MANUFACTURING COMPANY, of Boston, manufacturers of "Economic" incandescent lamps, were represented by Mr. N. V. Titus, of Boston. About 150 of these lamps were used to decorate the kiosque of the Simplex company, and produced a very fine effect, being of all colors. The Economic lamp has got a fine foothold in Canada, and are handled exclusively by the Canadian Electric Supply Company, of which Mr. Corrivieu, is the head. Mr. Titus is a Canadian by birth, having been born in St. Johns, and during his leisure moments, had the pleasure of meeting many of the friends of his boyhood and visiting the scenes of his early youth.

THE PAGE BELTING COMPANY, of Concord, N. H., were represented by Mr. J. H. Burghardt and Mr. C. W. Currier, of Boston. They displayed samples of various styles of belting, especially the Eureka dynamo belt made with slots specially for dynamo work. Samples of the 30 inch and 16 inch belts recently made for the Georgia Electric Light Company, of Atlanta, Ga., were shown. Mr. Burghardt seemed to be everywhere in his particularly felicitous way, and made friends wherever he went. The value of Page belting and Burghardt are synonymous, and he will find many friends in Montreal whenever he returns.

MR. T. W. NESS, of Montreal, had a very complete exhibit of all kinds of push buttons, annunciators, telephones, batteries, telegraph instruments, induction coils and medical batteries, and all household goods. A C. and C. motor was also shown driving a sewing machine. Mr. Ness also showed a very convenient combination of switchboard and telephone, which is particularly applicable to factories having several 'phones in the building, as it is only necessary to turn the arm of the switch to any desired point, when communication is instantly afforded to any of the various telephones in the building.

MILLER BROTHERS & TOMS, of Montreal, exhibited samples of the famous Hill friction clutch, so commonly used in electric light stations, and showed a few interesting photographs of stations using this clutch. They are the Canadian agents for the Hill Friction Clutch Company, of Cleveland, O.

THE WESTON ELECTRICAL INSTRUMENT COMPANY, of Newark, N. J., showed an extremely handsome assortment of voltmeters, with multipliers, ammeters, station ammeters, and new alternating current voltmeters. The Weston new alternating current voltmeter is accurate to ½ of 1 per cent., and can be adjusted to any temperature. It has a brake on the movable coil to stop the vibration of the needle. The new station ammeter is well worthy of interest, and is quite new. It is accurate to one per cent., and is made to read up to 2,000 amperes. The company was represented by Mr. Wm. Moore and Mr. Wallace Hill.

THE DOMINION WIRE MANUFACTURING COMPANY, of Montreal and Toronto, were represented by Mr. A. E. Hanna, and exhibited an exceedingly attractive display of brass and copper wire for electrical purposes, galvanized iron and steel telegraph and telephone wire, barbed wire, chains, screws, nails, and some very neat sample boards tastefully designed for the occasion. All the wire is drawn in their factory at Montreal, and the copper comes from Lake Superior.

MR. M. C. SULLIVAN, of New York, exhibited samples which he carried in his pockets—a new electric slate, which he is going to push for all electrical insulating purposes. The particular feature of this slate is that all the deleterious substances have been removed by a patented process, leaving the pure slate as an excellent insulating material, and removing all the objectionable features which have hitherto attended the use of slate for high tension insulation.

THE JOHNS PRATT COMPANY, of Hartford, Conn., and New York, exhibited a neat sample board on which were mounted samples of Vulcabeston goods for insulating magnet coils of dynamos and motors, trolley hangers, and various samples of electrical appliances where good insulating material is required. Mr. J. R. Burdick, of New York, representing the H. W. Johns Company, and Mr. E. R. Hatch, of Hartford, looked after the interests and future welfare of Vulcabeston.

MR. ALFRED E. BRADDELL, of Philadelphia, electrical inspector of the Underwriters' Association of the middle department, and W. H. MERRILL, JR., of Boston, electrical inspector of the Boston Fire Underwriters' Union, attended the Convention and listened with interest to all that was going on.

PASS & SEYMOUR, of Syracuse, N. Y., exhibited samples of almost every conceivable appliance in which porcelain can be used for electrical purposes. These pieces were all made out of superior porcelain for which Pass & Seymour have earned a wide reputation for its excellence. The porcelain was shown also in various colors, and Mr. A. P. Seymour, who was in attendance, showed also a very handsome tea set made out of the same material.

THE PETTINGELL-ANDREWS COMPANY, of Boston, were represented at the Convention by Mr. C. B. Price, of Boston, who was always on hand to explain the mysteries of K. W. cut-outs and rosettes, a few of which were exhibited in the stand of the Toronto Construction Company, who are their agents in Canada.

GEORGE CUTTER, of Chicago, exhibited his famous lamp-supporting pulley in operation, and Mr. Cutter was in attendance to explain to his many friends "why the lamp did not drop," as the explanation has never been published. The only feature missing was the little devils on the suspending rope, which have become so familiar to all by his clever advertisement.

THE UNION ELECTRIC MANUFACTURING COMPANY, of Bridgeport, Conn., showed, in conjunction with the Toronto Construction Company, samples of their new sockets, switches, single and double pole, and Mr. J. M. Orford was in attendance looking after the interests of his company, as well as representing the Bridgeport Electric Light Company.

THE JENNEY ELECTRIC MOTOR COMPANY, of Indianapolis, exhibited, in conjunction with the above exhibit, a 7½ h. p. Jenney electric motor, and a Jenney dynamo. These motors and dynamos are equipped with their new carbon brushes, which bear vertically on the commutator, and the carbons of which are kept in good contact by a series of springs.

DANSEREAU'S ELECTRIC WIRE SUBWAY SYSTEM was exhibited by itself, and attracted some attention by its possibilities. The subway is built at the sides of the street, next the curb-stone, and the model showed a section of the street at a crossing, and was very complete in every detail.

ROBERT MITCHELL & COMPANY, of Montreal, had a very pretty exhibit of all kinds of electric light fixtures and brass and bronze chandeliers, all manufactured in Montreal. They were of extremely tasteful design and presented a very pleasing appearance. Mr. Robert Mitchell represented the company.

THE PERU GLASS AND CARBON COMPANY, of Peru, Ind., showed samples of glass jars and carbons for all kinds of batteries. They had mounted on one of their boards a large piece of carbon about two feet long and four inches in diameter. The Peru Company will make carbons for any style of battery.

THE CROCKER-WHEELER MOTOR COMPANY, of New York, was represented by Dr. S. S. Wheeler and Mr. George W. La Rue. They exhibited a $\frac{1}{16}$th h. p. 10 ampere arc motor driving a 16 inch fan, and a ¼th h. p. arc motor, with a new automatic governor for controlling the speed. Fireproof indestructible resistance boxes and regulators combined were also shown in operation, by which any speed on a motor may be obtained. They showed a 1 h. p. 110 volt incandescent circuit motor, of the reversible type, which can be run in either direction without changing the position of the brushes. This motor was shown driving a 5 light dynamo of the new pattern, with a new style of ventilated armature. The regular $\frac{1}{16}$th h. p. fan outfit was shown and the "La Rue combination" electric fan, consisting of a ¼th h. p. electric motor, mounted on a fan base and driving a 24 inch exhaust fan 600 revolutions per minute. Both the motor and the fan were provided with self-oiling bearings. In another part of the hall they exhibited a ¼th h. p. fan outfit, and a Crocker-Wheeler "Infant" dynamo, of two light capacity. They also showed Crocker-Wheeler motors driving sewing machines of various sizes. The exhibit was in charge of Mr. La Rue.

THE INTERNATIONAL OKONITE COMPANY, of New York and London, had a very tasteful display of their wires and cables, and were represented by Capt. Willard L. Candee, Mr. George T. Manson and Mr. Jean A. Wetmore. They showed a very complete lot of sample reels of all kinds of wires and cables, underground and submarine. Two large drums of "Acme" lead cable, recently described in the columns of THE ELECTRICAL ENGINEER, were shown, these cables being specially designed for high tension underground work. Aerial wire, lamp cords, Manson and Okonite tape, improved Candee wire, were all displayed in profusion, there being a large pyramid of Okonite and Candee tapes in the centre of the exhibit. Special mention should also be made of the very handsome sign board on the grand staircase of the hotel, with the letters of the name and address of the company all made out of submarine armored cable of large size, and tastefully arranged.

THE HART AND HEGEMAN MANUFACTURING COMPANY, of Hartford, Conn., were represented by Mr. G. W. Hart, the inventor of the well-known Hart snap switch. They exhibited a complete line of these switches from 5 ampere single pole to 100 ampere double pole. The 15 ampere double pole switch, which they have just brought out, was shown and attracted considerable attention on account of its accurate work and exceptionally long break. Mr. Hart also showed a sample of a 100 ampere double pole switch mounted on slate, with connections arranged so as to conveniently fit on to the bus wires in a central station. The movements of Hart switches are all rotary, the make and break are instantaneous, and the current passes from one contact to the other through solid metal and not through pivoted joints.

THE GLOBE ELECTRIC CORDAGE COMPANY, of Philadelphia, exhibited samples of their flexible silk and cotton-covered cords for incandescent work. To show the excellence of their manufacture, an incandescent lamp was shown burning through a flexible cord which was immersed in a jar of water.

THE AMERICAN CIRCULAR LOOM COMPANY, of Boston, were represented by Mr. A. S. Clark, of Boston. As advertised, Mr. Clark was forced to make "moonlight" excursions to show up the peculiar virtues of his insulated wire.

ALUMINIUM CARBON COMPANY, LIMITED, of Buffalo, had their representative, Mr. Fred. V. Doty, on the ground to look after their interests. If personal appearance can sell carbons, the Aluminium Company ought to do a large business.

THE MASSACHUSETTS ELECTRICAL ENGINEERING COMPANY, of Boston, were represented at Montreal by Mr. R. Vose, who circulated around in a modest manner, leaving neat little sample bobbins of tested fuse wire wherever they would be appreciated.

C. MCINTYRE & COMPANY, of Newark, showed samples of their valuable McIntyre connectors, and Mr. C. H. McIntyre looked well after the interests of his company in his usual happy and affable manner.

WM. SCLATER & COMPANY, of Montreal, exhibited a comprehensive sample lot of all kinds of asbestos covering for steam pipes, cotton waste, and asbestos packing for cylinders and piston rods.

THE NATIONAL CARBON COMPANY, of Cleveland, were well represented by Mr. C. D. Smith, who quietly distributed numbers of their useful electrical directory, and talked "carbon" when desired.

THE PERU ELECTRIC MANUFACTURING COMPANY, of Peru, Ind., exhibited a fine sample board containing a number of their special cut-out and branch boxes of all sizes, made out of porcelain.

THE THOMSON-HOUSTON INTERNATIONAL ELECTRIC COMPANY was represented by Mr. George W. Davenport, Mr. Lomax, Mr. Chauncy Belknap, Mr. J. W. Kirkland, and Mr. J. H. Waterman, who had complete charge of the erection of the exhibit, and who accomplished wonders in the short time at his disposal, having set up over 40 tons of material in less than two weeks.

THE TORONTO CONSTRUCTION AND ELECTRIC SUPPLY COMPANY, of Toronto, Can., were represented by Mr. Fred. Nicholls, manager, and Mr. George C. Stannard, who was in charge of the exhibit, and Mr. A. J. Christie, of St. Johns, N. B. They exhibited a large board showing the new "Vulca" ducts and interior conduit, recently brought out by the New York Insulated Wire Company. The board was fitted with all the necessary junction boxes, branch boxes, elbows, bends, and samples of connections were exhibited to show how to make joints in the tubes. The system is completely worked out, and everything is now in readiness for the complete equipment of buildings. The ducts are made of a rubber compound, are perfectly water-proof and have a certain amount of elasticity. This is the first time tne system has been shown. Mr. James W. Godfrey and Mr. George H. Meeker, and Mr. Augustus Noll, of the New York Insulated Wire Company, were in attendance to explain the system. All types of Grimshaw wires and cables were exhibited, and rolls of Grimshaw tape. The Toronto Company are sole Canadian agents for the Grimshaw and "Vulca" specialties. The Toronto Company also exhibited three Ward arc lamps, for which they have the Canadian agency, one working on a 50 volt alternating circuit and two on a 110 direct incandescent circuit. Crocker-Wheeler motors, already noticed, were shown in operation, one of them driven as a dynamo, by a 1 h. p. Eddy motor, exhibited by the Toronto company, as agents for the Eddy Electric Manufacturing Company, of Windsor, Conn., who were represented at the Convention by Mr. A. D. Newton and Mr. M. E. Baird. The Toronto Company showed also a complete imported line of very beautiful switches, cut-outs and rosettes, and showed samples of Samson batteries, Hussey blue stone batteries, Crosby dry batteries, flexible brackets, cigar lighters, and all sorts of household goods. A line of instruments from James W. Queen & Company, of Philadelphia, were exhibited, as also instruments from the Standard Thermometer Company, of Peabody, Mass. At the back of the exhibit, hung on the wall, were large sample boards showing a complete line of goods, including bells, annunciators, push buttons, etc., manufactured by The Partrick & Carter Co., of Philadelphia.

THE RIES ELECTRIC SPECIALTY COMPANY, of Baltimore, Md., represented at the Convention by Mr. Elias E. Ries, president, and Mr. Lewis S. Greensfelder, vice-president, exhibited a regulating socket for alternating circuit incandescent lamps, by means of which the brilliancy of the light can be varied as desired, from full brilliancy to a dull red when the lamp is only consuming about one-tenth of the current consumed when burning up to full candle-power. One is thus enabled to handle the lamp in the same manner as has been customary with gas jets. A sample lamp fitted with the Ries socket was shown with a small ammeter in circuit, and as the lamp was "turned down" it was clearly shown that it consumed current proportional to its brilliancy. This device thus saves a large amount of current, when the lamp is not required to be up to candle-power, and, it is claimed, saves the filament of the lamp, as the current cannot be switched on suddenly, but has to pass all the gradations of the socket. The Ries Company are making two sizes of these regulating sockets, one for lamps from 16 to 25 c. p., and the other for lamps of from 32 to 50 c. p. There is no resistance used in the mechanism, but the working of the socket depends upon a small choking coil. Though a small exhibit, it attracted a vast amount of attention, the novelty of being able to "turn up or down" an electric lamp appearing to attract not only electricians, but the general public in large numbers. The Ries socket may be said to have formed the most interesting feature of the exhibition.

THE STANDARD UNDERGROUND CABLE COMPANY, of Pittsburgh, New York and Chicago, were represented by Mr. George L. Wiley, of New York, and Mr. J. W. Marsh, of Pittsburgh. The exhibit, though not large, was unique in its way. The initials of the company, "S. U. C. Co.," formed of rolled brass, about a foot long, were mounted on a wooden base, and short samples of underground cable were attached to the frame work of the letters, making a very pleasing combination. There was also a sample board containing a few samples of the 82¼ miles of underground arc light, incandescent and power cables recently sold to the Minnesota Brush Electric Company, of Minneapolis. Samples were also shown of 1,750,000 feet of No. 4 B. & S. wire, sold for underground work in the cities of New York and Washington.

THE RUSSELL ELECTRIC COMPANY, of Boston, were represented by Mr. H. E. Chapman and Mr. H. Dewar, and exhibited the Russell disc carbon arc lamp, which is now so widely and favorably known. Two 18-hour and two 12-hour lamps were shown, though most attention was paid to the "Baby" lamp, which measures only 27 inches over all, and 23 inches from the hanger board, and burns eight hours at 1,200 c. p. The Russell lamps have now been tried for nearly a year in practical work and are giving good satisfaction all over the country.

THE STEELE & JOHNSON MANUFACTURING COMPANY, of Waterbury, Conn., were represented by a Mr. A. H. Mills, who carried most of his exhibit around in his pocket, in the shape of incandescent lamp shade-holders and other samples of sheet metal work, turned work of every description, castings, and machine screws.

GERMANIA ELECTRIC COMPANY, of Boston, represented by Mr. Otis K. Stuart and Mr. Harry Bottomley, made a very beautiful and interesting exhibit of the improved Schaefer incandescent lamps and Freeman transformer. The design for showing the lamps was unique in its way, and attracted a good deal of attention by its clever arrangement. In the back of their exhibit was situated a large white cabinet with gilt moulding, containing fifteen folding shelves or drawers. On opening these shelves rows of incandescent lamps were displayed upon various colored felt background, which, as the shelf was lowered into a horizontal position, became illuminated, the current entering through a brass quadrant attached to each shelf. On these shelves were mounted various designs of the improved Schaefer lamp; some being ordinary plain glass, others colored by a special imported process, by which the fading of the color is made impossible. There were also exhibited a number of lamps showing the Khotinsky matting process on the lamp, by which an effect is obtained similar to ground glass. These matted lamps give an apparent increase of candle power, though there is an actual loss of somewhat less than five per cent. In other shelves were shown lamps with double filaments, lamp with twisted filaments, and lamps with tied filaments for railway work, the filaments being tied by small platinum pieces to prevent their vibration. The current for these lamps was derived from three Freeman transformers, mounted at one side of the exhibit, which have only recently been put on the market. They are built on an entirely new design and are said to be the lightest transformers made. In one corner of the exhibit was shown an elegant piano lamp, showing the application of the incandescent lamp for this purpose, and on a table was displayed a very tastefully designed fanciful exhibit representing a camp fire, with a pot boiling. The effect was produced by placing a red colored lamp amongst a number of twigs representing a log fire, over which was suspended a purple colored lamp in a white opal shade, which resembled a pot hanging over a camp fire for the preparation of the evening supper. In addition to the lamps, the Germania shade holder and socket were shown, the shade-holder especially attracting much attention amongst electric light people, as it has no detachable parts nor screws to work loose.

H. WARD LEONARD & COMPANY, of New York, were represented by Mr. H. Ward Leonard and Mr. A. S. Vance, and showed an entirely new method of operating an electric motor, extremely interesting to electricians, as results are achieved never before thought possible. Mr. Leonard showed an Edison dynamo furnishing current direct to an Edison motor, which was geared direct by a worm wheel to a hoist, which raised and lowered a heavy weight. By Mr. Leonard's arrangement, the speed of the motor, as well as the torque, can be varied independently, and the number of watts required by the motor varied directly with the work done under all conditions. This system or arrangement is not only new in electric devices, but is an entirely new principle in mechanics, for up to the present time there never has been any motor, steam, water, gas, electric or otherwise, which would enable one to attain any speed desired, and hold that speed constantly, when the load varied from zero to its maximum. The control of the motor is effected by an electric device, which consumes only a quarter ampere. The speed is increased or decreased at will, and the direction of rotation can be instantly changed. The application of this principle is almost universal, the most important being to hoists, railways, elevators, pumps, planers; in fact, to all classes of work in which it is desired to vary the speed and vary the pull or torque. Mr. Leonard cannot disclose at present the principle underlying his invention, owing to his foreign patents, but will read a paper soon before the American Institute of Electrical Engineers, when the system will be fully explained. In the exhibit shown it was decidedly curious to see a motor doing heavy work, while the armature was only running at a very few revolutions per minute, in fact, just visibly crawling round.

THE NORWICH INSULATED WIRE COMPANY, of New York, were represented by Mr. F. Day Voorhees, who had fitted up for them a very tasefully designed stand. The exhibit consisted of a number of reels and coils of saturated and dry paper insulated, lead covered underground wires for electric light and power, high insulated line wire, house wire, office wire and waterproof magnet wire. All these wires and cables are covered with paper insulation specially prepared, the waterproof magnet wire making a particularly interesting exhibit to builders of electrical apparatus, especially those who build railway motors. A new form of T and straight splice for arc light underground joints was shown, consisting of a brass casting in halves, with a recess to fit the cables and a rubber gasket, also in halves, to protect the bared part where the joint is made. The two halves of the casting are then screwed tightly together, making a perfectly waterproof joint. The cables of the Norwich company are all covered with lead at their own factory, by a special patented process of their own, which is subject to no royalty.

L. E. WILCOX & COMPANY, of Meriden, Conn., exhibited a number of their "Speed" wire stretchers, which are calculated to save a large amount of labor in running wires and enable a wireman to make work neat and symmetrical.

THE CANADIAN ELECTRICAL CONSTRUCTION, MANUFACTURING AND SUPPLY COMPANY, of Montreal, were represented by Mr. A. J. Corriveau, whom everybody knows, and to whose untiring efforts much of the success of the Convention was due, from a scientific and social point of view. To describe his exhibit, is impossible, as he represents (we prefer to call the exhibit Mr. Corriveau's, as we strenuously object to print more than once the headline under which this note is written. The name of the company is all we have against Mr. Corriveau) many of the exhibits already enumerated, amongst which are the Thomson-Houston International Electric Company, the Fort Wayne Electr c Company, the Excelsior Electric Company, the Simplex Electrical Company, the Crocker-Wheeler Motor Company, the Economic Electric Manufacturing Company, the Bryant Electric Company, the Standard Oil Filter Company, and many others. Mr. Corriveau's headquarters were in the kiosque, built especially for this exhibition by the Simplex Electrical Company, of Boston, and described elsewhere, but he was to be found everywhere, attending to everybody's wants, and giving all a true Canadian welcome. His efforts to entertain and please will not soon be forgotten.

SIMPLEX ELECTRICAL COMPANY, of Boston, the manufacturers of the famous wire upon which the "Sun Never Sets," had probably the most artistically designed exhibit in the hall. In the centre part of the building they had erected a beautiful kiosque of unique design, built entirely of wire, and manufactured at their own factory in Boston. This was lit up by Economic incandescent lamps, and made a specially attractive display. Mr. Corriveau used the kiosque as headquarters of his exhibit, and had installed in it a small desk and comfortable chairs for his own and the Simplex company's many guests. The word "Simplex" in large letters adorned the the top of the kiosque and reels of Simplex wire were displayed all around. It was whispered also that a large amount of Simplex wire had been used for the wiring of the numerous exhibits in the hall. Dr. A. F. Mason, of Boston, was in attendance at the Convention, as usual, renewing many old friendships and making many new ones.

THE STANDARD PAINT COMPANY, of New York, manufacturers of the famous P. & B. compounds, were represented at the Exhibition by Mr. R. L. Shainwald and Mr. Frank S. DeRonde, of New York, and Mr. W. W. Castle, of Boston, who interviewed their numerous friends beside two tables representing the letters P. & B. They showed a sample representing the roof of a central station painted with P. & B., and carrying two poles painted with P. & B. and supporting P. & B. insulated wire; also a complete sample of P. & B. paints, tapes, armature varnish, insulating compounds, and papers. A genuine stuffed rooster, the trade mark of the company, graced the exhibit, and bore in its beak a small incandescent lamp. Mr. Castle also showed samples of P. & B. conduit, which is handled by a separate company.

THE JEWELL BELTING COMPANY, of Hartford, Conn., occupied a prettily draped booth, and had a variety of samples of leather belting on exhibition. Mr. C. L. Tolles had the honor of representing the Jewell company alone as Mr. C. E. Newton found it impossible to be present, much to the regret of his many friends. The exhibit consisted of a 30-inch double belt for the Manufacturer's Electric Light Company, of Philadelpha, and several other double belts built for electric railway work, made of especially thick leather for this purpose. A picture of the factory adorned the exhibit, and also a photograph of the heaviest belt in the world which the Jewell company built some time ago, and which weighs 2,730 pounds, is made four ply, and transmits 1,500 horse power.

MR. FRED. W. ROYCE, of Royce & Marean, of Washington, D. C., without whom no convention would be complete, was on the ground and exhibited the Carpenter storage battery. The active material consists of native carbonate of lead or "Cerusite," which is contained within a hard rolled lead shell which is perforated, to admit of the circulation of the electrolyte. It is claimed that the cell will not buckle and the active material is so held that it is impossible for it to become separated from the plate. The cell is said to weigh from one-third to one-half less than the usual type of storage cell for the same output. A local company has been formed in Washington to exploit the Carpenter battery.

THE STANDARD ELECTRIC TIME COMPANY of New Haven, Conn., represented by Mr. C. D. Warner and G. W. Hutchinson, had an interesting exhibit of the Warner system of electric time, furnishing accurate time to the exhibition hall. In the small space allotted to the company they had fitted up one self-winding regulator fitted with the Warner system, which furnished electric time to three 24" dials, and six smaller dials distributed throughout the hall, in various departments. They showed also an ordinary self-winding clock and a synchronized self-winding clock. In addition to the clocks the well-known Warner electric gauges were shown, both for station and battery use.

THE THOMSON ELECTRIC WELDING COMPANY had an interesting board mounted with a complete line of samples of copper, brass, rods, chains, etc., welded by electricity. The exhibit was included in Mr. Corriveau's territory.

THE E. S. GREELEY & COMPANY, of New York.—Among the scientific and technical class of visitors at the exhibition great interest was taken in the exhibit of this company from the distinctively pronounced character of their display in standard measurement apparatus, embracing as it did their American pattern of the Thomson galvanometer, with various modifications and patented improvements, also several types of galvanometers, such as the Western Union Standard, Helmholtz Gaugain, half-meter ring, sine and tangent combined, and particularly a model of a new form of Ballistic galvanometer, which has not yet been placed upon the market. In fact, a line of galvanometers so complete as to fill every requirement in all departments of electrical measurement.

Not less complete was the display of rheostats, testing sets, high resistance boxes, many of which latter were of new design, in addition to their regular advertised lines of portable apparatus and standard resistance boxes.

Their telegraph department was also well represented by the renowned prize-winning Victor telegraph-key, with sounders, relays, switches, and incidental apparatus innumerable. Their improved ink-recording register was deserving of special mention, as it is so justly a favorite in Morse, district telegraph and fire-alarm work, owing to its accuracy and reliability. A peculiarity in the service of this register is its employment on railroad and other telegraph lines in the capacity of a "tell-tale," as its provisions for self-starting and self-stopping enable it to make a complete record of all that transpires on the wire during the day without waste of space or paper and permits each day's work to be filed away, giving a complete record for future reference.

In addition to the above was shown a full line of electric light and power appliances, amply testifying in their character and number not only to the difficulties of keeping pace with electrical progress in this direction, but also the fact that the Greeley Company succeeds in doing it. Electric bell, burglar and fire-alarm and general house supplies with their annunciators push buttons, and other paraphernalia were displayed in full force. Of the only two primary batteries put on exhibition at Montreal, one was presented by the Greeley exhibitors, and that one was the now well known Champion Battery, which for the past year has been exciting the attention of all users of this class of goods. It has been remarked by Custom House officials that outside of those exhibiting expensive apparatus, such as large dynamos and motors, the Greeley exhibit, probably, intrinsically represented the highest value of any contribution sent into the country, while the decoration of their booth was everything that taste, skill, patriotism and liberality could suggest.

THE FORT WAYNE ELECTRIC COMPANY, of Fort Wayne, Ind., had in their exhibit one 750 light compound-wound "Slattery" alternating dynamo. Off this machine were run about 150 incandescent lights which were used to light the "kiosque" where Mr. Corriveau had his office. They also exhibited one 15 light "Wood" arc dynamo, with full complement of lamps. This machine was used to light that part of the building in which the exhibit was situated. The Fort Wayne Company have very generously donated this arc apparatus to the Department of Applied Science of the McGill University. The alternating machine has been sold to the Electric Light & Power Company, at Lachine, (together with a 50 light "Wood" arc, 1,200 c. p). Power to run this exhibit was furnished by the Royal Electric Company from their works, over a mile from the exhibition hall. A 50 h. p. generator and two motors, one 15 h. p. and the other 35, manufactured by the Thomson-Houston Company, Boston, were used to transmit this power. The belting used by the Fort Wayne Company on their exhibit was furnished by the Charles A. Schieren Company, New York. This exhibit also contained two Bradley alternating fan motors which were very much admired. The Fort Wayne Company were represented at the exhibition by their general agent, Mr. W. J. Morrison. Mr. R. L. Denis was the electrician who had charge of the plant.

THE ENGINEERING EQUIPMENT COMPANY, of New York and Boston, were represented by Mr. F. A. Magee, of Boston, and Mr. W. F. D. Crane, of New York. They exhibited samples of the Anderson trolley, the new Ætna lamp hanger, indurated fibre pipe, and samples of Underwood cotton leather belting. Mr. Magee is a valuable man on such occasions due to the fact of his large acquaintance amongst electrical people. So, too, with Mr. Crane.

THE HAZELTINE ELECTRIC CO., of St. Louis, were represented by Mr. Hazeltine, who showed in the Fort Wayne exhibit, on an arc lamp, his "carbon protector," which has been illustrated in THE ELECTRICAL ENGINEER, and which serves to prolong greatly the life of the carbon, and thus cuts down the labor required in trimming.

ROBIN & SADLER, of Montreal, exhibited a few samples of leather belting, made for the Royal Electric Company, of Montreal, and showed their special dynamo belt.

DRAKE, PAYSON & WHITTIER, of Providence, R. I., were represented at the Convention by Mr. R. H. Whittier, who appeared to enjoy the Canadian hospitality to the full.

THE ELECTRICAL PRESS was very much to the fore as usual, all the papers being well represented. Mr. Fred DeLand acquitted himself nobly on the familiar bulletin of *The Electrical World;* while *The Electrical Age* also, for the first time, went into the bulletin business in great shape, its sheet being partly printed in colors—besides securing some excellent group portraits of the delegates. THE ELECTRICAL ENGINEER, besides holding a long reception from Sunday to Sunday in its hotel parlor, had a space reserved in the exhibition for the general distribution of copies of the paper, circulars, etc.

THE WESTERN ELECTRIC CO. were represented by Mr. S. A. Chase, who had a genuine "multum in parvo" exhibit in some wonderful trunks, which seemed to contain everything but a telephone exchange and a central station. Mr. Chase has shown great judgment in collecting his samples and still more success in selling from them. He has recently been making an Eastern trip, and found his way to Montreal in search of new worlds to conquer.

JAMES W. QUEEN & CO. were adequately represented by Mr. E. G. Willyoung and by a small but excellent display of their apparatus, including the new photometer, illustrated in these columns last week; a new portable testing set, a combined portable galvanometer and battery "fault-finder," and a new design of Siemens electro-dynamometer.

THE ABENDROTH & ROOT MFG. CO., mindful of the fact that steam boilers are a big feature in central nations, distributed copies of their very handsome pamphlet on that subject, describing their own well-known apparatus, and embracing much valuable data.

THE GOULD PACKING CO., of East Cambridge, Mass., exhibited samples of their steam and water packing that has become so popular in central station steam plants and is in rapidly increasing demand.

THE CARD ELECTRIC MOTOR AND DYNAMO CO., of Cincinnati, gave away copies of the handsome and instructive catalogue recently issued by them, descriptive of their well known motors, &c.

THE RELIANCE GAUGE CO., of Cleveland, O., called attention to their various good qualities of their Reliance water columns, in the way of securing vigilance from employees, economy in fuel, increased safety, etc.

JAMES LEFFEL & CO., of Springfield, O., circulated copies of a new and useful catalogue describing their various productions and giving a good deal of valuable information as to turbines and other power transmission machinery.

THE PRIOR INSULATING JOINT, was also shown in Mr. Corriveau's headquarters, though Mr. Peck, of Boston, carried one around in his pocket and showed it to all interested in this class of goods.

LEWISSOHN BROS., the great copper house of New York, were on the spot in the person of Mr. S. Rosenstamm, whose good humor reflected a rapidly improving condition of the market with many large sales.

THE BROOKS CARBON WORKS, of Peterboro, Ont., were represented by Mr. J. W. Taylor. This concern is in the field to produce carbons in Canada the equal of any made in the United States.

THE E. P. GLEASON M'F'G CO. were represented by Mr. W. F. Cullen, who made a neat display of their glassware and various electric light details in his room at the Windsor Hotel.

THE SHULTZ BELTING CO., of St. Louis, were represented by their vice-president, Mr. W. P. Mullen, of Boston, who showed some fine samples of their products.

THE BRIDGEPORT BRASS CO. was represented by Mr. H. D' Stanley, who bore the burden of responsibility with his accustomed cheeriness and alacrity.

MR. H. A. ROGERS, the well-known dealer in New York in electrical and machinists' supplies, was an attendant at the Convention.

THE SMITH & VAILE steam pumping machinery was represented by Mr. J. M. Duncan, who distributed pithy literature on that subject.

FELTEN & GUILLEAUME, of Germany, were to have made an exhibit of their wires and cables, but it did not arrive on time.

THE NEW YORK BELTING AND PACKING CO., of New York, were on band with a variety of printed matter, data, &c.

GOULD & EBERHARDT, of Newark, N. J., circulated descriptions of their admirable drill presses, machine tools, etc.

THE EDISON GENERAL ELECTRIC COMPANY, CANADIAN DISTRICT.—The largest exhibit in the hall was made by the Edison Company, who occupied floor space extending the whole length of the hall and across one-half. The motive power was derived from the McGill University, where there was installed a small power plant, consisting of a 150 horse power Laurie engine, a 120 horse power Edison 500 volt generator, and a 50 light Edison arc light dynamo. The current was brought over No. 00 wires to a 500 volt 120 horse power motor in the exhibit, which was belted to a 100 horse power generator, which furnished current to all the Edison exhibit and to various lamps distributed through the hall.

An interesting feature of the Edison exhibit was the miniature central station, deriving its power from a 1 horsepower motor. Two ¼ h. p. generators were shown coupled up as a three-wire system, through a regular station switchboard, to a complete system of underground Edison tubes. In the centre was a junction box, one feeder running into it, and two service taps connecting with mains, forming a square with joint boxes and everything complete. The junction box was shown open and in section, to show clearly the inside wiring. The little station was shown in actual operation and furnished current to two chandeliers, one at either end of the hall. Three braiding machines were shown working, making silk-covered cord, and driven by a 1 h. p. motor. A ¼ h. p. motor was shown, driving a Wing disc fan, and a 1 h. p. motor was keeping the air circulating by being coupled to a Sturtevant blower. A large reel of lead-covered cable was in close proximity to these exhibits, and also coils of copper wire drawn at the Edison works at Peterboro, Ont. In the middle of the floor was arranged a very beautiful stand of flowers, interspersed with incandescent lamps of all hues, topped by a bronze figure of "Night" holding over her head an incandescent lamp in the shape of a sphere. Here also were exhibited an Edison diamond drill, an Edison coal cutter, and an Edison percussion drill. An interesting board was set up in the middle of the exhibit, containing a number of very beautiful specimens of amber mica, taken from the Lake Girard Mines, at Wakefield, P. Q., Can.

Crossing the centre aisle of the exhibit, the beautiful fixtures attracted the eye, the fixture in the centre exhibit of the hall being valued at $600. A most complete line of fixtures was shown of most elegant design, made in bronze and other materials, with all kinds of lamps, including their most recent product, the beautiful "candle lamp." This is a lamp shaped like a wax candle, containing an incandescent filament, and being rated at 16 c. p. The effect of this lamp is distinctly novel and attractive.

Near by was shown a 30 light Edison arc machine, and a complete line of Edison dynamos from 80 h. p., tapering down to a ¼ h. p. machine. In connection with this was also shown a miniature dynamo, with complete working parts, the whole machine measuring but 1 inch high and 1 inch long.

Passing along, the lamp shades of very beautiful design formed a pleasing picture, and a sample board of all kinds of incandescent supplies also attracted attention. Some of these shades were very artistic, one being shown of ruby cut glass worth $22.50; the aluminum shades were also much admired. An interesting board containing samples of incandescent lamps in all stages of their manufacture attracted much attention. At the extreme end of the exhibit were shown glass cases of all kinds of Edison supplies, Edison-Lalande batteries, meters, wires, cables, magnet wire, office wire, flexible cords, and a large rack containing samples of all sizes of Edison underground tubes. In the gallery the Edison company exhibited a Huntington search light, receiving current from one of their generators.

The exhibit was in direct charge of Mr. F. A. Barr, of the Edison Canadian district, ably assisted by Mr. W. R. Rosenstengel, to whom great credit must be given for affording so complete and interesting an exhibition of the Canadian Edison industries.

THE THOMSON-HOUSTON INTERNATIONAL ELECTRIC COMPANY, of Boston, made a very complete exhibit of electric light and power appliances, covering about one quarter of the floor space of the hall. As in the exhibit of the Edison company, the electric power was derived from a generating plant at the McGill University, consisting of a 120 h. p. McIntosh and Seymour engine, driving two 50 h. p. 500 volt Thomson-Houston generators. Six No. 0 wires conducted the current to their main switch-board in the exhibit hall, which was fitted up with a main switch, and four circuit switches, the current being distributed by bus wires. From the switchboard, current was taken to a 75 h. p. motor, which furnished the power to drive a 650 light alternator and exciter, lighting a bank of 400 lights under the band stand, and also a series of twenty 50 c. p. lamps distributed on goosenecks round the exhibit. A 45 h. p. motor was shown driving a 50 light Excelsior arc dynamo, furnishing current to 7 arc lights outside the building and 12 arc lights inside the building, and also to a 10 h. p. Excelsior motor. In connection with these dynamos and motors were shown an alternating switch-board, complete with resistance boxes, ammeters and voltmeters. The new arc light plug switch-board was also exhibited, fitted with lightning arresters, and all in complete working order. Coming down to smaller sized motors, a 15 h. p. Thomson-Houston motor was shown driving a 15 h. p. 110 volt incandescent dynamo, lighting 100 16 c. p. lamps distributed throughout the building. This dynamo was also used to furnish current for the Crocker-Wheeler exhibit, the Thomson-Houston International Company having recently been appointed exclusive foreign agents for the Crocker-Wheeler specialties.

Next in order was shown a 10 h. p. motor driving a special generator of 220 volts, supplying current to operate a Van Depoele reciprocating rock drill, being equipped with a third revolving brush, the invention of Mr. C. J. Van Depoele. This dynamo also furnished current for a 15 h. p. electric hoist, used to raise a 500 lb. bale of cotton, and to a 5 h. p. electric mining pump. A special feature to be noted about this generator is the fact that it was shown operating ordinary rotating armatures and was at the same time furnishing current for a reciprocating drill. This part of the exhibit was furnished with a special switch-board, which had also mounted upon it various meters, all in operation, measuring the current being consumed from the McGill University, and also the current going out from the various dynamos shown in operation. These meters are the same type as those which were awarded the first prize this year at Paris. In connection with this switch-board was also shown a bank of 20 incandescent lamps controlled by a dimmer, as used for theatre work. The electric hoist shown was equipped with a 15 h. p. motor, geared to the drum by means of a friction clutch and strap brake for lowering. The electric pump shown was manufactured by the Goulds Manufacturing Company, of Seneca Falls, N. Y., and is fitted with three cylinders 4 x 6, with a capacity of 100 gallons per minute, and operated by a 5 h. p. motor on the same base, specially waterproofed.

The Thomson-Van Depoele rock drill exhibited was of the type known as "D." and is equipped with drills to make 1½ to 2 in. holes. Practical experiments in the hall showed it to have a penetrating capacity of about 2½ inches per minute on hard granite. There is no make and break of the electric circuit in the plunger, and the plunger is always magnetized in the same direction. At the further end of the exhibit there was erected a pyramid of wood fitted with 21 type "S" transformers, all in service, connected up in ten circuits of 40 lamps each, each circuit being controlled by a switch on the pyramid. A sample board was also shown containing a complete line of switches, cut-outs, etc., also all electric light supplies. A Robinson radial car truck fitted with two 15 h. p. single reduction motors completed the exhibit. A neat little office was annexed at one end for the reception of guests.

The Ferracute Machine Company, of Bridgeton, N. J., were represented by Mr. Fred. F. Smith, secretary and treasurer. Mr. Smith showed a pamphlet giving cuts of their various presses, from a small foot-press up to presses weighing 20,000 pounds, for the manufacture of all kinds of metal goods required in electrical work. Their presses are divided into five different kinds, as follows: (1) Presses for punching out tin and brass and light metals. (2) Heavier presses for cutting thick metals and also for shearing and punching. (3) Double action or drawing presses for producing all kinds of deep articles in sheet metals. These machines are extensively used in electrical work for parts of electroliers, gauges, push buttons, shells and parts of lamps. (4) Very large presses for cutting out armature discs, and large sheet metal work. In connection with these presses, Mr. Smith showed some photographs of a mammoth cutting press, the largest ever built in this country, being 100 inches between columns, having a total length of 12 feet, and weighing 19,000 pounds. To show the size of this large press, a photograph was displayed with seven men with their shoulders and heads extending through between the jaws of the press. (5) Punching and shearing presses for heavy girder, bridge, and other heavy work. The machines of this class stand high, but occupy a very small floor space. The Ferracute Company also make dies of every description to suit the above machines, and exhibited a number of samples of the kind of goods manufactured by these machines. They are at present getting out special presses for coining, and have recently built some machines for the United States Mint.

The Eureka Tempered Copper Company, of North East, Pa., had a very interesting exhibit of their goods in charge of Mr. N. S. Possons, general sales agent, assisted by Mr. J. B. Phillips. Mr. Possons was for 12 years general superintendent of the Brush Electric Company at Cleveland, and brings a valuable practical experience to aid him in selling the Eureka metal. On a convenient board the Eureka Company exhibited samples of commutator segments and brushes for arc and incandescent dynamos, finished commutators, samples of tempered wire for trolley work, or for work where great strength is required. They showed also the Eureka trolley wheel which is made with detatchable sides, the centre piece being tempered extra hard, and having a metal-line bushing. A large number of samples were also shown as they come from the sand, sheet metal in all thicknesses, bearings, soldering irons of various sizes, one of them being of immense size for soldering trolley joints. It is worthy of note that the tensile strength of Eureka tempered copper wire is increased to 64,000 pounds per square inch, with a compression strain of 109,000 pounds to the square inch.

The La Boiteaux Electric Motor and Fan Company, of Cincinnati, O., attracted vast attention with their novel oscillating fan motors, and were represented by Mr. F. M. La Boiteaux, the inventor. The motor is fixed upon an upright shaft which is considerably out of line with the centre of the motor. The natural effect is, therefore, when the motor is running, for one side of the motor to recede, and as it continues receding the motor slowly revolves, distributing the blast of air in every direction, instead of in one unvarying direction. This style of motor is specially adapted for setting in the centre of a room. The action of the oscillating motor is as follows: A bracket is supported from the base of the motor, supporting a horizontal flat surface shaped in a circle having for its centre the centre of the motor, or vertical shaft upon which the motor oscillates. The shaft of the armature extends out to this bracket, and in turning with the motion of the armature, its friction on the horizontal bracket causes the motor to oscillate in one direction until the shaft is carried past the bracket. Its motion is then stopped by rubber covered stop-pins and the shaft then comes back to the bracket, but this time rotates on the underside of the bracket, and as the armature is always running in one direction, the direction of oscillation is thereby changed. The principle is extremely simple, but ingenious and effective, and makes a very convenient combination for fitting up on one wall or corner of a room, as it assists in distributing the breeze over its entire area, and is undoubtedly a great improvement upon existing fan motors.

The Ball Electric Light Co. of Canada, Toronto, Can., were represented by Mr. W. A. Johnston, manager, and had an interesting exhibit of the Ball apparatus, which is peculiarly different in design from any other type of dynamo. First, they showed a 7 h. p. Ball 500 volt motor driving a 75-light incandescent dynamo, which furnished current to numerous lamps all around the exhibit. Another 7 h. p. Ball motor was shown driving a Ball double armature, two commutators, four ampere 35-light arc dynamos, furnishing current to about a dozen arc lights distributed round their space. These dynamos are capable of furnishing three 1,000 c. p. lamps to the horse-power and are largely used for factory and other kinds of internal work, besides street use. The Ball single-carbon arc lamps use a $\frac{7}{16}$ carbon, and as they run on only four amperes, they will burn all night without retrimming. This apparatus is all made in Toronto. In connection with this exhibit it may be noted that Mr. H. M. French, of Boston, was present, looking after the interest of Ball apparatus in general, and laying in a stock of information.

The Bryant Electric Company, of Bridgeport, Conn., were represented by Mr. W. C. Bryant and Mr. L. W. Eston. They made a very handsome display of the famous Bryant sockets, switches, cut-outs, and Orford pendants. The switches shown were for five and ten amperes, and they showed their new style of five ampere single pole switch, which has been so favorably received. The Bryant Company have just brought out a very interesting and beautifully illustrated catalogue of their goods, a copy of which every one in the electrical business ought to secure. The samples were all neatly mounted on a handsome board, specially designed for this Convention.

Delaware Hard Fibre Company, Wilmington, Del., represented by Mr. W. H. Stanhope, displayed a beautiful lot of samples of their product, embracing all kinds of insulated parts of electrical devices. Hard fibre tubes, rods, magnet heads, switch handles, washers, gear wheels, special parts for switches were displayed in great profusion, and made a very pretty exhibit. Hard fibre is now used for almost every kind of purpose, and it is hard to imagine any insulated part of a machine which cannot be made out of this material.

The Bernstein Electric Co., of Boston, had their exhibit adjoining that of the Ball Company and took the current from the Ball dynamos for their lamps. They showed a few very handsome interior or house fixtures for the Bernstein series lamp, and also showed the famous Bernstein street fixture and lamp, which is so well-known for municipal street lighting. These lamps were shown operating in series with the Ball arc lamps. They exhibited also a number of their switches, sockets, cut-outs, etc., and various apparatus required in the Bernstein series system. Mr. Henry B. Cram, of Boston, treasurer of the company, was present.

The Perkins Electric Switch Manufacturing Company, of Hartford, were carefully attended to by Mr. F. A. Davis, of Hartford, who had displayed in the centre portion of the hall a neat sample board of the well-known Perkins electric switches, sockets, and rosettes. In the centre of their board was shown one of their large 100 ampere switches, which attracted considerable attention by its clever arrangement and accurate workmanship.

Standard Oil Filter Company, of Chicago, showed one of their Ellis Filters, which have became so familiar a figure in electric light stations, and which are guaranteed to save central station men large quantities of oil in the course of a year.

THOMPSON & ROBERTSON, of New York, had an excellent exhibit of their new fibrous battery under the charge of Mr. Louis Walsh, who is ever ready to see his friends and impart information on the wonderful virtues of his new battery. Mr. Walsh is justly proud of the fact that he was the only exhibitor who had exclusively batteries to show. His pluck is to be admired. One of the fibrous batteries was shown ringing a bell, and at the time of writing these notes had been running continuously for four days, and showed no signs of abatement.

J. FITZGERALD, Montreal, exhibited in a convenient corner of the hall, an ingenious combination gas and electric universal bracket, with universal joints so that the bracket can be turned in any direction. The gas is conveyed in a small rubber pipe inside the brass pipe, and the electric wires are cotton covered and also run in a small rubber pipe, which is then twisted round the rubber gas pipe.

THE FIBRONE COMPANY, of New York, exhibited a complete set of samples of fibrone goods, including inkstands, brushes, switches, rosettes, cut-out boxes, push buttons, switch handles, and all kinds of bases for different electric devices. The samples were of all colors, from a pure white to a jet black, and made, as usual, a very pretty and attractive display.

THE GLOBE CARBON COMPANY, of Cleveland, Ohio, was represented by its general manager, Mr. Chas. Rodman. Mr. Rodman is naturally in good spirits over the increased facilities his company will enjoy after October 1, when they will remove into their new factory at Ravenna, Ohio. This factory has an output of no less than 100,000 carbons per day. Three railroads offer a choice in the matter of shipping, and the company owns land sufficient for a still further increase of the plant if necessary. Mr. Rodman has returned to Cleveland with a number of good orders in his pocket as mementoes of the Convention.

THE CARPENTER ELECTRIC COMPANY, of 620 F street, N. W., Washington, D. C., was ably represented by Mr. Fred Royce. The increased interest in storage-battery traction consequent upon a recent legal decision, gave Mr. Royce an opportunity to expatiate on the superiority of the Carpenter battery. The Carpenter Electric Company are now ready to place their batteries on the market, and will be glad to enter into correspondence with any one who may be interested in the matter.

BIG BELTS FOR ELECTRICAL WORK.

THE largest belt ever made in this part of the country, says the Concord, N. H., *Monitor*, is being prepared for shipment at the shops of the Page Belting Company. It was made for the Reading Electric Light and Power Company, of Reading, Pa., and is 58 inches wide, 127 feet long, and nearly one-half an inch thick, and 140 ox hides were required to make it. The largest ever made before this was 52 inches wide. The belt is securely pegged together and some of the best workmen in the employ of the company were engaged in producing it. With this belt there is also an order for 800 feet of 12-inch double dynamo belt for the same firm.

There have also recently been made by the Page Belting Company two belts 48 inches wide, one 97 feet long and the other 1.› feet long, for the Georgia Electric Light Company, of Atlanta, Ga. These are double and are made in the same manner as the large one first mentioned. Besides these, a recent order has been filled for a belt 26 inches wide and 90 feet long, for the electric lighting station in this city, and eight belts, 20 inches wide, to go on Edison dynamos in Chicago.

LIEB RAILWAY APPLIANCES.

AMONG the more recent specialties produced by the Lieb Machine Works, of this city, are those shown in the accompanying illustrations, Figs. 1 and 2. Fig. 1 shows a line cut-out box, designed

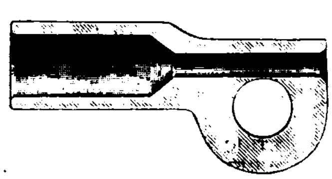


FIG. 2.—LIEB'S CABLE TERMINAL.

to fasten on wood or iron poles. The cover has an endless rubber ring for a packing to keep out moisture, and the safety fuses can readily be replaced. The casing is made all in one iron casting, and the interior mechanism is made of hard brass, all thoroughly insulated.

The cable terminal, Fig. 2, is very substantial, and, for switchboard work, commends itself particularly on account of its strength. These are made of various shapes and sizes. The end of the cable, after removing the insulating material, is introduced into the large hole, which fits over the insulating material, and the naked wires fit the smaller hole and project through, where they they are soldered. The insulating material acts as a cushion, and

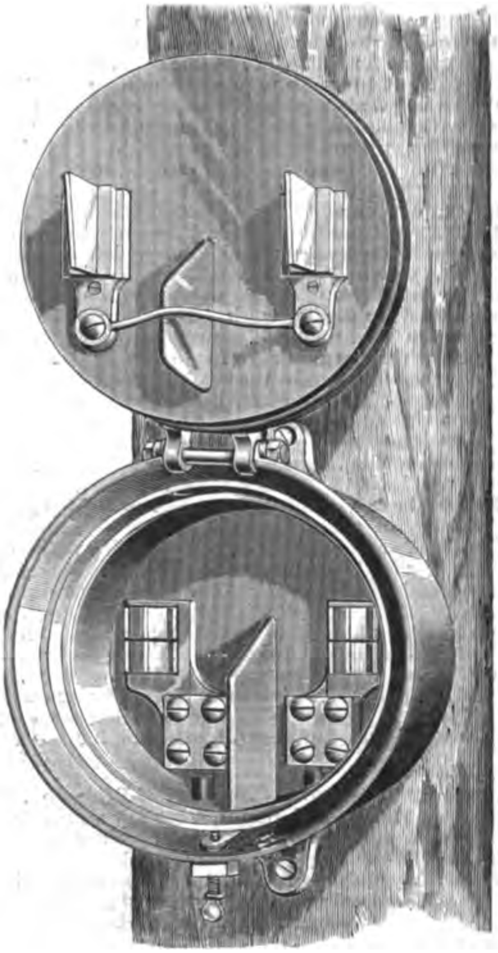

FIG. 1.—LIEB'S RAILWAY LINE CUT-OUT BOX.

prevents the cable from breaking, and, at the same time, protects and hides the end of the insulating material, saving the labor of making a finish between the cable and terminal.

THE ROCKFORD, ILL., ELECTRIC MANUFACTURING CO.

THE above company are installing a 15 h. p. motor in the composing room of the Chicago *Inter-Ocean*, for running type-setting machines. This will probably be the first type-setting machine plant to be operated by electricity in the West. A number of motors, ranging from 7½ to 40 h. p., have been installed in other printing establishments and are giving the utmost satisfaction. The following letter was recently received by the company from the *Inter-Ocean*, and speaks for itself:

"CHICAGO, March 12, 1891.

"ROCKFORD ELECTRIC MFG. CO.,
"Rockford, Ill.

"*Gentlemen*: In reply to your inquiry—and for that matter to the inquiries of many other people—I will say that the Rockford motors, which you sold *The Inter-Ocean* last spring, have given, and are now giving, most excellent satisfaction. All our presses and our stereotyping machinery are run by the motors. We have in all four of fifteen horse-power, and one of seven and a half horse-power. We continue to heartily recommend them to all who make inquiry of us regarding electric machinery. They are simple and easy to manage.

"Very respectfully yours,
"WM. PENN NIXON."

THE BALL ENGINE CO., Erie, Pa., have opened a branch office in Chicago in the Rookery Building, room 506. Mr. Albert Fisher, widely known as a successful salesman, has been appointed manager, and will be glad to see his friends in his new quarters. Mr. Fisher has had a large experience in engines.

THE

Electrical Engineer.

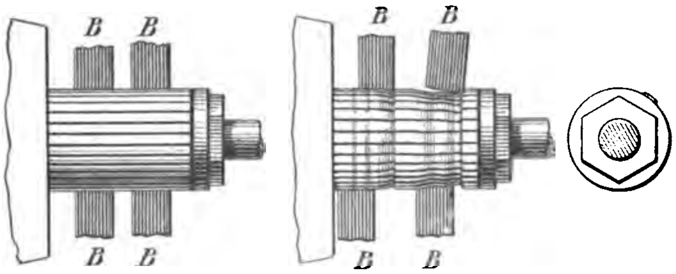
VOL. XII. SEPTEMBER 23, 1891. No. 177.

THE LOCALIZATION AND REMEDY OF TROUBLES IN DYNAMOS OR MOTORS.—II.

BY

Francis B. Crocker and S. S. Wheeler

3. Cause.—*Commutator* (*a*) *rough*, (*b*) *eccentric, or* (*c*) *has one or more "high bars" projecting beyond the others*, or (*d*) one or more flat bars, commonly called "flats," any one of which causes brush to vibrate or to be actually thrown out of contact with commutator. (Figs. 1, 2 and 3.)



FIGS. 1, 2 AND 3.—1. COMMUTATOR IN GOOD CONDITION. 2. COMMUTATOR IN BAD CONDITION. 3. HIGH BAR ON COMMUTATOR.

Symptom.—(*e*) Note whether there is a glaze or polish on the commutator, which shows smooth working; (*f*) touch revolving commutator with tip of finger and the least roughness is perceptible. If the machine runs at high voltage (over 250) the commutator should be touched with a small stick or quill to avoid danger of shock. In the case of an eccentric commutator, careful examination shows a rise and fall of the brush when commutator turns slowly.

REMEDY.—Smooth the commutator with file or fine sandpaper (in latter case be careful to remove sand and *never* use emery), or if commutator is very rough or eccentric, turn it off with a fine cut in a lathe.

In order to have the commutator wear smooth and work well it is desirable to have the armature shaft move freely back and forth about one-sixteenth or an eighth of an inch in the bearings, and the position of the bearings, pulley, collars and shoulders on the shaft and of the machine with respect to the belt should be such as to cause this to take place of itself. (See Heating of Bearings, No. 6.)

---

4. Cause.—*Brushes make poor contact with commutator.*

Symptom.—Close examination shows that brushes touch only at one corner, or only in front or behind, or there is dirt on surface of contact.

REMEDY.—File, bend, adjust or clean brushes until they rest evenly on commutator with considerable surface of contact and with sure but light pressure.

(See directions for care of brushes below.)

---

5. Cause.—*Short-circuited coil in armature.*

Symptom.—The particular commutator bar connected to short-circuited coil is burnt by the spark which occurs when brush passes over it.

The short-circuited coil is heated much more than the others, and is very apt to be burnt out entirely; therefore stop machine immediately. If necessary to run machine to locate the short circuit, one or two minutes is long enough, but it may be repeated until the heat of the short-circuited coil is found by touching the armature all over. Considerable power is required to run armature free. An iron screw-driver or other tool held near the revolving armature vibrates perceptibly as short-circuited coil passes. Current pulsates and torque is unequal at different parts of a revolution, these being particularly noticeable when armature turns rather slowly.

REMEDY.—A short circuit is often caused by a piece of solder or other metal getting between the commutator bars or their connections with the armature, and sometimes the insulation between these bars is bridged over by a particle of metal. In any such case the trouble is easily found and corrected. If, however, the short circuit is in the coil itself, the only real cure is to rewind the coil.

In an emergency a short-circuited coil may be temporarily cut out by connecting together the two commutator bars to which its terminals are connected or the two adjacent coils, as described in the Remedy for Sparking, No. 6. But be sure to unwind or open the circuit of the short-circuited coil, as otherwise the trouble will continue.

---

6. Cause.—*Broken circuit in armature.*

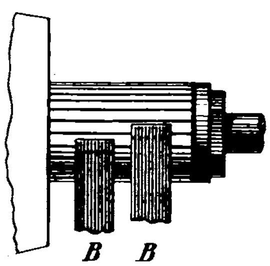


FIG. 4.—STAGGERED BRUSHES.

Symptom.—Commutator flashes violently while running and commutator bar nearest the break is badly cut and burnt, but in this case no particular armature coil will be heated, as in the last case (No. 5), and the flashing will be very much worse, even when turning slowly. This trouble, which might also be confounded with a bad case of "high bar" or eccentricity in commutator (Sparking, No. 3), is distinguished from it by slowly turning the armature, when violent flashing will continue if circuit is broken, but not with eccentric commutator or even with "high bar," unless the latter is very bad, in which case it is easily felt or seen.

REMEDY.—The broken circuit is usually found where armature wires connect with commutator, and not in the coil itself, and the break may be repaired or the loose wire may be resoldered or screwed back in place. If the broken commutator connection cannot be fixed, then connect the disconnected bar to the next by solder, or "stagger" the brushes; that is, put one a little forward and the other back so as to bridge over the break (Fig. 4). If the break is in the coil itself, rewinding is generally the only cure. But this may be remedied temporarily by connecting together by wire or solder the two commutator bars or coil terminals between which the break exists. It is only in an emergency that armature coils should be cut out or commutator bars connected together, or other makeshifts resorted to, but it sometimes avoids a very undesirable stoppage. A very rough, but nevertheless quick and simple way, to connect two commutator bars is to hammer or otherwise force the coppers together across the mica insulation at the end of the commutator. This can be afterwards easily picked out and smoothed over. In carrying out any of these methods care should be taken not to short circuit an armature coil, which would cause Sparking, No. 5.

7. Cause.—*Weak field magnetism.*

Symptom.—Pole-pieces not strongly magnetic when tested with a piece of iron. Point of least sparking is shifted considerably from normal position, due to relatively strong distorting effect of armature magnetism. Speed of a motor is usually high unless magnetism is very weak or nil, in which case a motor may run slow, stop, or even run backwards. A dynamo fails to generate the full E. M. F. or current. The particular cause of trouble may be found as follows: A broken circuit in the field is found by purposely opening the field circuit at some point, taking care to first disconnect armature (by putting wood under the brushes, for example) and to use only one hand to avoid shock, and if there is no spark there must be a broken circuit somewhere. A short circuit is found by measuring the resistance roughly to see if it is very much less than it should be, and usually a short circuit is confined to one magnet and will therefore weaken that particular one most, and a piece of iron held half way between the pole-pieces will be attracted to one more than the other. "Grounding" is practically identical with short circuiting, since one ground would not produce this effect until another occurred, and then we should have a double ground, which is equivalent to a short circuit.

REMEDY.—A broken or a short circuit or a ground is easily repaired if it is external or accessible. If it is internal the only remedy is to rewind the faulty coil.

THE "BI-TELEPHONE."[1]

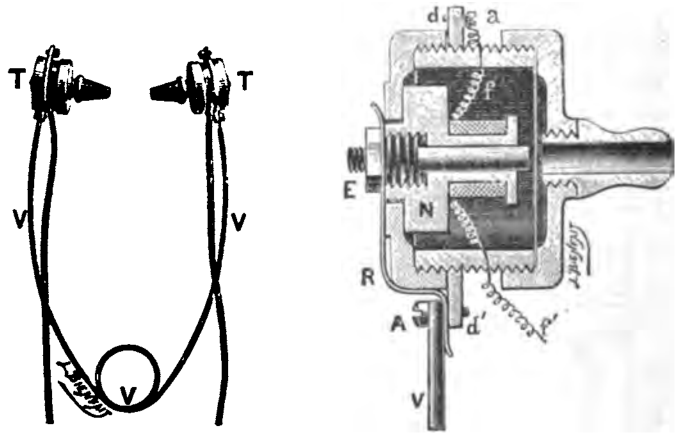
BY E. MERCADIER.

In a telephone which has to serve as a receiver, it is possible to combine clearness in the reproduction of the varied inflections of articulate speech, and the intensity necessary for all the usages of a telephone. For this purpose it is sufficient first to give to the diaphragm of the telephone a thickness just sufficient to absorb all the lines of force of the field of its magnet; second, to diminish the diameter until the fundamentals and harmonics of the enclosed diaphragm are higher than those of the human voice. It will be remembered, moreover, that in satisfying these two conditions, it is possible to obtain with telephones, by means of a very feeble field of force, results comparable in intensity, and superior in clearness, to those obtained with instruments having a field much more intense, and which, in consequence, have a much greater weight and volume.

It follows then that it is possible on the one hand to take very small magnets having two branches, or even one only, as in the earlier Bell telephones, and hence very small bobbins, which permit of a reduction of weight of this part of the telephone in the proportion of one to five; on the other hand, to reduce, as indicated below, the thickness and diameter of the diaphragm. From this there results first a diminution of the size of the box containing the diaphragm, and second, on account of its thinness, the possibility of replacing the metal boxes by those of ebonite, which still further reduce the total weight.

Having had occasion to employ in certain electrical researches, telephones which could act as galvanoscopes, I conceived the idea of utilizing the foregoing results to construct a very light telephone which could remain fixed to the ears for an entire day without fatigue, thus leaving both hands always free.

I have made several types of this kind of instrument, by employing telephones of one or two poles connected by a steel wire spring two millimetres in diameter, shown at V, Fig. 1, which shows, reduced to quarter size, one of these instruments, to which I have given the name of "Bi-telephone." The boxes, T T, are of ebonite, the covers terminating in rubber ear nipples, which may be taken off and



FIGS. 1 AND 2.—MERCADIER'S BI-TELEPHONE.

changed at will (each operator having his own for his personal use), and which extend into the interior of the ear. It is held in place close to the auditory passage, assisted by the light pressure of the spring. These telephones weigh not more than 50 grammes (while those in ordinary use weigh about 400), do not exceed 4 centimetres in diameter, and produce no fatigue or pain after a few minutes' use.

The steel spring connects electrically two of the four ends of the bobbins, so that two flexible cords are sufficient to connect the instrument to the telephone set. The spring may also be magnetized so as to reinforce the magnetism of the telephone cores. It plays, therefore, a triple role—mechanical, electrical, and magnetic.

In spite of the feebleness of its field, the intensity of the effect of this telephone is comparable with that of the instruments in ordinary use, while the clearness is greater. This fact has been established by tests on subterranean lines 50 to 74 kilometres in length, on one telephone line 800 kilometres long, and on the new line between Paris and London, no matter what transmitter was employed.

Fig. 2 shows a section of one of the receivers of a "Bi-telephone" having a rectilinear magnet of the Bell type. The illustration shows the instrument full size. The triple function of the spring V is here clearly shown. The mechanical function results from its form, which tends evidently to exercise a pressure. The magnetic function is exercised through the steel strip R, connecting the spring with the magnetized core N of the electromagnet by means of the screw A and the nut E. Finally the electric function results from one end, *f*, of the bobbin of the electromagnet, being connected with the metallic collar *d d'* by the screw *a*, and thus to the spring V by the screw A.

THE FRANKFORT INTERNATIONAL ELECTRICAL EXHIBITION—VIII.

BY

Richard O. Heinrich.

Steam Economizing Devices.

THE importance of the utmost economy in central station work has been pointed out from time to time in THE ELECTRICAL ENGINEER by a number of the most competent engineers in the profession. It may therefore interest central-station managers to give an account of a number of patented devices exhibited by the firm of Klein, Schanzlin & Becker, of Frankenthal, Rheinbaiern.

The water-cooling apparatus, as shown in Fig. 1, will be

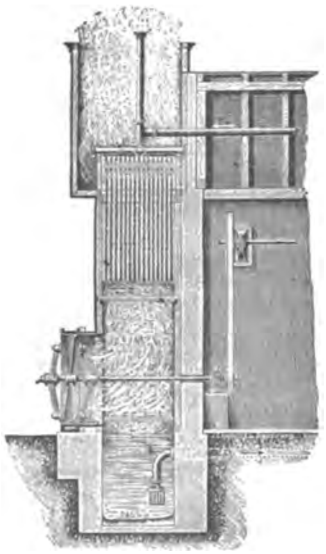

FIG. 1.

of special interest to the designer of central stations, when he has to economize space, and when the water supply for the condensing engines is inadequate. The heated condensing water is lifted to the top of a square tower about 20 feet high. In this tower are vertically suspended a great number of boards about 3½ inches apart. The hot condensing water runs down the boards in a steady, thin surface coating without spraying. A very rapid cooling takes place, favored by the direct air, and by the surface evaporation. The amount of cooling is a very constant factor throughout the year. The cooling by evaporation is great in summer, though the cooling by direct absorption of heat by the air is small; in winter it is just the opposite. To

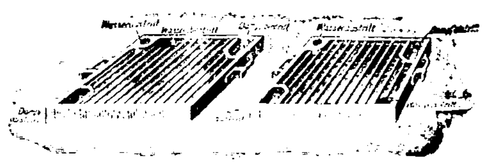

FIG. 2.

increase the cooling effect air is driven upwards against the falling water by means of an electric fan. The cooling capacity is very great; with a fan 6½ inches in diameter, and a tower of 6 x 7 feet in cross-section, 18,000 to 20,000 gallons may be cooled within an hour from 126° F. to 76° F.

The process is almost perfectly continuous, since the evaporated water is always fully supplied by the condensed steam. Another advantage claimed is that the water is almost devoid of air after it has passed the apparatus a number of times, so that it is not difficult to obtain a vacuum of 27.6 inches with the air pump of the condenser. The lubricating oil contained in the water collects at the surface of the water and may be drawn off, the small amount remaining being of advantage for the working of the air-pump.

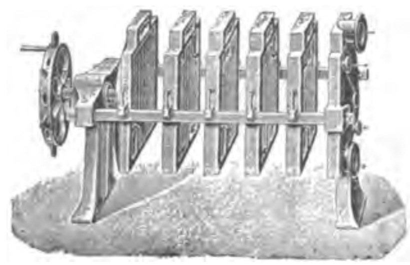

FIG. 3.

Another patented device of this firm, which is to be introduced in America, if the occasion is offered, is the feed-water heater and surface condenser, shown in the accompanying engravings. The cast-iron feed-water heater consists of hollow plates, Fig. 2, which are put together in a frame, as shown in Figs. 3 and 4. The joints between the frame-plates are made tight by pasteboard packing. A large screw at one end of the supporting frame keeps the plates together, and the ease with which they may be separated allows them to be easily and readily cleaned. The inside space of the plates is heated by steam, and the water or fluid to be heated fills the intervening spaces. Numerous ridges, cast on to the plates, cause a quick and complete propagation of heat through the cast-iron. Almost all solid substances contained in the heated water are deposited on the plates, whence they are very easily removed. If the water comes to the heater under low pressure (up to 30 lbs.) rectangular frame-plates are used; if the heater, however, works directly into the boiler with a pressure of from 45 to 105 lbs., the frame-plates are circular, and the packing is laid within a groove.

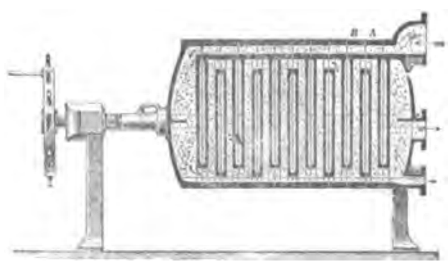

FIG. 4.

In combination with a filter press the feed-water heater is well adapted for the cleaning of the feed-water, Fig. 5. The feed-water is made alkaline by the addition of carbonate of soda. As soon as the temperature of this alkaline water is raised, the lime and magnesia are precipitated, and the water becomes turbid. This water is pressed through the filter part of the apparatus, whence it enters the boiler perfectly clean and pure. The heaters just described may also be used as surface condensers. To prevent leakage of air from the outside into the steam-chest, the whole apparatus is immersed in water. Experiments which have been made with it have shown excellent results.

To dispose of air and condense water together, the firm in question employs the combined wet air and water pump, shown in Fig. 6. At first sight, the connection of the coaxial piston rods, shown in detail in Fig. 7, appears remarkable. The curved connecting piece is made of the best steel. It is evident that the employment of this new and original construction saves considerable space; the fly-wheel comes between the two pistons, and the construction of the machines is greatly simplified.

In such a combined air and water pump the pistons change their up and down motion simultaneously, one beginning to move up as the other begins to move down,

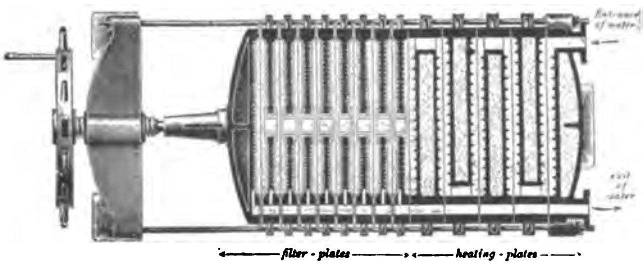

FIG. 5.

and one of the slide-valves opens when the other closes. In this case the two slide-valves may be combined in one, so that the exhaust of the smaller passes from the rear of the combination valve to the larger.

Figs. 8 to 12 show such a combination valve from which of the foregoing description will easily be understood.

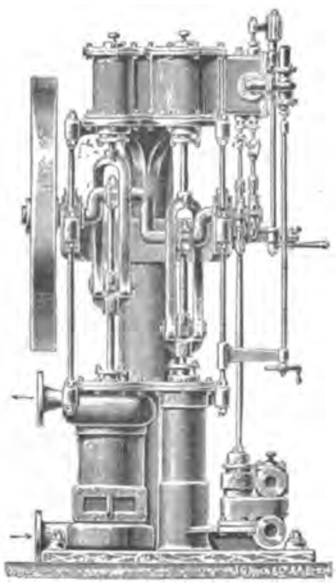

FIG. 6.

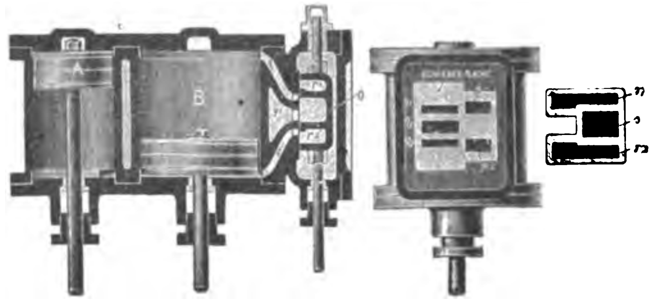
Fig. 8 is a section through the steam channels of the large cylinder; Fig. 9, a section through the steam channels of the small cylinder; Fig. 10 shows the sliding-plane of the combination-valve; Fig. 11 shows the combination valve from below, and Fig. 12, a horizontal section through the cylinder and steam channels. In Fig. 8 the smaller piston

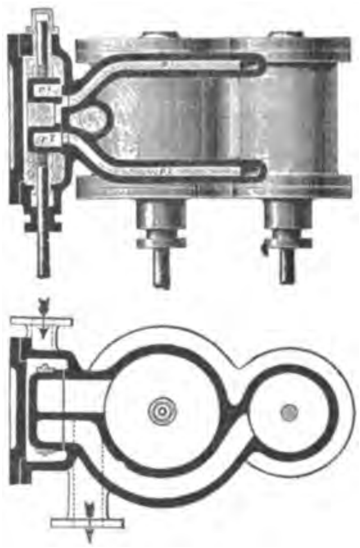
FIG. 7.

begins to move downward, and the larger one upward; therefore, the channel p_1, Fig. 9, receives fresh high-pressure steam, while through channel p_2 high-pressure steam flows into r_2, whence it goes through the opening s, Fig. 8, into the channel q_2 of the larger cylinder, where it acts expansively on the piston of the large cylinder. The exhaust of the large cylinder goes through channel q_1 into the chests of the slide-valve, and the exhaust pipe q_2 into the air. The steam enters the small cylinder simultaneously



FIGS. 8, 10 AND 11.

in two places, half of it through r_1 towards p_1, and the other half directly at p_1. The steam in the channels of the small cylinder expands together with the steam in the



FIGS. 9 AND 12.

cylinder itself into the large cylinder. The long channels of the small cylinder are, therefore, not detrimental, and the channels of the large cylinder are very short.

ELECTROLYTIC SEPARATION OF ZINC.

THE process introduced by M. Neuhausen may be applied to the electrolytic separation of zinc by employing a bath, the temperature of which can be lowered according to the density of current employed. The inventor notices that the temperature must be lowered as the density of current is reduced. The mean of 120 observations is shown in the following table:

Density in amperes	State of metal obtained: 10 deg.	20 deg.	30 deg.	40 deg. Cent.
10	compact	spongy	spongy	spongy
50	—	semi-comp.	—	—
100	—	compact	semi-comp.	—
150	—	—	compact	semi-comp.
200	—	—	—	compact

If it is desired to work with a density of "100 per square metre," the bath, to obtain compact metal, must be kept about 20 deg. C. In commercial practice it is always preferable to use currents of less than 50 amperes density, and to maintain the temperature below 10 deg. C., by means of ice or refrigerating apparatus.

THE IMPORTANCE OF THE POINT OF VIEW FROM WHICH THE TRANSMISSION OF POWER IS REGARDED.

BY

Cary T. Hutchinson

MR. H. WARD LEONARD, a well-known electrical engineer, has published a paper in THE ELECTRICAL ENGINEER for Sept. 2, 1891, which shows forcibly the necessity of looking at every question from all sides before making positive statements, especially if these statements are to be uncomplimentary.

In this paper he, scanning the field from his point of view, the generator, deduces certain formulæ, and then proceeds to berate Mr. F. J. Sprague, who had before this[1] looked over the same ground very carefully from his point of view, the motor; Mr. Leonard, seeing that his side of the shield is silver, cannot conceive that the other side is gold, but insists that it is a base alloy. Mr. Leonard, then goes into detail, and points out with great minuteness just how Mr. Sprague is wrong, and shows marvelous cleverness in giving us the exact logical fault in Mr. Sprague's reasoning, not noticing that the very next moment he employs the same process for the same purpose. Mr. Leonard also strengthens his case very greatly by several misquotations and epithets, such as "no engineer of practical experience," becomes amusingly cynical, and pityingly calls attention to the "beauty of simplicity" of certain laws which he characterizes as "absurd," "erroneous," and which he conclusively proves to be so by referring us to Chart 1 or 2 or 3 (Copyright ! !). A beautiful method of proof !

I purpose showing that Mr. Sprague's formulæ, which Mr. Leonard criticises, are entirely correct, and, moreover, that they are implied in Mr. Leonard's own work; and this implies that Mr. Leonard has unconsciously been calling himself hard names, declaring that he is "no practical engineer," which, coming from so good a source, we are reluctantly forced to believe.

For simplicity's sake, I shall use as far as possible the notation of Mr. Leonard's paper, it being much more accessible than Mr. Sprague's.

Let E, be the P. D. at generator brushes,
e, " " " " motor "
V, " " " " ends of the line,
D, " " " " distance of transmission.

These are the variables; I do not intend going into numerical work, and shall, therefore, simplify the equations by massing constants as much as possible. Calling C the cost of generator and line (bare) per kilowatt at the motor brushes, and assuming that the constants of cost are independent of the voltage, we have:

$$C = a\frac{E}{E-V} + b\frac{D^2}{V(E-V)} \qquad (1)$$

This is Mr. Leonard's equation (7) with the correction of a typographical error and a change in constants; and it is also Mr. Sprague's equation (7), substituting $E - V$ for e and massing constants.

Assuming D constant,

$$\frac{dC}{dV} = a\frac{(E-V)\frac{dE}{dV} - E\left(\frac{dE}{dV}-1\right)}{(E-V)^2} - b D^2 \frac{E + V\frac{dE}{dV} - 2V}{V^2(E-V)^2} \qquad (2)$$

1. Journal of the Franklin Institute, March-April, 1889.

To determine minimum cost this first derivative must be equated to zero, and the conditions for which the minimum is to hold must be carefully defined.

First. From Mr. Sprague's point of view, in which the motor P. D. is assumed constant:

$$E = e + V; \qquad (3)$$

$$\frac{dE}{dV} = 1,\ e \text{ being constant}; \qquad (4)$$

Substituting this value from (4) in (2) and putting (2) = 0,

$$a = b\frac{D^2}{V_0^2};\ \text{or } V_0 = D\sqrt{b/a} \qquad (5)$$

This is equation (10) in Mr. Sprague's paper, and is strictly correct; but the person reading it must have sufficient knowledge to interpret it. Mr. Sprague interprets it faultlessly by saying:—"That is, with fixed conditions of cost and efficiency of apparatus, the number of volts fall to get the minimum cost of plant is a function of the distance alone, and is independent of the electromotive force used at the motor." That is to say, if we wish to use 500 volts at the motor, and with certain coefficients of cost and efficiencies of generator (not of line) the value of $\frac{V_0}{D}$ is ten, then for 1,000 volts at the motor, the value of $\frac{V_0}{D}$ is still ten; and this value of V_0, when substituted in the equation for minimum cost, will, in both cases, give the minimum cost, but this cost will of course be different for the two cases. Putting the value of V_0 from (5) in (1), the minimum cost C_0 is

$$C_0 = a + \frac{2D\sqrt{ab}}{e} \qquad (6)$$

This gives the minimum cost of plant for any motor P. D., when V_0 is given the value demanded by (5); it depends both on the motor P. D. and on the distance.

Second. From Mr. Leonard's point of view, generator P. D. assumed constant:

$$\text{From (3)},\ \frac{dE}{dV} = 0, \qquad (7)$$

when E is constant.

Substituting in (2) and equating to zero,

$$aE - bD^2\frac{E - 2V_1}{V_1^2} = 0 \qquad (8)$$

This is Mr. Leonard's eq. (8) (with correction of another typographical error), and it gives the value which V_1 must have in order that the cost of plant, with any particular value of E and D, may be a minimum; from (8)

$$V_1 = -\frac{bD^2}{aE} + \left\{\frac{bD^2}{a}\left(1 + \frac{bD^2}{aE^2}\right)\right\}^{1/2} \qquad (9)$$

The minimum cost is then, for any P. D. at generator and distance

$$C_1 = a\frac{E}{E-V_1} + b\frac{D^2}{V_1(E-V_1)} \qquad (10)$$

where V_1 has the value given by (9), which is too complicated to substitute.

Putting $V_1 = E\vartheta_1$, or, in general, $V = E\vartheta$, where ϑ is the fractional part lost in the line,

$$C_1 = a\frac{1}{1-\vartheta_1} + \frac{bD^2}{E^2\vartheta_1(1-\vartheta_1)} \qquad (11)$$

Mr. Leonard's Chart 1 can be plotted directly from eq. (11); Chart 2 can be plotted from eqs. (1) and (11), although he gets them in a very much more roundabout way.

Having now shown that Mr. Leonard's equations are substantially the same as Mr. Sprague's, from a different point of view merely, it will prove interesting to show just where Mr. Leonard has strayed. On p. 252 we have:

"By careful (sic !) examination of the paper (Mr. Sprague's) it will be found that after having assumed the value of the E. M. F. at the motor brushes, and the distance also being fixed, the error is made afterwards of considering the results obtained as applicable to cases in which these values are variable." This is, of course, a heinous offense; incomparably worse than assuming the value of the E. M. F. at the generator brushes, and the distance, as fixed, and then varying them in the equation obtained from differentiation; another case of point of view.

To continue: "Now, according to Mr. Sprague, the minimum cost of plant is a function of the distance alone, and is independent of the E. M. F. at the motor;" this is not "according to Mr. Sprague," who has never made such a statement. Mr. Sprague says, "the *number of volts fall* to get the minimum etc."—a very different thing. This erroneous idea pervades Mr. Leonard's mind, and causes him to make a number of curious statements. The numerical example quoted to prove his point has another error in addition to this fundamental one; he says, "With same efficiency of apparatus, that is, 30 per cent loss in condnctor;" even if the "careful examination" of Mr. Sprague's eqnations had not shown Mr. Leonard that the efficiency of the generator was the only efficiency entering the equation, still the exercise of a little mother wit would have shown him that a constant efficiency of line with constant volts drop (for given distance) fixes the value of the motor and generator P. D.; that is, makes it a mere numerical case.

Mr. Leonard next criticises the statement that, "With any fixed couple and commercial efficiency, the cost of the wire should bear a definite and fixed ratio to the cost of the generating plant." This statement in Mr. Sprague's paper lacks one clause, that is, "Under conditions of minimum cost, and with any fixed, etc.;" the meaning is perfectly clear from the equations it is derived from, and any one reading with the slightest care would see it; it is perfectly true, the commercial efficiency being that which gives the minimum cost, corresponding to V_0 of eq. (5). Mr. Leonard attempts to show the absurdity of this by giving numerical examples from Mr. Badt; all these can be explained by keeping in mind the fundamental misconception regarding "volts to get minimum cost" and "minimum cost" itself; but here, as before, Mr. Leonard confuses percentage loss in line and volts drop, making matters much worse.

Again the "beauty of simplicity" of "17.5 volts per thousand feet" is unassailable, provided the numerical work is right; it is not "eminently absurd," and "the transmitter of power who follows these tables" (if conditions implied are met and the arithmetic is correct) will not go astray. Mr. Badt shows himself to be an eminently "practical engineer" by endorsing these statements. One more word and I have finished; quoting Mr. Leonard again, "Mr. Badt, on p. 42, quotes from Mr. Sprague the following misleading rule, etc." Mr. Badt makes no such quotation from Mr. Sprague, nor is there such a rule in Mr. Sprague's paper.

From my point of view the question obtrudes itself, Has Mr. Leonard read Mr. Sprague's paper?

AN ELECTRIC VENTILATOR.

L'Electricité, notices a curious electric ventilator for supplying a building with fresh air, either cold or warmed, as desired. An electric motor sets the ventilator revolving and the revolution sucks cold air in. When warm air is desired, a current is sent into a network of fine wire possessing a high resistance, and through the network the air is obliged to pass: the current heats the wires, and the air necessarily becomes heated. The movement of a switch is sufficient to change the character of the air supplied by the ventilator. This system is capable of considerable adaptation, and it is stated that the hygienic results are uniformly good.

MINIMUM FIRST COST OF PLANT AND MAXIMUM ECONOMY OF OPERATION IN THE ELECTRICAL TRANSMISSION OF POWER.

BY

Chas. J. Reed

In THE ELECTRICAL ENGINEER of September 2, 1891, under the above title, Mr. H. Ward Leonard gives some formulæ, the deduction of which does not seem to me very clear. In equation (2), for instance, is a numerical error which follows through all the other equations. The numerical factor in the denominator should be 15 instead of 7.5, and the equation becomes, $T = \dfrac{D^2 \times K.\ W.}{V(E - V) \times 15}$.

Equations (12) and (13) express a peculiar state of facts, viz., that for any loss between zero and 50 per cent. the cost of conductors increases very rapidly with the loss in transmission! They show also that the cost of conductors depends altogether upon the cost of motors, (G), and the loss in transmission. It seems to me the cost of conductors depends to some extent on the price of copper!

It is not clear that the cost of bare copper and generator are the only elements to be considered in determining the minimum first cost of a plant. It seems to me that the general solution of this problem requires us to consider a number of both dependent and independent variables. In Mr. Leonard's deductions the only independent variable seems to be loss in transmission. This is not in accordance with his preliminary assumption. If it is correct, it ought to make no difference in determining the minimum first cost of a plant, whether we use gold or copper for conductors. There is really no more reason in this assumption then in Mr. Sprague's alleged assumption that distance is the only independent variable. We might as well say the minimum first cost depends only upon the cost of copper, and by assuming all other conditions to be given, derive an entirely different set of formulæ, equally valueless.

The objections raised to Thomson's law are on the assumption that in some cases "*the interest on the plant, even when at its minimum cost, will far exceed the value of the energy wasted.*" If Mr. Leonard can show such a case, we will cure it by simply wasting more energy and using less copper until Thomson's law is satisfied. We shall then find that we have reduced the first cost *below the minimum!*

MINIMUM FIRST COST OF PLANT AND MAXIMUM ECONOMY OF OPERATION IN THE ELECTRICAL TRANSMISSION OF POWER.

BY

H Ward Leonard

MR. CHAS. J. REED has sent to me a copy of his criticism upon my recent article appearing in THE ELECTRICAL ENGINEER under the above title[1] and I beg to make the following comments in regard to his criticisms:

Mr. Reed states that there is a numerical error in equation (2). He states, in effect, that equation (2) gives a value which is double as large as it should be. I find that Mr. Reed has fallen into the error of forgetting that we are dealing with a complete metallic circuit, and that we must provide for a conductor both ways. The formula which Mr. Reed gives would give the correct weight of the copper conductor for the distance D, but, of course, for any

1. See issue of Sept. 2, 1891.

distance of transmission D we must provide a conductor whose total length would be 2 D, so that the equation (2) as given in my article is entirely correct.

The next point Mr. Reed makes is as follows: "Equations (12) and (13) express a peculiar state of facts, viz., that for any loss between zero and 50 per cent. the cost of conductors increases very rapidly with the loss in transmission." Mr. Reed's statement is hardly a correct one. The formula does not apply to any loss between zero and 50 per cent., but to any loss which is the proper loss for conditions of minimum total first cost of plant. By examination of Chart 1 we find that, at the same distance, the greater the percentage of loss in the line, the higher the price of conductors. While this appears paradoxical, it is due to the fact that the initial volts, which at any distance make the smaller loss that of minimum first cost, are very much higher than the initial volts which at the same distance make the greater percentage of loss correspond to the minimum conditions. Formulæ (12) and (13) do not state, that for any given initial E. M. F. at any given distance the cost of conductors increases very rapidly with the loss in transmission, which Mr. Reed has apparently assumed to be the case. Mr. Reed states that these formulæ appear incorrect because they are independent of the price of copper. This is in reality not surprising when it is remembered that we are not considering the general case of the cost of conductors, but that we are considering that cost of conductors which corresponds to the minimum total first cost of plant. Under these latter conditions, it is entirely true that the amount which must be invested in the conductor is independent of the price per pound.

Mr. Reed states that it is not clear that the cost of bare copper and generator are the only elements to be considered in determining the minimum first cost of the plant. Theoretically speaking, he is correct, but, practically speaking, these two items are the only ones worthy of notice, and such other items as the labor in stringing the lines, etc., are not only extremely small in amount, but they do not, under any fixed conditions of loss in transmission and cost in materials, vary in proportion to the amount of power transmitted, nor do they conform to any fixed law which can be followed mathematically. It is evident that the cost of stringing a conductor ten times the size of a second one is not ten times the cost of stringing the second one. If, by making the necessary complicated assumptions and deductions, we inject such insignificant factors into the problem it is evident that our loss in transmission in order to conform to minimum for cost conditions, would have to vary for every different amount of power transmitted, and that we would introduce a serious error, instead of gaining any additional accuracy.

Mr. Reed states that, according to my deductions, "It ought to make no difference, in determining the minimum first cost of the plant, whether we use gold or copper for conductors." This is entirely correct, that is, the laws governing the conditions of minimum first cost are the same if we use a material for the conductor of a certain conductivity entirely regardless of its price. This is, of course, entirely different from the statement that the first cost will be the same whether gold or copper be used, which interpretation Mr. Reed has apparently placed upon it.

Mr. Reed's last point is as follows: "The objections raised to Thomson's law are on the assumption that in some cases '*the interest on the plant, even when at its minimum cost, will far exceed the value of the energy wasted.*' If Mr. Leonard can show such a case, we will cure it by simply wasting more energy and using less copper until Thomson's law is satisfied. We shall then find that we have reduced the first cost *below the minimum!*"

In reply to this, let us suppose that the interest and depreciation upon our plant is \$9 per annum per kilowatt delivered; also, that the value of one kilowatt is \$5 per annum; so that under conditions of 15 per cent. loss in transmission, the value of the energy wasted is 75 cents per annum. In order to make the interest and depreciation equal to the value of the energy wasted, it will become necessary, in following Mr. Reed's suggestion, to increase the loss. As we increase the loss in the conductor, it is evident that we are increasing the cost of the generator capacity required for every kilowatt transmitted; and it is this very point, namely, the increase in the cost of the generator with every increase of loss in the conductor, which makes Thomson's law inapplicable, and Mr. Reed seems not to have followed this point to which my article calls special attention.

By reference to Chart 3 it will be found that the fourth curve from the top, at the left., is the curve of interest and depreciation at 15 per cent. per annum; the lowest curve on the chart is that of the value of the energy wasted in the conductor per annum when one kilowatt at brushes is worth \$5 per annum. In order to apply Thomson's law, it would be necessary to project these two curves to a point where they cross, which they never will, and even within the range of the chart it is evident that both values are rapidly increasing and any attempt to make the two values equal by further increasing the energy wasted, is evidently leading further from the minimum value, and not toward it. The minimum value, under the conditions given, will be at 15 per cent. loss, as is indicated by the third curve from the top, which expresses the maximum economy in operation when the interest and depreciation is 15 per cent., and one kilowatt per annum is worth \$5; but instead of these two values being equal under conditions of maximum economy, the interest and depreciation is found to be more than ten times as large as the value of the energy wasted.

ELEMENTARY GEOMETRICAL THEORY OF THE ALTERNATE-CURRENT TRANSFORMER.—XV.

BY

Chas. Steinmetz.

HAVING produced this *curve of induced* E. M. F., or "TRANSFORMER-CHARACTERISTIC" we determine the correct curve of *eddy-currents.*

The eddy-currents are proportional to the magnetization, hence proportional to I, and, if the variability of the magnetic susceptibility is taken into consideration, the curve of the eddy-currents, or rather of their M. M. F., will be no longer the straight line G^1, used in the diagrams, Figs. 5 and 6, but a curve, g, Figs. 27 and 28, which is proportional to the curve of induction, i.

In Figs. 27 and 28, the horizontal distance, $\overline{FG}$ of g from $f = \overline{OF}$, represents the M. M. F. of eddy-currents, corresponding to the resulting M. M. F., $F = \overline{OF}$, $\overline{FG}$ being proportional to $\overline{FI}$. Hence we only need to determine the M. M. F. of the eddy-currents for one particular resulting M. M. F., $\overline{OF}$, which gives us one point of the curve, g, to be able to produce the whole curve, g, by means of the proportionality of $\overline{FG}$ with $\overline{FI}$.

The *hysteretic curve*, or curve of the ideal M. M. F. representing the loss of energy caused by hysteresis, can be derived in a similar way. The loss of energy by hysteresis was represented in the diagram by the product, $E_1 \times H^1$, where E_1 is the induced E. M. F., H^1 the ideal hysteretic current.

This hysteretic loss I found, as before said, to be proportional to the 1.6th power of the magnetization; that is, other things being equal, proportional to the 1.6th power of the induced E. M. F., E_1 or I. Hence the ideal hysteretic current H^1, and therefore its ideal M. M. F., H, is proportional to the .6th power of the induced E. M. F.. $I = \overline{FI}$, corresponding to the resulting M. M. F., $F = \overline{OF}$.

Thus we only need to determine the hysteretic loss for one particular M. M. F., F, compute therefrom the ideal M. M. F. of hysteresis H for this particular resulting M. M. F., F, and produce $\overline{FH} = H$ horizontally from F, to get one point of the hysteretic curve h (Fig. 27 and 28).

Then by means of the proportionality of $\overline{FH}$ with the .6th power of $\overline{FI}$, we derive the complete and correct curve of hysteresis. At the same time, this gives us means to separate the loss of energy due to hysteresis, from the loss caused by eddy-currents.

For, determining the whole loss of energy in the iron, hysteresis and eddy-currents for two different M. M. F.'s, $\overline{OF_1} = F_1$, and $\overline{OF_2} = F_2$, calculating therefrom the ideal current and the ideal M. M. F., $\overline{FK} = K$, representing hysteresis and eddies combined, we derive, from the two equations,

$$\overline{F_1K_1} = \overline{F_1H_1} + \overline{F_1G_1} = \varepsilon\, I_1^{.6} + \beta\, I_1$$
$$\overline{F_2K_2} = \overline{F_2H_2} + \overline{F_2G_2} = \varepsilon\, I_2^{.6} + \beta\, I_2$$

the coefficient ε of the ideal M. M. F. of hysteresis H, and the coefficient β of the M. M. F. of eddy-currents, G.

Having so determined the curve of *ideal* M. M. F. *of hysteresis*, h, and the curve of M. M. F. *of eddy-currents*, g, in their dependence upon the resulting M. M. F., F, we produce the curve of *impressed* M. M. F., k, by adding both curves, h and g, together, so that $\overline{FK} = \overline{FH} + \overline{FG}$.

This curve k is the curve of *magnetic lag*, α, and of the *primary* M. M. F., L^{∞} *at open secondary circuit.*

Now, after we produced the curves, i, h, g, k, we can proceed to the construction of the *complete transformer diagram.*

Suppose the transformer has in the primary and in the secondary coil the same *number of turns*, $n = n_1 = 40$. The *secondary* E. M. F. may be, $E_1 = 73.8$ volts maximum value, the *secondary resistance*, $r_1 = 2$ ohms. Hence the *secondary current* will be, $C_1 = 36.9$ amperes, and the *secondary* M. M. F., $L_1 = 1476$ ampere turns.

We then make, in the diagram, Fig. 27, $\overline{OE_1} = E_1 = 73.8$ volts, and erect in E_1 a perpendicular line upon $\overline{OE_1}$, which intersects the transformer characteristic, i, in the point I.

Through I we draw a horizontal line which intersects $\overline{Of}$ in F. Hence $\overline{OF} = F$ is the *resulting* M. M. F., necessary to induce the *secondary* E. M. F., E_1.

Continuing $\overline{IF}$, until it intersects the curve k in K, $\overline{FK}$ gives the *ideal* M. M. F. *of hysteresis and eddy-currents combined*, $\overline{FH}$ *the ideal* M. M. F. *of hysteresis*, $\overline{FG}$ *the* M. M. F. *of eddy-currents.* $\overline{OK} = K$ is the *impressed* M. M. F.

Completing the parallelogram of M. M. F.'s $\overline{OL_1}$, $\overline{KL}$, that is, producing $\overline{KL} = \overline{OL_1}$ horizontally from K, $L = \overline{OL}$ is the *primary* M. M. F.

Carrying out this construction of L for different secondary E. M. F.'s, E_1, or for different resulting M. M. F.'s, F, we derive l, the complete *curve of primary* M. M. F., L, corresponding to the secondary resistance, $r_1 = 2$ ohms.

In the usual way, the primary M. M. F., L gives us the *primary current* C, and the *primary resulting, or heating* E. M. F., E, for different magnetizations, but the same secondary resistance, traveling on the curve, e. Primary resulting E. M. F., E, and primary induced E. M. F., $E_1 = E_1$, give, by the parallelogram of primary E. M. F.'s, $\overline{OE_1}$ $\overline{EE_0}$ the *primary impressed* E. M. F., E_0, traveling on the curve, e_0.

OZOKERITE.

The principal ozokerite mines are situated in Galicia, the produce being about 200 tons per week. It is estimated that about half this quantity goes to Russia, where it is used in the manufacture of ceresine candles for churches.

DYNAMO PULLEYS AND BELTING AT THE FRANKFORT ELECTRICAL EXPOSITION.

BY

Chas. A. Schieren

An electrician or engineer is generally so much absorbed in the mechanical construction of the dynamo that he gives the belt only a passing glance; at least this has been my conclusion from observation and experience at the International Electrical Exposition now being held in Frankfort, Germany; hardly one person out of ten would notice the belts at all, as they passed by the various dynamos and machinery exhibited there. All engineers, however, will readily admit that the belt plays an important part in the satisfactory and successful running of the dynamo.

The special correspondent of The Electrical Engineer, Mr. Richard O. Heinrich, in his excellent reports has not yet mentioned anything of the belting exhibited here. I will therefore give a brief sketch of the leather belting on exhibition and in operation here, which may be of interest to some of your readers.

In a small, out-of-the-way building, set apart for "Maschienen Bestandtheile," I find eight firms exhibiting belting; it can hardly be called "International," because outside of the fine display of leather link belting made by the American Leather Link Belt Co., of New York, no foreign firm is represented. The remaining exhibits are of German manufacture, and consist principally of the usual European heavy, thick belt, stitched with alum-tanned lace leather; some have six or more rows of this stitching in one width of belt. One creditable exhibit, which shows considerable progress in point of quality and finish, and also excellent workmanship, is that of Klinge Bros., of Dresden, Saxony.

As a rule, the belts intended fór dynamos are made single, and most of them are very uneven, with the stretcher marks left on the joints (the most vital part of the belt), and these belts cannot run satisfactorily on a dynamo; they must necessarily be unreliable and slip badly when in operation. Many devices for making belts endless are also exhibited, some as crude and heavy as they can possibly be made. One of these, in the shape of a hinge intended for a four-inch belt, weighs half a pound. The lace leather exhibited is generally good, and much like ours in the United States.

Messrs. Schark & Co., of Mayence, exhibit pulleys covered with small pieces of leather, strung together with lacing edgewise, then cemented on the face of the pulley and turned off very smoothly. It makes a fine covering, but very expensive, and is of doubtful durability. The same device, except that a thin, flat steel plate is used, was recently patented in America; however, the German patent is an improvement.

Evidently the German belt-makers are not restricted as to the length of pieces put into belting, and very sensibly cut the pieces of leather according to the quality of the hide. The ridiculous notion has been introduced in America, especially among electric light people, that the length of pieces should be only four feet four inches, as if hides could be grown to order; it naturally necessitates a great waste of material. Messrs. Kaulhausen & Son, of Aachen, exhibit a bungling imitation of the well-known "Perforated Electric Belt." The device is a sort of nickel-in-the-slot affair, consisting of rows of long, narrow slots put irregularly in the belt.

Of the belts in operation in Machinery Hall I will have something to say later, several machines not being ready. However, from the leather belting exhibit made by the Germans, it is evident they are not up to the demands of the present progressive age, and the American manufacturers lead them in many ways.

THE DETROIT ELECTRICAL WORKS NEW STREET CAR GEARS AND CARBON BRUSH-HOLDER.

RECENT improvements introduced by the Detroit Electrical Works on their electric railway system are worthy of attention as they indicate a decided step in advance in the operation of electric cars. As our readers are aware, in this company's system the power is transmitted from the motor to the axles through the medium of a pair of beveled gears. Heretofore these gears have been of the usual type, cut very accurately on a special machine, and under the general conditions of service left little to be desired in smoothness of operation and as regards wear; but in climbing heavy grades, and where severe loads are brought upon the gears, some difficulty was encountered due to the fact that one set of teeth, after some wear, would sink too far into those of the other, which in some instances led to the fracture of the teeth. This difficulty has now been entirely avoided and at the same time the cost of the gears largely reduced by the type of shrouded bevel gear just adopted, and which is now in successful operation on the Rae cars at Aurora, Ill., and Lawrence, Mass.

The accompanying illustration, Fig. 1, will give a good idea of the new type of gear. It will be noted that at each end of the teeth the rim is left plain, one-half the teeth projecting above the rim and the other half being sunk below it. It will thus be evident that under no circumstances can the relative depth of mesh of one gear with the other vary in the slightest degree, the two plain surfaces at the end of each gear forming a bearing which limits the depth of mesh under all conditions. In addition to the increased life obtained by this form of gear, it also permits of the use of wheels just as they come from the casting mould, and they require no finishing whatever of the teeth; in fact, these are now cast with almost perfectly round surfaces, and the results already obtained would seem to indicate that a valuable improvement in electric railway work has been inaugurated by the application of the shrouded gear. Another interesting improvement brought out by the Detroit Electrical Works is the carbon brush-

FIG. 1.—DETROIT ELECTRICAL WORKS NEW CAR GEARS.

holder, applicable both to railway and to stationary motor and dynamo purposes of all kinds. Recognizing the difficulties encountered with bolts and nuts which work loose, especially in railway service, the company have brought out a brush-holder in which no device whatever of this kind is employed, the brushes being controlled entirely by a spring arranged in an ingenious manner so that its tension can be regulated at will.

The accompanying engraving, Fig. 2, shows the brush-holder, the left-hand brush being shown under tension, effected by means of the spring with a loop at the top. The tension of this spring is regulated by means of a pin controlled by a lever, which has a pawl attached to it and which meshes with the ratchet shown, the spring being coiled around the pawl pin. By merely raising this lever so as to disengage the pawl from the ratchet-teeth and sliding it forward or backward, the tension can be regulated to a nicety, and the pressure of the carbon upon the commutator is thus effected with precision. When it is desired to remove or replace the carbon, the spring can be pulled down, and, by means of the loose ring, held in the position shown at the right-hand brush-holder, which leaves a perfectly clear space for the insertion or removal of the carbon. The spring where it bears against the carbon is re-enforced by a strip of brass so that it is well able to stand the slight frictional wear brought upon it during the process of altering the tension. The brush-holder, it will be noted, is made in

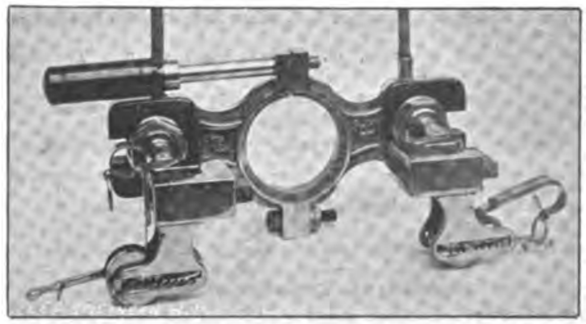


FIG. 2.—DETROIT ELECTRICAL WORKS BRUSH HOLDER.

two sections, which are bolted together at their lower end, and are held together, and at the same time clamped, by the long clamping bolt, provided with an insulating handle.

This brush holder was exhibited by Mr. Ch. A. Benton at the New York State Street Railway Convention, held in this city last week, and elicited much favorable comment from the electric railway men present.

AN ENORMOUS MICROSCOPE.

THE Poeller Physical Optical Institute of Munich have under construction an enormous microscope for exhibition at Chicago in 1893. It will magnify to 16,000 diameters, or, as ordinarily fitted, to 11,000 diameters. An electric light of 11,000 c. p. is to be used for illuminating the image, which is to be projected on a screen. As the heat from this powerful light would derange the focus by expansion of the metal, an ingenious cooling device is used. This consists of a small copper cylinder filled with liquid carbonic acid under a pressure of 350 lbs. to the square inch. It is connected with the microscope in such a manner that an electric regulator automatically opens a valve and allows a drop of the acid to escape in a spray on the metal to be cooled; the liquid immediately evaporates and produces intense cold. The whole cost of the instrument is said to be nearly $10,000.

THE ELECTRIC UTILIZATION OF WATER-POWER IN BAVARIA.

A COMPANY has been formed in Lindau under the name of the Elektricitätswerk der Argau for the purpose of supplying Lindau, Langenargen, Friedrichshafen Tettnang, Ravensburg, Weingarten and Wangen with electric light and power. At a meeting recently held, Herr Huber, of the Maschinen Fabrik Oerlikon, recommended the adoption of the rotary current. About 3,000 h. p. will be available for distribution. It is estimated that the yearly charge for 1 h. p. will not exceed $30 or $35, and that lamps will cost about $5 per annum.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, *150 Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XII. NEW YORK, SEPTEMBER 23, 1891. No. 177.

Nature is our kindest friend and best critic in experimental science, if we only allow her intimations to fall unbiased on our minds.—Faraday.

ARC LAMP TRIMMING.

FOR some reason the very important item of recarboning, or, as it is technically called, "trimming", arc lamps has not been much discussed either in the electrical press or at meetings and conventions bearing on the subject. This cannot be because it does not need such discussion, as those at all familiar with the work are aware that it does, and that badly.

The satisfactory working of the lamp depends largely on the trimming, and if this is indifferent or poor, so likewise will be the light. Not only will customers growl, but extra expense will grow out of repairs thus made necessary. Trimmers are usually of a class who will be careless unless held rigidly to their work, as tested by close inspection. Rods not well cleaned will become covered with blotches or specks from poor contact in the works. They will stick and cause the lamp to flame and otherwise burn badly, and often burn out magnets. This can be caused only in two ways, carelessness and too long a route for the trimmer. If carbons are placed crooked or are not of proper length, one of the holders is sure to be burned and destroyed—if the lamp lights at all. Many stations buy "seconds" of carbons because they are cheap, but it is in some cases doubtful if the cost of destruction of carbon holders is not in excess of the difference of price, not to mention the extra time used in trimming. The time does not enter largely into the calculation, as routes are usually laid out so that the work is done some time before lighting up, and if an especially bad or crooked lot of carbons is struck, part of this period is available.

These are only a few of the troubles that could be mentioned. The question of size and style of carbon also demands some attention, but this can usually be settled best by the persons in charge of the plant, if good judgment is employed. The use of plain or copper-coated is largely a matter of opinion, but is more or less governed by the location of the lamp. Whether to use all of one length or in pairs, *i. e.*, one 12 inch and one 7 inch must also be decided by those in charge, as it is controlled by the length of time of burning of the lamps. It is found in practice that for all ordinary work on 0 ampere current lamps, a copper-coated ½ inch carbon 12 inches long answers the most generally. For double lamps, one carbon broken in the middle will answer all purposes. In all cases trimmers should be compelled to bring in a carbon stump for every one used. In many places where such a system has been tried the saving in carbons has been very large. In discussing the cost of trimming lamps we find that no attention is generally given to the location and distance apart or length of route. It will readily be seen that this is an important item and should be made a part of the factor of cost. It has been suggested that the cost of trimming per lamp-foot might properly be used as a unit—that is, the number of lamps multiplied by the distance traveled in feet would be the basis of laying out a route. There is so little difference of time required for one system as compared with another, that it need not enter into the discussion at all. In the large cities where lamps are close together, many more can be trimmed than in a country place where they are widely spread. For instance, it has been found that 85 or 90 lamps can be well trimmed by one trimmer in New York city, and in cases of extra good workman, a hundred or more. We have heard of one place where lamps were run away out into the country and all the farms and parks lighted up. In this case 40 lamps were a big day's work for the best trimmer. Therefore, when a man says that his trimming costs two cents or two and a half or three cents a lamp, and another that his costs four or five cents, they hardly meet on a common basis for figuring costs; whereas, if they both use the unit of lamp foot, neither has the advantage and a proper comparison can be made at once.

Of course, all costs will be governed by the price of labor in the different localities, but this will not change the comparison in any way.

The whole subject will bear wide discussion, and there is scarcely another item in the entire field of arc lighting which is more vital to the good working and growth of the business, and consequently the satisfaction of customers.

THE EXPENDITURES OF AMERICAN CITIES.

"UNTIL our American cities demonstrate their capacity to do a few things well, it would seem to be clearly unwise to enlarge their inherent powers upon the theory that because they have not done a little well, they still would be able to do a great deal well." Thus President Seth Low, of Columbia College, in an article in the September *Century* on the government of cities in the United States. He says, moreover, that no business within the city could be successfully managed by the bodies to whom has been committed the management of city affairs. And yet in face of facts so self-evident that every newspaper in the country is full of them and depends on them for its most sensational headlines, we are told that the next thing in the line of civic and municipal development is the setting up of city electric light plants. A special committee at Haverhill, Mass., for example, has just reported as the result of its investigations that the first and only conclusion to be drawn from a study of certain figures it has accumulated is that cities can furnish their own electric lighting more cheaply and advantageously than it can be procured from private parties. What utter nonsense this is. Half the figures are lies, to begin with, and as to the inference on the whole of them, we will simply quote Mr. Low again, with the reminder that he was once mayor of Brooklyn. As to "the question whether a city should or should not manufacture its own gas, and either build or conduct its own street railroads, * * * the city surely is fortunate which is competent to do things of this sort for itself; but few American cities have manifested so great competency in other directions as to justify a very strong inference that they would administer successfully business of this kind."

MECHANICAL AND STEAM APPLIANCES AT THE FRANKFORT EXHIBITION.

ALTHOUGH professedly devoted exclusively to electricity, the Frankfort Exhibition, being one designed to illustrate the present state of electrical engineering, of necessity gives occasion for the display of numerous accessory apparatus employed in connection with nearly every electrical plant. The belts exhibited, of which Mr. Ch. A. Schieren gives an interesting expert account, would hardly seem to compare favorably with those of American manufacture, but on the other hand one must not lose sight of the fact that the electric light has been a most potent factor in the perfection reached by our belt makers, an influence which has until within a short period been lacking in Germany, and on the continent generally. The acknowledged superior quality of American belting illustrates once more the direct influence of a new art on another older one. The steam appliances at the Frankfort Exhibition described by our correspondent, Prof. Heinrich, will also be of interest to station managers, especially those who have to contend with impure water for boiler purposes.

THE TELPHERAGE INTERFERENCE.

A DECISION which happens to be of unusual importance in its relations to electrical interests was rendered by Commissioner of Patents Simonds, on September 12th, in the interference case of Hunter v. Jenkin. The particular subject-matter in issue was the well-known system of automatic electrical transportation, invented and patented some years since by the late Fleeming Jenkin and termed by him "telpherage." The immediate importance of the decision is due to the circumstance that it is virtually a test case, involving substantially the state of facts, and the same proofs as a very large number of other cases which have been some time pending in the Patent Office, in behalf of the same contestant, covering not only most of the fundamental principles, but a large number of absolutely essential details of the construction and operation of electric railroads. The decision of the new Commissioner is not only of interest to the many inventors and attorneys engaged in the cases referred to, but possesses no small intrinsic value as an able, exhaustive and accurate statement of the doctrine of our patent law with reference to the frequently recurring question of diligence on the part of the party first to conceive, in a contest for priority of invention before the tribunal of the Patent Office. It once more places the legal position of the Office in harmony with that which has been uniformly held by the Federal courts, the marked divergence from which in some recent instances has given occasion for much unfavorable comment among parties having cases pending before that tribunal.

THE ADVANCE OF ELECTRIC RAILROADING.

THE meeting of the New York State Street Railway Association last week was almost wholly devoted to electricity, and that with the more significance that just outside of its hall were the new tracks of the Broadway cable road—one of the wildest pieces of folly that this generation of New Yorkers has seen. Splendidly built as the road is, one can but see in it the evidence of poor judgment and expensive short-sightedness. It is as though a man had invested heavily in fine stage coaches at the moment when steam locomotion had begun to make its triumphant demonstration. The paper by the incoming president, Mr. Beckley, of Rochester, was enough to show which way the tide was running, for admitting all the defects of the electrical method, he was still compelled to advocate it as that which, par excellence, is the best for nearly every large community in the United States. The proof of the pudding is in the eating. Three years ago there were a dozen operative electric roads in this country. To-day there are 375, with another hundred getting ready for work.

Composite Electric Light Stations.

THAT the days of the "one system" stations are passed and gone was forcibly brought out in the address of President Huntley, and the paper read by Mr. H. Ward Leonard at the Convention served to show in what manner the operation of the composite station could be carried on in the most economical way. Mr. Leonard, it will be noted, started out with the proposition of solving two distinct problems in electrical distribution, namely, the overcoming of distance and of low economy in operation. If a single station is to surmount both these bars to commercial success, it must be so organized that the apparatus to be employed at any one time must operate at its highest economy at that particular time, and with the variable load which we know to exist to-day on electrical distribution circuits, it requires not a little ingenuity to work out such a system. The plan suggested by Mr. Leonard seems to be quite a feasible one and certainly possesses the advantage that it affords a means of obtaining current for every possible purpose with the apparatus at command to-day.

THOMSON'S CONSTANT CURRENT TRANSFORMER.

In an interesting letter appearing in The Electrical Engineer of July 1, 1891, Prof. Elihu Thomson drew attention to a new type of constant-current transformer invented by him several years ago, but of which the full details could not be made public owing to the peculiar position in which American inventors, applying for foreign patents, are placed. The recent issuance of the patent referred to by Prof. Thomson enables us now to give a more detailed description of this interesting machine, which is illustrated in the engraving, Fig. 1.

As pointed out by Prof. Thomson at the time, the machine was designed and constructed for use in systems of distribution with continuous currents, being a continuous-current transformer compounded for drop in the machine itself, for drop in the secondary, and for drop in the high potential or main line leading to the machine. The machine also admits of ready compounding for the combined drop.

The diagram, Fig. 2, illustrates the method of operation of the system. The generator G feeds a system of mains, m m', which branch into subsidiary mains, n n' n^2 n^3. The armature is divided into two sections, A A'. The core A has a winding which is connected in the ordinary manner with

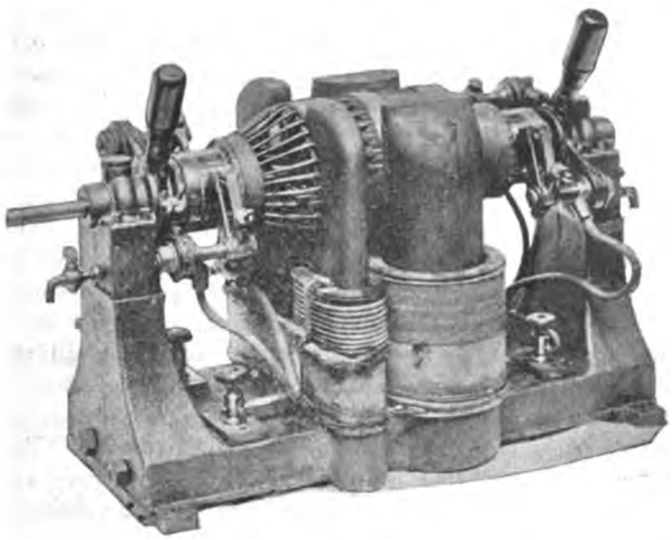

Fig. 1.—Thomson Constant Current Transformer.

the commutator C, and the combined sections A A' have a winding which covers both, and the terminals of which are connected to the commutator C'. In the left-hand transformer, Fig. 2 it will be seen that the commutator C takes current from the sub-main n n', and that the magnets affecting the section of armature A are shown as wound with fine wire coils, S S', and are energized in shunt. They are therefore of fairly constant magnetism, except for drops of potential in the line. It will also be seen that the connections from the brushes resting on the commutator C', which is the local-circuit commutator, are carried through and around coils D D, which affect a separate set of field-poles acting on the armature-section A' alone. The local circuit passing through the magnet-coils D D', then passes to the lights or other load which are fed by it. This arrangement may, however, be modified, as shown in the right-hand transformer, Fig. 2. Here the coils D D' are traversed by the current in the sub-mains n^2 n^3, which practically become the path of a direct current passing through the commutator C', while the local mains and commutator are connected directly without intervention of any coil between them. This is seen to the right hand of the figure, where the work circuit L is fed direct from the commutator by a connection to its brushes, while the shunt S S' is worked, as before, in derivation from the sub-mains n^2 n^3.

Now, assuming that the winding on the armature has been properly done, so as to give whatever reduction of potential is required when the load is light, as when there are no lamps burning at L, then this relation will have to

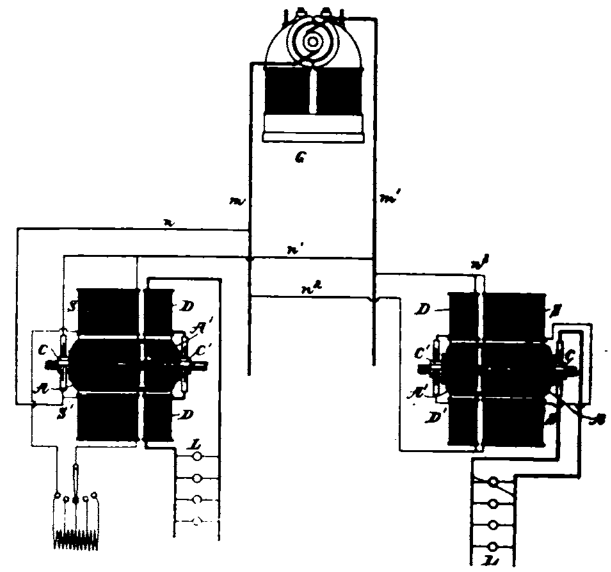

Fig. 2.

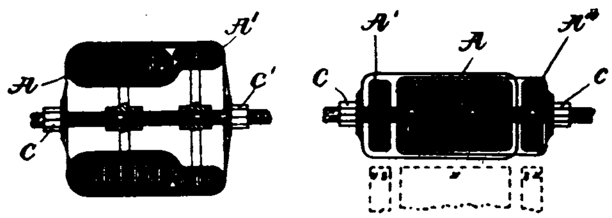
be changed whenever the load is thrown on in consequence of a drop which occurs not only in the machine, but in the local mains and in the feeding mains n n'. It is to compensate for this drop that the accessory portion of the armature A' and the winding which is upon it come into play. As lights are turned on, the current which flows in the local circuit in the transformer, Fig. 2, will evidently increase, and the coils D D' will therefore be able to magnetize their cores and affect the armature-core A' and the coils which correspond—that is, the potential will be raised in the local circuit when the magnetism of the cores D D' is added to that of the shunt-coils S S'—and tends to enhance the value of the local coil on the armature. This enhanced value is obtained without affecting the value of the other armature-winding, which is connected to the commutator C. The effect would be then equivalent to an increase of the effective length of the local circuit armature-winding, while maintaining the high potential or main-circuit armature winding the same. The power to be given to the added field coils and the added armature-section A' will depend upon the amount of this increase required to compensate for the drop, and is a matter to be determined in each particular case.

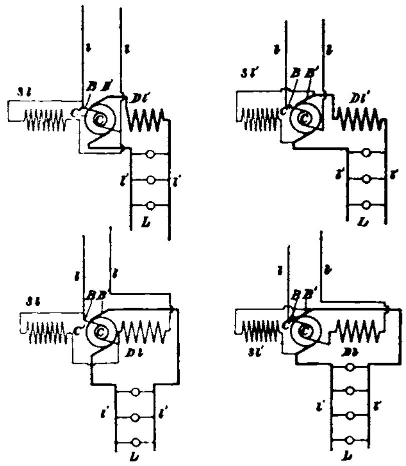


Figs. 3 and 4.

Fig. 3 shows a ring-core, the winding of the main body of the core being connected to the commutator C. Alongside of it is a similar ring-core, A', which is wound over with another winding connected to the commutator C'. This armature has the same properties as the armature shown in Fig. 2, and may be used in a similar field.

In Fig. 4 an arrangement is shown in which there are three sections of armature. The winding overlaps two of them in each case; but the winding connected to the commutator C overlaps the section A' and A, while the winding connected to the commutator C′ overlaps the section A A². In this case three sections of the field-pole are used—N, N S, and S N—the outer smaller poles being made alternately south and north, respectively, and in the desired direction for the two windings, so as to increase or diminish the effect of one with respect to the other, as the need arises.

Fig. 5 shows a circuit connection in which the shunt-winding is a connection taken out at S *l*, taken from the feeding-main *l l* in shunt to the brushes of the commutator C, which corresponds to one winding on the armature, while the commutator C′ is the one which feeds the local mains,



FIGS. 5, 6, 7 AND 8.

and the direct circuit D *l′* or direct magnet is placed in this circuit, feeding the lights L and the local mains *l′ l′*.

Figs. 6, 7, and 8 show other modifications, which will be readily understood.

THE "VULCA" ELECTRICAL WIRE DUCTS.

OF the improvements constantly going on in the electrical arts at the present time, none are more pronounced than those which pertain to the methods of wiring and the distribution of conductors for general service in the streets, as well as in the interiors of buildings. The attainment of the highest safety, especially in house wiring, is being brought out more and more prominently and insisted upon by the various boards of fire underwriters, so that it is to be hoped that the time will soon come when the badly installed electric wiring plant will be as little tolerated as a leaking gas pipe system. To attain this high standard of house

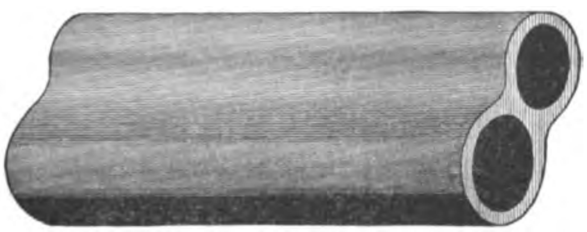


FIG. 1.—DUPLEX VULCA DUCT.

wiring, it has been recognized that wires require to be laid in passages or conduits especially provided for that purpose, and one of the latest efforts in this direction is that embodied in the system now placed before the public by the New York Insulated Wire Company and known as the "Vulca" electrical wire ducts. The aim of the manufacturers of this tube has been to supply a non-inflammable and moisture-proof tube, which should at the same time have a high tensile strength and which should not collapse when placed in wet mortar, cement or plaster, a property which is evidently a *sine qua non* of a tube designed for application below the surfaces of walls. At the same time the tube must be of such a nature as to permit of the easy insertion and withdrawal of wires, and for that purpose the "Vulca" ducts are made with a smooth and hard surface, both within and without.

These tubes, when used singly, are made in sizes of from ¼ to 1¼ inch inside diameter, and when used double or duplex, as shown in Fig. 1, vary from ¼ to ½ inch in diameter. Besides the tubes, the system has been worked out completely as regards its accessories, and a full set of elbows, right-angles and S-offsets for all sizes have been designed. In running these tubes the joints are

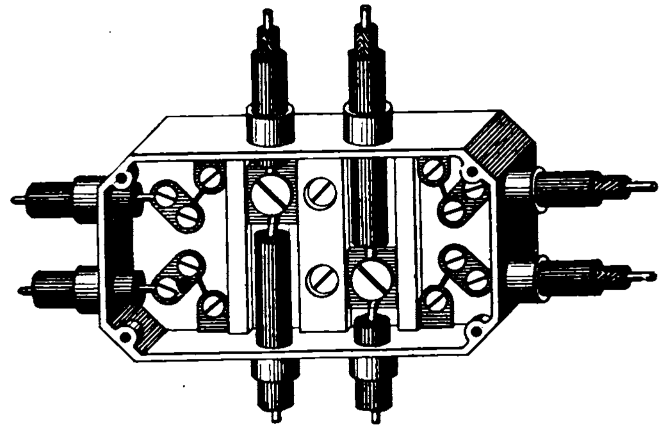

FIG. 2.—2-WIRE DOUBLE BRANCH CUT-OUT.

made by squaring the ends of the tubes and slipping them into a brass tube, one conduit tube abutting against the other. Over all this there are wrapped two layers of pure rubber, making the joint absolutely moisture-proof and the insulation at that point equal to that of the rest of the tube. The company advocate the insertion of only one wire in each tube and that wire covered with a high-grade insulation. For convenience sake, however, it is

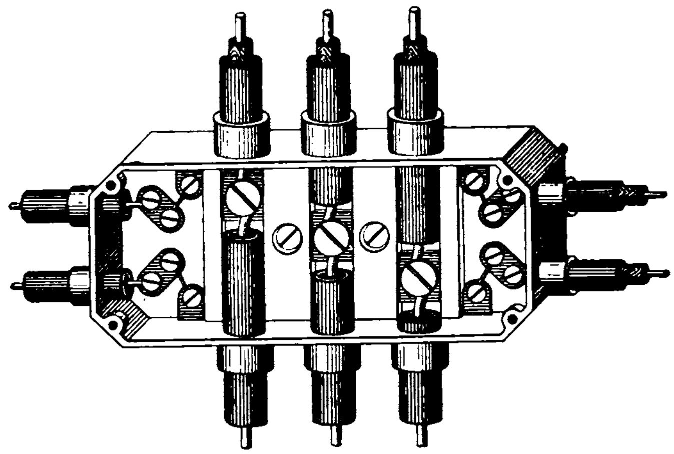

FIG. 3.—3-WIRE DOUBLE BRANCH CUT-OUT.

frequently desirable to use the "duplex" tube and all the appliances are also made for this tube.

Among the distributing boxes employed with the "Vulca" ducts are the single and double branch cut-outs for the two and three wire systems, shown in Figs. 2 and 3; while the straight-away cut-out and fishing-box is shown in Fig. 4. Figs. 5 and 6 show respectively the single-branch cut-out and the angle boxes

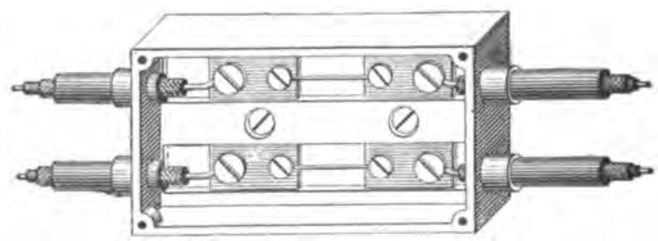

FIG. 4.—STRAIGHT-AWAY CUT-OUT AND FISHING BOX.

for fishing and turning corners. All these appliances are mounted on porcelain bases and inserted in boxes fitted with sockets for the entrance of the tubes, the diameter of the sockets being slightly smaller than those of the tubes, so that the tube, when forced in, makes a moisture-proof joint. The company advocate shortening the length of the tap circuits as much as possible and placing the cut-out boxes as near as possible to the lights, and hence they prefer to place the boxes at the baseboard near the floor, as shown in Fig. 7, or under the

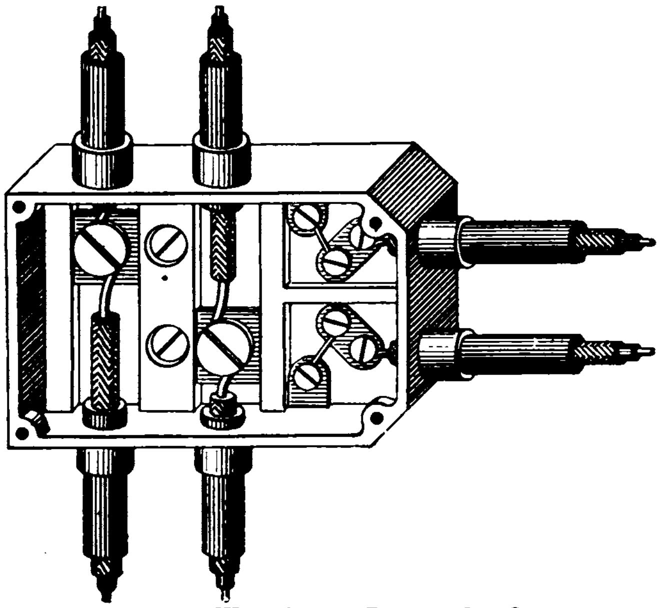

FIG. 5.—2-WIRE SINGLE BRANCH CUT-OUT.

cornice, as shown in Fig. 8. For vertical mains or risers their practice is to place all the boxes in recesses in the wall and to

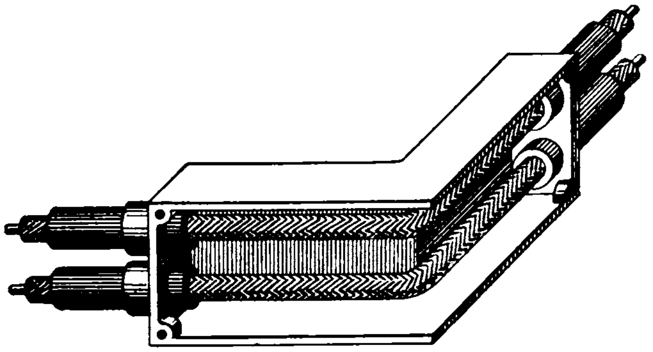

FIG. 6.—ANGLE BOX FOR FISHING AND TURNING CORNERS.

have at each floor a main-floor cut-out, as shown in Fig. 9, from which all the wires start out that feed the circuits on that floor.

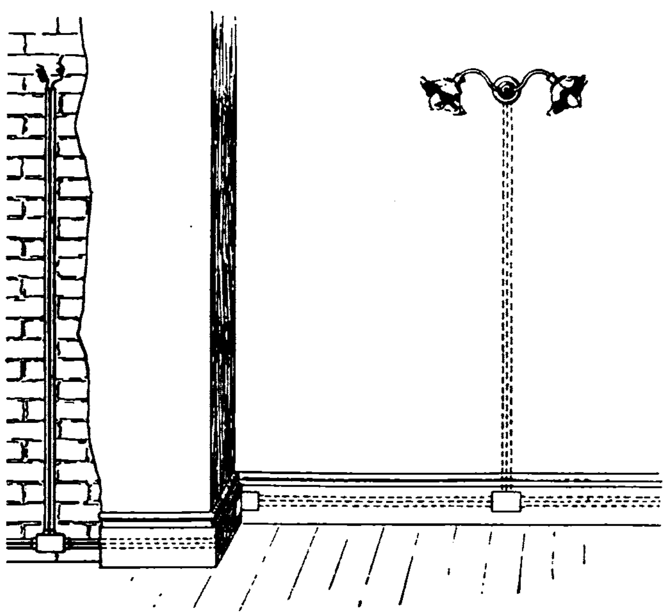

FIG. 7.—VULCA DUCTS BEHIND BASE-BOARD AT FLOOR.

The recess is provided with a removable cover, so as to be accessible at all times.

The material of which the "Vulca" tubes are made possesses, it is claimed, a rare combination of qualities; thus while, as above stated, it is moisture-proof and non-inflammable, it can be drilled, tapped, filed and threaded, being about as tough as good, hard wood. It can also be used with safety where the ceiling and side walls are to be decorated, as it will not exude or stain; hence, it can be placed directly in cement or plaster without any outside protection, such as a metal tube. Where it is used for surface work it can be polished like hard rubber and can be japanned and stained to match any wood-work. The duplex tube can also serve as a very convenient picture rod. The method of fastening the tube to rough walls is also very simple. For this purpose a nail is driven in and the tube fastened with wire twisted around the nail.

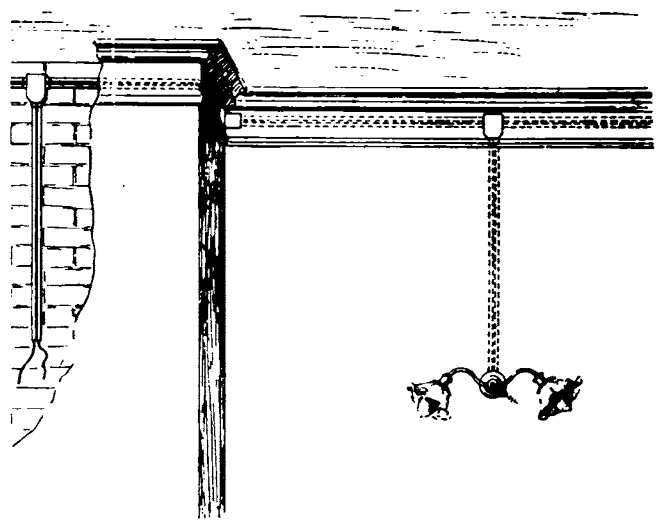

FIG. 8.—VULCA DUCTS BEHIND CORNICE AT CEILING.

At the Electrical Exhibition just held at Montreal, under the auspices of the National Electric Light Association, a full line of samples of these tubes was exhibited, stained in imitation of all the favorite decorative woods, such as ash, black walnut, mahogany and oak, as well as bronzed and silvered. The New York Insulated Wire Company, the well-known manufacturers of the

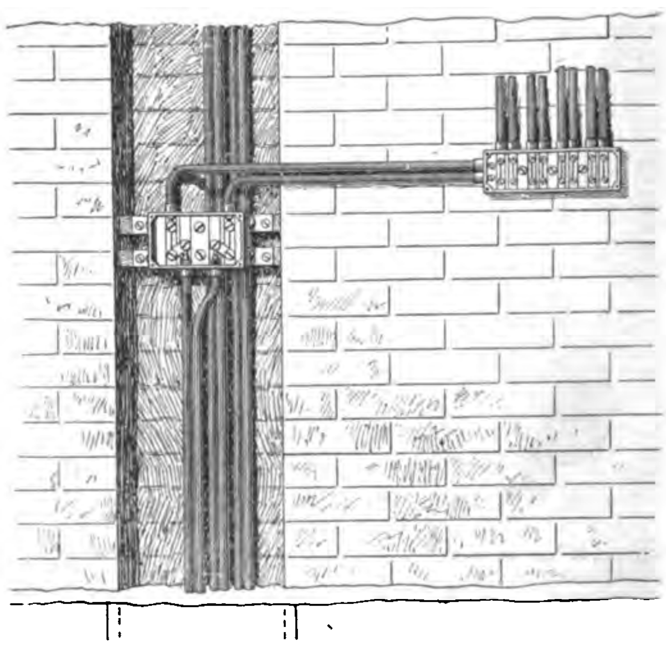

FIG. 9.—MAIN FLOOR CUT-OUT.

Grimshaw wires and cables, are now thoroughly prepared to furnish these tubes in any quantity, and their many excellent qualities will no doubt soon create a large demand for them.

MR. C. E. HUGHES, manager of the Western Union office at St. Paul, Minn., has resigned.

MEETING OF THE STREET RAILWAY ASSOCIATION OF NEW YORK.

THE Ninth Annual Meeting of the Street Railway Association of the State of New York was held at the Hotel Metropole, New York City, on Tuesday, September, 15, 1891. President Daniel F. Lewis called the meeting to order.

The following delegates were present:

Beckley, John N., pres. Rochester Railway Co., Rochester.
Beers, Edwin, pres. Broadway Railroad Co., Brooklyn.
Calhoun, John M., pres. Forty-second St. and Grand St. Ferry R. R. Co., N. Y. City.
Cannon, Duncan B., sec. Brooklyn City and Newtown R. R. Co., Brooklyn.
Curtiss, Frank, pres. Sixth Avenue Railroad Co., N. Y. City.
Delancey, Wm. H., supt. North and East River R. R. Co., N. Y. City.
Field, C. J., engineer Buffalo Railway Co., Buffalo.
Foster, John S., pres. Forty-second St. M. & St. N. Ave. Ry. Co., N. Y. City.
Graham, Benjamin, vice pres. Rochester Railway Co., Rochester.
Hasbrouck, Daniel B., sec. Houston, West St. and P. F. R. R. Co., N. Y. City.
Kruesi, John, pres. Schenectady Railway Co., Schenectady.
Landon, E. T., auditor Dry Dock, E. B. and B. R. R. Co., N. Y. City.
Law, George, pres. Eighth Avenue Railroad Co., N. Y. City.
Lewis, Daniel F., pres. Brooklyn City Railroad Co., Brooklyn.
Linch, George W., sec. Christopher and 10th St. R. R. Co., N. Y. City.
Littell, H. H., pres. The Cross-Town Railroad Co., Buffalo.
McIntyre, L. H., supt. Harlem Bridge M. & F. Ry. N. Y. City.
McLean Thos. H. sec. Twenty-third Street Railway Co., N. Y. City.
McNamara, John W., pres. Albany Railway Co., Albany.
Masson, Milton I., sec. Central Cross-Town Railroad Co., N. Y. City.
Minary, C. K., gen. manager Rochester Railway Co., Rochester.
Partridge, John N., pres. Brooklyn City and Newtown R. R. Co., Brooklyn.
Richardson, W. J., sec. Atlantic Avenue Railroad Co., Brooklyn.
Scribner, G. Hilton, pres. Central Park, N. & E. R. R. R. Co., N. Y. City.
Thompson, Henry, pres Broadway Railroad Co., N. Y. City.
Valentine, Johnson L., treas. Central Park N. & E. R. R. R. Co., N. Y. City.
Watson, Henry M., pres. Buffalo Railroad Co., Buffalo.
Wyman, C. Densmore, vice-pres. Central Park, N. & E. R. R. R. Co., N. Y. City.

There were also present the following street railway officials:

Barr, Thomas C., pres People's Passenger Railway Co., Philadelphia, Pa.
Lawless, Edward J., supt. Paterson Railway, Paterson, N. J.
Perrine, Lewis, pres. Trenton Horse Railroad Co., Trenton, N. J.

The street railway and electrical press were represented, as follows:

T. C. Martin, THE ELECTRICAL ENGINEER.
C. E. Stump, C. B. Fairchild and J. H. McGraw, *Street Railway Journal.*
F. L. Kenfield, *Street Railway Review.*
P. G. Monroe, *Street Railway Gazette.*
E. V. Cavell, *Street Railway News.*
Charles W. Price, *Electrical Review.*
E. V. Cavell, *Electrical Age.*

MR. G. GREEN, the proprietor of the Metropole, being an old street railway president, constituted himself the host. The session was opened by President D. F. Lewis, who made a pithy and pertinent address on the general situation, referring hopefully to electricity, and emphasizing the need of closer union among street railway men. The report of the Executive Committee also touched upon electric power as "surely the most brilliant and magnetic, the loftiest and most promising." Mr. J. Beckley, of the Rochester, N. Y., city railway, then presented an admirable report on the use of electric motive power for street railways. In the course of his remarks, he said:

"Five years ago the only street surface railways which were in successful operation anywhere in the United States were horse and cable railways. Within that five years more than 4,000 street cars have been electrically equipped, and to-day more than 3,000 miles of track in 300 cities and towns in this country have been constructed on which these electric cars are run with satisfaction to the people, and, in the main, with profit to the companies operating them.

"The development of the street railway has had as much to do with the growth and prosperity of the towns and cities of this country as, or perhaps, more than, any other thing. The transportation of people by street railroads is most intimately connected with the social and business life of the people. Nearly 500 cities in the United States have street railway systems in operation. More than 800 corporations are operating street railways in such towns and cities. As many as 30,000 street cars, horse, cable and electric, are to-day running upon the 8,000 miles of street railroads in this country. In these cars, and on these tracks, are carried as many as 3,000,000,000 of people yearly, or fifty times the entire population of the United States. When we consider that the number of people carried by all of the steam railroad companies in all of the States of this Union last year is estimated at less than 500,000,000, and that more people are carried on the street surface railroads in the city of New York in a year, than are carried by all the steam railroads of the State in the same period, we come to have some conception of the immense importance to the people of the rapid, efficient and safe service of street cars in the rapidly growing cities and towns of this wonderfully prosperous country. Think for a moment of the daily loss to the people of any city where horse cars are run at from four to six miles an hour, as compared with the operation in the same city of electric or cable cars, running from six to twelve miles an hour. Consider the immense increase in the value of property in our municipality, caused by the introduction of rapid transit. Consider the wholesome influence upon the people of every community where the husband, or other head of a household, is able, by means of facilities of quick transportation, to take his midday meal with the members of his family. The best thought of this time may well be expended upon this great question of furnishing quick, safe, cheap and comfortable transportation to the people whose lot it is to dwell, as dwell they do in such vast numbers, in the towns and cities of this land.

"The problem which is presented to the street railroad man of to-day must be considered, not simply with reference to the populations as they now exist, but with reference to the great increase of population, which is certain to come There are seventy-four cities in the United States which have a population in excess of 40,000. The total population of these seventy-four cities, as shown by the last census, is nearly 13,000,000, and the average increase of population in these cities during the last decade is nearly forty-seven per cent. In this State there are twenty-eight cities having a population in excess of 10,000, and a total aggregate population of nearly 3,500,000. The average increase in population of these cities, in the past ten years, has been more than thirty-three per cent. For all these growing towns and cities in our own State, and throughout the country, what can electricity do as a motive power for the operation of their street railroads?

"We who have had to do somewhat with the change of the system of operation of street surface railroads from horse to electric power, know that we have now passed beyond the experimental stage, and are beginning to tread upon ground which seems firm under foot. We hear, now and then, fears expressed by doubting Thomases as to whether the motors are going to last, as to whether the repair bill is not going to wipe out all profit, and as to whether the great expenditure which has been, and is being made on our railroads, may not be thrown away, because some new and wonderful principle is to be discovered which will enable our railroad companies to operate their roads with commercial success by means of storage batteries. We find in some communities so great a prejudice against overhead wires that railroad companies are unable to obtain the necessary franchises and privileges, the granting of which would result in giving those communities the benefits of rapid transit with electricity as motive power. Hour by hour, however, experience is teaching all doubters that the problem of rapid transit for cities has been solved, and that the trolley has come, and come to stay."

After complaining of the inadequacy of Mr. Cooley's recent census figures on street railway work, Mr. Beckley said:

"The company which has had the greatest experience as to these matters is the West End Street Railway Co., of Boston. That company has published a statement showing its earnings and expenses both with the electric and the horse car system, for the months of April, May and June of this year. I ought perhaps to state that, as it seems to me, the conditions involved in the consideration of these questions are so diverse in different cities that the only proper basis of comparison of cost of operation is the cost per car mile. It is quite common for the street railroad officials to consider this question of the relative cost of operation upon the basis of a percentage of gross receipts. It will be readily seen, however, that this basis of comparison is necessarily misleading and inaccurate. The other basis is not exact, but approaches at least approximately to exactness. The total expense, as shown by the West End company, for motive power, car repairs, damages, wages of conductors and drivers, and all other expenses per mile run with electric power, during the three months mentioned, was as follows:

April	21.75 cents.
May	22.36 "
June	20.37 "

The total expense per mile run with horse power, for the time mentioned, was as follows:

April	24.54 cents.
May	24.04 "
June	23.52 "

"Earnings upon the two lines, during the period under consideration, with the two systems, were as follows:

April—Electric	....34.05 cents.	Horse	....31.77 cents.
May—	" ...33.43 "	"	....34.22 "
June—	" ....42.71 "	"	....36.85 "

"It will be observed that the earning power of the electric cars is considerably in excess of that of the horse cars, and that the expense per car mile is considerably below. The West End company states that the electric cars of this company are run on the longer and less remunerative lines. If this be true, the showing made is very greatly in favor of the electric car from a commercial standpoint.

"Permit me to refer to the experience of the company at Rochester, with which I am connected. In the month of May last, the Rochester Railway Co. operated 44 18-foot vestibule electric cars. The gross receipts from passengers riding on these cars during the month was $37,053, or 23.15 cents per car mile for a mileage of 159,567 miles. The total expense of operation of these cars for that month was $18,332, thus leaving a net profit of $18,721. The total cost of operation per car mile was 11.4 cents, and the profit per car mile was therefore 12.11 cents. It may be observed in passing that the operating expense was a trifle under 50 per cent. of the gross receipts.

"The cost of operation was divided as follow:

Motive Power	2.8 cents.
Car repairs	.7 "
Conductors and motormen	4.9 "
Other expenses	3

"During the same period the company operated 62 horse cars, all of them without conductors. Most of the horse cars were one-horse or bobtail cars. The total cost of operating the horse cars, without conductors, during this period was about ten cents per car mile, but the total receipts per car mile were but little above twelve cents.

"In the month of June the Rochester Railway Co. operated 54 electric cars and 60 horse cars. The electric cars earned each per day $23.60, or 22.77 cents per car mile, and the total expense of operating them per day was $10.50, or 11.07 cents per car mile. The cost of operation per car mile was divided as follows:

Motive power	2.40 cents.
Car repairs	1. "
Conductors and motormen	5 66 "
Other expenses	2.01 "
Making a total per car mile of	11.07 cents.

"The cost of operating the horse cars during the same month per car mile was 11.06 cents, and they earned 14.37 cents per car mile. These illustrations are fairly indicative of our experience in Rochester month by month. My experience in the operation of street railroads has convinced me that the most economical system of operation is the electric system. I have not, in the statements which I have now made, taken into consideration the greater fixed charge in the operation of an electric railroad as compared with a horse railroad, due to the much greater cost of the former; but in arriving at the conclusion which I have above expressed due consideration has been given to this one of increased cost. We know that when a horse railroad is changed over and operated by electricity, the receipts are very largely increased. It is safe in any case to say that the increase in gross receipts will be at least 15 per cent., and the average increase is probably as high as 30 per cent. Some of this increase is undoubtedly due to the greater mileage which the cars make, and still more is due to the cleaner, more rapid and more comfortable transportation of the people.

"We have reached the conclusion also that the bugaboo, which formerly somewhat frightened us, of the cost of maintenance and renewals of electric motors, need frighten us no longer. We have had motors in constant service on one of the first electric lines equipped in this country, namely, the line extending from Rochester to Charlotte, and these motors seem as efficient and in every way as satisfactory as they did the first month they were operated. We have, of course, renewed various parts of the motors, and we have replaced gears which have worn out, the expense of which has gone into the cost of maintenance. But the motors are still there, doing their work, and likely, with proper care and renewal of parts, to be doing their work ten and even twenty years, from to-day. The cost of maintenance and renewal of parts has not been so large as to carry operating expenses up to anywhere near the expense of operating the same number of cars, at the same mileage, by animal or cable power.

"Those who propose to substitute electric for horse-power will make a great blunder if they attempt to put in cheap construction or material. We who have gone into this matter have learned that the track upon which it is proposed to operate electric cars should be of girder or T rail, of not less weight than fifty pounds to the yard of T, and sixty-two pounds to the yard of girder rail. The weakest place in the track is, of course, at the joint, and no cheap contrivance at that point should on any account be permitted. With girder or T rail construction it is, it seems to me, a useless expense to lay a continuous supplementary wire. The rails should, of course, be well and heavily bonded at the joints with iron, not copper, wire and cross-connection of rails be frequently made. Where tram rail track is used, I think a continuous wire should be laid and connected with the bond wires.

"The overhead wire cannot be too well put up. Cheap devices should never be used because they are cheap. The best and strongest are none too good. In putting up the feed wire and putting in the ground wire return to the generators, do not spare copper. I am convinced that much that we have heard about the inefficiency of generators and motors is due to trying to get too great a quantity of current through too small a quantity of copper. In the power station do not make the units too large. Accidents will happen as long as machinery is run, and an accident to a 500 h. p. plant is serious, while you can keep your cars or most of them moving, if one of two or three small engines breaks down. The same rule, of course, holds as to the generators.

"Always put in a condensing steam plant. One large item of expense of operation is the coal bill. Cut that down at least forty per cent. by erecting condensing engines. The first cost is, of course, a little more, but your stockholders, as they examine your statements of operation in the years to come, will say you were wise in your day and generation.

"Locate your power station as near as may be in the centre of your system, but above all, if possible, on a stream large enough to furnish all the water you require for the boilers and condensers. City water, where your consumption runs into the millions of gallons fast, is expensive.

"It seems to me a mistake to equip a car body of greater length than eighteen feet, and I think a sixteen-foot car is better still. During the hours of the day when travel is heavy, it is easy to pull a trailer, and when traffic is light, you are then not using up your power in hauling around a great, lumbering double-truck structure practically empty."

The president having called upon electric railway representatives for some remarks

MR. CHARLES A. BENTON, representing the Rae system of the Detroit Electrical Works, addressed the delegates briefly. The system, he said, was unique. They manufactured a single motor made in three sizes, 15, 30 and 40 h. p. The peculiar advantage claimed for the system is that it gives to both axles a traction on the rails, which cannot be got by any other system. While the system was one of the most recent in the field, it had a respectable record, and while others might need a corps of expert electricians, it would do its work steadily with only the help of a single blacksmith.

MR. C. C. CURTIS, of the Short Company, said: "When this Convention met in Rochester last September, the Short Company came before you and made some very strong promises as to the showing that would be made when the road in Rochester was started. What that showing has been you have heard in the very able report that has just been read. The question in which you are all vitally interested is the question of repairs; repairs to your motors, repairs to your lines, and repairs to your generators. In the city of Rochester there has been kept day by day an accurate record of the motor and generator repairs. That road started running last November; and giving it eight months of run through the winter months—the hardest months in the year—up to the first day of August, the average cost of repairs per car mile was four mills. This is a very fine showing, as I think every gentleman who has kept a similar record will admit. The report just made gives the total repair account. That repair account as given month by month by Mr. Beckley, will, of course. include the repairs of the line, generators, motors, rail, etc. When I say four mills per car mile, I mean only the repairs on the generators and the repairs on the motors; that is, the electrical repairs. In Muskegon, Mich., where we have been running about a year and a half, our record shows two mills per car mile. We have two new motors to offer to you. We are prepared to give you the double-reduction motor or the single-reduction motor, and the low-reduction motor. You know how great and excessive the repairs on gears are. One of the gentlemen who was on the floor of this Convention stated to me a month ago, that in his judgment, if our gearless motor was really what we claimed for it (and we are prepared to back up our claim with strong guarantees) it would save his company seventy-five per cent. of the repair account. If this is true, no road should be equipped without looking carefully into the merits of this Short gearless motor. I have a report of a test made in Cleveland, Ohio, about two weeks ago, by Mr. Al. Johnson, with whom, no doubt, many of you are acquainted. It was a trial between one of his cars and one of the Short gearless motor cars. These two cars ran over the Brooklyn street railroad line, running about twenty minutes apart, doing commercial work. The gearless car checked up some eighty passengers, and the single reduction motor, which Johnson was running, checked up forty-seven. The car ran for about two hours and a half, and we have the half-minute readings. The report and the readings show that the single-reduction motor takes twenty-four per cent. more current than the gearless motor."

MR. M. K. BOWEN then described the Short generator recently described in THE ELECTRICAL ENGINEER.

MR. G. W. MANSFIELD spoke very forcibly and eloquently on the work done by the Thomson-Houston Co., whose roads were now to be found all over the world. After referring to troubles from snow, he introduced

MR. BARR, of the same company, who described their new snow-sweeper, which is equipped with a broom fitted with flat steel blades and flat steel wire brushes. The blade does the major part of the work, and will actually cut ice. The steel brush does the rest of the work. This "broom" runs at 150 turns a minute.

MR. H. W. GRANNIS described briefly the Westinghouse railway motors and methods, especially the gearless type of car. In the first year of their work, they had installed their motors successfully on about 70 different roads.

MR. C. J. FIELD, of the Field Engineering Co., insisted on the necessity of good construction work in electric railway plants.

MR. C. D. SHAIN made a very brief and business-like statement in behalf of the Edison General Electric Co.

MR. C. C. BOWEN described the plans of the Multiple Distributing Station Electric Railway Co., which proposes to feed into the railway circuit from block to block, as the car progresses, by special devices, the remainder of the line being "open."

The recommendation of the Executive Committee that the By-Laws be amended so that companies whose annual gross receipts from passengers are less than one hundred thousand dollars may be admitted to membership upon the payment of nominal annual dues, viz., five dollars, was adopted.

The following officers were elected for the ensuing year: President, John N. Beckley, Rochester; First Vice-President, Thomas H. McLean, New York City; Second Vice-President, George Law, New York City; Secretary and Treasurer, W. J. Richardson, Brooklyn.

Executive Committee.

President and Secretary, Daniel F. Lewis, Brooklyn; G. Densmore Wyman, New York City; Charles Cleminshaw, Troy.

Saratoga Springs, N. Y., was selected as the place for the next meeting of the Association, which will take place on the third Tuesday in September, 1892.

The meeting then adjourned.

All in attendance at the Convention were photographed in a group in front of the hotel just before luncheon. After luncheon, the party, as the guests of the retiring President, Mr. Daniel F. Lewis, went for a drive through Central Park and along the Riverside drive to High Bridge and Ft. George.

In the evening Mr. George Green, proprietor of the Hotel Metropole, tendered a complimentary banquet to the Association, to which all in attendance at the Convention were invited. About fifty gentlemen composed the party. It was of an entirely informal nature, although everything necessary to make the occasion thoroughly enjoyable was bountifully provided.

There was some brief speech-making indulged in, and shortly before nine o'clock the gathering dispersed.

THE BRUSH ELECTRIC CO.'S NEW DYNAMO AND MOTOR.

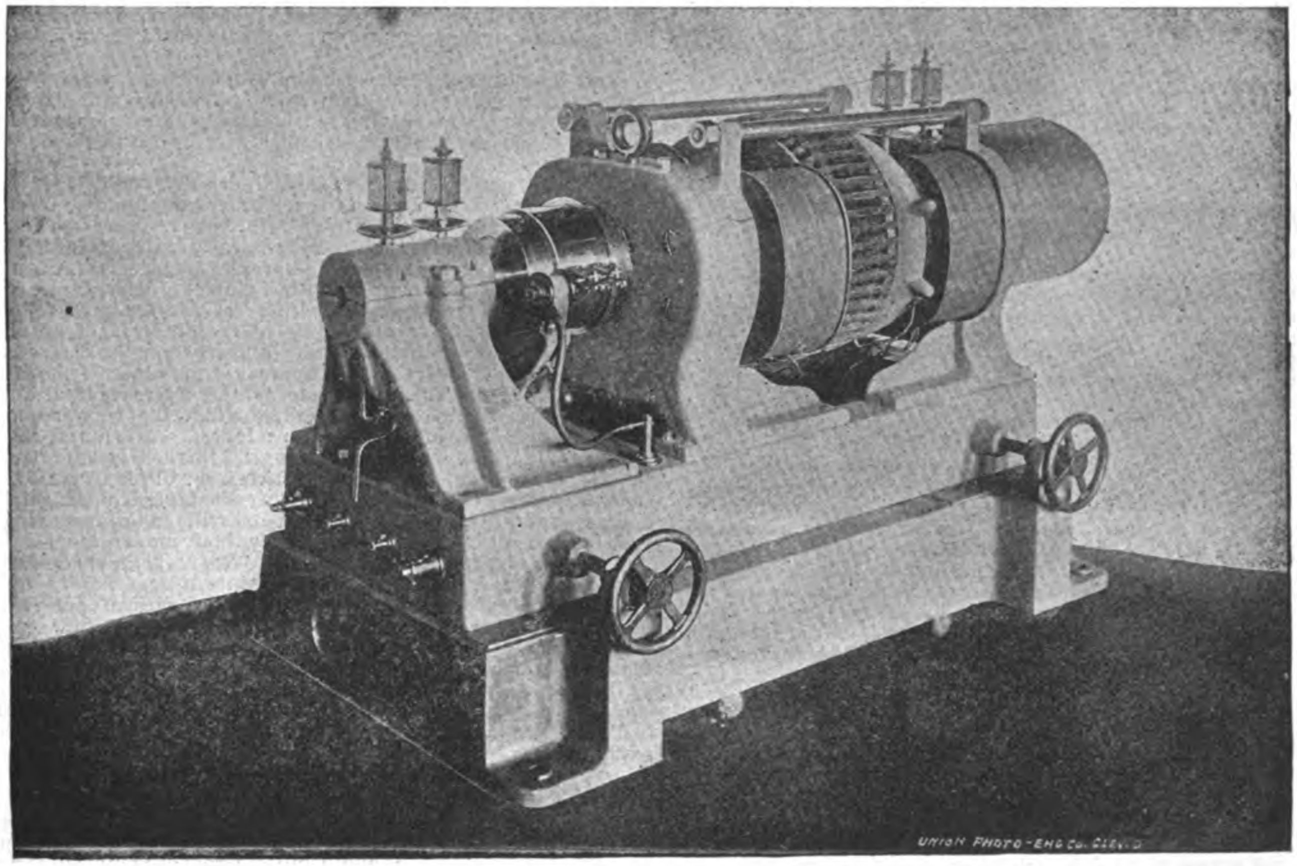
THE accompanying illustration shows the dynamo and motor recently designed by Mr. S. H. Short, the chief electrician of the Brush Electric Co.

The generator is capable of furnishing 100 h. p. at its pulley. The armature is of the closed coil type and its core is made up of thin sheet iron wound on a foundation ring and firmly riveted; the edges of this ring are then milled out slightly to allow for the bobbins of wire. The wires leading from the armature to the commutator are carried along the shaft, and are very carefully and thoroughly covered to protect them from dirt or damage of any kind. The bearing on the commutator side of the dynamo is placed outside of the commutator so as to allow a clear way for the connections between armature and commutator.

These generators are very compactly built, and the ventilation obtained is practically perfect. Any part of the machine can be inspected without disarranging other parts, and, in case of accident, the armature or magnets can be removed quickly, and repaired with little trouble. Any one of the armature bobbins can easily be rewound without disturbing the remaining bobbins.

The construction of the motor is very similar to that of the generator. One point, however, deserves special attention, and that is, the fact that the motor requires no outside governor of any kind, being entirely automatic in its regulation.

These generators and motors will be wound for an E. M. F. of 1,000 volts, thus allowing power to be carried over a considerable distance by means of a comparatively small wire. The new type of commutator, with which both motor and generator are fitted, runs with practically no spark, so that there is no trouble at that usually troublesome point.



BRUSH CO'S NEW DYNAMO AND MOTOR.

DIFFERENT FORMS OF CARBONS USED IN ARC LIGHTING.[1]

BY E. P. WARNER.

IN the period just preceding the introduction of the arc electric lighting commercially, experimenters and inventors had brought forward numerous plans, ideas, and theories regarding the size, form and manner of using carbons, and in view of the fact that no reasonably cheap method of generating the electric current then existed, a surprising amount of attention was given to the subject, and the developments of the art shown by many publications form no small part of our history of arc lighting.

It is not my purpose to dwell at length upon the history of carbons generally, but rather to touch lightly on some of the more notable forms known at the time of which I am speaking, and then to pass on to a consideration of the utility and practical results obtained with the different forms of carbons in use at the present time, paying special attention to the matter of form and size as affecting the results.

The form of a cylinder or pencil, it is noteworthy, was that used by Sir Humphrey Davy, in his earliest experiments, and he even devised special holders or clamps to retain the carbon pencils in alignment and facilitate their adjustment with a view of maintaining a constant and steady light. Archereau subsequently adopted the pencil form of carbon and used it in his lamp, now so justly considered as the first practical arc lamp; it does not appear, however, that he turned his attention particularly to the matter of form. Wright and others stand on record as experimenters with carbon discs brought edge to edge and made to rotate as they were consumed, and the combination of a disc placed on edge above a vertical pencil of carbon was also tried at this early date.

Wallace and Farmer made use of broad, flat plates of carbon, placed in a vertical plane, one above the other, the arc forming between the edges as they were drawn apart and shifting back and forth from one end of the plates to the other. Another inventor, at about this same date, placed flat plates of carbon side by side and an intervening insulation of some refractory material, the arc forming at the upper edges of the plates, and gradually consuming them. Jablochkoff in 1876 introduced his well-known electric candle, a form of arc lamp in which cylindrical carbons are employed, placed in a vertical position, and held separated by a thin filling of refractory insulating material.

Now, when we look back at the work of these early inventors, and consider what special object they had in mind in making their experiments, it is at once apparent that it was continuity of action, and it stands on record that they met with fair success so far as that feature is concerned, some of the lamps being capable of twenty hours' burning without attention.

In 1874, Mathias Day produced an arc lamp in which two cylindrical pencils were placed in the upper holders, and two in the lower holders, the upper ones occupying a plane with the lower and directly over them; here the avowed object of the invention was to secure long-continued operation of the light without requiring attention, and it is certain that he accomplished it in a very creditable and ingenious manner.

Coming now to the time of the commercial birth of arc electric lighting, we find Jablochkoff in the lead, closely followed by Brush and Weston, each making use of the cylindrical form of carbon pencil, and turning their attention most assiduously to the feature of continuity of operation, the first move being an increase in length of the pencils. Carré, a French manufacturer, at this time, became prominent as a maker of carbons, and succeeded in producing pencils about $\frac{7}{8}$ inch diameter and 32 inches in length, and it was thought, by the use of lamps of suitable length, these long carbon pencils could be advantageously used when long-continued burning was a necessity, but owing to the difficulties encountered in the manufacture, and also trouble in maintaining proper alignment for the carbons, a length of 22 inches was soon settled upon as most practicable and convenient.

As the business increased and the demands became better understood, the inventors again essayed to solve the problem of continuity of action, but, in many cases, such attempts were but returns to old forms and methods, and did not result in any practical advance.

Various forms of double carbon lamps were introduced, and, for a time, these were thought to be the only practical and commercially successful way out of the difficulty, but more recent developments have shown a far simpler and better way, and one, furthermore, that cannot fail to impress the practical electrical engineer. I refer to the simple expedient of using a carbon pencil of $\frac{5}{8}$ inch diameter, 14 inches in length, in an ordinary single carbon lamp. It is true that this is not new, and that carbon pencils of such size, or even greater, were tried long ago; nevertheless, the introduction of carbons of this size and form has a very great bearing on the commercial side of the situation; but before going into that matter I wish to say a few words regarding the lighting efficiency of $\frac{5}{8}$ inch carbons.

Having noticed that the question had been raised as to whether these carbons would give as much light for a given expenditure of electrical energy as would those of one inch diameter, I tried the following experiments:

Two single lamps were connected in series in an arc circuit, one being supplied with $\frac{5}{8}$ inch carbons 14 inches in length, the other with $\frac{1}{2}$ inch carbons 12 inches in length; around each lamp was branched a voltmeter indicating the voltage. The lamps were then adjusted until they had the same voltage, and as the current was of necessity the same in each, it was a safe conclusion that equal amounts of energy were being supplied. Photometric comparison of the two lights was then made at the horizontal and at many different angles above and below, with the result that no perceptible difference could be found in the power of the lights; during the tests the current was maintained as constant as practicable and care was taken to base the comparison on an average deduced from a large number of readings.

Now, while this matter of lighting efficiency is one that concerns the people operating electric plants, it does not interest them to the extent that other features upon which I have yet to touch may, as I happen to know that the management of lighting stations look long and lovingly on any plan that seems to give good promise of reducing running expenses. To begin with, there is the difference in first cost between a single and double carbon lamp, and the difference in the expense for repairs and attendance, these items varying of course with the different lighting systems. Still another important saving is in the cost of carbons, the cost for a given number of hours' run being fully thirty per cent. greater with $\frac{1}{2}$ inch than with $\frac{5}{8}$ inch carbons. There is the further important saving in the breakage of globes which often is caused by the sudden shifting of the arc in the double carbon lamp.

Twin carbons consisting of two cylindrical pencils placed parallel and in close juxtaposition to each other other, and connected by a web throughout their entire length, have of late been introduced, and when in use the arc alternates between the different pencils comprising the upper and lower twin carbons. A test of these carbons made principally with a view of determining the life and lighting quality gave unsatisfactory results in the following particulars: It was observed that the duration of burning for a given weight of material was not nearly equal to that which could be obtained with the same amount of material in a single cylindrical pencil. This I attribute to the more rapid disintegration of the twin carbon resulting from the very frequent heating and cooling of each member; indeed this is found to be true of two carbons which were arranged as in the Day lamp, or so that the arc alternates frequently between the different sets, and there is quite a noticeable difference in consumption of carbon for a given duration of lighting as compared with an ordinary single carbon of the same diameter burning without interruption.

Another undesirable feature of twin carbons is the shadow cast by the non-burning members, which, while it may not be disagreeably noticeable when the lamp is provided with an open globe, most certainly operates to reduce the total output of light.

It may be argued that the main item of expense in the manufacture of carbons does not lie in the material, and the fact that $\frac{5}{8}$ inch carbons cost so little more than $\frac{1}{2}$ inch, would bear out such a position, and I have merely mentioned the fact of the rapid disintegration and burning away of the twin carbons by way of explanation.

1. A paper read by title before the N. E. L. A. at Montreal, P. Q., Sept. 12, 1891.

ELECTROCULTURE.

EXPERIMENTS have been carried out in France, in Lot-et-Garonne, by M. Barat, upon the application of electricity to the culture of potatoes, tomatoes and hemp. A row of hemp, subjected to the influence of the electric current, produced a row of stalks 18 in. higher than those not electrified in the same time. A kilogramme (2.2 lbs.) of potatoes planted in the path of the current produced 21 kilogrammes of very large and healthy tubers, while the unelectrified patches only gave $12\frac{1}{2}$ kilogrammes of medium size. The electrified tomatoes also became ripe some eight days before the others. A curious fact has been remarked by M. Barat in his experiments. If a quantity of manure is near the positive pole, the constituent parts of this manure are transported towards the negative pole, and their effects make themselves felt around a distance of some yards. This would seem to be a fresh proof of the opinion long advanced upon the part played by electricity in the growth of plants, an opinion also adopted by M. Specnew, who has given some attention to these phenomena; this is, that the action of the electric current upon plants seems to consist in the more active dissolution of the organic principles existing in the soil which are thus brought within the reach of the roots.

WHAT IT WAS THAT SAVED HIM.

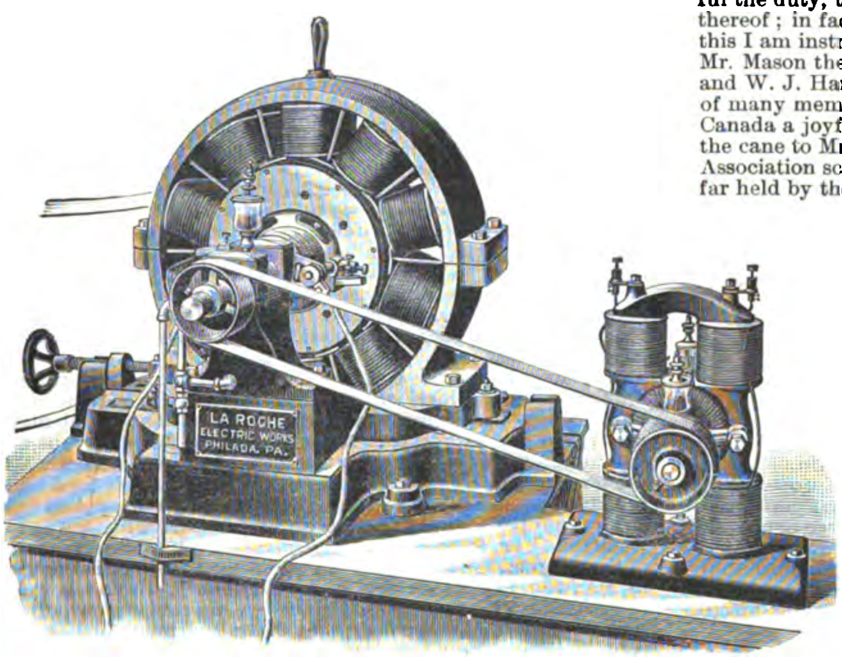
EXPLAINING why a lineman recently escaped with his life after making contact with a live arc light wire, the *Saginaw News* says: "Fortunately the wire was a small one and he had taken a firm hold of it; otherwise, as the dynamo at the works was running 2,000 voltage power, he would have been instantly killed. A slight contact, it appears, is much more dangerous."

THE LA ROCHE ALTERNATING SYSTEM.

ALTHOUGH alternating dynamos have been made for several years by the La Roche Electric Works, of Philadelphia, the march of progress in the electrical field has led to the design of a machine embodying several improvements peculiar to itself.

This dynamo is shown in the accompanying illustration. It is set on an insulated base, the belt tightener being also insulated to avoid any possibility of accident, and is so constructed that in case it should be necessary to remove the armature, the top or one-half of the fields can easily be taken off by one man. The iron in the fields is made expressly for this purpose, and the coils being locked by a new style of bolt, can be taken off or put on without any adjustment whatever.

The armature has no iron supports, and the brushes and brush holders are automatic and self-adjustable, and are claimed to have absolutely no wear at the collector rings. The insulation is of mica throughout.



THE LA ROCHE ALTERNATING DYNAMO.

None of these dynamos have ever been known to burn out by excessive load or lightning, and, although some have been put to the severest tests, they have given perfect and universal satisfaction. They are entirely automatic, and run at very slow speed.

CONVENTION AFTERMATH.

AFTER the adjournment of the National Electric Light Association, and after the famous trip on the Richelieu River, about 50 of the delegates and members visited the Citadel City of Quebec. They were guided by Mr. A. J. Corriveau and Mr. Mohr, manager of the Quebec Electric Light Company. On Sunday they were taken in carriages to the Citadel, over the Heights of Abraham, and through the city generally, visiting the Basilica and other points of interest. On Monday the party were taken in carriages to the Montmorency Falls. On the heights above the falls is the ancient building which a century ago was the home of the Duke of Kent, the father of Queen Victoria. Into the grand old home they were welcomed by Mr. and Mrs. Hall, who now own this beautiful place. A royal lunch was spread, and a delightful hour was spent with this hospitable lady and gentleman.

From the veranda of their house one looks over the mighty St. Lawrence River, which here is two miles wide. The continuous roar of the falling waters of Montmorency as it makes its grand leap of 250 feet over a perpendicular precipice made fair music in a perfect diapason. The waters of this river furnish an inexhaustible power which is utilized for the running of large mills, and also for the Quebec Electric Light Station. The visitors missed the night view from this point. They were told that at this season the Aurora Borealis shoots its continuous rockets into the dark northern air, but that, splendid as are these natural scenes, they are outrivaled by the illumination of the Citadel and the city of Quebec, lighted by electric lights, six miles distant, and which form a half-circle of several hundred suns, each equal to the splendid Venus when at her brightest, all reflected in the still waters of the river below.

This wonderful water-power is controlled by Messrs. Hall and Price. The water is conducted from above the falls in large pipes to the mills and to the electric light station. In this station are 16 dynamos, supplying the current for 300 arc lights and two 750-light machines for incandescent lighting. Over 1,200 miles of conductors are in use. More dynamos are being built for this station, their present supply being all inadequate to meet the demand.

On Monday the party returned to Montreal, and on Tuesday Mr. Corriveau was the most surprised man in that city. In behalf of the members remaining in Montreal, an elegant gold-headed cane was presented to Mr. Corriveau. Mr. A. F. Mason, in making the presentation, said to Mr. Corriveau: "Sir, during the last week certain gentlemen have had their eyes upon you and have observed conduct of yours which they cannot overlook, and however painful the duty, they feel called upon formally to take this notice thereof; in fact, they have determined to cane you. Before doing this I am instructed to read you this formal communication." Mr. Mason then read a letter signed by himself, W. J. Morrison, and W. J. Hammer, as a committee, conveying the appreciation of many members of his successful efforts to make their visit to Canada a joyful and pleasant one. Mr. Morrison then presented the cane to Mr. Corriveau. After this episode the members of the Association scattered, and so ended the grandest meeting thus far held by the National Electric Light Association.

THE STANDARD ELECTRICAL WORKS.

THE above company, in their capacity of Cincinnati agents for the Western Electric Co., of Chicago, have been awarded the contract for the wiring of the new City Hall, in the fomer city. This company was organized and incorporated about ten years ago, since which time they have steadily extended their operation until now their working territory covers a wide scope of country.

They handle extensively the Okonite wire, and have furnished over $100,000 of this material to the street railroads of Cincinnati and vicinity. This company furnish buildings with complete electrical plants in any section of the South and West. They have just placed the electric plant in the Neave building, one of the largest office buildings in Cincinnati, and the City Hospital, Pike's Opera House, Crane, Breed & Co., Addyston Pipe Works and others.

College Notes.

UNIVERSITY OF WISCONSIN.

As our readers are aware, Mr. Dugald C. Jackson has recently been appointed professor in charge of the electrical course of the School of Mechanics and Engineering of the University of Wisconsin, Madison, Wis. The circular issued as to the reorganization in this branch of studies is very interesting, as it sounds the first note in a call for a departure from the old and established methods in vogue in engineering colleges. Coming from the West, it shows how rapidly the demand for thorough technical training has taken root on the prairies. The division of engineering into three branches, sharply defined, is abandoned, and it is split up into a number of co-ordinate courses, each of which has at its head a specialist, who is entirely independent within wide limits. Far better results are expected.

The university as a whole has a reputation unexcelled west of the Alleghany Mountains, and equaled by only one other institution. With about 1,000 students, and a liberal income, its influence is strengthening. The president is Mr. T. C. Chamberlain, one of the geological authorities of the country, and a man in sympathy with liberal technical education. Under these conditions, Prof. Jackson hopes to make the electrical engineering course the best in the country. His facilities are already excellent and will at once be greatly improved.

ALABAMA POLYTECHNIC INSTITUTE, AUBURN, ALA.

The electric laboratory of the Alabama Polytechnic Institute is being rapidly equipped with dynamos, motors, accumulators, instruments, etc. The authorities intend to make this the leading electrical school of the South. Prof. A. F. McKissick is in charge of the electrical department.

MR. THOMAS F. CLOHESEY, the electrical engineer, of Kansas City, has been publishing an excellent article on the "Transmission of Electricity," in the *Kansas City Architect and Builder.*

Society and Club Notes.

NEW YORK ELECTRIC CLUB

THE club will resume its entertainments on Thursday, September 24, 1891, at 8 p. m., when Mr. Allen R. Foote, the special agent for the collection of the statistics of the electrical industry for the Eleventh Census, will read a paper on "The Making of a Model New York City."

This paper will deal, in an original manner, with the industrial and social needs of the city, the problems of rapid transit and workingmen's homes, and the relation borne by electricity to the evolution of a perfected New York.

AMERICAN STREET RAILWAY ASSOCIATION.

THE rate of a fare and a third has been allowed to delegates and all others, including members of their families, in attendance at the tenth annual meeting of the Association, which will be held in Pittsburgh, Oct. 21, 22 and 23, by the following traffic associations, namely, Boston Lines Passenger, Central Traffic, New York and New England Passenger, Southern Passenger and Trunk Line; also on the Chicago and Alton Railroad from all points in the State of Illinois. Michigan is excepted from the Central Traffic Association. The above covers nearly all the United States, with the exception of the territory controlled by the Western Passenger Association.

Letters to the Editor.

IN your issue of August 19 (p. 210), under the title of "Electric Traction at Bremen," we find it stated that the Bremen Strassenbahn-Gesellschaft was the first company in Europe to purchase outright an electric tramway. It seems that you are not aware of the existence and successful operation since September, 1890, of the Electric Tramway Florence-Fiesole, owned by the "Societa Italiana per il Tramvia del Chianti e dei Colli Fiorentini," which has been completely equipped with American electrical apparatus by Mr. E. P. Wetmore, expert of the Sprague Electric Railway and Motor Company, of your city.

This is the most remarkable electric line operating on our continent, and it possesses many special features not met with in any other road which we are aware of.

SOCIETA ITALIANA,
PER IL TRAMVIA DEL CHIANTI E DEI COLLI FIORENTINI.
FENZI, *President*.

FLORENCE, ITALY, September 5, 1891.

Literature.

The Electromagnet and Electromagnetic Mechanism. By Silvanus P. Thompson, D. Sc., B. A., F. R. S. London and New York, 1891. *E. & F. N. Spon.* Cloth, 450 pages, 5 x 8 inches.

ALTHOUGH magnetism in general—and the electromagnet in particular—has absorbed the attention of, and been the subject of the closest study by, some of our most able physicists, the fact, nevertheless, remains that until recently the student who desired to avail himself of the knowledge and results which have been obtained found himself confronted by a vast amount of literature which but few were so situated as to command and employ with profit. The truth of this was proved by the avidity with which Prof. Silvanus P. Thompson's lectures before the London Society of Arts, on the Electromagnet, were read by the numerous class interested in this subject at present, and these lectures only served to whet an appetite which, we are glad to say, Prof. Thompson has now succeeded in satisfying to a measurable degree in the volume before us.

The present work is an amplification of the Cantor lectures, but such an amplification as entitles it to rank practically as an independent work. Before taking up the subject in detail, Prof. Thompson gives an excellent introduction, in which he traces the history of the electromagnet, dating from the discovery of Oersted, which finally found its application in the electromagnet of Sturgeon. These are followed by the researches of Henry, Wheatstone and Joule, and descriptions and dimensions of notable magnets, among which we note the gigantic electromagnet constructed by Major King, U. S. A., by winding the muzzle ends of a pair of 25-ton guns. Prof. Thompson then takes up the discussion of the electromagnet in general, and the properties of the magnetic lines emanating from it, and discusses the elementary propositions in electromagnetics, which give the reader an excellent idea of the direct application of electromagnetic units. Then follow the descriptions of typical forms of electromagnets, beginning with the straight-bar magnet, and passing through the various forms of two-pole magnets, the iron-clad magnet, etc. Not the least interesting addition to this chapter is the description of the materials required for the proper construction of the cores, the coils and the insulation.

Looked at from the standpoint of of the constructor of electromagnetic apparatus, Chapter III., on the properties of iron, will command a good share of attention. It is evident that a knowledge of the exact magnetic properties of the metal entering into the construction of any electromagnetic apparatus is necessary in order to predicate at all accurate results, and, recognizing this, the author has justly devoted considerable space to its consideration. He begins by discussing the diagram of the curve of magnetism for the various magnetic materials, such as iron and steel, soft and annealed, etc., and thus leads up to the various methods of measuring permeability, among which we find that of Hopkinson carried out in detail. The various results obtained by Ewing, Rowland and Bosanquet, all of which are directly applicable, are also given with considerable fullness. Prof. Thompson has rightly laid special stress on the effect of the air gap in the magnetic circuit, the influence of which is pointed out in a very clear manner, and cannot be too strongly impressed upon the mind of the student. Under this head also we note a discussion of the effect of joints in the magnetic circuit, and straight cores of various lengths; also those of vibration and of heat, which latter, we believe, is destined to play a more important part in the construction of electromagnetic apparatus, especially converters, than has heretofore been contemplated. Magnetic hysteresis, with some other minor properties of magnetic bodies, closes a chapter of surpassing interest.

The author then takes up the principle of the magnetic circuit, the treatment of which will be quite refreshing to those who have been brought up on the older works, of which that of Dub may be said to be the prototype. After explaining the law of the magnetic circuit, and stating it in the form of an equation, viz., that the magnetic flux equals the magnetomotive force divided by the reluctance, the author shows how this law can be applied to the various properties of the magnet, and begins with the law of "traction" or what was formerly called the "portative force" of the magnet. After noting the law of magnetic attraction given by Maxwell, and its verification by Bosanquet, we find a variety of designs of electromagnets for tractive or carrying purposes, together with the methods of calculation and the influence of the polar surfaces, and a large amount of information which can be applied in many ways in the workshop.

The succeeding chapter explains the law of the magnetic circuit applied to cases of attraction of an armature at a distance, and here, of course, the calculation of magnetic leakage enters into the problem, and is treated in the same lucid manner as applied in the former chapter, the practical examples given enabling the experimenter to repeat directly, or apply the principles enunciated. This is followed by a discussion of the various shapes of armatures and their influence on the action of the electromagnet. The rules for winding copper wire coils on magnets are here fittingly introduced, and some valuable tables contained in this chapter will be found of great use. The author then takes up the special designs of magnets to produce rapid action such as that required in relays and chronographs. Chapter VIII. is devoted to that familiar form, the coil and plunger magnet, and contains a complete description of the work done on this type, and the laws of its action.

Having thus described the general appearance and types, the author describes various mechanisms in which the magnet in one form or another is the actuating device, including the presentation of its application to arc lamps and regulators of all kinds, polarized electromagnetic devices, including the relay and the telephone, etc. Electromagnets operated by alternating currents also receive their proper share of attention, a subject which we believe has here for the first time been systematically presented, and the importance of which is evident in view of the increasing application of alternate current apparatus involving magnets in their construction. In a short chapter there are also described the older forms of electromagnetic motors, such as those of Ritchie, Jacobi, Froment, etc., in which the action was due to the successive attraction of electromagnets.

The work ends with a series of short chapters on electromagnetic machine tools, such as hammers, riveters, etc., the modes of preventing sparking in the operation of electromagnets, the electromagnet in surgery, and a very extended discussion of permanent magnets and their properties. Three appendices also give respectively a biography of William Sturgeon, a short exposé of electric and magnetic units, and the calculation of excitation, leakage, etc.

We have here but briefly hinted at the contents of a work which is easily the most complete and valuable of its kind available at the present time. Aside from the fascination of the subject itself, the author's easy diction lends an added charm to the work, so that the reader is not only thoroughly instructed, but positively entertained. There are few technical works of which this can be said, and we think no higher praise than this can be bestowed. It adds another to the many lasting obligations which every electrical reader owes to Prof. Thompson, whose books have had such a powerful formative influence on the younger generation of electrical engineers. The work is handsomely gotten up in clear type, and we are glad to note that the illustrations are clear and well executed throughout.

Patent Notes.

DECISION OF THE COMMISSIONER OF PATENTS IN THE INTERFERENCE CASE OF RUDOLPH M. HUNTER vs. FLEEMING JENKIN.

THIS was a rehearing of an interference which was originally declared by the Patent Office on November 22, 1887. The invention in issue is the well-known system of electric telpherage devised some years since by Professor Fleeming Jenkin. The issue was originally decided by the Examiner of Interferences in favor of Hunter, but the Board of Examiners-in-Chief, on appeal, decided in favor of Jenkin, as noted in THE ELECTRICAL ENGINEER of Oct. 15, 1890. Hunter then took an appeal to the Commissioner, which was decided by Assistant Commissioner Fisher in his favor, reversing the decision of the board. Jenkin's attorneys then petitioned for a rehearing, alleging that the last-named decision was contrary both to the law and the evidence, and a rehearing was granted by Commissioner Mitchell, which, however, did not come up until after he had resigned and turned over his office to his successor.

One of Jenkin's patents for the improvement in controversy was dated September 16, 1884, having been applied for February 1, 1883; he has also a British patent for the same thing, dated April 17, 1882. It appeared that the contestant Hunter conceived of the invention in 1879, and applied for a patent May 22, 1886, with no intervening reduction to practice. It appeared that he did reduce it to practice subsequently to his application. Between his conception of the invention and his application for a patent he was interested in the procurement of 21 other patents. The Commissioner says:—

"The general rule is that he who is the first to conceive of an invention is entitled to a patent for it if he reduces the same to practice with reasonable diligence; but if he do not reduce to practice with reasonable diligence, he who is subsequent to conceive but first to reduce to practice will prevail."

"'In a race of diligence between two independent inventors he who first reduces his invention to a fixed, positive and practical form would seem to be entitled to a priority of right to a patent therefor. The clause now under consideration seems to qualify that right by providing that in such cases he who invents first shall have the prior right, if he is using reasonable diligence in adapting and perfecting the same, although the second inventor has in fact perfected the same and reduced the same to practice in a positive form.'" (*Reed* v. *Cutter*, 1 Story, 590.)

Other cases cited are: *Ransom et al* v. *N. Y.*, 1 Fisher, 252; *Savary et al.* v. *Lauth*, 1 Mac A. P. C., 691; *Johnson* v. *Root*, 1 Fisher, 351.

In reference to the question of constructive reduction to practice, the Commissioner says:

"An application for a patent which eventuates in the grant of a patent is constructive and presumptive reduction to practice. This is so, in the first place from necessity, for there is no other logical way of treating an application for patent in this regard. It is so in the second place, because of the fundamental reason for granting patents, that is, 'to promote the progress of science and the useful arts,' and he who makes the disclosure to the public in a patent, benefits the public in this regard equally with him who makes the disclosure by actual reduction to practice. In a contest for priority of invention, the presumption referred to is conclusive against all of the parties to the proceeding, because each one is, by the fact of his making a claim to the improvement in dispute, estopped from denying its operativeness and completeness. The reasonable diligence which is required in a contest over priority of invention applies alike to actual reduction to practice and to the constructive reduction to practice involved in an application."

"'Where the invention is not of a mere philosophical speculation, abstraction or theory, but of something corporeal, something to be manufactured, the applicant need not show that he has reduced his invention to practice otherwise than by filing his specification and furnishing drawings and a model, as required by the statute, where the nature of the case admits of drawings or of a representation by a model.'" (*Heath* v. *Hildreath*, 1 MacA. P. C., 12.)

Although a party may be prior in the date of making his invention, he—

"must proceed to perfect and patent it with due diligence, otherwise a succeeding inventor who is more diligent in perfecting his, though not in getting out a patent, may prevail against or defeat him." (*Allen* v. *Blunt et al.*, 2 W. & M., 121.)

Reducing to practice differs from bringing into use. There is no law requiring the applicant to reduce his invention to actual use before he can obtain a patent. (*Perry* v. *Cornell*, 1 MacA. P. C., 68.)

Other cases cited are *New England Screw Co.* v. *Sloan*, 1 MacA. P. C., 210; *Stephens et al.* v. *Salisbury*, ibid. 379; *Ellithorp* v. *Robertson*, ibid. 585; *Farley* v. *National Steam Gauge Co.*, ibid. 618; *Seymour* v. *Osborn*, 11 Wall., 516; *Hubel* v. *Dick*, 28 F. R., 132.

In the present case Jenkin had a patent, while the contestant Hunter was a subsequent applicant. In view of this state of facts, the Commissioner holds:

"When one of the contestants has a patent for the invention in dispute and the other is an applicant for a patent, the latter, in order to prevail, must present a case, both as to conception and as to reasonable diligence, which does not admit of a reasonable doubt. This is as it should be. The issue of a patent is an event that is deliberate, certain, and official, in a high sense. It ought not to be lightly set aside. The courts have agreed that in all attacks upon it of this same general nature (*i. e.*, on the ground of public use, prior use, abandonment, or prior invention), a case, in order to succeed, must be made out beyond a reasonable doubt."

"'It is not enough, to defeat a patent already issued, that another conceived the possibility of effecting what the patentee accomplished. To constitute a prior invention, a party alleged to have produced it must have proceeded so far as to have reduced his idea to practice and embodied it in some distinct form. It must have been carried into practical operation.'" (*Parkhurst* v. *Kinsman et al.*, 1 Blatch., 488)

Other cases cited: *Ellithorp* v. *Robertson et al.*, 4 Blatch., 307; *Cox* v. *Griggs et al.*, 1 Bissell, 362; *Brodie et al.* v. *Ophir Co.*, 5 Sawyer, 608; *Draper* v. *Potomska Mills*, 3 B. & A., 214; *U. S. Stamping Co.* v. *Jewett et al.*, 18 Blatch., 469; *Electric R. R. Signal Co.* v. *Hall R. R. S. Co*, 6 F. R., 603; *Union Met. Cartridge Co.* v. *U. S. Cart. Co.*, 7 F. R. 344: *Odell* v. *Stout*, 29 O. G., 862.

Hunter, in his evidence, sought to excuse his delay on account of lack of means and the necessity of devoting a large part of his time to other inventions. Respecting this, the Commissioner holds that time spent upon other inventions does not excuse delay otherwise unreasonable. This proposition is established in *Signal Co.* v. *Molecular Telephone Co.*, 23 Blatch. 253; *Telephone Cases*, 126 U. S., 1.

As long ago as 1859, Judge Merrick stated this principle as follows:

"If a man be utterly destitute of money and without friends, and incapable thereby of prosecuting an enterprise, much indulgence may be shown to him; but where he has the means of carrying on sundry enterprises of a kindred sort, equally demanding money and friends, and does carry them on, his elections to pursue those other enterprises will not be regarded in the law as an excuse for delay in the one where valuable rights of others equally meritorious with himself, and in the outset of their successful struggles, equally poor, are to be prejudiced. An election thus made for his supposed advantage or gratification at the time, according to the plainest principles of equity, must not be invoked for the subsequent detriment of another innocent party." (*Wickersham* v. *Singer*, 1 MacA. P. C., 645.)

Applying these principles to the case in hand, the Commissioner reverses the decision of the former Assistant Commissioner and awards priority to Jenkin.

Legal Notes.

SUING UNDER THE EDISON LAMP PATENT.

THE Edison Electric Light Company has begun suit against the Mount Morris Electric Light Company for infringement of Edison patents in incandescent lamps, in the United States Circuit Court. The Edison Company asks for an accounting of all profits made by the Mount Morris Company and for an injunction restraining them from using the alleged infringed improvements.

TELEPHONE vs. ELECTRIC RAILWAY AT TROY, N. Y.

JUSTICE EDWARDS, in the general term at Saratoga last week, handed down a decision reversing the decision of Referee Isaac Lawson in the case of the Hudson River Telephone Company against the Watervliet Turnpike and Railroad Company. Referee Lawson denied the application of the telephone company for a perpetual injunction restraining the railroad company from operating its line by electricity and dismissed it with costs. This decision returns the case to its former standing, the injunction being revived and the railroad company compelled to furnish the security demanded by the telephone company, if an appeal is taken to the court of appeal. The telephone company will now bring a suit for damages.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED SEPT. 8, 1891.

Alarms and Signals :—

Telegraphic Transmitting Apparatus, M. Martin, 459,018. Filed July 14, 1890.
Designed to be operated automatically when the message is to be sent, as, for example, upon the breaking out of a fire.

Conductors, Conduits and Insulators :—

Support for Electric Conductors, G. H. Winslow, 459,168. Filed May 19, 1891.
Relates to improved devices for supporting overhead trolley wires and has for its object a construction which can be quickly and easily applied to the conductor and will offer but slight obstruction to the movement of the trolley.

Electric Conductor, E. D. McCracken, 459,378. Filed Mar. 5, 1891.
Relates to that class of insulated conductors in which a paper ribbon constitutes the insulating material.

Flexible Electric Conductor, H. W. Libbey, 459,385. Filed July 26, 1889.
Consists in placing upon the wire oblong beads of glass with rounded ends and inserting them in a flexible india-rubber tube.

Dynamos and Motors :—

Controlling Mechanism, C. R. Pratt, 459,090. Filed Oct. 30, 1890.
Claim 1 follows :
Combination of a motor having a suitable source of power for driving it, a controlling device for the motor made in two sections, one for admitting said power to the motor in one direction, and one for admitting power to the motor in the opposite direction, and a lock operated by the movement of either section to hold the other in its normal position.

Electrically Operated Brush, F. A. Lehmann, 459,222. Filed Oct. 25, 1890.
Consists in the combination of a handle formed by the field-magnet and a longitudinal shaft having a revolving armature at one end and a revolving brush at the other.

Armature for Dynamo Electric Machines or Motors, R. Lundell, 459,866. Filed Nov. 24, 1890.
Consists of a novel winding of the armature coil in an improved mode of insulating and protecting the coils and inserting other features of construction.

Commutator-Brush and Holder, R. Lundell, 459,367. Filed Apr. 4. 1891.
Relates to devices for conducting currents from a supply-circuit to the armature of an electric motor or to take current from the armature of the dynamo to supply an external circuit.

Commutator-Cylinder and Method of Making the Same, R. Lundell, 459,368. Filed Apr. 4, 1891.
Claim 1 follows :
A commutator cylinder composed of alternate conducting and insulating sections, a filling of insulating material between the cylinder and a sleeve or shaft on which it is mounted and a metal ring imbedded in said insulating material.

Lamps and Appurtenances :—

Electric Light Fixture, E. T. Greenfield, 459,098. Filed May 11, 1891.
Has for its objects the production of a socket for use with different types of incandescent lamps and of a simple and effective switch mechanism.

Incandescent Electric Lamp, E. P. Roberts, 459,100. Filed July 15, 1891.
Relates to an improved method of connecting the socket to the bulb of an incandescent lamp.

Hanger for Incandescent Lamps, P. J. Chassagne, 459,266. Filed Jan. 16, 1891.
Provides a spring-actuated roller around which is wound a flexible cord conducting the current to the lamp.

Medical and Surgical :—

Electrode for Chairs, G. W. Overall, 459,127. Filed July 8, 1891.
Relates to the application of electrodes for use in vapor baths, etc.

Electro-Therapeutic Truss, H. W. Matthews, 459,143. Filed June 26, 1891.

Electro-Therapeutic Belt, H. W. Matthews, 459,141. Filed June 26, 1891.

Miscellaneous :—

Electrically-Heated Wristband-Ironer, W. Mitchell, 459,070. Filed Nov. 29, 1890.
Employs a rotary cylinder in combination with a stationary device for heating and pressing the article to be laundered.

Mechanism for Operating Dampers or Similar Valves, J. V. Stout, 459,091. Filed Mar. 9, 1891.
Relates to means of automatically opening and closing a damper by means of an electric current.

Electric Switch, L. D. Castor, 459,219. Filed May 20, 1891.
An electric snap switch actuated by a removable key.

Electric Elevator, H. H. Blades, 459,229. Filed Sept. 19, 1890.
Has for its object the simplification of electric elevator mechanism by providing the elevator with a storage battery as a counterpoise weight.

Process of Purifying Brine, C. G. Collins, 459,236. Filed Dec. 2, 1890.
Renders impurities contained in brine insoluble by means of the passage of an electric current.

Fuse and Detonator, P. Ward and E. M. Gregory, 459,321. Filed May 13, 1890.
A cheap fuse and detonator uniformly sensitive to a small current of electricity and protected against the influences of moisture and climate.

Electric Contact Apparatus, C. Weuste, 459,323. Filed June 12, 1890.
Has for its main object the indication of the level of water in reservoirs, &c., upon a dial at a great distance through the medium of an electric current.

Railways and Appliances :—

Mounting for Motors of Electric Cars, S. H. Short, 459,024. Filed Dec. 24, 1890.
Relates to the mounting for the motors of electric cars which have their armatures axially placed with reference to driving axle and directly connected with the same.

Railway-Car Step, H. C. Farquharson, 459,170. Filed Jan. 8, 1891.
Claim 6 follows :
The combination of a stationary step, of a movable step, side bars for supports for the same and a circuit closer actuated by the movement of the step, an electromagnet and an alarm operated thereby for giving a signal when the movable step is in its depressed position.

Telephones and Apparatus:—

Telephone Receiver, J. H. Howard, 459,205. Filed March 3, 1891.
An improved telephone receiver embodying in its own construction the switch which cuts out from the circuit the coil of said receiver when the receiver is not in use.

Hook or Crotch for Telephone-Receivers, J. H. Howard, 459,218. Filed March 3, 1891.
A support for the receiver of the telephone when not in use.

Telephone, J. H. Howard, 459,214. Filed March 3, 1891.
Has for its object a construction which shall allow the current of the primary circuit to pass around the Siemens armature when the armature is not in use, thus avoiding the resistance of the armature coil.

THE AURORA INCLINOMETER.

Before the Mathematical and Astronomical Section of the A. A. A. S., at Washington, Prof. Bigelow exhibited and explained a new instrument called the aurora-inclinometer. Prof. Bigelow has been working for some years on the problem of the physical interactions between the earth and the sun aside from those due to gravitation. Several important discoveries have already been made. It has been found that the same law which underlies the working of electricity and magnetism is operating on the sun and gives the beautiful curves of the corona which are seen at the times of total eclipses. This corona is like the aurora and is confined to a narrow belt in each hemisphere of the sun.

Prof. Bigelow believes he has discovered the causes of terrestrial magnetism and the variation of the magnetic needle all over the earth in periodic motions. He assumes that the sunlight acts as a magnetic field, and that the magnetized earth rotates in it, just like the armature of a dynamo. By a sort of magnetic refraction the rays of force enter the dark side of the earth in peculiar curves, pass through it in straight lines, and emerge in similar curves on the sunny side of the earth, turning all the needles in a corresponding way. Now, the aurora marks the pathways by which these forces enter and leave the earth, or the modifications that are produced by them, or the ordinary magnetic field surrounding the earth, due to its permanent magnetism, and it therefore becomes essential to study carefully the data that they can give. Prof. Bigelow's instrument is for this purpose, and will be sent to Alaska this autumn, where the aurora is seen in the best conditions.

THE KOUSMINE DIFFUSION BATTERY.

The diffusion battery of M. Kousmine has been much used in Russia. By making use of the phenomenon of diffusion, M. Kousmine has succeeded in overcoming the increase in internal resistance of the bichromate of potash battery due to the formation of crystals on the positive electrode. The positive carbon electrode consists of four strips attached to the lid of the battery. The negative zinc electrode consists of a circular grating resting on the bottom of the battery. By means of a funnel a 15 deg. Beaumé solution of sulphuric acid is introduced until it just reaches the lower end of the carbon strips. A 6 to 7 per cent. solution of bichromate of potash is next introduced. The two liquids do not mix on account of the great difference in their densities. When the battery is short-circuited it is easy to see that chemical action only takes place close to the lower end of the carbon strips, which are gradually surrounded by a violet ring two or three millimetres deep. Above this region the bichromate solution retains its original color. The bichromate solution being very weak, the chromic crystals dissolve as soon as they are formed, and the positive electrode is not covered by a deposit as in other batteries. The solution of these crystals, having a greater density than the surrounding liquid, falls to the bottom. The sulphate of zinc also falls to the bottom of the cell, causing more sulphuric acid to rise. A cell having the following dimensions has been tested by a committee of experts: Height, 20 centimetres; diameter, 15 centimetres; surface of zinc, 176 square centimetres; bichromate solution, 6 per cent.; sulphuric acid, 15 deg. Beaumé. The committee reported that after having been circuited for 8½ hours on an external resistance of .32 ohm, and then left on an open circuit for 10½ hours, the cell continued to work for 4½ hours, when the circuit was again closed, and that it gave during 18 hours 36 ampere-hours for an expenditure of 48 grammes of zinc.

Mr. Carl Young has been appointed superintendent of the Williamsport, Pa., Passenger Railway Company.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

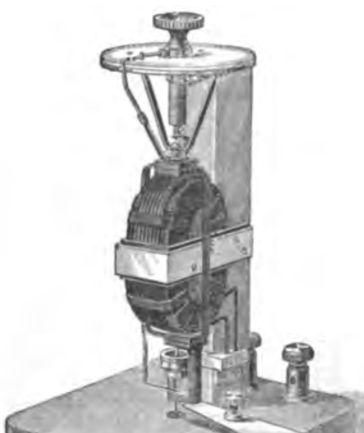
Persistency is a main element of success in advertising.

QUEEN'S NEW TYPE OF SIEMENS' ELECTRO-DYNAMOMETER.

SIEMENS' electro-dynamometer is an instrument too well-known to electricians to require any description. The ease with which it may be standardized, even by those not familiar with instrumental work, its constancy and freedom from variable elements, and its immediate applicability to the measurement of either direct or alternating currents, have placed it in the hands of all those requiring to make accurate measurements of such currents. With a view to improving certain weak points in the type commonly made, as well as to producing a more convenient and perfect instrument, Messrs. Queen & Co., of Philadelphia, have designed a form of electro-dynamometer shown in the accompanying illustration.

In this type the coil hangs by a small hardened steel centre in a cup centre of highly polished agate. The coil, hung in this way, is free from any perceptible friction and the sensitiveness of the instrument is very greatly increased. To reduce the moment of inertia of the suspended coil, an index made of light aluminum wire has been used instead of the usual heavy brass index. Just below the agate a small brass pin extends downward and fits into a cylindrical opening, a trifle larger, in a rubber block clamped to the upper part of the movable coil; hence, by releasing the spring shown on the base the coil is lifted from its agate and held tightly, so that, despite the roughest handling in transportation, the jewel cannot be broken, while the steel centre will accurately reseat itself in the agate, owing to the guidance of the pin, when the the spring is depressed by means of its screw. Instead of two uprights, as in the Siemens' made type, Queen's design employs but one, thus considerably lightening the instrument, as well as making its working parts more accessible. The binding posts are placed at the rear of the instrument instead of in front, thus getting the connecting wires out of the way.

The instrument is thus far wound to but two ranges, viz., from 2-10 to 20 amperes, and from 1 to 60 amperes. Other sizes will be made for higher and lower ranges of current as soon as possible. Each instrument is furnished with two sets of windings; thus in the 20-ampere type one set allows measurements to be made



QUEEN'S IMPROVED ELECTRO-DYNAMOMETER.

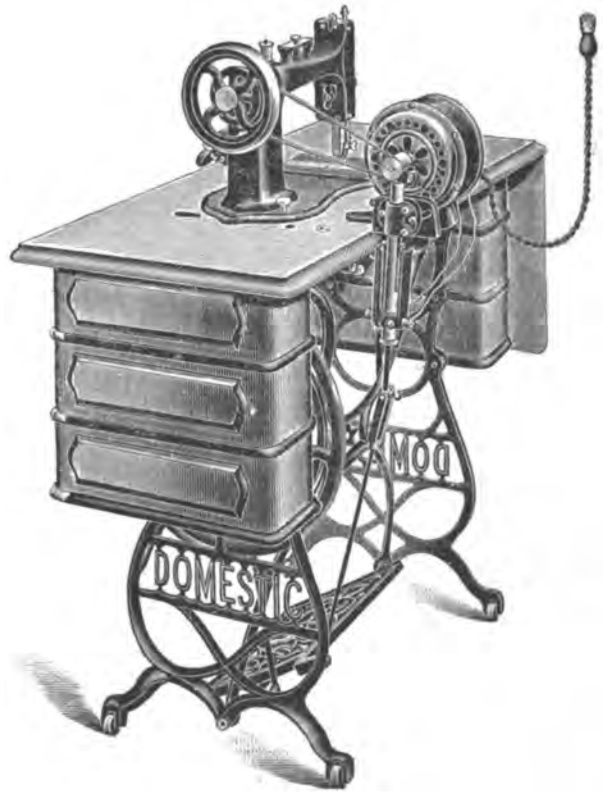
varying from 2-10 to about 4 amperes, while with the other set the range extends from about 1 to 20 amperes.

The whole instrument is finely finished in polished mahogany and lacquered brass and copper. The dial is of opal glass and graduated in 400 equal divisions. These instruments are also being made enclosed in glass cylinders, and with a brass instead of wood support, a silvered instead of opal dial, and otherwise more handsomely finished.

MR. W. E. CORSON, engineer of the Haverhill, Mass., electric light plant has resigned to accept a more lucrative position in Boston.

THE EMERSON ALTERNATING CURRENT MOTOR FOR SEWING MACHINES.

THE accompanying illustration shows an alternating current motor for sewing machines, now being placed on the market by the Emerson Electric Mfg. Co., St. Louis. In applying the motor to a sewing machine the fly-wheel and connecting-rod are removed, and in place thereof is substituted a simple electro-mechanical



EMERSON ALTERNATING MOTOR WITH SEWING MACHINE.

regulating device, which is actuated by foot-pressure on the treadle, which is connected to the regulating device by means of a connecting-rod. Various speeds are given to the machine by pressing the treadle down. The farther down it is pressed, the greater is the speed of the machine. The device controls the speed very sharply, it being possible to bring the machine to a dead stop from full speed almost instantaneously.

The motor is of the same size—$\frac{1}{8}$ h. p.—as the fan motors which they have been selling during the summer, but is wound somewhat differently.

The device is also applicable to dentists' and jewelers' purposes and other light work.

THE NEW PROCESS RAW HIDE COMPANY.

THE above company was recently the recipient of the following letter, which speaks for itself:

THE NEW PROCESS RAW HIDE COMPANY,
Syracuse, N. Y.

Gentlemen:

We have yours of the 13th instant asking our experience with your raw hide pinions.

Our large orders for your pinions in the fifteen months past, amounting to thousands of dollars, must speak pretty well for your goods, and the satisfaction they are giving. A number of our best customers use your make of pinions exclusively, and they have pronounced themselves as being satisfied that the Patent Raw Hide Pinion is by far the most economical and satisfactory. On the Wightman single-reduction motor we have adopted your pinions as being the most satisfactory way of transmitting the power from armature to car axle.

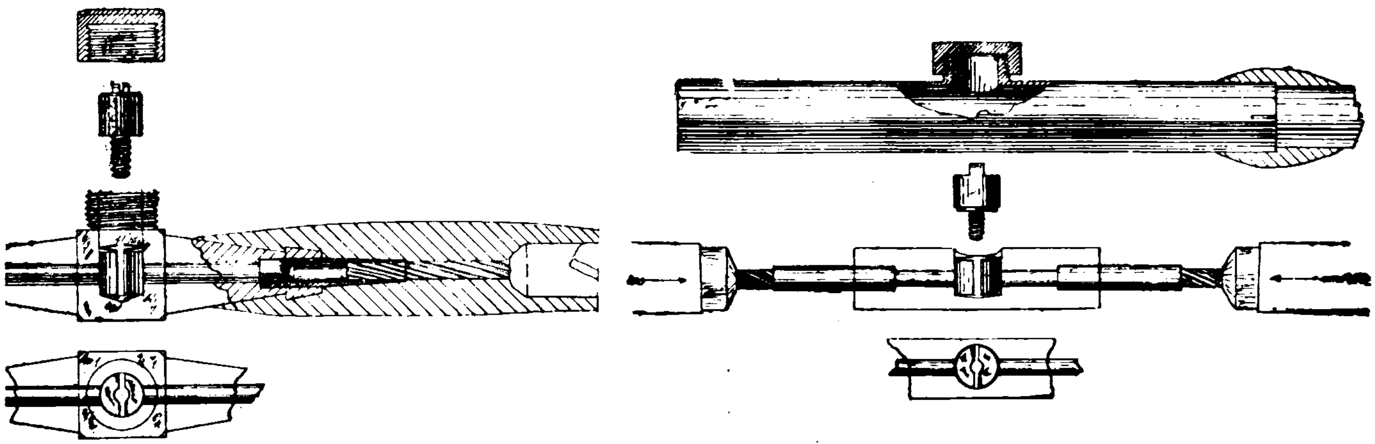
Respectfully yours,
THE WIGHTMAN ELECTRIC MFG. CO.

SCRANTON, PA., August 17, 1891

MR. L. R. EMMET has been appointed engineer of the Central District of the Edison General Electric Co., in the place of Mr. Dugald C. Jackson, who becomes professor of electrical engineering at the University of Wisconsin.

CUTTER'S CONDUIT CONNECTOR.

In operating underground electric circuits the problems connected with proper insulation and the location of faults are somewhat different from those met in overhead lines, and a number of new devices have been brought out to solve these problems. Thus any leakage in an underground cable is apt to be more serious than in an overhead line, and as the leakage resistance may be very high in proportion to the resistance of the conductor, the ground may be hard to locate. So with an underground arc light circuit winding through many streets, it would be a hard task to locate a fault without disconnecting different sections. For this purpose George Cutter, of Chicago, has brought out his conduit connector, which enables the different sections to be quickly separated for testing by simply removing a screw plug. When this is replaced, it forms a good connection and the joint is closed up water-tight.

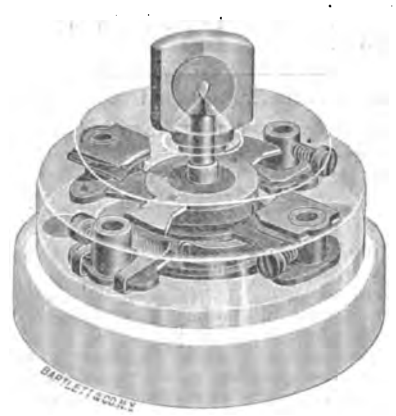


Cutter's Conduit Connector.

The cut shows two forms of this connector. The first has the two metal terminals imbedded in a hard rubber shell and a cap of the same material closes the opening. The ends of the cable are soldered into slotted sleeves, and a heavy wrapping of rubber tape covers the joint. This form is used with rubber wires, while with lead cables the parts are placed in a brass sleeve which slips over the lead coating and is soldered to it. In either case the whole is sealed tightly and yet allows of readily disconnecting the wires. The good points of such a connector can be seen at a glance, and it may be added that it is used on the underground arc light circuits operated by the city of Chicago.

THE HART SWITCHES.

The Hart double-pole switch, which has just been put upon the market by the Hart & Hegeman Manufacturing Co., of Hartford, Conn., possesses all the merits of the Hart single-pole switches, viz., durable construction, quick rotary movement in one direction; positive action, the switch-plates being locked in position until they are under the control of the actuating spring; large contact surfaces and unusually long break for the diameter of switch. The length of break in the fifteen ampere double-pole switch, illustrated herewith, is three inches, the outside diameter of base being two and seven-eighths inches. The length of break increases with the size of switch until in the one hundred ampere switch it is six and one-half inches. The one hundred ampere switch is mounted on a slate base six inches square and is provided with clamping devices or binding posts which will take up to No. 0000 B. & S. wire, or flat bar up to three-eighths by three-quarter inches, and is so arranged that the wire or bar may be brought down the face of the switchboard, or enter clamps from back of board, without bending it in either case. This feature facilitates neat and rapid construction. The long break and quick action allow the double-pole switches of all sizes to be used on railway or power circuits of five hundred volts, and on primary alternating circuits of one thousand volts.



Hart Double Pole Switch.

THE ORANGE MACHINE AND REPAIR WORKS.

When the Standard Cash Register Co. went out of business some time since, the machinery, tools, etc., were bought up by Messrs. C. E. Hathaway, H. L. Edge and Wm. Edge, who formed a manufacturing and repair business under the name appearing at the head of this article. Light machinery of various kinds is built and it is intended to shortly undertake the manufacture of small dynamos, motors, and electrical appliances.

PHILADELPHIA NOTES.

Messrs. Walker & Kepler are installing a plant for the John B. Stetson Co., 4th Street and Montgomery avenue, consisting of two 500 and one 250 light Edison dynamos; also an Edison arc light dynamo with twenty 2,000 candle power capacity.

The Lamokin Car Works, of Chester, Pa., are turning out electric cars as rapidly as their present factory will permit. They have just completed 20 cars for the Metropolitan Street Railway Co., of Denver; 60 cars are now being constructed for the Citizens' Street Railway Co., of Memphis, Tenn. The Rock Creek Railway Co., of Washington, D. C., will also be supplied with cars from these shops.

Messrs. Thomas H. Dallett & Co., manufacturers of the Billberg motors and generators, have opened an office, 126 Liberty street, New York, for the sale of their motors and dynamos, and also the Triumph Compound Engines, for which they are agents. This firm have recently built a large factory at the corner of York and Sedgley streets, which has been filled with the latest improved machinery. All of this is being used, and an addition to their works is contemplated.

The Heisler Electric Light Co. are installing a 500 16 c. p. light plant at West Toronto Junction, Canada, and also a 600 16 c. p. light plant at Waterloo, Ill., through their agents, the Interstate Complete Electric Construction Company, of St. Louis, Mo.

Mr. G. A. Wilbur, agent for the Fort Wayne Electric Company, has installed five 60 arc light Wood dynamos for the Southern Electric Light & Power Company, of this city, and a 60 arc light plant for the People's Electric Light Company, of York, Pa.

Messrs. J. W. Parker & Co., Philadelphia agents for the Ball Engine Company, have just sold a 80 h. p. engine to the Citizens Electric Illuminating Company, of Pittston, Pa.

Mr. G. A. Wilbur, of this city, has the contract from the People's Electric Light Co., of York, Pa., for a 60 Wood arc light plant.

The Southern Electric Light Plant and Power Co., of this city, is installing five Wood arc light dynamos.

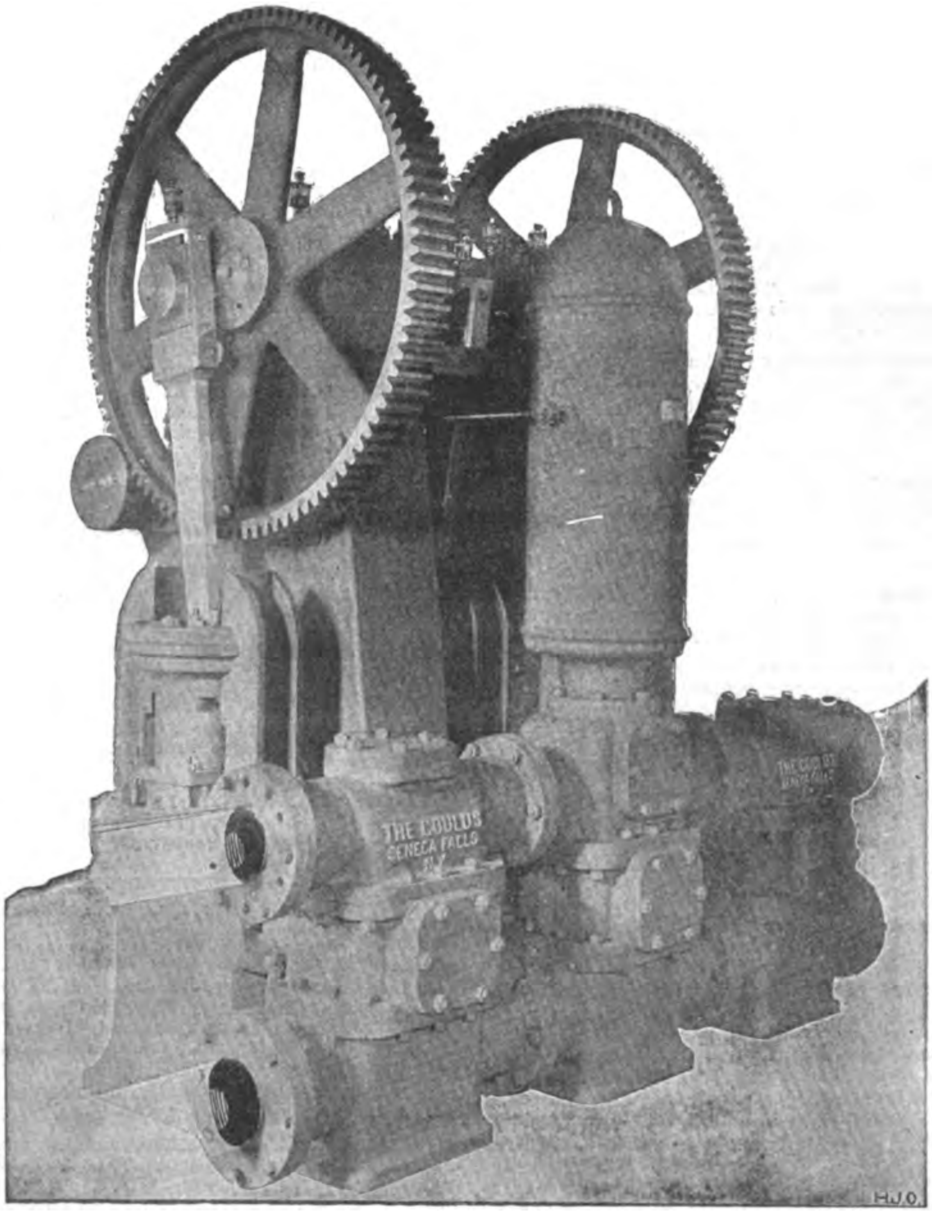
THE TRIPLEX ELECTRIC PUMP.

The Triplex or three-cylinder pump, made by The Goulds Manufacturing Company, of Seneca Falls, N. Y., and with offices at No. 16 Murray street, N. Y. City, possesses important advantages in combination with electric motors. The pump offers absolutely even and unvarying resistance to the motor under all conditions, and consumes but a minimum of power in friction of parts. Careful tests of the outfit complete have shown a high efficiency. The three-throw crank shaft, in the stroke of which there is no dead centre, prevents jerky motion and vibrations.

In villages or cities where power can be had from electric light or power circuits, electric pumping offers relief from the discomforts of insufficient or hard and unfit water supply, and the hardly lesser trials of disagreeable, noisy and dangerous pumping engines in vogue.

The Triplex electric pump will take water from any source, as spring, cistern or well, and force to upper supply tanks of residences, shops, warehouses, buildings, etc., or force city water to a higher point than its own pressure will carry it, as is often the case in the more elevated city districts or in very high buildings.

In factories, such as large cotton mills, woollen mills, steel works, etc., and, in fact, in any large establishment where work is distributed over a large territory, the employment of electrical transmission of energy for pumping can be used to great advantage. The steam pump is now in common use for that purpose. Steam is generated in the boiler and transmitted through long lines of pipe to pumps, where the work of pumping is performed. It has been found by actual experiment and demonstrated repeatedly that these direct-acting steam pumps are most wasteful consumers of steam, using in the neighborhood of 25 pounds of coal per horse-power per hour. With electrical pumping outfits all this is changed.



The Goulds Triplex Electric Pump.

One of the most troublesome questions in mining operations is the disposal of water. By the introduction of electricity for underground work the problem is greatly simplified. The necessity for long lines of steam pipe is removed, and in the place of hot steam pipes spreading dry rot in the vicinity, a small copper wire is suspended from wall or ceiling; or the current may be taken from the trolley wire, if the mine is equipped with an electric haulage plant. In some cases, where transmission from the surface by steam or compressed air was utterly impracticable, and an underground steam plant seemed necessary, it has been found that the cost of excavating and drilling holes for the chimneys would exceed the total cost of the electric pumping plant.

The pumps are adapted so as to be readily combined either by gearing or belting with all of the standard electric motors, and a large number of them are already in use.

DEATH OF G. MURRAY GRIFFITH.

We regret to record the death of Mr. G. Murray Griffith, a member of the Philadelphia engineering firm of W. S. Griffith & Co. His death occurred on August 28.

STARTING THE ELECTRIC ROAD AT ESCANABA, MICH.

Escanaba, Mich., is a thoroughly progressive town with a population of 8,000. Its streets are wide and well paved and from its immense ore docks, perhaps the largest in the world, large shipments are made, which makes the tonnage greater than from any other part of the country, except New York. Under such conditions, Escanaba could not, of course, permit its sister towns to surpass it in facilities for rapid transit and nothing less than the latest electrical equipment would satisfy the present desires of the community. The road, which was recently completed and formally opened for traffic on September 13, certainly reflects credit on its owners and others concerned in its construction. It extends from the railway station, on Stephenson avenue, about three-quarters of a mile, thence through Ludington street for a distance of one and a half miles. The latter street is the main business thoroughfare, and is lined throughout its entire length with the principal stores of the city.

At the opening of the road the scenes which have become so familiar were repeated. Crowds of passengers, enthusiastic citizens and delighted owners all testified their satisfaction with what is fast being recognized as the only method of rapid transit, suitable alike for cities or villages. On examination of the road and its construction, it was seen to be one of the most carefully constructed in the West. The track is laid with 45 pound Johnson girder rails, and the rolling stock consists at present of two Pullman cars mounted upon Hubbard trucks, manufactured by the McGuire Manufacturing Company. The electrical equipment of each car consists of one 20 h. p. single-reduction Westinghouse motor. All the line material was furnished by the Electric Merchandise Company, Chicago, and the overhead work presents a neat and handsome appearance. The cars will be heated during the coming winter with the Burton electric heater, thus making the system purely electrical. The tracks were laid under the care of James B. Moran, who is to be manager of the road, and the installation at the power house, together with the construction of the overhead work, was in charge of Mr. J. F. McBeth.

ST. LOUIS EXPOSITION NOTES.

THE EMERSON ELECTRIC MANUFACTURING CO. make a very complete display of their goods. Their alternating current motor is shown in operation, driving sewing machines and jewelers' lathes. The sewing machines attract much attention. Their new model Bagnall live trolley crossing is shown in position. The Bagnall fuse switch, the Emerson improved cross-over and strain insulators are shown among their railway appliances, and also their ideal switch-back for arc light switchboards, and a number of new model spring-clip cut-outs.

THE SHULTZ BELTING CO. have a working display showing the manufacture of their patent woven leather link belting. They also display samples of their well-known raw-hide belting, one roll of which is quite noteworthy, being 72 inches wide and 154 feet long, and weighing 2,000 lbs. This belt was made for the St. Louis and Suburban R. R., which is now being changed from cable to electric power.

THE LACLEDE POWER CO. show a 80 h. p. electric power plant in operation. A 35 h. p. Westinghouse engine drives a 30 K. W. 500 volt C. & C. generator, which supplies current to a 20 h. p. C. & C. motor in the *Post-Despatch* exhibit in a distant part of the building. The 20 h. p. motor is used to drive a printing-press. Current is also supplied to a number of smaller motors about the building.

W. D. BOYCE & CO., who have lately taken the agency for the Porter-Allen engine, have one of 100 h. p. in operation driving a 250-light Edison, and 180-light Standard dynamo, supplying lights to various parts of the building. This well-known engine is meeting with much favor in the West.

THE ST. LOUIS ELECTRICAL SUPPLY CO. have a large display of their well-assorted goods—Crocker-Wheeler, Edison, Emerson, and Wagner fan motors, Edison-Lalande, Crosby and other batteries, wires and cables, and a varied assortment of general merchandise arranged in a very attractive manner.

THE ST. LOUIS IRON AND MACHINE CO. have one of their 100 h. p. Corliss engines in operation, driving a line of shafting in the basement. The engine has some novel improvements in valve-actuating devices and dash pots, which render its operation almost noiseless.

THE HEINE SAFETY BOILER CO. have one of their well-known boilers set up in position with one side wall of the furnace removed so as to show the special features of the boiler and furnace setting.

THE ROSE ELECTRIC LIGHT SUPPLY CO. have a 350-light Ft. Wayne Jenney dynamo in operation, supplying lights to various exhibitors in the building. Power is supplied by a Russell engine.

THIS season no special inducements were offered by the Exposition Association to electrical manufacturers and dealers, and the electrical exhibit is therefore entirely local.

C. A. WOLFRAM makes a display of electric bells, annunciators, lamp fixtures, fans, and other merchandise.

THE ELECTRO-DEPOSITING CO. show the process of electroplating by means of dynamo currents.

NEW ENGLAND TRADE NOTES.

THE THOMSON-HOUSTON ELECTRIC COMPANY, lighting supply department, have just published a most comprehensive and carefully-compiled catalogue of electrical supplies. The book contains 200 pages, is bound in hard cardboard, and is profusely illustrated. It is divided into three sections, part 1 containing articles manufactured solely by the Thomson-Houston Electric Company, such as transformers, switchboards, lamps, meters, indicators, switches, commutator brushes, arc lamps and hoods, carbons, cut-outs, rosettes, sockets, etc. Part 2 contains miscellaneous supplies which the Thomson-Houston Company do not manufacture, such as insulated wires and cords, tapes, hard-rubber tubing, connectors, cleats, insulators, insulated joints, brackets, lamp guards, lamp shades and reflectors, mouldings, mast-arms, poles, lamp hangers, and tools. Part 3 is devoted entirely to tools for electrical construction, such as magneto-bells, speed indicators, callipers, wire gauges, tongs, pliers, screwdrivers, ratchet braces, augers, saws, hacksaws, files, drills, chisels, hammers, wrenches, pole-diggers, picks, shovels, spades, etc. The volume is very complete, and the cuts are excellent, the whole being compiled in so careful a manner that it must become of immense value to every electric light man who is fortunate enough to possess one.

JEROME REDDING & COMPANY.—Messrs. Jerome and Harvey Redding have separated from the Redding Electric Company, and have formed the above company, with headquarters at the old address, 48 Hanover street, Boston. They will continue to manufacture all the old specialties, consisting of general electrical household supplies. The disque battery will continue to be a strong feature of their business, and they are bringing out a number of new specialties, of which particulars will be given later.

THE GERMANIA ELECTRIC COMPANY, of Boston, are commencing to manufacture their new Germania direct incandescent dynamo. The patents controlling the inventions covering this machine are the well-known Lahmeyer patents, under which the Continental Dynamo Company, of New York, formerly operated. This dynamo is in successful operation in a large number of representative buildings, amongst which are the Cotton Exchange, New York; the Belvedere House, New York; the John Hancock Building, Boston, etc. The Germania Company are now manufacturers of dynamos, transformers, incandescent lamps, sockets, shade-holders, and other electric materials, and are thus well equipped for general electrical manufacture, construction and installation.

THE GOULD & WATSON COMPANY.—The West End Street Railway Company, of Boston, in the extension of their electric system of street railways, have placed very large orders with the Gould & Watson Company, of Boston, for various overhead line material. This order embraces strain insulators for span wires, line insulators for trolley wires, and guard wire insulators of an entirely new pattern, possessing extraordinary strength. They are also supplying clips, anchor ears, splice ears, and other necessary material. It is gratifying to the Gould & Watson Company that their factory is as busy as possible, turning out all kinds of insulators for railway work, and moulded mica appears to be quite a favorite after several years' hard test.

H. N. BATES & COMPANY, of Boston, have just completed the equipment with shafting, clutches, pulleys, etc., of the station of the Augusta, Gardner, and Hollowell Street Railway, at Hollowell, Me., and the station of the Woonsocket Electric Light and Power Company, at Woonsocket, Mass. They have just received the contract to furnish shafting, clutches, pulleys, etc., for the Fall River Electric Light Company, at Fall River, Mass., and they have a big contract on hand for the Kearney Cotton Manufacturing Company, at Kearney, Neb. This order will include, in addition to pulleys, hangers, shafting, and clutches, the whole electric plant, consisting of a 500 light dynamo, fixtures, lamps, and the work of installation.

THE REDDING ELECTRIC COMPANY have been reorganized, and Mr. John C. Holman has been appointed president. The board of directors now stands as follows: John C. Holman, president; H. B. Stanwood, treasurer; H. M. Nicholls, secretary, and S. C. Whipple. The business of the company is steadily increasing in electric light and general electrical supplies.

THE GERMANIA ELECTRIC COMPANY, of Boston, have appointed Mr. B. B. Stoddard to represent them in Philadelphia, and he will have his headquarters at 505 Girard Building, in that city. Mr. Stoddard has been connected with the Woonsocket Electric Machine and Power Company for several years, and has had a wide experience in the use of all kinds of incandescent lamps.

TROPICAL AMERICAN TELEPHONE COMPANY, of Boston, has been allowed three important patents in telephones and magneto bells, embodying many new features.

WESTERN TRADE NOTES.

THE CHICAGO ELECTRIC MFG. CO., 73 West Jackson street, Chicago, have their factory crowded with specialty work and testing instrument manufacture. Mr. J. D. Claghorn, the popular manager of the company, has been compelled, through ill health, to take a long vacation, and will probably spend the winter in Southern Nebraska. The appointment of a superintendent to assist Mr. Irving Usner, the treasurer of the company, in its management will shortly be made, and meanwhile Mr. Usner is looking after the company's large business.

CHANDLER & LITTLEFIELD, manufacturers' agents, Marine Building, Chicago, have sold a 70 h. p. Foote regulator to the Edison Company, of Appleton, Wis. In addition to being the Western agents for the T. M. Foote Regulator Co., of Boston, they carry a general assortment of machinist's and engineer's supplies, and are Western agents for the Lexington Gear Works and the Providence Steam Trap Co.

THE POND ENGINEERING CO. has just contracted, through its Chicago office, to furnish two 60 horse-power Armington & Sims engines, with foundation boxes, to the Gas Works in Chicago. One of them goes into the north station of the People's Gas Light and Coke Co., and the other into the south station of the Chicago Gas Light Co. Both will be used for driving blowers.

☞ ***Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Miscellaneous, etc., will be found in the advertising pages.***

Electrical Engineer.

VOL. XII | SEPTEMBER 30, 1891. | No. 178.

THE LOCALIZATION AND REMEDY OF TROUBLES IN DYNAMOS OR MOTORS.—III.

BY

Francis B. Crocker and S. S. Wheeler.

HEATING IN DYNAMO OR MOTOR.

General Instructions.

THE degree of heat that is injurious, or even objectionable, in any part of a dynamo or motor is fortunately very easily and quite definitely determined in ordinary practice. All that is necessary is to place the hand on the various parts, and if it can remain without discomfort the heat is entirely harmless. But if the heat is unbearable for more than a few seconds the safe limit of temperature has been passed, and it should be reduced in some of the ways that are given below. If the heat has become so great as to produce an odor or smoke, the safe limit has been far exceeded, and the current should be shut off and the machine stopped immediately, as this indicates a serious trouble, such as a short-circuited coil or a tight bearing. The machine should not again be started until the cause of the trouble has been found and positively overcome. Of course neither water nor ice should ever be used to cool electrical machinery, except possibly the bearings in large machines, where it can be applied to the bearings as a cooler without danger of wetting the other parts.

The above simple method will answer in ordinary cases, but, of course, the sensitiveness of the hand differs, and it makes a very great difference in the feeling whether bare metal or cotton-covered wire is touched. Hence, for accurate results, a thermometer should be applied and covered with waste or cloth to keep in the heat. In proper working the temperature of no parts of the machine should rise more than 40° C. or 72° F. above the temperature of the surrounding air. If the actual temperature of the machine reaches boiling point, 100° C. or 212° F., it is seriously high.

It is very important in all cases of heating to locate correctly the source of heat in the exact part in which it is produced. It is a common mistake to suppose that any part of a machine which is found to be hot is the seat of the trouble. In every case all parts of the machine should be felt to find which is the hottest, since heat generated in one part is rapidly diffused throughout the entire machine. It is generally much surer and easier in the end to make observations for heating by starting with the whole machine perfectly cool, which is done by letting it stand for one or more hours, or over night, before making the examination. When ready to try it, run it fast for three to five minutes, then stop and feel all parts immediately. The heat will then be found in the right place, as it will not have had time to diffuse from the heated to the cool parts of the machine. In fact, after the machine has run some time any heating effect will spread until all parts are nearly equal in temperature, and it will then be almost impossible to locate the trouble.

HEATING OF ARMATURE.

1. Cause.—*Excessive current in armature coils.* Symptom and Remedy the same as Sparking No. 1.

---

2. Cause.—*Short-circuited armature coils.* Symptoms and Remedies the same as Sparking, No. 5.

---

3. Cause.—*Moisture in armature coils.*

Symptom.—Armature requires considerable power to run free. Armature steams when hot, or feels moist. This is really a special case of No. 2, as moisture has the effect of short circuiting the coils through the insulation. Measure insulation of armature.

REMEDY.—Dry the armature in a warm, but not hot, place. This may be done very neatly by passing a current through the armature, which should be regulated so as not to exceed the usual armature current.

---

4. Cause.—*Foucault currents in armature core.*

Symptom.—Iron of armature core hotter than coils after a short run, and considerable power required to run armature when field is magnetized and no load on armature. This may be distinguished from No. 2 by absence of sparking and absence of excessive heat in a particular coil or coils after a short run.

REMEDY.—Armature core should be laminated more perfectly, which is a matter of first construction.

HEATING OF FIELD MAGNET.

1. Cause.—*Excessive current in field circuit.*

Symptom.—Field coils too hot to keep the hands on.

REMEDY.—In the case of a shunt-wound machine decrease the voltage at terminals of field coils, or increase the resistance in field circuit by winding on more wire or putting resistance in series. In the case of a series-wound machine, shunt a portion of, or otherwise decrease, the current passing through field, or take a layer or more of wire off the field coils, or rewind with coarser wire. This trouble might be due to a short circuit in field coils in the case of a shunt-wound dynamo or motor, and would be indicated by one pole-piece with the short-circuited coil being weaker than the other; one of the coils would also probably be hotter than the other; but this can only be remedied by rewinding short-circuited coil. Measure resistance of field coils to see if they are nearly equal. If the difference is considerable (*i. e.* more than 5 or 10 per cent.) it is almost a sure sign that one or both coils are short circuited or double-grounded.

---

2. Cause.—*Foucault currents in pole-pieces.*

Symptom.—Pole-pieces hotter than coils after a short run. The pole-pieces being bare metal and coils being covered, when making comparison it is of course necessary to keep hand on coils some time before full effect is reached, and even then it is reduced.

REMEDY.—This trouble is either due to faulty design and construction, which can only be corrected by rebuilding, or else it is caused by fluctuations in the current. The latter can be detected, if the variations are not too rapid, by putting an ammeter in circuit, or rapid variations may be felt by holding a piece of iron near the pole-pieces and noting whether it vibrates. A direct current does not usually vary enough to cause this trouble, but in the case of an alternating current it is necessary to use laminated fields to avoid great heating, and the ordinary arc currents fluctuate enough to cause some trouble in this way.

---

3. Cause.—*Moisture in field coils.*

Symptom.—Field-circuit tests lower in resistance than normal in that type of machine, and in the case of shunt-wound machines the field takes more than the ordinary current. Field coils steam when hot, or feel moist to hand.

REMEDY.—Dry the field coils in a warm but not hot place. This may be done simply by passing a current through the field coils, which must be regulated so as not to exceed the usual field current.

PIPING ELECTRICITY—A TALE FOR WIRE BUYERS.

BY

Albert Scheible

THERE was once a place—perhaps Jules Verne can tell you its name—where the natives had learned to produce a certain mysterious fluid, and could make this medium do their many chores. Indeed, so useful was this fluid that it was thought best to pipe some of it to remote parts of the town where many would want its help. But it was found quite a problem to keep the mysterious fluid from oozing out and choosing paths of its own, so that it was necessary to produce as much more of the fluid as was lost on the way. Besides, this leakage created quite a prejudice in the minds of many who did not know that this fluid was so truly docile. So some set out to make pipes which would more completely restrain the subtle fluid, and they succeeded in a varying degree in producing such an article. Indeed, a few managed to make very good pipes, and some which would save so much leakage as to pay for their higher cost in a short time.

Now when such pipes grew in demand and many, many feet of them were used month after month, there were others who sought to supply the fluid-makers with their wares. So they figured this way, and that, but always found that no salable pipe could be made for less than a certain amount per foot, and it seemed evident that the users would buy it (as they would use it) by the unit of length. Then there was more discussion and deliberation, and some experimenting. Bye and bye it happened that some makers offered their make of tubes for sale by the pound, and claimed that this made their pipes really cheaper than the thoroughly tested ones, which were sold by the foot. And they found many buyers who did not stop to look into the lasting quality of the tubes, but who would buy whatever required the least outlay. Then when they renewed their pipes—for most of these did not last many months, and their breaking down was often quite annoying—they would buy some more by weight at the same "bargain figure." Only here and there some practical man would examine some of the various pipes, and would figure out that it was really far cheaper to use the tubing which was sold by the foot at what seemed a much higher price. For it was remarkable how clearly every leak would show its effect in the coal pile, and the coal bill came every month, while that for pipe (if it was a first-class article) needed no repetition. Gradually there were more and more who knew that much of the material in the "cheap-by-the-pound" pipes was put in more to add to the weight than to keep the fluid within bounds. Indeed, some of the materials used were anything but suitable for this purpose, and, in order to overlook these ingredients, the buyer had to have both eyes blinded by the apparently low price. Still, many such tubes were nicely polished and decidedly pretty when new; indeed some were quite serviceable as long as neither water, nor the hot sunshine, nor strong fumes could get at them, and as long as they were not touched by ungloved hands.

Since then many months have passed; the old prejudice against the mysterious fluid is dying out, and mile after mile of the tubing is in steady use. Yet a few weeks ago when I visited this place I found that the old methods of the pipe-makers had not been outgrown, and that the number of different brands sold on the hay-scale plan was larger than ever. To be sure, many of these are replaced every month by some of the kinds which are sold, not for their light weight, but for their thorough and lasting qualities. It is even claimed that the first of these carefully-made pipe-lines is still in use. Yet I found many buyers who seemed to think a pound of rubber worth little, or no, more than a pound of wax or lead paint when used as a material for a pipe.

Perhaps there is some truth in what one of the residents—a bright engineer who looked thrice before he bought an article, and judged it by its true merits—told me about a large pipe-buyer. He said that this wise man was so impressed with the idea of buying these tubes by the pound that he had applied this principle to nearly everything about the station, and now had his belts, oil and carbons weighed out and paid for accordingly. And is not this just as reasonable?

I also noticed the coal-dealers all seemed to favor the "cheap-by-the-pound pipes," and so did many of the supply men. I remonstrated with one of the latter for selling such wares, but he merely smiled, slapped his hand against his pocket half full of coin and then whistled the familiar refrain, "Still there's more to follow." I turned in disgust, but only to see the station manager across the way lengthen his face as he scanned the last coal bill. O Father Time, pipe us some progress!

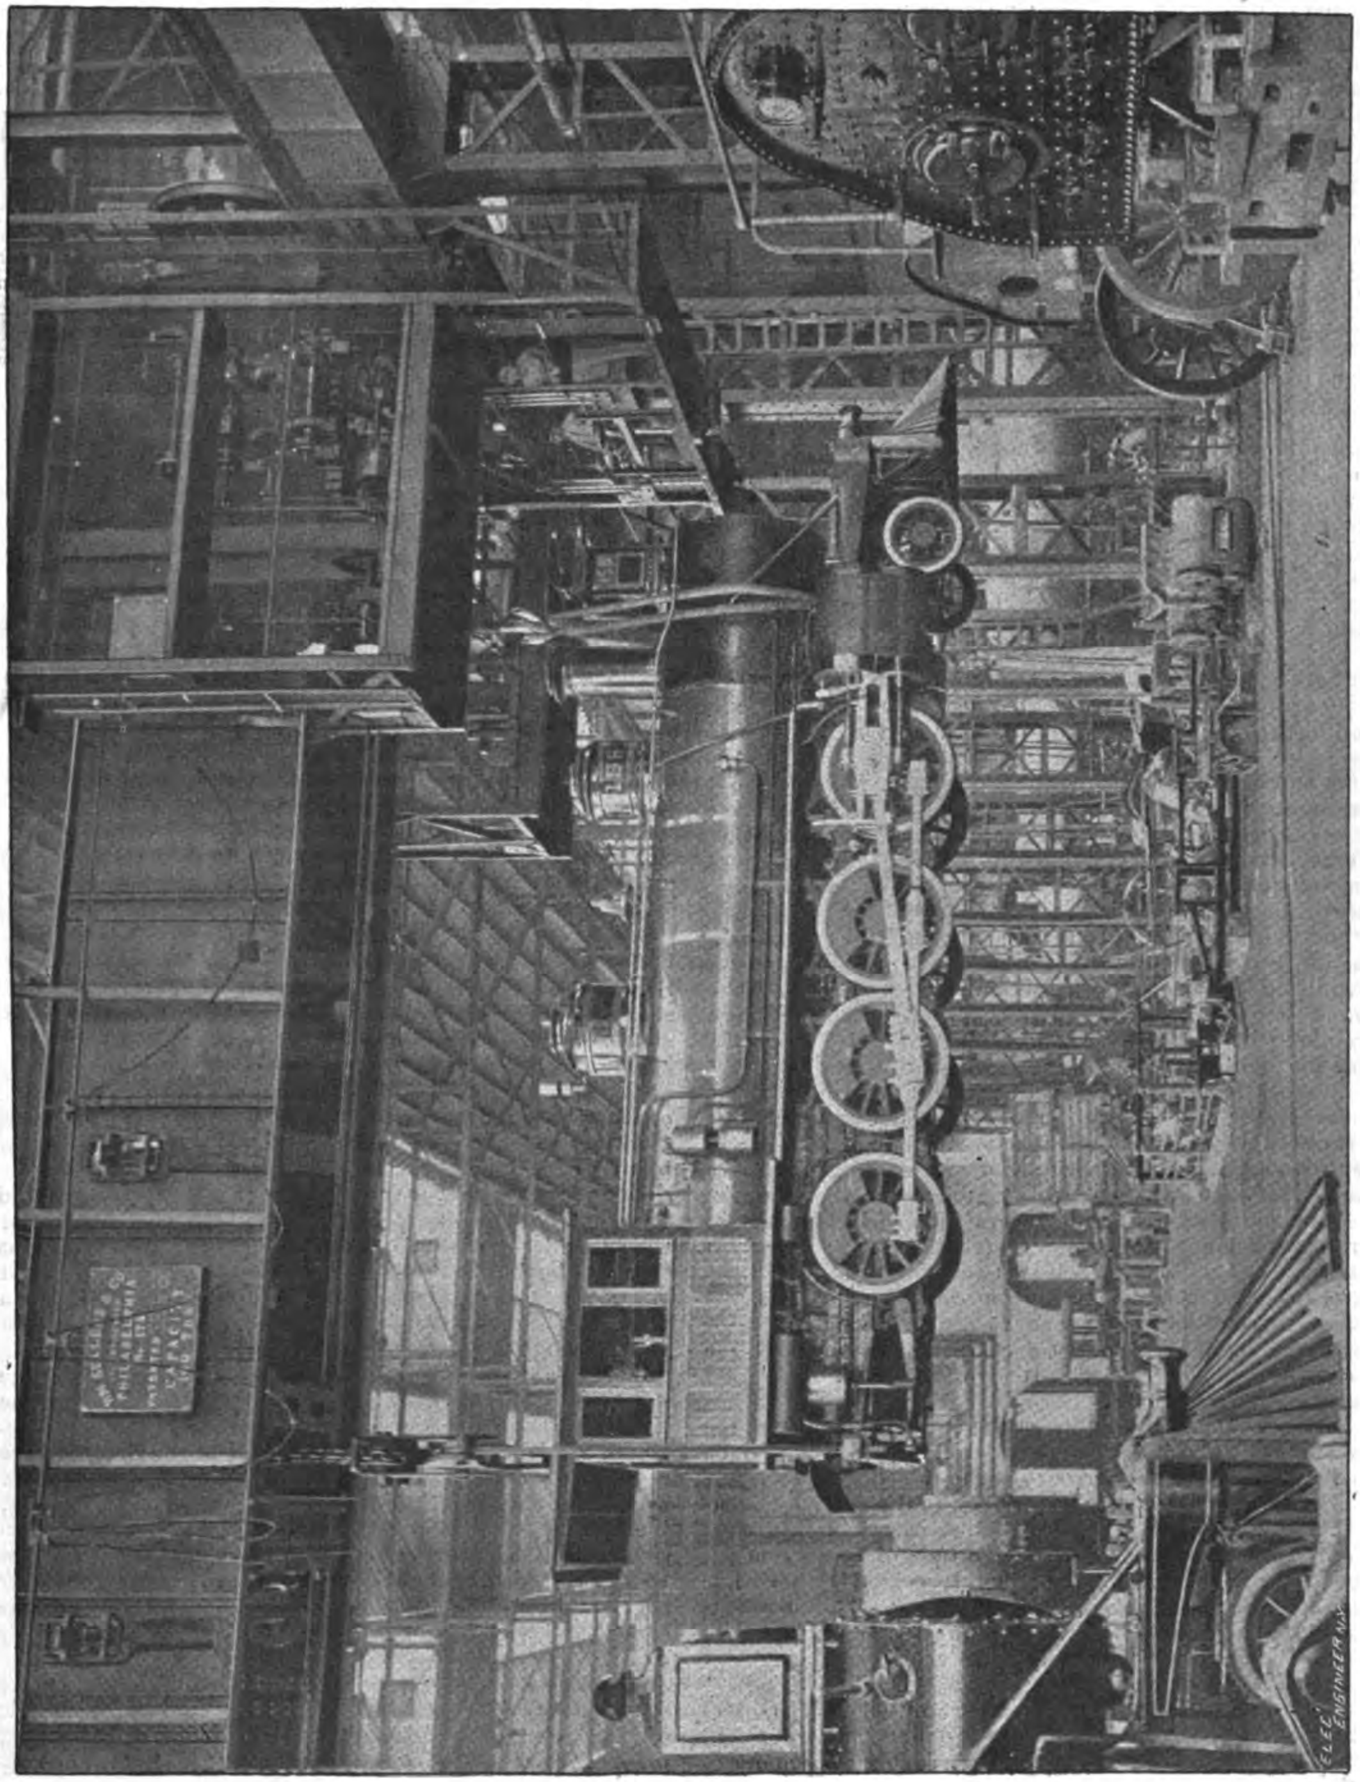
ELECTRIC CRANES AT THE BALDWIN LOCOMOTIVE WORKS, PHILADELPHIA.

MUCH has been written lately of traveling cranes and the possibilities and advantages of operating them by electricity, but up to the present no details have been made public of the electric cranes at the Baldwin Locomotive Works, in Philadelphia, which comprise probably the most powerful cranes of this type thus far constructed.

There are there two large traveling cranes, each of 100 tons capacity, running side by side in the new erecting shop lately built by this company. The cranes proper were built by Messrs. Wm. Sellers & Co., of Philadelphia, who are well known as builders of this class of machinery, and it was at their suggestion that electricity was adopted as a motive power.

On each crane there are two 40 h. p. Westinghouse constant potential, shunt-wound motors, geared independently to the driving machinery by vertical belts; the motors being mounted on the extreme top of the bridge of the crane. The motors run in one direction at all times, and the reversing of the crane is accomplished through friction clutches, and through these clutches the power is distributed to the various parts of the crane for moving the bridge, moving the lifting trolleys and hoisting the load.

Each crane is provided with two 50-ton lifting trolleys, that is, each trolley is capable of lifting fifty tons, and the



100-Ton Traveling Electric Crane at the Baldwin Locomotive Works, Philadelphia.

power is conveyed to these trolleys by a square shaft running the entire length of the bridge inside the girders.

The accompanying engraving shows the method employed in lifting a locomotive; a rope is placed around the front end of the engine, and a large iron frame is placed on the rear end, and the two trolleys are worked simultaneously, although either one can be stopped and the other raised or lowered at the discretion of the man who is operating the crane. The large hooks and chains on these trolleys are very massive and move rather slowly, and are used only for lifting the very heaviest loads; but a 5 h. p. quick hoist has been placed on the far lifting trolley for lifting loads under one thousand pounds. This quick hoist is operated by a 5 h. p. Wenstrom motor, series wound and reversible, and is controlled from the cab of the crane. This motor and drum move forward and backward with the trolley, and it takes eight wires between the switch and the motor to give the various speeds and to change the direction of running.

The current is taken to this motor from the stationary controlling switch through a stranded cable, which hangs at the side of the crane bridge, and falls in loops as the trolley is moved toward the operator, each loop being hung from a pair of small wheels running on a steel track at the side of the bridge. This cable was made by the International Okonite Co., of New York, and is composed of eight wires, each wire being made up of seventy-two strands of very fine copper.

Both cranes move the entire length of the erecting shop and are capable of picking up at any point the heaviest locomotive that the Baldwin Locomotive Works build and disposing of it at any other point in the shop. The operation of lifting a locomotive from the far end of the shop and lowering it on the shipping track consumes about five minutes, while the same work, before the cranes were installed, used to take a large gang of men an entire night. These cranes work very smoothly. For all lighter work only one of the 40 h. p. motors is run, the other one being started only in case of necessity.

Our engraving shows a large compound locomotive in the air, weighing sixty-five tons. When this locomotive was lifted, but one of the motors was in operation. These cranes move laterally through the shop on steel T-rails, weighing 135 lbs. per yard. This rail was rolled especially for this plant and is the heaviest steel rail in use.

Besides the two large traveling cranes above described, there are in use four jib cranes operated by electricity. These jib cranes have a capacity for lifting from five to ten tons, each crane being supplied with a 5 h. p. Wenstrom slow-speed, constant-potential motor; and there are, in various parts of the shops, several other electric motors driving machine tools or lines of shafting. The current for these motors is furnished by two 80,000 watt Westinghouse constant-potential, compound-wound generators, and have an electromotive force of 250 volts. Each generator is driven by a Westinghouse compound engine, and the steam is supplied by a battery of Babcock & Wilcox boilers.

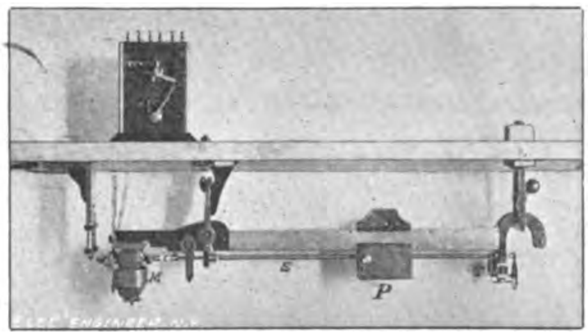
The current for the motors on the crane is taken from the overhead double-trolley line, each trolley wire being $\frac{1}{2}$ inch in diameter and laid in a groove cut in the edge of a strip of yellow pine. These strips are $\frac{3}{4}$ inch in diameter by about 3 inches wide, and are bolted through porcelain insulators to a yellow pine girder 3 x 8 inches square, hung from the roof by iron rods, and are thoroughly coated with shellac and otherwise insulated from the building. The current is taken from the trolley wires through Wheeler trolleys, each of which has four wheels, and each crane being supplied with two trolleys.

There is a considerable flow of current when the motors are working to their maximum capacity, and it was found that the two four-wheel trolleys were none too many to safely carry the current.

The entire plant has been in operation since the early part of the present year and has been satisfactory in every way. The electrical work was placed in the hands of the Equitable Engineering and Construction Co., of Philadelphia, Pa., by whom all the details were carefully worked out and put into effect, and several new features in the method of applying motors to this class of work were designed and introduced by that company in this installation.

THE DAVIS ELECTRIC TRACK SCALES.

ALTHOUGH electricity has found most important applications in railroad service in the telegraph, the working of switches and signals, and, latterly, in its direct utilization for the propulsion of cars, there are still other uses which can be found for it which will tend to still further increase the dispatch of trains. It is evident that in weighing a large number of freight cars, while accuracy is absolutely essential, rapidity in weighing is equally desirable. In seeking to fulfill both these requirements Mr. J. V. Davis, of this city, has designed the scales illustrated in the accompanying engraving. Having been weighmaster in the service of a large railroad company, Mr. Davis was thoroughly cognizant of the conditions which a track



THE DAVIS ELECTRIC SCALE.

scales must fulfill, and hence designed it with special reference to rigorous usage by unskilled handlers.

To attain this end the inventor has very ingeniously applied a small electric motor to the beam of the ordinary standard scales. The poise P is moved backward and forward along the beam by a screw rod, S, turning in ball-bearing journals; the motor M is mounted upon the shorter or inner arm of the beam, with the armature in line with, and coupled directly to, the screw. The motor is of the shunt type, with special winding, providing for instantaneous starting and stopping at full speed. It is so wound and connected with the switch terminals that when a weight is on the platform that is lighter than the last weight registered, the motor turns the screw in such a direction as to move the poise inward until it reaches the point of balance, when, by the mere act of balancing, the circuit through the armature is broken, and the fields, remaining in circuit, provide an instantaneous stop to the revolutions of the screw and the motion of the poise. When the weight on the platform is heavier than the last, the poise moves outward to a balance. It must be understood that the normal position of the poise is at the last weight recorded, and therefore, the poise has only to cover in its motions the difference between the weights of the cars; this renders the operation of weighing extremely rapid.

A series of type wheels, T, actuated by the screw are seen at the outer end of the beam. An electromagnetic device, arranged in series with the armature of the motor, prints a ticket at the instant of balancing. There is no connection whatever between a fixed and a movable part of the scale different in any way from the ordinary scale, the beam being as free to move in every way necessary to produce an exact balance and an accurate weight. In fact, it is merely a standard scale with means provided to move the poise quickly and automatically, and to provide against all mistakes.

The poise moves from end to end of the beam in four seconds, and will ordinarily come to the point of balance in $\frac{1}{4}$ to $\frac{1}{2}$ second, while the weight is recorded in plain, printed charaters at the instant when the beam is swinging in perfect balance. Furthermore, it will only weigh one car at a time, refusing to record any weight if another is touching the platform. For example, if a car comes on the platform, is weighed, and rolls partly off, leaving a pair of wheels, or any part of its weight, touching the platform, another car coming on the platform will not affect it, no weight being recorded until the first car has entirely cleared the scale. Moreover, it will not weigh a car unless all its wheels are on the platform. All these features are secured by means absolutely certain and simple in operation, and the whole machine requires no more attention to keep in order than an ordinary track scale.

A virtue of the machine, which will be appreciated by railroad men, is that its adoption will not necessitate a new installment from the pit up. Only the beam is different from the ordinary track scale, and taking the old one out and hanging the new one in its place serves to completely change to the new system. This will greatly lessen the cost and reduce the time necessary in changing, and will, no doubt, hasten the adoption of this machine.

This type of automatic scale is evidently not limited to track scales, but can be built in all sizes from counter scales up to railroad scales. We may add that Mr. Davis will exhibit his automatic electric scales at the American Institute Fair shortly to be opened in this city.

THE SCOTT-SISLING ACCUMULATOR SYSTEM.

BY

W. B. Sisling.

PRIVATE installations generally involve the use of accumulators, and to charge these the dynamo voltage must, of course, be raised some 25 per cent. above the lamp voltage.

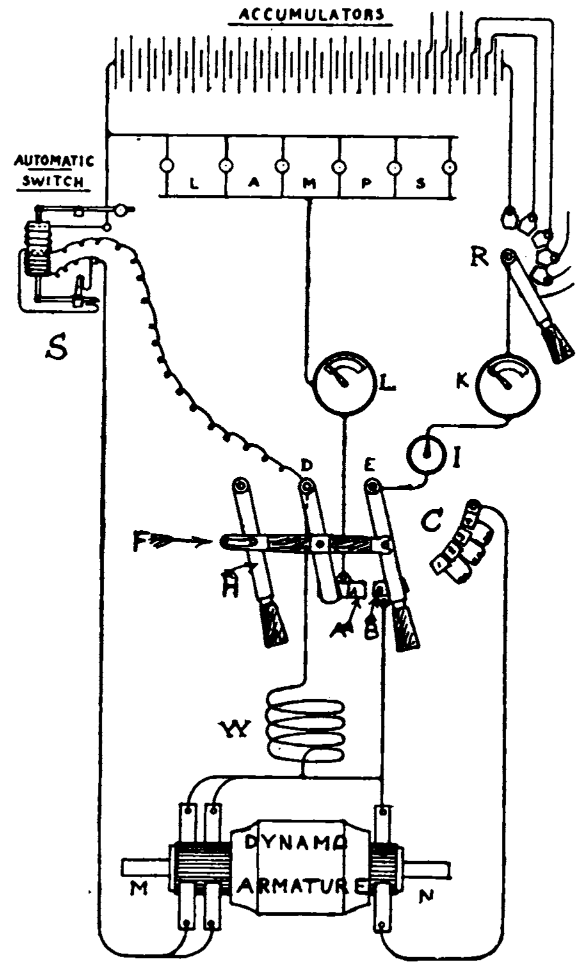
In many cases this is inconvenient and wasteful, as the dynamo must be "run up" to this increased voltage, although only a portion of the current generated may be used for charging, the remainder being required for the lamps at the normal voltage. The accompanying illustration shows an arrangement devised by Mr. W. H. Scott and the writer, which seems to overcome this difficulty, and has several features which ought to prove advantageous in a private installation.

The arrangement may be described as a compound dynamo with a small supplementary winding on its armature, connected to an extra commutator which gives a voltage usually about one-quarter of that given by the main commutator. A branch is taken from the main circuit, and connected so that the extra commutator raises its voltage by about 25 per cent. This forms the charging circuit.

The dynamo can thus be driven at constant speed and will supply constant voltage to the lamps from its main circuit, undisturbed by the increasing voltage from the cells during charging. The whole of the cells can be charged, and a large current supplied to the lamps at the same time, as this does not pass through the regulating cells. The charging can therefore be accomplished during the hours of lighting, instead of the dynamo having to be run specially during the day.

As will be seen, the dynamo armature has a main commutator, M, and an extra commutator, N. These two commutators are connected in series, either directly or through the dynamo series winding W. The switchboard contains two switches; the dynamo switch D, which connects the dynamo to the lamps, and the accumulator switch E, which connects the accumulators in either of three different ways, viz., A to the lamps alone, or B to the lamps and dynamo, or C to the charging circuit. These two switches are of the lever pattern, and are interlocked by the thrust rod F.

The handle H acts on the thrust rod so that it can only put the dynamo switch "on." To take it "off" the accumulator switch must be moved so that the accumulators are connected to the lamps alone. When the dynamo switch is put "on" the thrust rod moves the accumulator switch from A to B, thus connecting the accumulators to the dynamo in such a way that they are in readiness to assist the dynamo in supplying current to the lamps, without risk of weakening or reversing its magnetism.



THE SCOTT-SISLING ACCUMULATOR SYSTEM.

If the dynamo does not need assistance, and spare power is available, the accumulator switch may be moved further from B to C, when the dynamo will begin to charge the cells by means of its extra commutator N, without interfering with the constant voltage which is supplied to the lamps from its main commutator M.

An index, I, shows whether the accumulators are being charged or discharged, whilst an ammeter, K, indicates the amount of the charging or discharging current. A second ammeter, L, shows the current taken by the lamps, and a pilot lamp on the switchboard lights when the dynamo starts up.

By means of this arangement the manipulation is made simple, and the charging current can be adjusted to form a complementary load, thus working the plant at its maximum efficiency and shortening the hours of running.

The arrangement is in use in some private installations, the latest being one erected for Baron V. de Barreto, of Brandon Park, Suffolk, England, which is driven by an oil engine giving 11 h. p. The engine is started by the accumulators, and these also work the coil which ignites each charge in the engine cylinder. The whole arrangement seems to work satisfactorily, and without specially skilled attention, which is an important matter for country houses.

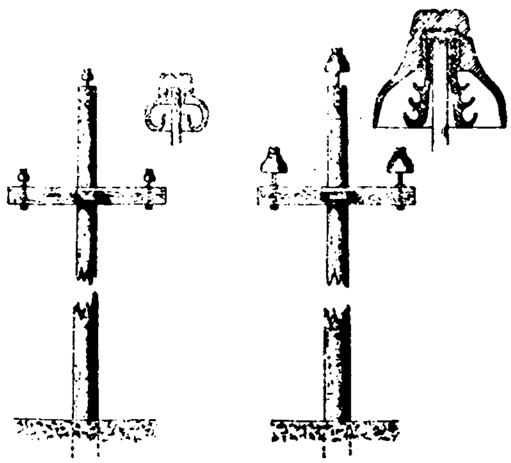
THE LAUFFEN-FRANKFORT ELECTRIC POWER TRANSMISSION.

We have on several occasions described some of the methods and apparatus employed in the transmission of electric power at high potentials from Lauffen to Frankfort, a distance of 112 miles, and our correspondent, Prof. R. O. Heinrich, has also described in detail the electrical

Fig. 1.—Switchboard at Lauffen.

system of transmission employed. There are some additional details, however, of this installation which our readers will be interested in, as they bear directly upon the question of the possibility of the transmission of alternating currents at high potentials. The dynamo machine situated at Lauffen generates a three-phase alternating current, each component of which has a pressure of 50 volts and delivers 1,400 amperes. From this machine the currents are at first led to a switchboard, which is illustrated in Fig. 1. This is equipped in the usual manner with the necessary measuring instruments, safety cut-outs and switches. From the switchboard the current is led to the transformers, which increase the potential from 50 volts to 30,000, the ultimate voltage capacity of the transformer. These transformers are placed in oil in order to obtain sufficient insulating power for the high-tension currents.

From the transformers the high-tension currents are conducted to the lines, three bare copper wires of four millimetres diameter. The line consists of poles eight metres high, placed about 60 metres apart, the number of poles employed for the whole distance being about 3,000. The copper wire employed has an aggregate length of about 530 kilometres. It has been furnished by the firm of F. A. Hesse Sons, who, in order to further this important work, have loaned it for this occasion at a very small compensation.



Figs. 2 and 3.—Poles and Insulators.

The most important point evidently in this undertaking is the proper insulation of the line. The Allgemeine Elektricitäts-Gesellschaft and the Maschinenfabrik Oerlikon, besides furnishing the generator, motor, and auxiliary apparatus and transformers, also bore the expense of the insulators—no small item. These were manufactured by the firm of H. Schomburg & Sons, Berlin. Two types of insulators are employed ; for a part of the distance that shown in Fig. 2 is used, giving but a single layer of oil between the insulator and the support, while for about one-third of the distance the type shown in Fig. 3 is used, lack of time preventing the equipping of the entire line with the latter type of insulator ; the total number of insulators reaches 9,000.

At Frankfort the high-tension circuits are conducted to three oil transformers of the type illustrated in Fig. 4. One of these, which was constructed by the Maschinen-

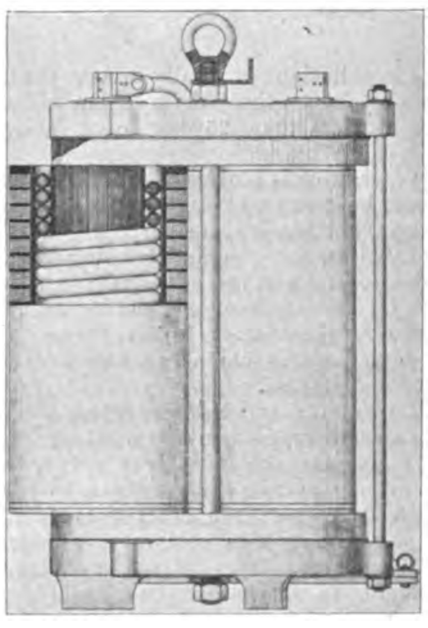


Fig. 4.—High Potential Transformer.

fabrik Oerlikon, reduces the potential of the line to 100 volts with a corresponding increase in the current strength. This transformer feeds a battery of 100 incandescent lamps arranged in the shape of an illuminated sign, and consumes about 100 h. p., that is, half of the power transmitted. The remaining part of the current, a trifle over 100 h. p., is converted by two transformers made by the Allgemeine Elektricitäts-Gesellschaft, and also reduces the tension to 100 volts. These transformers, as will be seen, consist of

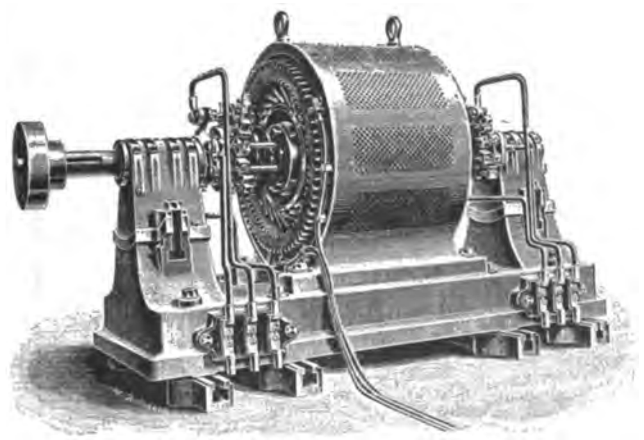

Fig. 5.—Large Rotary Phase Motor.

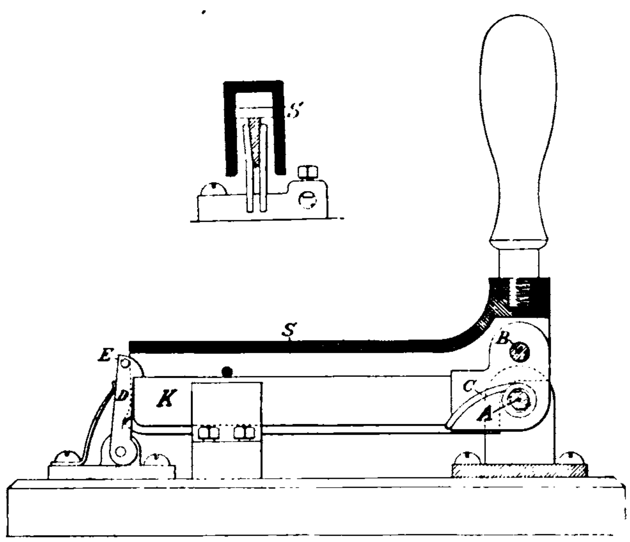
three cores having the low potential secondary wound next to the iron and surrounded by the high potential primary, which is built up in sections to secure more thorough insulation. The secondary current from these transformers drives the large electric motor of the Allgemeine Elektricitäts-Gesellschaft, which is illustrated in Fig. 5, as well as a number of smaller motors also built on the rotary phase system. The large motor has current led to it through six circuits, and makes 600 revolutions per minute. It is connected directly to a centrifugal pump, built by Brodnitz & Seydel, of Berlin, and raises the water for a large artificial waterfall to a height of 10 metres.

THE KINTNER JACK-KNIFE SWITCH.

A very simple and effective quick-break switch for high-tension currents has recently been designed by Mr. Charles J. Kintner, of this city, and is clearly shown in the accom-



Kintner Jack-Knife Switch.

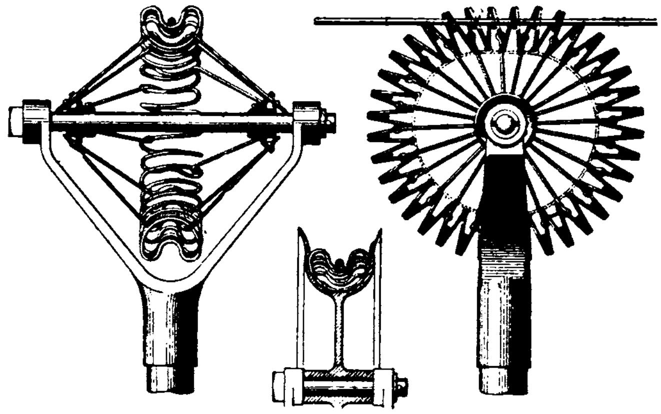
panying engravings, Fig. 1 being a longitudinal, and Fig. 2 a transverse, section.

As will be seen, the jack-knife K is pivoted at A, and completely covered and protected by the shield S, made of insulating material, and turning about the pivot B. A powerful spring, C, is coiled about the pivot A, and tends always to keep the switch open, while the pawl D firmly holds it in position when once closed. A pin, E, passing through the upper end of this pawl, rests normally against the curved end of the insulating shield, shown in dotted outline in Fig. 1.

The operation is as follows: The switch being closed, as shown in Fig. 1, the handle, fastened to the insulating shield, and in noway connected to the switch itself, is drawn aside, or down. The shield, rotating about the pivot B, moves upward, pushing againt the pin E, and throwing the pawl D out of contact with the knife K, which, thus released, is violently thrown open by the action of the spring C. The pawl is held at right angles to the base of the switch by a spring, and re-engages the knife-blade automatically when the switch is again closed.

THE WETMORE MULTIPLE CONTACT TROLLEY WHEEL.

In the operation of overhead electric railways, considerable annoyance has been experienced from the sparking at the trolley wheel, due to insufficient contact with the trolley wire. In order to obviate this difficulty, Mr. Jean A. Wetmore, of this city, has designed a trolley wheel, by the use of which contact is obtained at several points simultaneously.



Figs. 1, 2 and 3.—Wetmore's Multiple Contact Trolley Wheel.

In this device, which is shown in the accompanying illustration, the periphery of the trolley wheel is composed of a helical conductor, the convolutions of which are capable of yielding under the pressure of the wheel upon the wire to such an extent that several of them are always in contact.

In the forms shown in Figs. 1 and 2, yielding arms or spokes are used, increasing still further the elasticity of the wheel. Fig. 3 shows part of a solid wheel, having a recess in which the helical conductor is seated. In this form the multiple contact is afforded by the yielding of the individual convolutions only.

NEW SYSTEM OF ELECTRIC RAILWAYS.

In a new system of electric railways, invented by Herr Heilmann, a steam engine and dynamo are carried in a vehicle which takes the place of the present locomotive. Current is conveyed by conductors, which pass under the cars, to a series of electric motors, which drive some or all of the axles. A triple-expansion engine is to be used, and in order to ensure equal work being done by all the motors, their armature coils are all in series with one another, and current is supplied from one dynamo. The field magnets of the motors and of the generating dynamo are excited by current from a dynamo working at a constant potential. The boiler is capable of developing 600 horse-power, and is of the type in general use on torpedo boats.

SOUND PRODUCED BY AN ELECTRIC CURRENT.

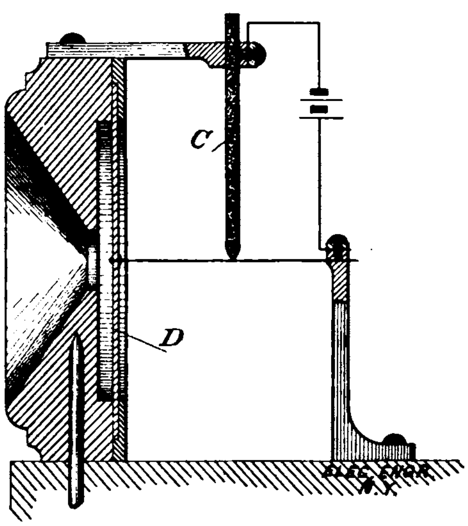
BY

Edward P. Thompson

During some tests in telephony, the writer employed a fine wire, which was placed under tension and in loose contact with a carbon rod C, as shown in the accompanying illustration. A diaphragm, D, of a telephone ear-piece served to hold one end of the wire. When the circuit was open, no sound was heard, but when closed, a faint musical note proceeded from the ear-piece. The cause of the sound was located at the point where the carbon touched the wire, because no sound was heard when the current was passed through the whole length of the wire.

The sound was not produced by disturbances of the air or contiguous objects, because no sound was heard when the circuit was open. When the carbon was replaced by metal, no sound was heard either with an open or closed circuit. When the wire carried a carbon in contact with the stationary carbon, the sound continued as long as the circuit was closed, but with the arrangement of one carbon touching the wire, as shown in the engraving, the sound ceased after a few seconds. The size of wire was No. 34 B. & S. copper, and the current was derived from two small Leclanché cells. When performed in the dark, intermittent minute sparking was visible at the carbon contact. The constant current of the cells was converted into a vibratory current, as evidenced by a telephone receiver introduced into the circuit.

Logical reasoning dictates that heat at the carbon contact is the cause of the vibration. According to this theory, the wire becomes heated at that point because the resistance is very high. Expansions of the wire, carbon and air, and chemical actions occur, producing relative displace-



Sound Produced by Current.

ment which varies the current and therefore the heat. The rapid repetitions of these actions vibrate the wire and sound is consequently heard at the diaphragm.

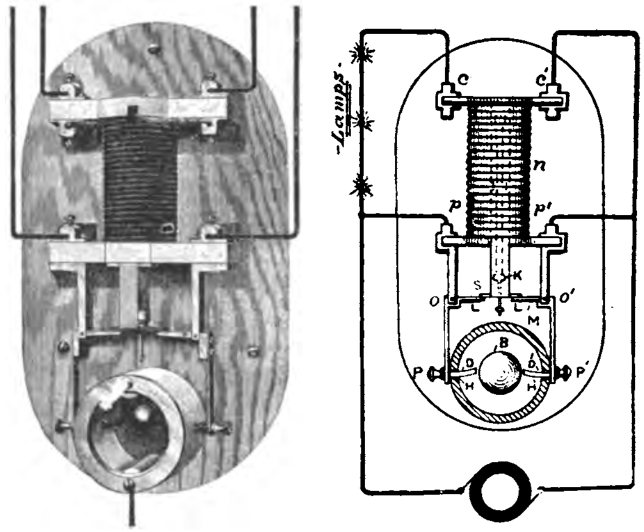
ELEVATED ELECTRIC RAILWAYS FOR BERLIN.

The Berlin correspondent of the *Daily Chronicle* says that Messrs. Siemens & Halske have submitted a proposal to the Minister of the Interior and the Berlin Municipality for the construction of elevated electric railways throughout Berlin and the suburbs. They propose to construct eight different lines, covering some 40 miles, at an estimated cost of 84,000,000 marks.

THE WESTINGHOUSE ARC LIGHTNING ARRESTER.

The first function of a lightning arrester is naturally to find a quick and sure path to the ground for the electric discharge. The second function is that of interrupting the dynamo current in the event of its following the lightning stroke and making a short circuit.

Both of these conditions have been successfully carried out in the new Westinghouse arc lightning arrester shown in the accompanying illustrations. As will be seen, it con-



Figs. 1 and 2.—Westinghouse Arc Lightning Arrester.

sists of a closed box, M, containing a carbon ball, B, connected to the ground. The box is penetrated by two electrodes, D, D', pivoted at O, O', and arranged to swing freely in the openings H, H.' Under normal conditions of running a plant, these electrodes are adjusted by the thumb-screws P P' to rest within one-eighth inch of the carbon ball. In the event of a lightning stroke the discharge passes through the binding posts P P', and traveling by way of the electrodes D D,' jumps the one-eighth-inch air spaces and escapes to the ground. On the dynamo current following, the solenoid n, regularly in series with the lamp line, is short-circuited, and the core K, being no longer held up by the magnetic field of the solenoid, drops upon the levers L L', and by the force of its blow causes the electrodes D D' to be drawn a little away from the carbon ball B. The arcs thus formed at once raise the air in the closed box M to a very high temperature, expanding it and causing a quick blast to escape through the holes H H', blowing out the arc and breaking the circuit. This allows the current to resume its normal path through solenoid n by way of the binding posts C C', draws up the core K, and, the electrodes falling back to their normal position, the arrester is ready for another discharge.

The beauty of this principle so successfully adopted in the incandescent lightning arrester is most clearly demonstrated again in the case of the arc arrester. In the laboratory tests of this instrument, the electrodes are adjusted so as to touch the carbon ball, thus forming a dead short circuit on the dynamo, other connections being made as in the diagram. A short circuit is, therefore, automatically and repeatedly opened and made, this being done without further demonstration than a slight puff as the arcs are blown out.

A LIGHTNING CONDUCTOR IN 1783.

According to *La Lumière Electrique* a curious discovery has recently been made in the shape of a speech by Robespierre, occupying 100 printed pages, in defence of Sieur de Vissery, who was appealing in 1783 against a judgment delivered by the sheriffs of Saint Omer ordering the destruction of a lightning conductor erected by him.

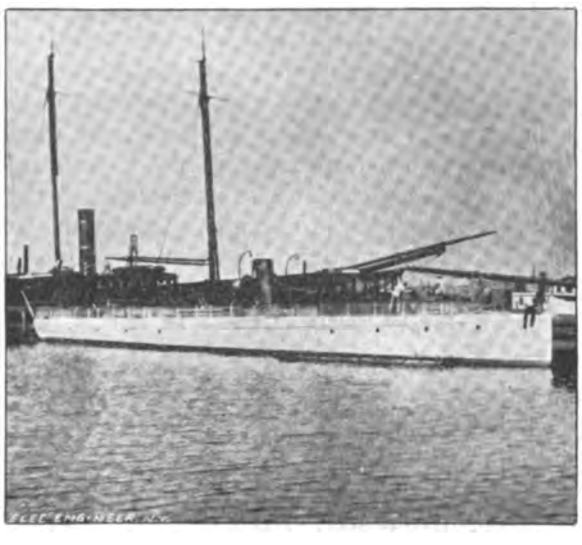
THE "VAMOOSE'S" COMPACT LIGHTING PLANT.

Andrew L. Riker.

Few craft of late years have attracted so much attention as the swift little "Vamoose," built specially for young Mr. Hearst, of San Francisco, who gave carte blanche to designers and constructors in order to secure from them a craft of unrivaled speed. Her recent performances around Rhode Island and in New York waters have been very promising and have aroused the liveliest interest. This week, on Saturday, she will race with the famous "Norwood," which has enjoyed the reputation of being the swiftest steam yacht afloat; and it is said, with regard to the "Vamoose," that she is likely to cover the 92 miles of the course in about 3½ hours.

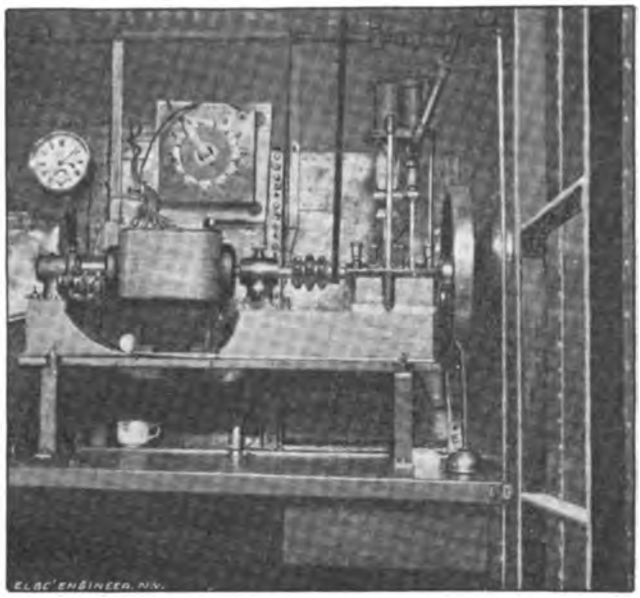
The "Vamoose," herewith illustrated, was built by the celebrated Herreshoffs, of Bristol, R. I., who have turned out a craft that looks fully equal to a steady 25 miles an hour, as called for by her contract. The rakish boat is 110 feet long and 12 feet beam, with a displacement of 31.62 tons. Her deck is flush, with only a pilot house forward, and is enclosed by a light railing of spun yarn—the only bulwark she possesses. Even her pilot house is said to be easily removable, if desired.

The chief consideration about such a boat is lightness, combined with great power in her machinery, and this applies as much to her electric lighting plant as to her propelling gear. Her engines are of the Herreshoff build, being quadruple expansion and of 800 h. p., with Thornycroft boiler tested to carry 250 pounds of steam. Refined and small as this machinery is, it occupies fully one-third of the available space in the boat, and the electric light plant had therefore to be extremely compact as well as light. The "Vamoose" is herself of composite build,



The "Vamoose."

with steel frame and wooden planking. With the object of securing just the plant they needed, the builders and owner called in the services of Mr. A. L. Riker, and the contract for the plant was given to the Riker Electric Motor Co., of Brooklyn, N. Y. The plant designed by Mr. Riker and furnished by the company is the only part of the yacht not furnished from the Herreshoff yard at Bristol, and had to be in every way up to the very critical and exacting ideas there prevailing. As shown in our direct-process engraving, the dynamo and engine are coupled direct and are mounted on the same base. The dimensions are: Length, 38 inches; breadth, 10 inches; height, 15 inches. The total weight is 450 pounds. The dynamo is a two kilo-watt bi-polar machine of the perfected Riker type, with self-oiling bearings and self-adjusting carbon brushes. It is compound wound, and is thoroughly water-



The "Vamoose's" Dynamo Plant.

proof. It is run by a 3 h. p. Herreshoff engine at 800 revolutions per minute, and is capable of supplying twenty-five 16 c. p. lamps and a search-light of 2,000 c. p. Such a plant evidently meets the prime consideration of lightness combined with high efficiency, and it also answers the requirement of compactness. The plant is placed on a small bracket made of iron, and thus fastened to the side-wall of the engine-room, where it runs so noiselessly that its presence is hardly noticed unless one is looking for it. The plant has given great satisfaction and is deservedly regarded as one of the most ingenious parts of this wonderful "lightning" craft.

THE PRACTICAL EFFICIENCY OF TELEGRAPHIC APPARATUS.[1]

The following table relating to the "efficiency" of the various telegraph instruments employed by the French Post Office is of interest. A message is reckoned at 20 words, and each word at 7.5 letters:

Apparatus.	Average number of messages per hour.	Number of operators.	Average number of messages per hour per operator.
Morse	25	2	12.5
" (duplex)	50	4	12.5
Sounder	40	2	20
" (duplex)	80	4	20
" (quadruplex)	160	8	20
Wheatstone	100	10	10
" (duplex)	200	18	11
Delany (quadruplex)	160	8	20
Baudot (quadruplex)	160	10	16
Hughes	50	4	12.5

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XII. NEW YORK, SEPTEMBER 30, 1891. No. 178.

Nothing is so good as an experiment which, while it sets an error right, gives as a reward for our humility in being reproved, an absolute advancement in knowledge.—Faraday.

ELECTRIC RAILROADS FOR THE FARMER.

AFTER seeing in the New York daily papers for months together nothing but abuse and falsehoods on the subject of electric railroads, it is refreshing to come across some statements that show the writer to have looked the facts fairly and squarely in the face. Not that it matters much what is said ignorantly against the electric road, but this improved method of travel will certainly the sooner benefit the public and perform its mission if the daily press is with it. The cheering utterances we refer to were published last week by the *Evening Post*, in the shape of correspondence from Cleveland, and their nature may be gathered from a single sentence: "Hamlets that have been left to one side by the steam railroads because of heavy grades or for more liberal patronage elsewhere, can find in the electric road something that solves the question of transportation for them better than anything else."

The article also shows that the superiority of the electric road holds good for city suburbs also, and it goes on to tell of what is being accomplished in and around Cleveland. Of one road it is stated that property has advanced several hundred per cent. since it was built, while the great boon to be conferred by others is clearly pointed out. But the main interest of the article lies in its allusion to the projects for rural roads. One of these, in which Mr. Charles F. Brush, the great inventor, has a hand, is to run twenty miles, touching five towns and eight post offices that have been left high and dry by the old steam railroads. This road will be equipped with freight cars of a carrying capacity of five tons or more for the special handling of farm products. Other roads of similar character are mentioned, and the fact comes out incidentally that they will but serve as links between electric roads already in successful operation. In reality the region around Cleveland, like that around Boston or Minneapolis, is becoming a vast network of electric roads, making money for the owners and doing good to the public under conditions that have rendered travel by horse and steam hopeless.

This use of electric roads for farm work is destined to be enormous. At the present time the state of the vast majority of our rural highways is such as to render transportation a frightful tax upon production. But nothing is easier than to track and wire these roads, furnish them with motor trucks upon which the farm wagons can be run fully loaded, and then turn on the current at stated intervals from the power house in the nearest town or at the nearest water power. These electric roads will continue running through winter and spring months when the ordinary dirt roads are utterly impassable and when the multitudes of draught horses kept by the farmers are simply eating their heads off in idleness. In 1880 there were 2,000,000 such horses on American farms. The bare possibility of getting promptly to market will stimulate the farmer to cultivate crops that now he dare not dream of. Moreover, the speed made will effect a most tremendous economy in the farmer's time.

These views were outlined in THE ELECTRICAL ENGINEER a long time ago and more than once, and every day sees some action on the part of projectors and capitalists that justifies them to the full. To quote again from the *Evening Post:* "Whatever verdict the future may pronounce upon electric traction as a means of rapid transit in great cities, no intelligent observer can doubt that one very important field of usefulness is open to the electric motor, for which it is unquestionably better adapted than any other means of transportation, and in which it easily surpasses all others—the development of the country surrounding a large city, and the furnishing of ready, cheap and usually reliable communication between country towns."

THE FREEHOLD OF THE AIR.

MODEL cities have always been a favorite topic of the philosopher and social reformer, but it is not often that a plan is drawn out intended to have direct and immediate application to the pressing needs of the hour in such a great centre of trade and population as New York. Such a plan is found, however, in the daring and suggestive paper read last week before the Electric Club by Mr. Allen R. Foote. He sees clearly, and says plainly, that the want is not only "rapid transit," but "cheap traffic," and that these demands cannot be met by simply carrying people further away from their work. Every mile that intervenes between the laborer and his labor is an added fine on industry. Mr. Foote therefore proposes to give the workingman the benefit of the freehold of the air, and to place the home and the factory under a common roof in huge "squares" along the fronts of the North and East

Rivers. These lofty buildings in closest access to all the facilities for handling raw material, yet lifting their "homes" into the pure, serene sky, will give New York more domestic comfort and cheaper manufacturing and larger commerce than she ever had before.

Who shall say that this is visionary? The trial of such a plan could be very simply made with one block on either river, and it would at least remove some of the horrible eyesores which, with blunt American frankness, we have put at our water's edge to greet the visitor with on his arrival. Already London and Brooklyn have such buildings and their success is not small. With electric light and power, their use and value can be increased many times over.

Let such plans be tried, and let us have also underground roads piercing in every direction; and then New York will be a city fit to live in and to work in. At the present minute it is one of the most conspicuous failures in the matter of city building and city governing in the world. We New Yorkers are proud of it, not so much because of what it is as of what we propose to make of it; and we are desirous that every thoughtful man of large heart and clear vision shall tell us how to shape the work.

THE FRANKFORT ELECTRICAL CONGRESS.

The recurrence at intervals of a few years of electrical congresses in various countries cannot but be looked upon as a sign that the electrical arts and sciences have attained an importance equal to that of any of the recognized professions of the day, a condition which, we have reason to believe, was until recently denied by many in the older professions. At all the congresses thus far held questions of international importance were brought forward, and although in this respect, probably, the Frankfort Congress shows the least results, it nevertheless served to bring into closer intimacy the workers of many nations, and thus advanced us one step nearer to the realization of uniform practice. From the reports of Prof. Heinrich, which appear in another column, it would seem that the German congress was not fully prepared to accept the "henry" as the designation of the unit of inductance, final action having been postponed until the meeting of the congress at Chicago in 1893. The reason for this delay is hardly apparent in view of the fact that the term has gone into use in all English-speaking countries, and that the German technical press has employed it exclusively since its introduction and adoption by the American Institute of Electrical Engineers. It is, however, only a question of time when it will receive a formal, general recognition, and thus become one of the established names.

POLE-PIECES AND THE AIR GAP.

The recognition of the importance of the air gap in dynamo-electric machinery served to call into existence a considerable amount of literature on the subject of the design of such machines, and probably most of the work done in the last five years is based largely upon the relation of the air gap to the rest of the magnetic circuit. One of the most important effects which the new theory of the magnetic circuit has had on modern construction is the return by many to the tooth form of armature. But that there are still numerous questions to be solved as to the best proportions to be adopted will be evident from a perusal of the paper read by Prof. Ryan before the American Institute of Electrical Engineers. It is gratifying to know that Prof. Ryan's results agree with those of Messrs. Swinburne and Esson on this subject, whose work we have reason to know has been followed by not a few in this country. As regards the pole-pieces, Prof. Ryan has, we believe, pointed out again the true cause of frequently unexplained irregular action in machines, which, as he shows, can be traced directly to the saturated corners of pole-pieces. The recognition of this phenomenon is especially valuable in the design of constant-current machines, and the experiments which Prof. Ryan cites show in a marked manner the importance of maintaining a uniform strength of field over the entire surface of the pole-piece. It must be borne in mind, however, that the restrictions here made, while applying to the pole-pieces, need not necessarily apply to the rest of the magnetic circuit, since in in some types of machines a saturated field-magnet core may be desirable in order to obtain certain effects.

WESTERN UNION AND THE POOL ROOMS.

The papers of Saturday last contained a very circumstantial account of the manner in which the latest scheme of the Western Union to defeat the managers of the local racecourses and give news to the pool sellers had been detected. The plan appears to have consisted in sending dispatches from an open barouche, by flashes from a little incandescent lamp, seen through the ventilating space in the coachman's hat, and read at a short distance by an operator on the tower of the hotel just outside the track, which, in this instance was that of the Brooklyn Jockey Club. As the barouche contained apparently, each day, an ordinary family party, it escaped notice for some time, but the lively movements of the occupants of the coach in getting the news and dispatching it at last attracted attention. The detectives then made it their business to investigate the carriage and they found it to contain a very complete set of telegraphic and electrical apparatus. The persons concerned in this truly ingenious scheme were arrested, but were afterwards bailed out by a Western Union officer and a pool-room and faro bank magnate named DeLacy. We can only say that this is pretty small business for the Western Union Company to be engaged in.

Aluminum.

Electrical engineers above all others have taken a lively interest in the production of aluminum, not only on account of the electrical methods involved in its modern manufacture, but owing to the fact that it will soon play an important part as one of his materials of construction, not merely, as heretofore, for the moving parts of measuring instruments, but also in heavy engineering, such as electric railway and motor work generally. Naturally some difficulties have been met with in the applications of this new metal, and the trouble as pointed out in an other column by Mr. W. F. Barnard is lack of purity. Still it seems to us that there are many applications for aluminum where purity is not a prime essential, and the reputation of the metal ought not to suffer because knowledge is still needed of the quality that will yield the desired results for certain specific purposes.

THE FRANKFORT INTERNATIONAL ELECTRICAL CONGRESS.

BY

Richard O. Heinrich.

THE International Electrical Congress held in connection with the exhibition at Frankfort was formally opened on September 8, by the Honorary President, SECRETARY OF STATE V. STEPHAN, who, in an excellent address, reviewed the objects of the Congress and welcomed the delegates. WERNER V. SIEMENS then took the chair as President of the Congress, and MESSRS. PREECE, HOSPITALIER, FERRARIS, WALTENHOFEN and W. KOHLRAUSCH were elected vice-presidents.

The first paper which came up before the meeting was that by PROFESSOR W. KOHLRAUSCH, of Hanover, on "The Most Suitable Course of Instruction for Electrical Engineers." In order to elicit the opinions of those present on this subject, the author spread before them the course he had laid out for the High School. Besides a large amount of mathematics and drawing, he laid special stress upon the value of physics and more particularly the study of electricity and magnetism. To this he would add special electro-technical knowledge, the study of the machines in most general use, and methods of construction, etc. He also pointed out the great value of chemistry in view of the importance which electro-chemistry will have in the near future. In the discussion which followed, DR. SLABY maintained that a distinction ought clearly to be drawn, and the selection early made, as between the studies for the physicist and the engineer. For those intending to become engineers, he suggested preliminary work in a machine shop, then a course of study at a high school with special reference to electrical engineering. He considered the *How*, not the *What*, of instruction, the principal point to be kept in sight. WERNER V. SIEMENS contended that there was no such thing as electrical edgineering as an independent profession, and that it was merely a science to aid other technical branches, and that a person could only become an electrical engineer by actual practice. HERR HARTMANN, of Frankfort, strongly advocated preliminary workshop practice for a year, which he considered quite sufficient for entrance into the High School. As long as no State factories existed for this purpose, he recommended the student to enter small shops in preference to the large ones. DIRECTOR RATHENAU, of Berlin, also considered the workshop indispensable and inclined to a course of two years.

PROF. SILVANUS P. THOMPSON, of London, who was greeted with great applause, presented a paper in German on "The New Domain of Alternating Currents. He traced the history of alternating currents from Faraday, and their application first to telegraphy, and their more recent applications to electrical distribution. He considered it almost inexplicable why the theory of Deprez and Carpentier, enunciated in 1881, had so long remained without application. He also alluded to the new application of alternating currents for the transmission of power and the experiments of Hertz on the propagation of electrical waves in space and to the more recent work of Mr. Tesla in alternating currents of high frequency. Still other questions remain to be solved by means of the alternating current, such as the transmission of pictures, ocean telephony, etc. He considered that the solution lay in the development of the wave theory of electricity.

In Section 3, Telegraphy, Telephony and Signals, DR. STRECKER, of Berlin, was elected president, and the first paper was presented by HERR BERG on "The Application of Electricity in Navigation." The author criticised the English rules by which it was intended to prevent the influence of the heavy electric currents on the compass, and then proceeded to describe the marine signal system, invented by the Austrian navy officer, Selluro. In the discussion which followed, HERR BECHTHOLD, of Vienna, remarked that in the Selluro system the signals were independent of the ship's dynamo, being operated by hand dynamos.

MR. WILLIAM H. PREECE then presented a paper on "The Progress of Telegraphy and Telephony in England." The author remarked that in 1852 Cooke and Wheatstone's double-needle instrument was in general use in England, and that one wire transmitted on an average 10 words per minute. At the present time over 600 can be sent over a single wire. MR. PREECE considered that there were four essentials requisite for the scientific success of telegraphy: 1. Well-built lines that must be free from interruptions. 2. Complete apparatus, which utilizes the current to the highest degree. 3. A thoroughly trained staff of employees who are not afraid to work and are accustomed to accuracy. 4. Rapidity in the delivery of the telegram. Mr. Preece then described the construction of the lines and apparatus employed in England, and also gave some account of the pneumatic tube system employed in some of the large cities in England. On the subject of telephony, Mr. Preece remarked that little progress could be noted here, and, in fact, that they were ashamed of the state of telephony in England at the present time. They were still in such a condition as led them to believe that the telephone was best taken care of in the hands of private parties. The Government had proved the practicability of long-distance telephony, and Mr. Preece referred more particularly to the line between Paris and London and the results obtained with it. Mr. Preece also referred to the great speed made possible in automatic telegraphy in England by the introduction of relay stations, the excellent construction of the apparatus, the complete removal of all retarding influence, which latter was the direct consequence of the introduction of shunted condensers, the application of which Mr. Preece considered as important an advance as was the compound engine in steam engineering.

In the discussion which followed, HERR GRAWINKEL, of Berlin, privy counsellor for Postal Telegraphs, remarked that much of the success of telegraphy in Germany was also due to the application of condensers. They had been able to talk over cables as long as the distance from Paris to London and with the ordinary arrangements. HERR GRAWINKEL, however, raised some objections to the well-known formula introduced by Mr. Preece for the limiting talking distance of telephone lines. MR. A. R. BENNETT, of London, remarked that telephony in London was cheap and nasty, and seemed to be run for the sole purpose of making a profit, but that marked changes would soon become apparent.

In the meeting of Section 2, devoted to Heavy Currents, a report was presented by HERR GEIST, of Cologne, on "The Dynamo as Arranged for the Measurement of Mechanical Power," in which the author described the application of the well-known cradle dynamometer principle. This was followed by DR. FOERDERREUER, of Nuremburg, who read a short paper on the multiphase alternating motor, and alluded to the simple manner by means of which such a machine can be placed in synchronism by noting the exact period with the aid of a voltmeter. HERR DÉRI, of Vienna, stated that several years ago he had applied for a patent in connection with Herr Zipernowsky for the application of the ordinary dynamo to the generation of multiphase alternating currents.

In Section 1, Theory and Methods of Measurement, HERR DR. KOEPSEL, physicist to the firm of Siemens & Halske, read a paper on "The Present Condition of Electrical Mensuration." The author divided the various measuring apparatus into two groups, namely, those measuring directly, and indirectly. Among the latter he classed the voltameter, the calorimeter and the shunt resistances to galvanometers. Among the former he counted the electro-dynamometer and other instruments. The speaker referred to the difficulties encountered in all instruments involving permanent magnets in their construction on account of the inconstancy of their magnetic strength. He considered the application of the static instrument as of increasing importance with the general introduction of high-tension currents. The speaker also referred to the lack of a reliable apparatus for the measurement of self-induction. After a brief note on "Standard Cells," by DR. LINDECK, a discussion arose on the paper of Dr. Koepsel. PROF. HEINRICH, of New York, declared that the Weston Electrical Instrument Company had constructed instruments direct reading with permanent magnets, the constancy of which was practically perfect. PROF. VOLLER, of Hamburg, added that the testing committee of the exhibition had made experiments with the Weston instruments and subjected them to severe shocks. Some of the instruments had shown no variation after this treatment, while others had changed considerably. It was quite possible, as Prof. Heinrich maintains, that those which changed were old instruments; nevertheless DR. KOEPSEL denied that it was possible to construct absolutely permanent magnets which could remain constant not only in the laboratory, but also in the vicinity of machines.

The American Institute of Electrical Engineers was represented by Profs. Nichols and Heinrich, and Messrs. Hering and Gutmann. They presented a resolution asking for the adoption of the "Henry" for the unit of induction. The matter was referred to a committee and definite action was postponed until the World's Fair at Chicago, in 1893, since it could not be adopted unanimously, Siemens and others opposing it.

The Institute Committee also suggested that either now or between this and the next Congress the two following subjects should be considered and discussed in order that they may be definitely acted upon:

First, the determination and naming of a practical unit of the intensity of a magnetic field, for which there exists a pressing need. They proposed to call this unit the "Gauss" and to fix its value at 1,000 lines of force per square centimetre.

Second, the determination of a standard value for the conductivity of copper for commercial purposes in order to facilitate the designation in per cent. of different qualities of copper. They also invited the members of the present Congress in the name of Institute to take part in the International Congress, which is to be held at Chicago in 1893 under the auspices of the American Institute of Electrical Engineers.

The attendance of the Congress is very large, the total number of participants aggregating 661, of whom 220 are foreigners, there being 7 present from America.

ON THE RELATION OF THE AIR GAP AND THE SHAPE OF THE POLES TO THE PERFORMANCE OF DYNAMO-ELECTRIC MACHINERY.[1]

BY HARRIS J. RYAN.

THE object of this paper is not to deal with the subject in a new light, but to add to its literature a limited amount of data, the deductions from which go to establish the correctness of the ideas, and the utility of the suggestions put forth in the papers read by Messrs. Swinburne and Esson, at the meetings of the London Institution of Electrical Engineers on Feb. 13 and 20, 1890. Up to the time of the publication of these papers, the air gap was usually treated by contributors to electrical literature as an evil in a dynamo having a necessary existence, and the smaller that it could conveniently be made, the better. The shape of the poles had often been spoken of as having a somewhat decided effect on the performance of the dynamo, while but little had been said regarding the cause of such an effect.

There exists some difference of opinion as to what should be known as the number of ampere turns on an armature. For our present purpose we will assume that the

$$\text{Armature ampere turns} = \frac{\left\{\begin{array}{l}\text{The No. of conductors on}\\ \text{the surface of the arma-}\\ \text{ture.}\end{array}\right\} \times \left\{\begin{array}{l}\text{Strength of current}\\ \text{on the armature}\\ \text{conductors.}\end{array}\right\}}{\text{Number of poles.}}$$

Referring to Fig. 1, it is evident that when we consider the magnetic forces acting in a working dynamo by the route O, I, J, O, that the entire number of ampere turns on the armature are directly opposed in action to the ampere turns on the field. By the route O, M, N, O, all the ampere turns on the armature except those that lie between the double angle of lead G, E, are acting with the field ampere turns, while those between G, E, are opposed to the same. Therefore, by this route the total number of amperes turns actually aiding the field ampere turns is the total number of armature ampere turns, minus twice the number of ampere turns that lie between the double angle of lead. By the route O, K, L, O, the number of ampere turns acting is the number of ampere turns on the field, minus the number of ampere turns

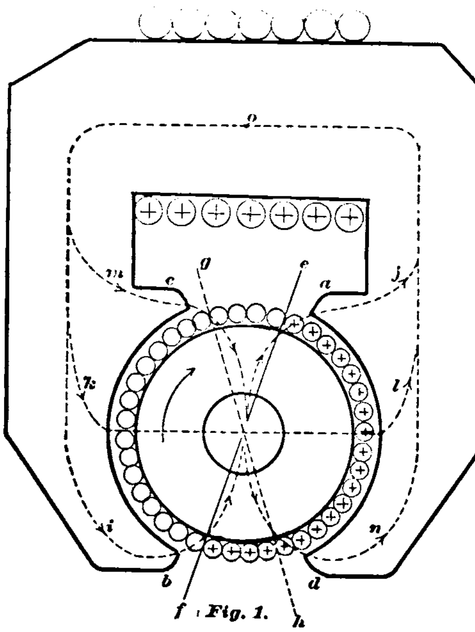

Fig. 1.

that lie between the double angle of lead. We can then estimate with ample practical accuracy the magnetic density in the air gap at all points, for any given total amount of magnetization through the armature. The ampere turns that lie between the double angle of lead are opposed to the action of the field ampere turns at all points. It is evident that the portion of the armature ampere turns not included between the double angle of lead will increase the magnetization through the air gap by the route O, M, N, O, just as much as they diminish it along the route O, I, J, O, as long as magnetic saturation does not take place in the strengthened pole corners C, D. If the pole corners are thin, as in the types shown in Figs. 2, 3, and 5, saturation is apt to occur. It is then that the magnetic resistance increases by the route O, M, N, O, and the magnetic density by this route is no longer increased by the same amount that it is diminished along the route O, I, J, O. On the other hand, when the pole corners are fashioned as seen in Figs. 4 and 6, so that saturation in the strengthened pole corners cannot occur in practice, the current in the armature can produce no modification of the total amount of magnetization through it, other than that which is produced by the action of the ampere turns that lie between the double angle of lead. This action can always be compensated for by putting an equivalent number of series ampere turns on the field acting with the field ampere turns. The double angle of lead can be determined with sufficient accuracy, for with pole corners slightly extended at the centre, see Fig. 11, the diameter of commutation at all loads is very near the weakened

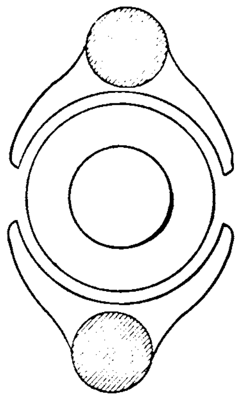

Fig. 2.

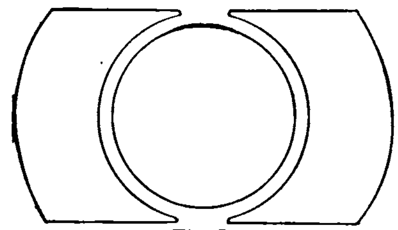

Fig. 3.

pole corners. The pole corners are slightly extended at the centre, so that the coils always enter the field of the weakened pole corners gradually. The E. M. F. developed in the coils as they pass under the poles can never be far different from that actually needed to reverse the current in the coil when passing under the brush. In this way the point of commutation in a dynamo can be kept the same when carbon brushes are used without undue sparking, as long as the armature does not reverse the magnetization under the weakened pole corners.

From the discussion of the magnetic relations of an armature to its field in a dynamo in connection with Fig. 1, it is seen that the magnetization in the air gap under the weakened pole corners becomes zero, when the armature ampere turns are equal to the ampere turns on the field, whose magnetizing force is impressed between its pole faces through the armature. This impressed magnetizing force is that due to the difference between the total number of ampere turns on the field and the number of ampere turns required to set up the magnetization through the field cores, from pole face to pole face. In order to commutate the current without spark at the commutator, the magnetization in the air gap under the weakened pole corners dare never be allowed to become zero. It follows then that the field ampere turns impressing a magnetizing force between the pole faces must always be somewhat in excess of the maximum number of ampere turns on the armature. The amount of this excess need only be sufficient to insure a positive field at A and B, Fig. 1, strong enough to reverse the current in the coils as they are commutated. When a certain amount of magnetization is to be set up through an armature with the application of the magnetizing force of a given number of ampere turns impressed between the pole faces, we must provide the requisite amount of magnetic resistance between these pole faces. The value of this resistance will have to be such that the impressed field magnetizing force will establish the desired amount of magnetization. This resistance in most cases is best provided for in a proper length of air gap. In general it is found best to avoid heating in the armature core as far as consistent, by the use of comparatively low magnetic densities for wrought-iron. The magnetic resistance of the armature core under these circumstances is very small and may be neglected.

The magnetic resistance between the pole faces is occasionally provided for largely, either through a saturated core of a ring armature, saturated lugs on armatures where the wires are placed in grooves, or both. This in addition to what air gap may be necessary from a mechanical point of view go to make up the total amount of magnetic resistance that is provided between the pole faces. Machines of this order have been developed largely through the old and rather expensive method of experimentation. This method has given us some types in which ordinary results are arrived at, through rather extraordinary means. Take the case of a machine with a ring armature, wires wound in grooves, a very small air gap, and poles shaped somewhat as shown in Fig. 2. Such a machine operated as a dynamo may require only a quarter of the number of ampere turns that it will have on the armature at full load, for field excitation in order to produce a

1. A paper read before the American Institute of Electrical Engineers, New York, September 22d, 1891.

certain E. M. F. at a given speed. Yet this machine produces a fairly constant potential at the brushes under all variation of load. and without undue sparking at the commutator in the following manner: For the production of a constant E. M. F. at constant speed, the total magnetization through the armature must remain constant. At no load one-fourth of the ampere turns needed on the field at full load are provided by a shunt winding. This shunt winding is sufficient to set up the total amount of magnetization for the production of the normal E. M. F. of the machine when there is no current in the armature. Now, in order to take the normal current from the armature without reversing the magnetization under the weakened pole corners, three times as many series ampere turns as there are shunt ampere turns must be added to the field. The addition of these series ampere turns must not increase the total amount of magnetization through the armature, which is accomplished by the thin pole corners. The strong pole corners become saturated when the armature is furnishing even a small amount of the normal current for which it is designed. For most values of the current, then, the armature ampere turns tend to diminish the magnetization under the weakened pole corners, but cannot increase it correspondingly under the saturated pole corners. The action of the series ampere turns on the field prevents the reduction of the magnetization under the weakened pole corners to zero, while the saturated portion of the pole pieces prevents the increase of the total magnetization through the armature, and thus a constant potential is maintained.

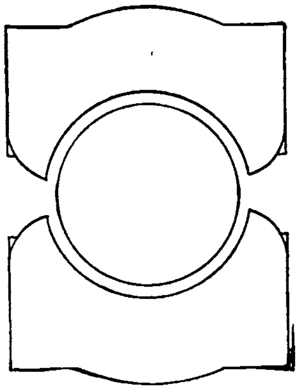

Fig. 4.

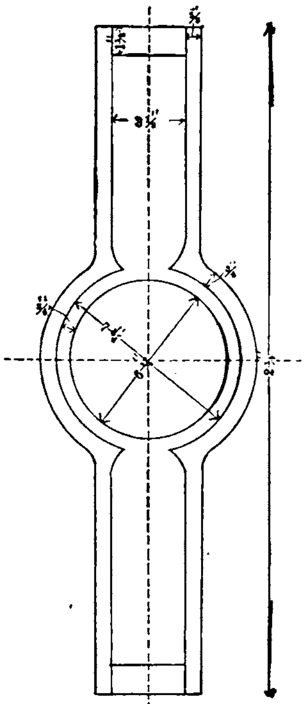

Fig. 5.

The "armature characteristic" IV., plotted in Fig. 7, was taken from the machine of the above sort, built with cast-iron fields. The cross-section of the field cores proved on trial to be too small, and became strongly saturated at full load—while they were quite a little under the point of saturation at no load. This curious result for a constant potential generator was due to the increased magnetic leakage, produced as the series ampere turns on the field came up with the load. Saturation took place as the curve indicates, when the armature furnished a current of about 140 amperes, and no possible compounding could ever make this generator produce even approximately a constant potential, with variation of load. Steel cores of the same dimensions were substituted for the cast iron cores. Saturation did not occur in them due to magnetic leakage. The pole corners were very thin, as in Fig. 2, and the "armature characteristic" III. was obtained. The machine was then furnished with a shunt winding that produced a slightly smaller number of initial ampere turns than curve III. indicates as required to produce 125 volts, and with series turns at such a number that the total number of ampere turns on the field for any current developed by the armature is shown by the broken line drawn through curve III. It was under these conditions that the machine performed in the manner described above, and did not vary more than 5 per cent. from the normal E. M. F. on either side. or a total variation of 10 per cent. It was then almost entirely rebuilt. The armature was provided with a core that was considerably larger in cross-section, and the maximum magnetic density used in it was 11,000 lines per sq. cm. as against 20,000 used before. The lugs on the core were dispensed with, and the wires wound on the surface of the core. The poles were made of cast-iron, and fashioned to accord more

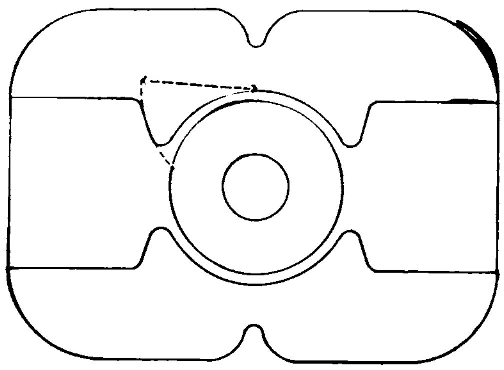

Fig. 6.

nearly with those in Fig. 3. The air gap required ten thousand ampere turns to set up the magnetization through it at no load, while the armature ampere turns were 8,000 at normal output, so that series ampere turns had only to be added to counteract the action of the ampere turns on the armature that lie between the double angle of lead, to increase slightly the E. M. F. by the amount equal to the fall of potential through the armature caused by its resistance, and to compensate for the slight effect of the pole corners that still became saturated to a limited extent for the higher outputs. It should be remembered that the magnetic leakage that takes place between the adjacent north and south pole corners, one of which is strongly and the other weakly magnetized, plays an important part in saturating thin pole corners. It is evident that unless the "armature characteristic" is a straight line as in curve I., Fig. 7, that the machine can not be made to regulate for constant potential with a high degree of refinement. The poles were again changed and shaped as in Fig. 4, when an "armature characteristic" given in curve I. was obtained, and the proper number of shunt and series ampere turns for a refined degree of regulation were readily decided upon. These experiments confirm what has been said above, and show how useless have been the attempts to diminish the air gap beyond certain limits.

It was shown on the outstart how we can calculate the actual magnetic densities in the air gap for any total magnetization through the armature, for any armature current. The results of the following experiments confirm the correctness of these methods. The curves in Fig. 8 give the values of the magnetic density at all points of the air gap of a generator producing

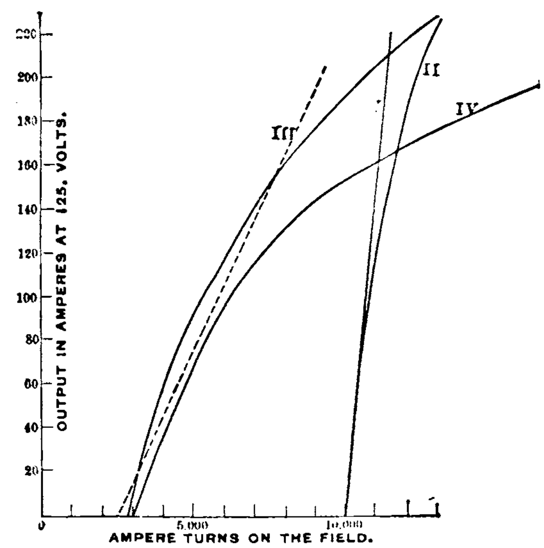

Fig. 7.

125 volts at the brushes and 80 amperes. The following are its dimensions and data:

Diameter of armature core..................	6.25 in.
Length of armature core	12. in.
Diameter of bore of poles..................	7.19 in.

Double depth of air gap	.94 in.
Armature sections	50.
Turns per section	2.
Resistance of armature	06 ohm.
Poles shaped as in Fig. 3.	
Shunt turns on field	6400.
Field current, no load, 125 volts	1.48
Field current, full load, 125 volts	2.10
Speed	1600.
Carbon brushes used without lead.	

The "armature characteristic" curved considerably, indicating that the pole corners become saturated. It is evident too that

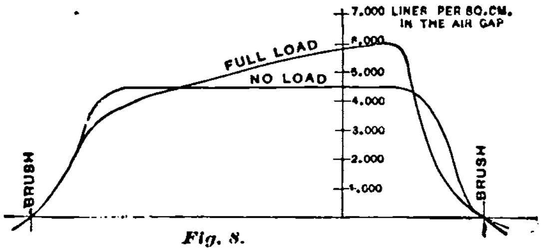

Fig. 8.

the normal magnetization in the pole corners in addition to the magnetic leakage which is greater there than anywhere else, produced saturation in all pole corners, even with no current in the armature. For at full load there were 4,000 ampere turns on the armature, while 4,000 series ampere turns had to be added to the field that produced 125 volts at no load to keep the E. M. F. the same. Therefore at full load we have the same number of ampere turns acting through the weakened pole corners as at no load, and the total amount of magnetization has only been increased 5 per cent., to compensate for the resistance of the armature couductors. The conditions, however, are not the same, for there are just 4,000 more ampere turns to cause magnetic leakage at the pole corners, so that on the whole the magnetization in them is increased. This increase of magnetic density in them greatly increases their magnetic resistance, for they are saturated to begin with. It is on this account that we find the magnetization under the weakened pole corners diminished, when apparently the forces acting have not been changed. The magnetization under the strengthened pole corners through the air gap is increased more than it is diminished by the effect of the added magnetic leakage, through the 8,000 additional ampere turns that act to produce magnetization by this route through the armature.

(*To be concluded.*)

ELECTRICAL DISTRIBUTION AT THE WORLD'S FAIR.

STEADY progress on the electrical work of the World's Columbian Exposition is being made by the Construction Department and an excellent method of distribution of the conductors devised by the able electrical engineer of the department, Mr. Frederick Sargent, has been adopted.

The general plan of distribution embraces the utilization of the elevated railway structure which will run around the grounds, and the building of a tunnel or subway which will contain such wires and cables as are necessary to supply those buildings which could not be reached from the elevated structure.

It has now been decided to place the electrical generators in the Machinery Building and not in the Annex, as before proposed. The generating plant will be arranged along the south wall of Machinery Building, a space being reserved 850 feet long by 200 feet wide for that purpose; the engines being located near the wall and the dynamos towards the centre of the building. Behind the Machinery Building is a covered alley 20 feet wide; then comes the Boiler House, which will extend the entire length of the Machinery Building, and have a depth of 60 feet, the boilers being set towards the north wall and fuel being delivered at the south end of the house direct from the cars brought clear to the doors on a track running in the rear.

The conductors after leaving the dynamos will be arranged in a suitable fireproof rack located under the main floor about 150 feet from the south wall and running lengthwise of the building. From this rack five distinct groups of feeding wires will start as follows:

The first group will supply all the territory contained in the space bounded by 59th street on the north, centre of basin on the south, Lake Michigan on the east, and the lagoon on the west; also the electric fountain, located at the west extremity of basin, and comprising the following: Fisheries Building, Government Building, Naval Exhibit, Manufactures and Liberal Arts Building, Electric Fountain and all the grounds within the territory. The main conduit for this group will be provided in the following manner: Starting from the rack already referred to in Machinery Building, a tunnel or subway will be constructed of sufficient capacity to accommodate 1 0 insulated cables or wires up to 600,000 circular mils area. The tunnel, which is shown in the accompanying engravings, Figs. 1, and 2, will run north from the rack under the floor of Machinery Hall to Electricity Building, with a tap for the electric fountain, the wires for which will be laid on the drawing-in system east from Electricity Building to the bridge, from the bridge to the Manufactures Building. From this point to the north end of the building, a fireproof conduit will be provided, which will gradually diminish in width as the wires are distributed. From the Manufactures Building to the Government Building and thence to the Fisheries Building the tunnel will be about three feet wide, with wires on one side only. The system will terminate at the Fisheries Building.

The tunnel itself, or any of the buildings through which it passes, may be tapped by the drawing-in system, buried in the ground wherever necessary to supply light or power to the grounds or any other buildings that may be erected in this territory. It will be constructed absolutely fireproof throughout. The cross-arms will be made of iron provided with holes at suitable points to receive pins, upon which insulators of various form will be placed; in the case of special insulators special forms of cross-arms will be provided where required.

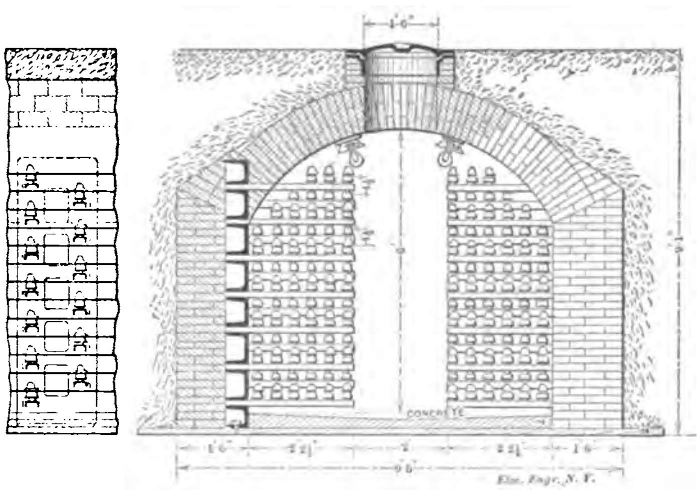
Group No. 2 will be provided for in a tunnel of the same capacity as that for the first group, and will run direct from Machinery Mall to Electricity Building, with branch for the Mines Building and tap for the Administration Building. It will also provide for all grounds adjacent to these buildings, and probably include the wooded island.

Group No. 3 will run direct from Machinery Hall to the Elevated Road, and supply all territory north of the Basin and Administration Building not reached by groups Nos. 1 and 2, including Transportation Building Transportation Annex, Service Building, Horticultural Building, Women's Building, State and Foreign Buildings, Art Gallery, Midway Plaisance and all grounds and smaller buildings in the territory mentioned. The drawing-in systems or buried conductors are to be used wherever elevated structure is not available.

Group No. 4 will provide for Machinery Hall, Machinery Annex, Boiler-House, western portion of Stock Exhibit, and western portion of grounds; the wires to be distributed under basement of buildings and on elevated railway, and thence to grounds and Stock Exhibit by drawing-in or buried systems.

Group No. 5 will provide for: Agricultural Building, Agricultural Annex, Saw Mill, Forestry Building, Dairy Building, eastern portion of Stock Exhibit, Pier and Casino; the wires to be distributed on elevated structure, basement of Agricultural Building, and on the piles under the roadway over the pier so far as practicable, and then by drawing-in or buried systems.

The tunnel system cannot well be continued further north than



FIGS. 1 AND 2.—ELECTRICAL SUBWAYS AT THE WORLD'S FAIR, CHICAGO.

the Fisheries Building, because of the ground not being of sufficient height above water line. The tunnel systems will all be six feet high in the clear, except from the Manufactures Building to the Fisheries Building, where it can only be five feet.

It should be mentioned that other designs are being prepared for the structure of the tunnel, one of which may be preferable to the one illustrated; but in any case the arrangement of supporting conductors and the general dimensions will be maintained. It is not intended to construct the tunnels until the bulk of the lighting and power transmission is contracted for, so that modifications can be made to meet special requirements, if necessary. Manholes will be provided at intervals along the subway to enable the conductors to be placed therein with the greatest facility, and are necessary, since sewers and water-pipes cross the subway at several points, which will not, therefore, permit of walking from one end to the other, although the wires will be arranged in such a manner as to be got at without difficulty.

The facilities afforded by using a combination of the tunnel system, elevated railway structure and basement of buildings, as herein outlined, for the main trunk lines are considered adequate for supplying all the requirements of grounds and buildings, and the whole arrangement is extremely practical. The ease with which any of the wires can be got at is an important and meritorious feature of the plan, which reflects credit on the designer, and which has received the unanimous approval of, and been adopted by, the Committee on Electricity.

THE REAL VALUE OF ALUMINUM.

BY

During the past winter and spring several interesting and instructive papers upon the manufacture and characteristics of aluminum were read before scientific societies in this country, the tenor of which and of the discussions and press criticisms resulting therefrom very gravely emphasize the fact (which is well known to those practically familiar with its physical, chemical and electrical properties) that aluminum is a metal concerning which there have been more misconceptions and a greater display of ignorance than any other in common use.

Ever since the researches of Deville, Debrey, Fremy, Fissier Bros., and other investigators directed attention to its metallurgy and properties, aluminum has been the victim of romancers, who have enshrouded it in a halo so distorting that it is a matter of no small difficulty, even for those whose material interests call for an accurate and dispassionate estimation of its qualities, to determine just what are the actual merits of this so-called "*Silver from Clay.*" It is not, therefore, remarkable that the mass of our people should have received fallacious and exaggerated ideas concerning it, through the suggestions and not unfrequently absurd speculations of scientific as well as trade journals, and the daily press, in respect to the value and adaptability of this metal to the arts and industries. Such general ignorance in respect to a metal and the uses to which its qualities make it specially applicable is not only unfortunate from an educational standpoint, but very seriously embarrasses and retards the general utilization of the metal itself. It is always a sufficiently difficult and tedious task to introduce a new element into the usages of life, but in respect to aluminum the natural difficulties have been greatly enchanced; partly by this cause much more than by its hitherto limited production and consequent high price.

Recently trade competition has sprung up between the two most prominent producers of this metal in the United States, and one of them is publicly advertising "Aluminum equal in purity to any on the market at $.50 per lb., in any quantities," and this company is known to have contracted to deliver a considerable quantity, guaranteed to be of 99 per cent. purity, at that price. (It is rumored, however, that the company is endeavoring to recede from this contract, which was made by an over-zealous canvasser.) The other company, while publicly advertising aluminum, "guaranteed to be equal in purity to the best in the market, at $1.50 per lb., in ingots," is meeting the cut rate of its rival, though it does not appear what grade of metal it offers at the cut rate.

It is quite apparent that in this situation of affairs a large number of persons interested in manufacturing, or in the metal aluminum for experimental purposes, will avail themselves of this exceedingly low price to purchase considerable quantities of the metal, under the not unnatural supposition, derived from the tenor of the advertisements of the said companies, that they are securing PURE METAL. Finding, as they unquestionably will when they deal with aluminum below 99 per cent. purity, that it fails to meet—even approximately—in almost all particulars the descriptions of its merits and brilliant properties with which the press has been flooded, users will become prejudiced against it and by example and precept will induce others to condemn the metal, which, in fact, has not been tried on its merits at all. Such, as a matter of fact, has been the fate of aluminum bronzes and brasses, than which no more valuable metals are known to the industrial arts. The introduction of these alloys in this country and in Europe was unfortunately controlled by a company whose process, although possessing much merit, is well known to be incapable of producing alloys free from fatal contaminations or of uniform quality, even with such contaminations. This company having the entire field to itself for several years, and having invested large capital in plants here and in England, made every effort which an intelligent and unusually energetic management could make towards establishing its wares on the market. Their merits were widely advertised and commented on in the scientific and industrial journals, and a great many people and industrial companies bought more or less of them and some spent considerable capital in plants to work them. The result has been uniformly disappointing and the introduction of these alloys is currently believed to be a commercial failure, not because there was not a good demand for aluminum bronzes and brasses, and not because they had not the merits claimed for them when uncontaminated with iron and silicon and other impurities, but because the process of the said company was not equal to producing metal that could be relied upon either in the matter of purity or uniformity of strength. It is quite certain that years must elapse and much money and hard labor be spent in this country as well as abroad, before the pure aluminum bronzes and brasses will recover the market that was already made when the poorer metals aforesaid were placed before the public.

It therefore becomes a public duty as well as a matter of business interest to those engaged in the production of aluminum to warn purchasers against availing themselves of the present low prices and purchasing metal that is not absolutely guaranteed by responsible parties to be of at least 99 per cent. purity. Indeed, every such purchaser of aluminum in large quantities, or intending to use it for important purposes, should insist upon the additional precaution of having their metal re-analyzed. With these precautions and with the dissemination of accurate and precise knowledge of the constitution of aluminum and its alloys, and especially of the important and sufficiently radical transformation that takes place in the physical, chemical and electrical properties of those metals in the presence of apparently insignificant contaminations, this interesting metal will surely, although slowly, establish its true position in the industrial world as one of the most useful metals yet discovered. The truth of the whole matter is that, while, from the most unfavorable point of view, aluminum possesses more than sufficient intrinsic merit, properly understood and applied, to secure its extensive utilization as an important factor in our civilization, it is now distinctly suffering from the reactionary effects of over-booming.

In fact, it is at this time on trial, so to speak, in the commercial and manufacturing world, and it therefore seems proper that those having practical knowledge of the *bona fide* characteristics of the metal should utilize their opportunities to counteract, on the one hand, the illusions still generally existing as to its paramount importance in the metallurgical world, and, on the other hand, the scepticism as to its real merits that has followed the disenchantment of those who, impressed with the statements of scientific investigators, have sought, but failed to find in the impure metal of commerce, those valuable qualities which *do* exist in *pure* aluminum, but which are extinguished proportionally as contaminating substances are incorporated with it.

Curiously enough, the value of aluminum and its place in our daily life seems to have been forecast with wonderful accuracy in the opening lines of the work "1" Aluminum, by Deville, the father of the aluminum industry, and who has given us more knowledge on the subject than any subsequent investigator, wherein he predicted that, in an intermediate position between the precious and base metals, it was destined to fill a long-felt and important want. In the preface of the work, he says:

"The metals that men employ in civilized countries, for the ordinary needs of life, are very few in number; they are divided into two very distinct and different groups; precious metals and common metals. Gold and silver in the one, and in the other, copper, tin, iron, lead and zinc. Between the common and precious metals there does not exist an intermediate material. This blank which men have tried to fill by means of different alloys, which have been successively abandoned because of their price, and above all because of their inconvenience, remains in the most manifest and often the most inconvenient manner. Some years ago, when I attempted to discover some of the curious qualities of aluminum, my first thought was that I had put my hand on this intermediate metal, whose place would be in the uses and needs of men as soon as means should be found to bring it into common use. This provision seemed to be realized each day, and the actual state of the industry of aluminum gives perfect reason to the conclusion of my first memoir published at the beginning of 1855.

"Placed intermediate between the precious and common metals by some of its properties, it is superior to the first in uses of domestic life."

While this by no means justifies the enthusiasm of many of its would-be admirers, it does offer every reasonable encouragement to the efforts of those engaged in its production or utilization, to cheapen its cost *while increasing its purity*, and to develop new fields of industry, where its peculiar and unusual attributes will place it beyond rivalry by anything now known. In respect to its effect upon established industries it is quite safe to predict that in the very near future aluminum will be commercially produced of a purity almost, if not quite, equaling the purity of the best brands of copper, at prices that will place them in direct competition. Already aluminum can be had under a guarantee of 99½ and 99¾ per cent. purity, and the established qualities of the pure metal are such that, at slightly lower prices, it will, to a certainty, largely supplant copper in many applications to the arts and manufactures. Its alloys are already well known through actual use no less than by experimental tests to possess such exceptionally useful physical and chemical properties that there is little hazard in predicting their substitution for most purposes for which pure copper is now chiefly used. It is only necessary now that purchasers should not be deceived as to the supposed purity of their metal.

Society and Club Notes.

MR. A. R. FOOTE, BEFORE THE ELECTRIC CLUB, ON A MODEL NEW YORK CITY.

THE winter entertainment sessions of the club began on Thursday evening last, when Mr. A. R Foote, special agent for Electrical Statistics in the Eleventh Census, read a most interesting and suggestive paper on "The Making of a Model New York City." Mr. Foote began by calling attention to the urgent need in this city for rapid transit and said that the problem is "so to fix conditions that increase of population and increase of business shall cheapen instead of increase the cost of comfortable homes for wage-workers, and the tax on commerce and industry for its accommodations and services." In other words, New York wanted a service that would answer for a hundred years, alike for passenger and for freight traffic, providing cheap and good homes close to the factory where employment was given. It was not a solution of the problem to banish the wage-workers long distances into the country. Moreover, he said: "It seems strange that rapid transit for passengers should be the only thing talked about when all the improvements of the century have been devoted to that object, while freight traffic is handled in wagons on wagon roads, as was done one hundred years ago. Is it not time that this slow-moving endless procession of freight wagons should be notified that the quicker, cheaper and tireless forces of steam and electricity have been tamed to the service of transportation?" Mr. Foote's plan therefore, was not to tunnel under the city, not to penetrate the rural wilds of Jersey, but to re-occupy, to begin with, the river fronts on each side of the city. The space between the docks and the first and second streets from the water would be given up to a surface railroad and an electric railroad, and all the "squares" or blocks along this would be rebuilt with fine, solid structures running up eight or ten stories into the air. The surface roadway and the first stories of the docks and squares should be utilized entirely for freight or manufacturing, and in such wise that a car from any railroad can be switched into any dock, warehouse or factory on the route, on either side of the city. The elevated road and the second stories of the docks and squares should be utilized for passengers, warerooms, manufacturing and stores. All trains on all tracks should be run by electric locomotives. Along the lower roadways provision should be made for sewage, gas, water-pipes, etc. The roadways above should be flanked their entire length by broad, well-protected sidewalks, always open to the public. A similar walk should extend around each story. Each "square" would be provided with every convenience of communication, comfort, sanitation, etc. The buildings being of uniform height would carry all the wires at their tops on standards. Every building would have its electric elevator, and while heavy electric power machinery would run the big factories on the lower floors, small electric motors would supply power to the homes on the upper floors, so that for fifty cents a month every man could do his own work in any ordinary trade and thus be his own master. For furnishing electric power and heat, or steam heat, if needed, there would be generating plants at proper intervals. If this plan were carried into effect, said Mr. Foote, it would wipe out the tenement house evil in New York city. "If 'squares' are carried up seven or eight stories, the floor space created will far exceed the present floor space of the entire city. The capacity of the warehouse and manufacturing premises will exceed that of any city in the world." Mr. Foote then went on to point out the various gains to the public, the wage-worker, and the nation. The main obstacles were the real estate titles and the existing ramshackle buildings, and while he would fairly compensate for all actual values destroyed, he would not let the selfishness of any owner stand in the way. "His defects of character should not be given a cash value." A competent commission with power to issue 3 per cent. 100-year bonds could carry out the whole work, and he believed it could be made a handsome investment. It would, moreover, do much for the commercial supremacy of New York. "By properly arranging hoists, traveling cranes, turntables, tram cars and signals, all operated by electrical energy, two or three intelligent workmen can handle freight without the use of their own physical strength, in bulk and weight so great that all the human hands that can be laid upon it, exerting their utmost strength, would not be able to move. A skilled workman using power-driven machinery under the conditions described can command electrical energy equal to his own physical strength for less than five cents a day. More than this, his intelligence can direct the effective energy of a hundred or a thousand men, so that his own wages, added to the cost of the energy used, will make his labor cheaper than that of the unintelligent unaided man at five cents per day." Under these conditions the cost of handling material in New York City would be reduced to the minimum. Mr. Foote concluded with the remark: "The best opportunity the present generation will have so to arrange economic conditions is included in the demand for rapid transit. This is a demand for a freer, larger life. It calls for the abolishment of old ways, and the providing of new ways, not only for the transportation of persons, but for the entire management of commerce, communications and industry."

At the close of Mr. Foote's paper, Mr. Erastus Wiman, vice-president of the Club, who was in the chair, made a most able and eloquent comment on it and on the conditions it dealt with, expressing his belief that it indicated a feasible and practicable solution. He was followed by Dr. A. F. Mason, of Boston, who suggested crowning the squares with gardens for the benefit of the children. He did not know the exact manner in which the problems touched on would be dealt with, but he did know that the modern worker would not be satisfied to remain under existing conditions, but would insist on living in closer approximation to all that the higher sentiment and knowledge of the day showed to be best for humanity.

Mr. Foote presented the Club with a finely bound volume of the "Electrical Schedules of the Census," and the vote of thanks to him for the gift expressed the hope that nothing would be allowed to interfere with the completion of the work therein laid out.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

AT the meeting of the Council of the Institute held Sept. 22, 1891, the following gentlemen were admitted to associate membership in the usual course:

Caldwell, Fordyce S., proprietor Western Electric Construction Co., 503 Delaware St., Kansas City, Mo., and 150 West 82d St., New York City.

Cartwright, Fred'k G., Electrical Engineer, and Agent Fort Wayne Electric Co., 35 New Montgomery St., San Francisco, Cal.

Cheney, W. C., Electrical Engineer, Willamette Falls Electric Co., Portland, Oregon.

Foote, Charles W., Agent Railway Dept., Thomson-Houston Elec. Co., Society for Savings Bldg., Cleveland, O.

Hall, John L., Manager Western Union Telegraph Co., 300 Market St., Wilmington, Del.

Hamilton, William H., Dealer in Electrical Supplies, 200 State St., Albany, N. Y.

Hosford, Henry H., Electrical Engineer, 1009 Society for Savings Bldg., Cleveland, O.

Land, Frank, 606 Salina St., Syracuse, N. Y.

MacMullan, Robert Heath, Treasurer and General Manager, Brush Electric Lighting Co., Lafayette, Ind.

Marple, Lucius E., Electrician, United Electric Railway, Nashville, Tenn., and Wollaston, Mass.

Mordey, Wm. Morris, Electrician, Brush Electrical Engineering Co., 34 Montserrat Road, Putney, London, Eng.

Morss, Everett, Electrician, Simplex Electrical Co., 297 Beacon St., Boston, Mass.

Pattison, Frank A., firm of Pattison Bros., Consulting and Constructing Electrical Engineers, 135 Broadway, New York City.

Rogers, Edward H., Patent Lawyer, firm of Pope & Rogers, 15 Wall St., New York City.

Rutherford, W. M., Electrical Engineer, Thomson-Houston International Electric Co., 620 Atlantic Ave., Boston, Mass.

Schlosser, Fred. G., Superintendent of Electric Dept., Laclede Gas Light Co., 1801 Washington St., St. Louis, Mo.

White, Geo. Montagu, Agent for West Indies, Thomson-Houston International Electric Co., Kingston, Jamaica, W. I.

The following report was presented:

REPORT OF COMMITTEE ON UNITS AND STANDARDS.

Your committee, considering that authorized and recognized names for four practical electromagnetic units, at present unentitled, are needed by electrical engineers in this as well as in other countries, for dealing conveniently with magnetic circuits in analysis, discussion, and design, recommends to the Institute the four units as appended in detail, of magneto-motive force, reluctance, flux, and flux-density, in the hope that if favorably considered, the Institute may further the endeavors of the next International Electrical Congress towards securing for them universally recognized titles.

A. E. KENNELLY,
Chairman.

LIST OF NEW UNITS PRACTICALLY NEEDED FOR CONVENIENCE IN DEALING WITH MAGNETIC CIRCUITS.

1st. *Magneto-Motive Force;* or difference of magnetic potential.
Simple Definition.—The analogue in a magnetic circuit of voltage in an electric circuit.
Strict Definition.—The magneto-motive force in a magnetic circuit is 4π multiplied by the flow of current linked with that circuit.
The magneto-motive force between two points connected by a line, is the line integral of magnetic force along that line. Difference of magnetic potential constitutes magneto-motive force.
Electromagnetic dimensional formula, $L^{1/2} M^{1/2} T^{-1}$.

The absolute unit of M. M. F. is $\frac{1}{4\pi} \times$ unit current of one turn.

The practical unit is $\frac{1}{4\pi} \times$ ampere of one turn, or one-tenth of the absolute unit—*i. e.*, 0.0796 ampere-turn gives the unit. The prefix kilo- would perhaps be occasionally used for practical applications.

2d. *Magnetic Flux.*
Simple Definition.—Total number of lines of force or total field.
Strict Definition.—The magnetic flux through a surface bounded by a closed curve, is the surface integral of magnetic induction taken over the bounded surface, and when produced by a current is also equal to the line integral of the vector potential of the current taken around the boundary.
The uniform and unit time rate of change in flux through a closed magnetic circuit, establishes unit electromotive force in the circuit.
Electromagnetic dimensional formula, $L^{3/2} M^{1/2} T^{-1}$.
The absolute unit is one C. G. S. line of induction.
The practical unit is 10^8 C. G. S. lines.
Fluxes range in present practical work from 100 to 100,000,000 C. G. S. lines, and the working units would perhaps prefix milli- and micro-.

3d. *Magnetic Intensity,* or induction density.
Simple Definition.—Flux per sq. cm.
Strict Definition.—The induction density at a point within an element of surface is the surface differential of the flux at that point.
Electromagnetic dimensional formula, $L^{-1/2} M^{1/2} T^{-1}$.
Absolute unit, one C. G. S. line per sq. centimetre.
Practical unit, 10^8 C. G. S. lines per sq. cm.
In practice, excluding the earth's field, intensities range from 100 to 20,000 lines per sq. cm., and the working unit would perhaps have the prefix milli- or micro-.

4th. *Magnetic Reluctance.*
Definition.—Unit reluctance in a magnetic circuit permits unit magnetic flux to traverse it under the action of unit magneto-motive force.
Dimensional formula, $L^{-1} M^0 T^0$.
The practical unit is 10^{-9} the absolute unit.
Reluctances vary in present practical work from 100,000 to 100,000,000 of these practical units, so that the working unit would perhaps employ the prefix mega-.

Appointments, Etc.

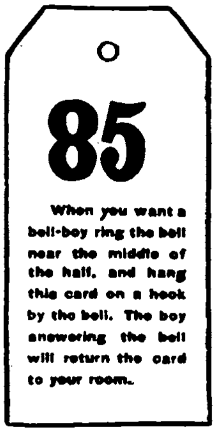
MR. J. M. STEPHENS, for many years manager of the Western Union telegraph office at Atlanta, Ga., has been appointed superintendent of the Fourth District, to fill the vacancy caused by the death of Mr. C. G. Meriwether.

MR. F. O. RUSLING, late of Wichita, Kan., and St. Joseph, Mo. has been appointed general superintendent of the electric railway at West Bay City, Mich. Mr. Rusling has had an electrical experience of eleven years.

H. B. SMITH has been appointed Professor of Electrical Engineering in the Arkansas State University.

Letters to the Editor.

A NOVEL HOTEL ANNUNCIATOR CALL SYSTEM.



I AM sure the readers of THE ELECTRICAL ENGINEER will be interested in the accompanying card, which constitutes a part of the novel hotel annunciator call system discovered by me in the wilds of Michigan during a recent trip to Traverse City. The card enclosed belonged in room 85, and I think I am, or should be, free from the charge of petty larceny for the service I am doing to mankind in disclosing this system to the world through your valuable journal.

C. J. KINTNER.

NEW YORK, Sept. 12, 1891.

UTILIZING THE LACHINE RAPIDS.

HAVING resided in Montreal for several years and being acquainted with its local peculiarities, I wish to call attention to a circumstance that has not been mentioned in the recent comments upon the water power, now apparently going to waste at the Lachine Rapids, near that city.

Although these rapids of the St. Lawrence carry more water than passes over the falls at Niagara, the fact must not be overlooked that for a few days in the early part of the winter when the ice-bridge is forming on the river opposite the city, and again in the spring when it is breaking up, the river below the rapids gets choked up with ice. This dams up the water, causing it to rise to such a height as to partly, and frequently almost entirely, neutralize any power obtained from the rapids.

This is undoubtedly the principal cause that interferes with the utilization of these rapids, as any electric or other plant deriving its power from this source would be obliged to shut down partially, if not entirely, twice a year during these periods, unless it followed the example of the Montreal City Corporation, which, at its water works, employs power from the rapids to pump water up to reservoirs on the mountain, but uses the steam engines of an auxiliary steam plant when the water power is not available.

LOUIS M. PINOLET.

Brooklyn, Sept. 17th, 1891.

DECREASE IN RESISTANCE OF LIQUIDS WITH INCREASE OF TEMPERATURE.

IT is a well-known fact that the resistance of liquids varies inversely with the temperature. I am not aware that any satisfactory explanation of this has been given, but it seems to me that it can be accounted for in the heat of combination. As the temperature is increased, the energy between the atoms of the molecules becomes less, and it may be that this energy really constitutes the opposing force of the current. The counter E. M. F. of an electrolyte should, therefore, be decreased by an increased temperature. This could be taken advantage of in practical electrolysis by heating the baths with waste steam, etc. If any of your readers can make any suggestions on the subject, it might be productive of good results.

JOSEPH W. HARRIS.

ORANGE, N. J.

NOTE.

THE practical utilization of the gain in conductivity of electrolytes by heating them is not a matter of recent discovery. It would be difficult in fact to trace back the date of its earliest use. The writer first had his attention called to it in 1876, at which period the heating of the electrolyte in an electrolytic operation was first used in this country by Mr. N. S. Keith, in connection with his electrolytic tin-scrap process for the detinning of scrap. About 1880 and for some years later, the writer had practical experience with this application of heating in connection with Mr. Keith's process for the electric desilverization of lead base bullion. In this process the temperature was maintained at a uniform degree, ranging up to 130 deg. Fahr. The gain in conductivity was considerable.

In Europe, also, it is the practice to use heat for increasing the conductivity of solutions in electro-metallurgical operations. In the case of processes for refining, the temperature can be regulated without great difficulty, as the current density is usually somewhat low, and the heat due to the passage of the current itself ($C^2 R$) is not a disturbing factor of so much importance.

However, in the case of electrolysis used in connection with the deposition of metals in the arts, for electroplating, electrotyping—particularly the latter—where a much greater current density is used, the heat due to the passage of the current itself is sufficient to maintain the temperature at approximately the desired point and thus automatically increase its conductivity. The writer has seen cases, in his own experience, where extreme speed of deposition was sought and realized, and wherein it became actually necessary to provide means for cooling the solution, even though the specific resistance of the solution had been reduced as far as possible by the proper chemical means; and its working resistance reduced by diminishing the distance between the electrodes. That is, the total heat due to the current ($C^2 R$) was greater than that which the surface evaporation, conduction, convection, etc., could carry off so as to maintain the temperature below practicable working limits.

In any electro-deposition process, involving the use of wax matrices, the limiting temperature is much more quickly reached. The heat will also be greater in the summer than in the winter, for obvious reasons.

The use of heat in electro-deposition was probably resorted to in this country even before the date above mentioned—1876—in connection with processes for depositing nickel, though in that case it may have been employed as much for chemical reasons as for electrical.

C. O. Mailloux.

"MINIMUM FIRST COST OF PLANT AND MAXIMUM ECONOMY OF OPERATION IN THE ELECTRICAL TRANSMISSION OF POWER."

BY

Chas. J. Reed

In The Electrical Engineer of Sept. 2, 1891, Mr. H. Ward Leonard made some remarkable statements, which, on account of the importance of the subject to a large class of prospective investors, and the recognized authority of Mr. Leonard in such matters, should not, it seemed to me, be allowed to pass without correction. I therefore called Mr. Leonard's attention to the matter and invited him to explain more clearly what seemed to me manifest errors. I regret that Mr. Leonard in his courteous reply published the 23d inst., has failed to make his position any clearer; but by a kind of circumduction has left the impression that my criticisms were not well founded.

If Mr. Leonard's conclusions are true, they are of sufficient importance to the public to go into the details, giving the reasons for his assumptions. If they are not true, it is equally important to a large and interested class to know it. For these reasons I again challenge Mr. Leonard, through the indulgence of The Electrical Engineer, to show his proofs.

He starts out with an arithmetical error and in his reply adheres to the error, insisting that it is correct. I will call his attention to it specifically. In his expression for the weight of the conductor he uses M, the area of 2 D as a factor, and then introduces the factor, "2," again, giving the weight of a conductor 4 D in length.

Mr. Leonard begins by saying: "*I shall first treat the subject generally and deduce the correct laws.*" If this does not mean that his formulæ are to be considered general, what does it mean? He then arbitrarily assumes variable conditions to be fixed and the absurdity of his conclusions is manifest. His explanation of equations (12) and (13) is not lucid. If these equations mean anything, they mean just what they say, viz., that under conditions of minimum cost of plant, the cost of conductors increases with the loss in conductors and depends only on the loss and cost of translating devices—an absurdity so obvious that it is unworthy of discussion. The reassertion, without proof, that the minimum first cost is independent of the price and conductivity of the conductor, is not convincing and not calculated to inspire confidence in Mr. Leonard's conclusions. If this is true, we might go a step further than using gold for conductors. We might use clay or wood! The conditions of minimum first cost would not be altered!

But the statement is *not* true. The condition of minimum first cost would be very different, for instance, with copper at one cent, and at one dollar, per pound, except in the particular case in which the weight of copper in conductors is to the weight of copper in the generators and accessories in such a relation that a variation in distance, electromotive force, or loss in transmission would not alter the total weight of copper employed—a condition that would be difficult to realize.

With any increase in the price of copper the mininum cost of plant would require smaller conductors, larger generators and greater loss in transmission or greater electromotive force, for all distances greater than that at which the weight of copper in conductors equals the weight of copper in the generators and accessories. For distances so small that the weight of conductors is less than the weight of copper in the generators the opposite conditions would obtain. Of course, for such small distances variations in the price of copper would, in practice, be ignored; but according to Mr. Leonard's assumptions the conditions of minimum cost (electromotive force, loss, relative size of generators and conductors, etc.,) would be the same whether the cost of conductors be equal to that of the generators or a thousand times greater.

The problem of determining the minimum first cost of a plant for the electrical transmission of power does not depend on any one or two conditions, but on many. Among the conditions that independently affect this cost are distance, conductivity of conductor, price of conductor, price of generator and accessories, price of power-generating machinery, and price of labor in construction. Among those that affect it dependently are electromotive force of transmission and loss in transmission.

The market value and physical properties of copper render it the only available material at present for conductors, and hence we may assume the conductivity to be constant and it needs no further attention. It is not so, however, with the price. The conditions of minimum cost would not be the same, as shown above, with copper at one cent, and at one dollar, per pound.

In order to bolster up his conclusions and show that Thomson's law is not practicable, Mr. Leonard offers the following unique example:

"*Let us suppose that the interest and depreciation upon our plant is $9 per annum per kilowatt delivered; also, that the value of one kilowatt is $5 per annum!*" In this case I should prescribe the same remedy as I would for a merchant who proposed opening a store where he would pay $9 per day rent and sell goods amounting in value to $5 per day. If $9 are expended per annum in interest and depreciation alone per kilowatt (to say nothing of fuel and operating expenses), how could the product be worth only $5 per kilowatt, especially if it were produced under conditions of "minimum first cost of plant and maximum economy of operation?"

THE IMPORTANCE OF THE POINT OF VIEW FROM WHICH THE TRANSMISSION OF POWER IS REGARDED.

BY

H. Ward Leonard

I have read the article of Dr. Cary T. Hutchinson, which appeared under the above title in The Electrical Engineer of September, 23, 1891. The article attempts a defense of the rules laid down by Mr. Sprague in his article on "The Transmission of Power by Electricity," which appeared in the *Journal of the Franklin Institute*, of March-April, 1889, and also attempts to show that in my recent article I made serious errors by misinterpreting Mr. Sprague's rules. I should feel inclined to delay replying to Dr. Hutchinson's points, if I thought that Mr. Sprague, or others, were likely to raise additional points which I could consider at the same time; but realizing that Dr. Hutchinson is at present intimately associated with Mr. Sprague in business, I shall assume that Dr. Hutchinson's present article gives expression to Mr. Sprague's views.

Dr. Hutchinson endeavors to show that, in reality, Mr. Sprague's deductions and mine are identical in effect, and by making certain plausible assumptions he finally, apparently, proves that Mr. Sprague's conclusions and mine are exactly the same. That Dr. Hutchinson's article is a masterpiece of ingenuity in disguising the assumptions made and in cleverly interpreting in an unexpected manner a perfectly positive statement made in the most definite language, I am bound to admit, and I think the article certainly demonstrates in one way "the necessity of looking at every question from all sides before making positive statements." The positive statements which I refer to are the two principal rules which Mr. Sprague lays down, and which are as follows:

1. "With any fixed conditions of cost and efficiency of apparatus the number of volts fall to get the minimum cost of plant is a function of the distance alone and is independent of the electromotive force used at the motor."

2. "With any fixed couple and commercial efficiency the cost of the wire should bear a definite and fixed ratio to the cost of the generating plant."

Although it seems impossible to find but one meaning for these rules, as laid down by Mr. Sprague, yet Dr. Hutchinson has skilfully pointed out a way to do so. It will be evident to those familiar with the calculation of conductors that, stated as above, the rules are very misleading and entirely incorrect. A few practical applications of the rules will satisfy anyone on this score.

The first rule states that if we have fixed conditions of cost and efficiency of apparatus and also have a fixed distance, the volts fall for minimum cost, being a function of the distance alone, will also become fixed. Suppose we determine the volts fall in this way for any case. Is it not evident that, whatever the cost of the conductor may be, we can reduce such cost by increasing the volts fall, and yet, by increasing the E. M. F. at the motor proportionately, keep the cost of apparatus the same as before, and hence effect a reduction in the total cost?

From rule 2 we learn that if we fix the commercial efficiency, the cost of copper for minimum cost of plant will also be fixed. With any fixed commercial efficiency the cost of apparatus is fixed, but not so the cost of copper; for we can preserve the commercial efficiency constant and yet, by increasing both the volts fall in the line and the E. M. F. at the motor in the same proportion, reduce the cost of conductor indefinitely and hence can reduce the total cost of plant.

Dr. Hutchinson claims that I interpret these rules incorrectly and would have us interpret them, as follows:

1. With fixed conditions of cost, efficiency of apparatus *and electromotive force at motor*, and *under* conditions of minimum first cost of plant the number of volts fall is a function of the distance alone, and is independent of the E. M. F. used at the motor.

2. *Under conditions of minimum cost* and with any fixed couple and commercial efficiency the cost of the wire *bears* a definite and fixed ratio to the cost of the generating plant.

I think any reader will readily see that the revised rules are radically different from those announced by Mr. Sprague. Mr. Sprague's comment regarding his first rule was, "a somewhat startling conclusion," but it will be noticed that the injection of the various conditions Dr. Hutchinson desires, takes all the "startle" out of the conclusion.

Any reader of Mr. Sprague's second rule would suppose that if we have a fixed couple and commercial efficiency we should, in order to operate at minimum first cost, have a cost of wire which would bear a definite and fixed ratio to the cost of the generating plant. But this now being manifestly incorrect, Dr. Hutchinson assures us that it means, that if we, in some way, find out how to operate under conditions of minimum first cost, we will observe that then the cost of the wire does, under such conditions, bear a definite and fixed ratio to the cost of the generating plant—an entirely different statement.

Since it is evident that Dr. Hutchinson can readily insert enough conditions and enough assumptions to make Mr. Sprague's rules give a correct result, it will perhaps be more conclusive to learn from Mr. Sprague himself exactly what he did mean when he laid down these rules. Mr. Sprague's article itself furnishes us clear evidence on this point. He says: "For example, suppose we wish to transmit 20,000 feet. The fall of potential on the line could be 362 volts, and this is independent of the commercial efficiency. If this latter is made, say, 60 per cent., then *E* (E. M. F. at motor) equals 1,086 volts and the potential at the terminals of the generator should be 1,448 volts."

It is evident from the above that Mr. Sprague overlooked the fact that it would be possible to maintain a commercial efficiency of 60 per cent., and hence keep the cost of apparatus constant, and yet, by raising both the volts drop and the motor E. M. F., reduce the cost of copper indefinitely, and that hence he has not correctly stated the minimum conditions. In fact, there could be no practical minimum conditions for the case assumed.

Dr. Hutchinson wonders whether I have really read Mr. Sprague's article. I beg to remove his doubts on this score, and also to say that, thinking that possibly Mr. Sprague had noticed his errors and corrected them in later articles on the same subject, I carefully examined another, later, paper by Mr. Sprague, published in the *Scientific American Supplement*, of July 20-Aug. 3, 1889, and found the same erroneous interpretation and statements, as is evidenced by the following quotation: "For example, suppose we wish to transmit a distance of 30,000 feet at a commercial efficiency of 60 per cent. What would be the required E. M. F. at the motor terminals? We find the E. M. F. to be 1,620 volts."

In conclusion I beg to acknowledge my error in ascribing to Mr. Sprague the rule given by Mr. Badt on page 42 of his handbook, which apparently is his own. I was led into this error by the fact that Mr. Badt did not use quotation marks in the case of any of Mr. Sprague's rules, but gave a foot-note on page 10, saying, "The rules in italics are taken from Frank J. Sprague's papers mentioned in the preface." This rule being in italics, I assumed it to be one of Mr. Sprague's, and did not take the precaution of comparing it, especially as it seemed consistent with Mr. Sprague's rules quoted above.

I think it will be seen from the above that I did not, in my article, place any different interpretation upon Mr. Sprague's rules than that which he himself clearly gives to them; I will gladly and promptly admit any other error on my part, besides that above acknowledged, if it be pointed out to me.

HOWARD'S IMPROVED TELEPHONE APPARATUS.

SOME recent improvements and modifications in telephonic apparatus have been devised by Mr. James H. Howard, of the Tropical American Telephone Co., of Boston, and will prove of interest, as they aim at the removal of some of the retarding influences met with in telephony.

In order to effect the cutting out of the receiver when it is hung up, and at the same time allow the current on the primary circuit to pass around the Siemens armature of the magnets when not in use, Mr. Howard has designed the arrangement shown in the accompanying diagram, Fig. 1.

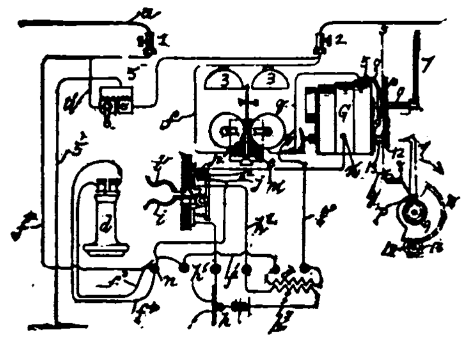


FIG. 1.

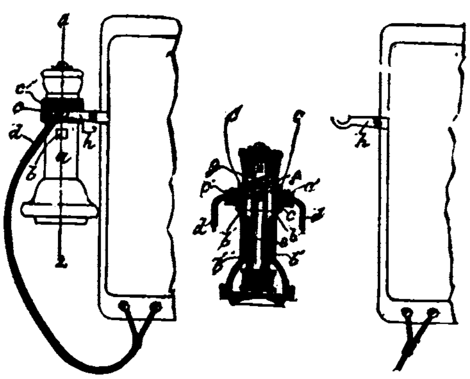
It will be seen that when the receiver is off its hook and the telephone is in use, the current follows the main line *b*, the wire *f* connected through the bell-magnet *e* to wire *f'*, through the induction-coil *g*, connecting-wires f^2 and f^3, receiver *d*, wire f^4, wire f^5, and so on to the main line *a*, with which the wire f^5 connects at 1. When the receiver is in this position, the secondary or induced current may be traced from the microphone or transmitter *h* through wire *h'* to a terminal connected with one arm *i* of the hook or crotch which supports the receiver *d* when the same is hung up, from the arm *i* to the other arm *i'* of the hook, thence by wire h^2 through the induction-coil *g*, and by wire h^3 to the transmitter *h*. Thus, when the telephone is in use the armature is cut out of circuit and its resistance and retarding influence is removed.

It will also be noted that the call-bell is operated by a lever 7 which is attached to a spindle carrying a toothed sector 10, gearing with the armature shaft; the crank shaft *o* also has a disc 9 mounted on it and insulated on its periphery, except at one point. When the receiver *d* is on its hook the current comes over the main line *b*, wire *f*, through the bell-magnet *e*, wires *q'* and *q* to contact-piece 8, and disc 9, through the frame of the armature to wire *m'*, through terminal *j'*, contact-maker i^2 and terminal *j* to wire *m*, and thence through wire f^5 onto the main line *a*. It will thus be

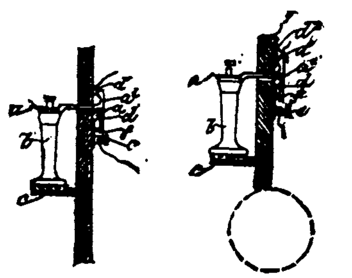


FIGS. 2, 3 AND 4.

seen that the current avoids the resistance of both the armature and the telephone-receiver when the latter is upon its hook and the armature is at rest, both being cut out of the circuit. The bell is caused to ring by moving the crank 7, this movement cutting the wire *q* and contact-piece 8 out of the circuit, the current then passing through the wire *q'* and contact-spring q^2, through the coils of the armature, and so on to the wire *m'* in the usual way.

The calling crank is brought back to its normal position by a coiled spring, so that one, or any number of signals, can be given with ease and certainty, where several stations on a line require a different number of rings or calls for each. It also does away with electrical connection with the ringer through the door-hinges, leaves the door free so that no hinges are required, three or four wood screws replacing them, besides providing a convenient place for a directory of those subscribers' numbers most used. The lightning arrester is a simple 2-point switch on the side of the call-bell, where it can be readily seen and operated, and the liability of losing the present crude lightning-arrester pin is obviated. The side crank, telephone support and gongs take up less space and are less liable to injury in packing and shipping, especially for export.

Mr. Howard has also devised a telephone receiver which embodies in its own construction the switch which cuts out from the circuit the coil of the receiver when the latter is not in use. The construction and operation of this apparatus is shown in Figs. 2, 3 and 4. It will be seen that when the receiver is detached from its hook, the conducting portions of the ring *c*, carrying the circuit-wires *d d*, make contact with the pieces *b b*, the current thus flowing through the coil of the receiver, the wires b' b^2 of tht coil forming the only conducting connection between the circuit-wires *d d*. When, however, the receiver is hung upon its hook, *h*, the arms c' resting on the hook, the weight of the receiver is such as to overcome the stress of the spring *g*, and the receiver moves slightly downward through its closing ring *c*, which is supported by its arms c' on the hook *h*, thus breaking the contact between the ring *c* and the contact-pieces *b*, connected with the coil of the receiver. Contact is then made between the conducting portions of the ring *c*, carrying the wires *d d* by means of the hook *h*, the arms c' c' resting on the arms of



Figs. 5 and 6.

the hook. It will be seen that the current then flows from one wire *d* to the other through the hook *h*, thus cutting out the coil of the receiver and avoiding its resistance.

Two nails, driven in the wall, between and on which to hang the phone, will suffice, with this device, to cut out the phone, and a 2-point switch, worth 50 cents, would cut in the ringer circuit of any call-bell, or this can be done by a simple circuit-closer on the telephone, as shown, called into action when the receiver is hung up.

Figs. 5 and 6 represent an improved hook, so arranged as to prevent the current passing through the receiver when on the hook. When the receiver *b* is not in use, its upper end is inserted under the arms *a a* of the hook, and the same are moved upwards until the lower end of the receiver rests upon the shelf *c*, as shown in Fig. 5, thus moving the upper end of the cross-piece a^2 away from the contact-piece d' and breaking the circuit at that point. When the receiver is again removed from its shelf *c*, the spring *f* again presses the cross-bar a^2 against the contact-piece d', thus completing the circuit. As shown in Fig. 6, a second contact may be arranged behind the upper end of the lever or the cross-piece a^2, as at d^2, to which may be connected a wire of a second circuit, which would be cut out when the receiver is removed. This arrangement could also be made to cut out the ringer or generator circuit.

Personal.

FRED. H. WHIPPLE.

The Electrical Engineer has for some time been receiving, from several sources, reports of very irregular money transactions on the part of Mr. Fred. H. Whipple, of New York and Detroit, implying methods so objectionable as to suggest a word of caution to electrical circles generally. We are informed of a number of dishonored drafts cashed for Mr. Whipple by gentlemen in electrical business, some of which have been held for several months and remain unpaid. We are not inclined to impute dishonesty to Mr. Whipple, but the effect of transactions of the kind referred to, even if due to carelessness, must be to diminish confidence in him.

Mr. John W. Lieb, the electrical engineer of the celebrated Milan, Italy, electric light station, is now visiting this country.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED SEPTEMBER 15, 1891.

Accumulators :—

Method of Making Plates for Secondary Batteries, S. C. C. Currie, 459,491. Filed Jan. 24, 1891.
Consists in converting electrolytically cast or rolled lead, enveloped or enclosed in asbestos or analogous material in a solution composed of a chloride of a metal, to a soft state ; then reducing the same to a spongy or porous metallic condition.

Secondary Battery, W. L. Silvey, 459,535. Filed June 27, 1891.
Process of preparing consists in mixing a suitable metallic oxide with water, placing the resulting paste on a suitable support and then pickling the whole in an acid solution.

Alarms and Signals :—

Till-Alarm, H. Garrett, 459,442. Filed Nov. 13, 1890.

Electrical Alarm System, J. P. McMahon, 459,501. Filed Jan. 24, 1891.
Improvement upon the system of the same inventor patented Dec. 3, 1889, No. 416,483. Applicable to fire-alarms and similar service.

Electric Push, J. F. Wollensak, 459,605. Filed Jan. 28, 1891,

Annunciator, F. Ritchie, 459,615. Filed Dec. 29, 1890.

Conductors, Conduits and Insulators :—

Conduit for Electric Wires, H. W. Johns, 459,509. Filed Apr. 27, 1891.
A seamless woven, knitted, or braided tube made from fire-proof strands of fibrous material and having an exterior coating of protecting and strengthening material, such as metal.

Cable-Box for Electric Wires, J. N. Keller & J. A. McCoy, 459,523. Filed May 23, 1891.
Relates especially to methods of partial or way distribution of conductors, and to arrangements for cross-connections.

Distribution :—

System of Electrical Distribution, E. Thomson, 459,423. Filed Dec. 19, 1890.
Regulates a continuous current transformer by subjecting a separate armature conductor, in circuit with a main winding of the transformer, to the action of an auxiliary magnetic field acting only on said separate conductor and varying the strength of said auxiliary field.

Dynamos and Motors :—

Dynamo-Electric Machine and Motor. E. Thomson, 459,422. Filed Oct. 31, 1885.
The armature core is provided with narrow slots extending longitudinally or parallel to the axis of the core and radially toward the centre of the core, but passing only part way through the iron of the core, leaving that portion of the iron close to the shaft continuous and unslotted. Employs independent magnetizing helices, one of which acts upon the portion of pole-piece next the diameter of commutation and is included in the main circuit.

Dynamo-Electric Generator or Motor, J. Hodult, 459,508. Filed May 23, 1891.
Designed for operation with either alternating or continuous currents.

Dynamo-Electric Machines, E. Desroziers, 459,610, Filed June 17, 1887.
Relates especially to a dis: armature for multipolar machines.

Electric Motor. J. W. Davis & J. B. Farrington, 459,678. Filed May 5, 1891.
Operated by static charges. Especially adapted for the use of students and for experimental purposes.

Electrolysis :—

Process of Electrolytically Obtaining Zinc, A. Watt, 459,556. Filed Mar. 22, 1889.
Claim 2 follows:
The improvement in the art of preparing zinc-bearing ores for electrolysis, which consists in digesting the powdered ore in acetic acid and sulphuric acid, at first separately and afterward jointly, to form an electrolyte.

Galvanic and Thermo-Electric Batteries :—

Fibrous Carbon Battery, J. H. Robertson, 459,447. Filed Nov. 17, 1890.
The negative element consists of fibrous carbon made from rattan.

Lamps and Appurtenances:—

Electric Switch, B. W. Allen, 459,465. Filed Nov. 6, 1890.
A device whereby one or more electric lamps may be lighted or shut off by one and the same switch, without regard to their number or location.

Electric Arc Lamp, E. R. Knowles, 459,510. Filed May 25, 1891.
Relates to regulating mechanism. A rack and pinion feed is employed.

Incandescent Electric Lamp Socket, J. O. Phillips, 459,514. Filed Dec. 3, 1890.

Electrical Fixture, E. T. Greenfield, 459,704. Filed Dec. 31, 1890.
Relates to switch or ceiling blocks for use in incandescent lighting and similar purposes.

Electric Light Fixture, E. T. Greenfield, 459,705. Filed Dec. 31, 1890.

Medical and Surgical :—

Electric Belt, C. H. Dorenwend, 459,681. Filed Sept. 16, 1890.

Miscellaneous :

Cut-Out, F. Bryan, 459,560. Filed Mar. 11, 1891.

Apparatus for Working Punkas, H. E. Walter, 459,663. Filed May 19, 1891.

Electric Snap-Switch, G. W. Hart, 459,706. Filed June 22, 1891.

Railways and Appliances :—

Railway Danger-Alarm, D. J. Haynes and O. Allen, 459,456. Filed Sept. 16, 1890.
Designed to indicate the destruction of a culvert or bridge.

Trolley-Wire Connection, R. L. Caldwell, 459,485. Filed June 10, 1891.

Trolley-Wheel, G. E. Lewis, 459,588. Filed Dec. 20, 1980.

Railway-Signal, H. C. Horstmann, 459,638. Filed May 15, 1891.
For block systems. A train entering a block causes the display of visible signals throughout the entire block, and also indicates the direction of the train.

Insulator, C. L. Gerrard, 459,686. Filed April 8, 1891.
Trolley wire insulator.

Slide-Shoe Trolley, S. H. Short, 459,689. Filed April 15, 1890.

Rheostat for Electric-Motor Cars, S. H. Short, 459,690. Filed Mar. 18, 1891. Composed of exposed strips of low conductivity, mounted and extending upon the roof of the car.

Safety Cut-Out for Overhead Wires, N. Froloff and W. Subbotin, 459,721. Filed Feb. 7, 1891. For trolley wires.

Telegraphs:—

Telegraphic Apparatus, W. E. Sloan, J. E. Hughes and O. S. Reed, 459,448. Filed July 5 1890. A pneumatic telegraph with local electrical devices.

Telephones and Apparatus:

Fastener for Spring-Jacks of Switch-Boards, C. E. Scribner, 459,711. Filed May 7, 1891. Relates to switchboards for telephone exchanges.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED SEPT. 22, 1891.

Alarms and Signals:—

Burglar Alarm, H. T. Wilson, 459,984. Filed Feb. 8, 1891. Relates to floor contacts.

Electric Show Case Alarm, R. C. Kruschke, 460,019. Filed Dec. 1, 1890.

Conductors, Conduits and Insulators:—

Automatic Disconnector for Overhead Conductors, A. L. Johnston, 459,-839. Filed Jan. 19, 1891. For improvements on same inventor's device patented Aug. 26, 1890, No. 455,098.

Insulator, V. A. Thomas, 459,843. Filed Nov. 22, 1890. A tree insulator.

Electric Cable, D. Brooks, Jr., 459,941. Filed Jan. 14, 1891. A flexible joint.

Electric Coupling, F. M. Farwell, 460,048. Filed Jan. 27, 1891. Adapted for electric connections on railway trains.

Process of Manufacturing a Composition Applicable for Electrical Insulating Purposes, etc., E. Fahrig, 460,056. Filed July 18, 1890. Mixes and beats up a pulp staff with manilla or other similar fibres, then adds a soap solution, then treats the resulting mass with a precipitate until the precipitate shows itself in the mass, then forms the pulp so prepared into sheets and applies an insulating powder; the material is then subjected to pressure and drying heat; finally the material is treated with an insulating solution and subjected to great pressure.

Dynamos and Motors:—

Commutator Brush Holder, H. H. Blades, 459,739. Filed June 12, 1890.

Electro-Magnetic Motor, N. Tesla, 459,772. Filed April 6, 1889. Claim 1 follows: An alternating current non-synchronizing electric motor coupled with a synchronizing alternating current motor, substantially as set forth, whereby the former starts the latter and throws it into synchronism with its actuating current, and switch mechanism for directing the current through either or both of the motors.

Governor for Dynamos, M. S. Conly, 459,810. Filed Dec. 23, 1890. An electro-magnetic regulator.

Governor for Dynamos, M. S. Conly, 459,811. Filed Aug. 25, 1890. Similar to the next above.

Conductor Fastening for Commutators, S. H. Short, 459,890. Filed May 26, 1891.

Armature for Dynamo Electric Machines and Motors, J. Beattie, Jr., 459,923. Filed Dec. 9, 1890. Core has grooves in its periphery parallel to the axis of the armature, in which grooves the wire is placed; iron wire and insulating material are wound upon the outside of the armature in alternate convolutions.

Method of and Apparatus for Converting the Electrical Energy of Alternating Currents into Mechanical Motion, C. S. Bradley, 460,046. Filed Nov. 8, 1890. Consists in raising the effective counter-electromotive force developed by the rotation of the motor relatively to the self-induction of the motor by cutting the field of force rapidly relatively to the period of the supply current.

Controlling Switch for Electric Motors, S. S. Wheeler, 460,076. Filed Sept. 22, 1891. Claim 1 follows: An electric motor having its armature connected in series with its field-magnets, there being one coil for each field-magnet, in combination with a switch having four fixed terminals connected, respectively, to the ends of the two field-magnet coils, and two movable terminals located in the path of the free ends of the fixed terminals and carried by a rotary switch-handle.

Electric Regulator, J. F. McElroy, 460,059. Filed Feb 11, 1891. An electromagnetic regulator.

Electrical Transmission of Power, R. M. Hunter, 460,071. Filed Nov. 9, 1887. Claim 1 follows: The method of transmitting electric energy, consisting in generating by induction currents of low intensity and of alternately increasing and decreasing potential, then converting them by induction into currents of high intensity, transmitting the induced currents of high intensity by a line-circuit to a distant place, and then reconverting by induction said high-intensity currents back again into low-intensity currents and supplying said low-intensity currents to one or more local circuits containing translating or current-consuming devices.

Electric Motor, E. M. G. Hewett, 460,087. Filed April 2, 1891. Rotating element consists of a series of straight bar electromagnets mounted upon a common shaft, with their like poles at one end; it is enveloped by a stationary magnetic shell serving as an armature to the rotating electromagnets.

Reciprocating Tool, C. E. Lipe, 460,069. Filed Oct. 8, 1890.

Lamps and Appurtenances:—

Guard for Incandescent Lamps, H. H. Hipwell, 459,749. Filed Oct. 20, 1890

Electric Arc-Lamp, M. S. Logan & J. H. Barley, 459,757. Filed Jan. 19, 1891. The carbon rod has longitudinally diverging surfaces; feed mechanism engages with said diverging surfaces.

Manufacture of Incandescent Electric Lamps, T. A. Edison, 459,835. Filed Jan. 22, 1883. Claim 1 follows: The method of obtaining a dry nitrogen atmosphere at a definite pressure in the inclosing globe of an incandescing electric lamp, consisting in producing an air-pressure in the globe slightly above the pressure of nitrogen desired, decomposing the air left in the globe, retaining the nitrogen in the globe, removing the oxygen by putting a receptacle containing a substance having affinity for oxygen into communication with the globe, and removing the moisture from the nitrogen.

Carbon Lamps for Arc Lights, V. A. Thomas, 459,845. Filed Dec. 27, 1890.

Attachment for Electric-Arc Lamps, V. A. Thomas, 459,846. Filed Jan. 8, 1891. Consists of an insulating hood or shield adapted to be readily attached to and to enclose the lower or exposed metallic portion of a lamp.

Electric Lamp, D. Tommasi, 459,872. Filed Jan. 14, 1891. A safety lamp adapted for use in mines, powder magazines, &c.

Combination-Fittings for Gas and Electric Lights, O. Strom, 460,095. Filed Dec. 27, 1890.

Measurement:—

Electrical Recorder for Voltmeters, Thermometers, &c., C. W. Ayton, 459,868. Filed Mar. 28, 1891. A dial or gauge actuated by electromagnetic devices.

Medical and Surgical:—

Electro-Therapeutic Bath, C. P. Hoffman and W. B. Van Houten, 459,852. Filed Mar. 16, 1891.

Miscellaneous:—

Electro-Magnetic Device, G. R. Lean, 459,786. Filed April 11, 1891. For opening or restoring a circuit after a definite length of time.

Rheostat, H. E. Waite, 459,800. Filed Dec. 23, 1890.

Contact for Electric Programme-Clocks, F. E. Smith, 459,917. Filed Feb. 21. 1891.

Magnetized Hat-Band, F. H. Brown, 459,912. Filed July 15, 1891.

Automatic Electro-Pneumatic-Tube System, W. G. Collins, 460,081. Filed. Nov. 7, 1890. Includes electromagnetic devices for diverting the carrier into a branch tube.

Railways and Appliances:—

Electric-Railway-Conductor Support, E. M. Bentley, 459,737. Filed Sept. 5, 1887.

Trolley-Line Circuit-Breaker, R. M. Jones 459,753. Filed April 16, 1891.

Rheostat for Electric-Motor Cars, S. H. Short, 459,794. Filed March 17, 1891. An exposed rheostat is located outside the car body in an open flue lengthwise of the car body.

Electric Railway, R. M. Hunter, 459,815. Filed March 16, 1888. Includes a common supply conductor extending along the line of two tracks, and branch conductors connecting the supply conductor with the working conductors of the two tracks at intervals in their length.

Automatic Disconnector for Overhead Conductors, A. L. Johnston, 459,840. Filed Jan. 19, 1891.

Trolley Wheel for Electric Railways, J. A. Wetmore, 459,848. Filed Feb, 4, 1891.

Motor Mechanism for Electric Cars, S. H. Short, 460,040. Filed Nov. 1, 1890. Ring armature mounted on and directly connected with driving axle; field magnets located between the armature and the car wheel and provided with yokes mounted by journal bearings on the axle.

Telegraphs:—

Duplex Telegraphy, J. J. Ghegan, 459,930. Filed Nov. 5, 1889. Transmitting battery located at one station only.

Patent Notes.

R. M. HUNTER'S PATENT ON HIGH TENSION ELECTRIC TRANSMISSION.

THE application of alternating currents to electrical distribution has progressed sufficiently to define the main characteristics of the methods which will be employed in the future for high-tension work. Thus it may be accepted with tolerabe certainty that the high potentials will not be generated by the machines directly, but that their currents, of low tension, will be converted upwards in transformers connected to the line, and reconverted to a lower potential for local distribution at the distant end, as is now done in the Lauffen-Frankfort transmission, in the method employed for local distribution by Ferranti in London, and elsewhere.

In view of the evident importance of this method, our readers will be interested to know that a U. S. patent covering ithas been granted to Mr. Rudolph M. Hunter, the first of the seven claims of which reads as follows:

> The method of transmitting electric energy, consisting in generating by induction currents of low intensity and of alternately increasing and decreasing potential, then converting them by induction into currents of high intensity, transmitting the induced currents of high intensity by a line-circuit to a distant place, and then reconverting by induction said high-intensity currents and supplying said low-intensity currents to one or more local circuits containing translating or current-consuming devices.

The patent is entitled Electrical Transmission of Power; No. 460,071, issued Sept. 24, 1891; original application filed Nov. 9, 1887. The patent is assigned to the Thomson-Houston Electric Company.

MR. C. R. FISH has severed his connection with the Woburn Electric Light Co., of Woburn, Mass., and has removed to Cambridge, Mass., where he assumes a position with another electric concern.

Legal Notes.

A NEW INCANDESCENT LAMP SUIT.—THE CONSOLIDATED ELECTRIC LIGHT CO. v. THE N. Y. LIFE INSURANCE CO.

THE Consolidated Electric Light Company, which is operated under lease by the Westinghouse Company, brought suit in the United States Circuit Court, on September 24, against the New York Life Insurance Company, of this city, alleging infringement of the Sawyer-Man patent for incandescent lamp carbons. The lamps in question were furnished by the Brush-Swan Company, and it is understood that this company will assume the defence of the suit. This is the same patent on which suit was brought against the McKeesport Electric Light Company, and defended by the Edison Company, and which was decided by Justice Bradley at Pittsburgh in 1888 adversely to the patent.

Reports of Companies.

WESTERN UNION TELEGRAPH CO.

THE Western Union Directors at their quarterly meeting declared a regular dividend of 1¼ per cent. The report for the quarter showed an estimated surplus of $680,207, with a total surplus of $12,097,948.

DIVIDENDS.

THE SOUTHERN MASSACHUSETTS TELEPHONE CO. has declared a semi-annual dividend of $2 a share.

THE WARE, MASSACHUSETTS, ELECTRIC LIGHT CO. has declared a semi-annual dividend of three per cent. on $20,000 stock.

THE EDISON GENERAL ELECTRIC CO. has declared its eighth quarterly dividend of two per cent.

Obituary.

CLARENCE E. LOOMIS.

WE regret to record the death of Mr. Clarence E. Loomis, a promising young mechanical and electrical engineer, who, after his graduation from Cornell in 1888, became connected with the Mather Electric Co. and the Thomson Electric Welding Co. About a year ago he went to Denver for the benefit of his health and to take charge of work on the West End Electric Railroad in that city. His death there is a grief to many friends all over the country.

CORRECTIONS IN MR. LEONARD'S ARTICLE.

WE beg to call the attention of our readers to two typographical errors which inadvertently crept into Mr. H. Ward Leonard's article appearing in our issue of Sept. 2, 1891.

In formula (7) the denominator of the second term should read 750 $V(E-V)$, instead of 750 $E(E-V)$.

Formula (18) should read as follows:

$$\frac{I}{100}\left(\frac{G\,E}{E-V}+\frac{D^2L}{750\,V(E-V)}\right)$$

THE RIGHT TO MANUFACTURE THE PORTER MOTOR.

WE are in receipt of the following letter from the Porter & Leavitt Electric Motor Co., of Providence, R. I., under date of Sept. 4, 1891.

"We understand that certain parties are manufacturing and offering for sale our electric motor under the name of 'Porter Standard Motor' without our license or consent. Mr. Harry H. Porter is the inventor and sole patentee of the Porter motor, and has granted to our firm, of which he is a member, the sole and exclusive right to manufacture and sell the same, and all persons are warned against using or selling the motor without authority from us, and we have instructed our counsel to commence proceedings to restrain the parties mentioned from making or selling the motor, and to recover damages against them for infringement of our patent.

"We will be obliged to you if you will insert this letter in THE ELECTRICAL ENGINEER, in order that the trade generally may have such knowledge as will enable them to avoid handling infringements of our patent, which will render them liable to pay damages."

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

Advertising is a great fertilizer in the business field.

THE RIES REGULATING SOCKET.

The Ries Regulating Socket.

THE accompanying illustration shows a novel socket for incandescent lamps on alternating circuits, by means of which the light may be turned up or down as readily as a gas jet, the current consumed being proportional to the brilliancy of the light. This was well demonstrated at the electrical exhibition held in connection with the Montreal Convention, where a lamp fitted with a Ries socket was shown with a small ammeter in circuit.

This device thus saves a large amount of current when the lamp is not required to be up to candle-power, and, it is claimed, saves the filament, as the current cannot be switched on suddenly, but has to pass all the gradations of the socket. The Ries Electric Specialty Co., of Baltimore, manufacture two sizes of this socket, one for lamps of from 16 to 25 c. p. and the other for those of from 32 to 50. There is no resistance used in the device, but the working of the socket depends upon a small choking coil.

EUREKA TEMPERED COPPER CO.

IT was a natural and proper thing that the Eureka Tempered Copper Co., of North East Pa., who, through the ingenuity of a Yankee, discovered the art of refining and tempering copper, should be awarded by the Committe on Science and Arts of the Franklin Institute the John Scott medal and premium by reason of this discovery. Their goods are now in universal demand for electrical purposes. The conductivity of the metal is increased by the tempering process. The castings are dense and free from pin holes, which has been deemed impossible with pure copper.

The company has increased its facilities for turning out goods promptly, their foundry room being 200 feet long and 50 feet wide, with twelve furnaces. The finishing departments are equipped with standard tools, and these departments filled with skilled workmen. The merits of their goods are attested by users in many high encomiums, the life being double under actual wear, and in some cases four fold.

REPORTS AND BIDS WANTED FOR SAN SALVADOR.

THE Compania de Alumbrado, of San Salvador, Central America, wishes to receive catalogues and price lists from electric lighting, electrical supply, wire companies, etc., addressed to their director, Mr. M. Cohn, who is about to call for proposals on another electric light plant. Mr. L. P. Pennypacker, C. E., is the chief engineer of the company.

THE CHAS. MUNSON BELTING CO.

WE are glad to publish the following received from the Munson Co.:

"Since the death of Charles Munson, the founder of this establishment, it has come to our notice that some of our competitors have set afloat certain false rumors that this company was going out of business. Although none of our friends placed any credence in these rumors, we deem it our duty to pronounce all such and similar rumors and statements concerning the future of this company utterly untrue and false. At the same time, we desire to inform our customers that this company will continue to exist and manufacture the same high grade of belting for which we have earned such a well-merited reputation in the past.

"THE CHARLES MUNSON BELTING CO.,

"E. A. GROETZINGER, Sec."

THE NEW "DICK & CHURCH" TANDEM COMPOUND ENGINE.

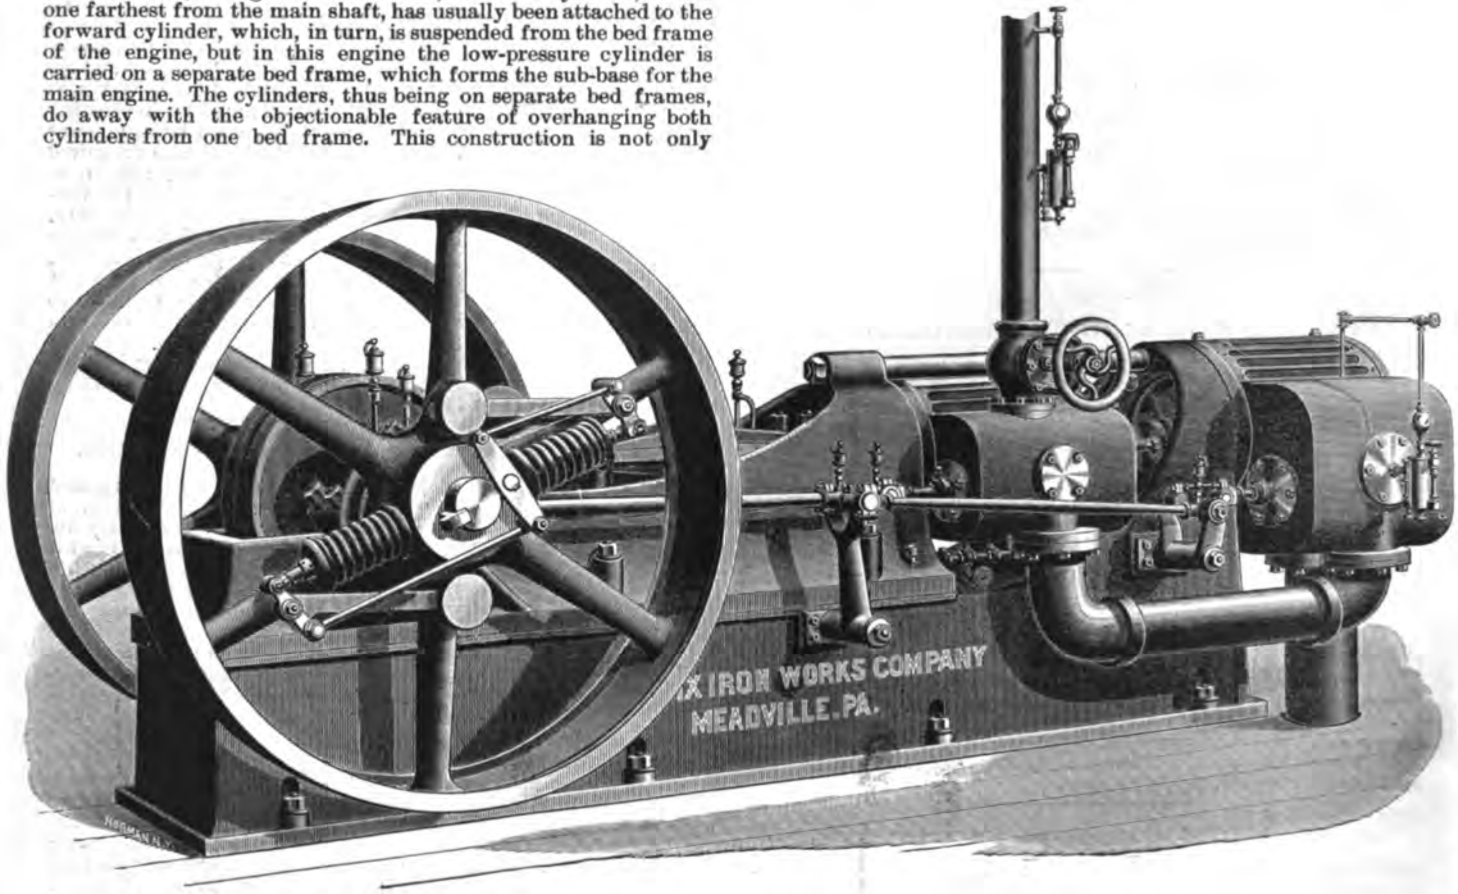
THE history of the modern development of electricity is that of the high-speed automatic cut-off engine, the latter having kept pace with the demands and improvements of the former. In the earlier stages of this development the question of economy was not so carefully considered as now, and, furthermore, it has not been considered that the single-valve type of engine could show such results as would justify its use except in small plants. The later developments have shown that this is not the case, and the peculiar adaptability of the high-speed engine for electrical purposes is now generally conceded. An excellent example of this type is the new "Dick & Church" tandem compound engine shown in the accompanying illustration, and as it embodies many new and valuable features, a description cannot fail to interest our readers.

Heretofore, in engines of this class, the rear cylinder, or the one farthest from the main shaft, has usually been attached to the forward cylinder, which, in turn, is suspended from the bed frame of the engine, but in this engine the low-pressure cylinder is carried on a separate bed frame, which forms the sub-base for the main engine. The cylinders, thus being on separate bed frames, do away with the objectionable feature of overhanging both cylinders from one bed frame. This construction is not only rigid, but allows each cylinder to expand independently of the other, always preserving the alignment; it also renders either cylinder easy of access without disturbing the other. The hoods which carry the overhanging cylinders are rigidly tied together by a rod which extends from one to the other, over the top of the high-pressure cylinder.

The valve gear is so constructed that the valves of both cylinders are controlled automatically by one governor; a new and valuable feature in engines of this class, and which gives practically a regular receiver pressure and proper distribution of load and temperatures between the two cylinders at all points of cut-off.

Special pains have been taken in designing this engine to have ample wearing surfaces, and to make the proportions such as to meet the requirements of extreme and varying loads, such as are met with in electric railway service. The oiling devices are thorough and ingenious, and particular care has been taken to prevent the throwing or waste of oil. The manufacturers have also lately brought out a centrifugal oiling device for the governor, which ensures the most perfect lubrication of all the working parts; in fact, every bearing on the engine can be thoroughly lubricated while the engine is in motion.

A test was lately made at Jamestown, N. Y., on one of these engines which gave most favorable results, considering the particular conditions under which the test was made. The engine is nominally rated at 150 h. p., but the greatest average load obtainable, at the time of the test, was less than 105 h. p. The engine, working under these conditions, developed a horse-power on 17½ lbs. of steam per horse-power per hour, and on an actual coal consumption of 2 lbs. per horse-power per hour, or 1.89 lbs. of combustible. The diameter of high-pressure cylinder was 11 inches; that of the low-pressure cylinder, 20 inches; stroke of both cylinders, 15 inches; revolutions per minute, 240, which gave a piston speed of 600 feet per minute. The boiler pressure carried during the test was 108 pounds. The coal used was an inferior grade of bituminous slack and nut mixed. The engine was charged with the entire cost of driving the condenser and boiler feed pump, and while the conditions of the load, etc., were very unfavorable for both the engine and the boiler, the results obtained were very gratifying to the manufacturers, and go to show that, with a proper load, the very highest duty may be expected. The test referred to was made by well-known experts. It is hoped to have a test made soon under conditions which will properly demonstrate what this engine is capable of doing.



NEW "DICK & CHURCH" TANDEM COMPOUND ENGINE.

The manufacturers have lately placed several of these engines, both of the condensing and non-condensing type, in electric street railway and lighting plants, and all are giving the very best results. In some cases duplicate orders have already been received. The well-known Phœnix Iron Works Company, of Meadville, Pa., are the builders of this engine. They have also branch offices at 15 Cortlandt street, New York, and 418 Chamber of Commerce Building, Chicago.

GREAT WESTERN ELECTRIC SUPPLY COMPANY.

THIS company, sole agents for the Sun arc lamp, are receiving many orders for their lamp. The sale is increasing wonderfully. This lamp is especially adapted for use in theatres, central stations, halls, stores, or in fact, any place where the ordinary arc lamp is undesirable. It gives a steady, clear, bright light, and for direct current incandescent circuits it is claimed to have no equal.

The Great Western Electric Supply Company, are also agents for the celebrated K. K. wire. A large amount of this was sold last month, and indications thus far this month point to even a larger sale than ever.

They have just issued a railway catalogue, one of the most elegant of its kind ever issued, and are also issuing two new catalogues of the house-goods department and the lighting department.

THE NEW FACTORY OF THE BERLIN IRON BRIDGE CO.

In enlarging their facilities to meet the demand that has arisen for their admirable products, the Berlin Iron Bridge Co. has had an excellent opportunity at its new factory, East Berlin, Conn., to illustrate and exemplify the principles. it has been preaching for factories and central stations. In fact, this new factory is built on the same lines as the Washington Electric Light Co.'s station, the Pawtucket Gas and Electric Light Co.'s plant, and others.

Owing to the limited amount of land available the company decided to build their new plant on the east side of the Mattabesset River, in the town of Cromwell, connected with the old plant by an iron bridge of sufficient capacity to not only carry the narrow-gauge cars which move their material about the premises, but also to carry an ordinary standard-gauge locomotive and loaded cars. The general plan of the company's new plant as now arranged comprises about three acres of land located along the line of the N. Y., N. H. & H. R. R. The main building is 400 feet long by 80 feet wide, constructed entirely of brick, iron and glass. The general features of the construction are shown in the interior view taken from a photograph.

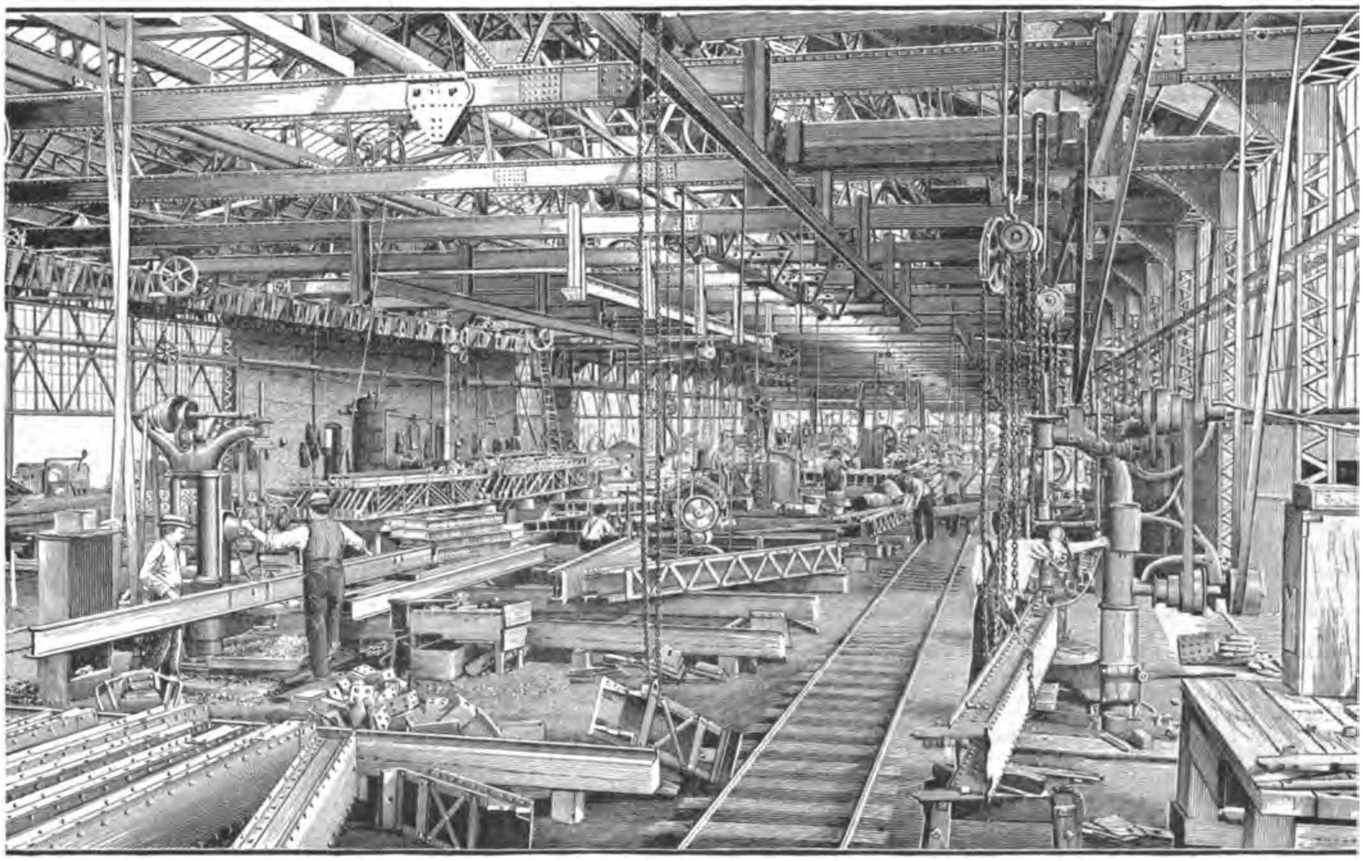
The sides of the building are made of glass for a distance of 10 feet from the eaves and below that are constructed of iron sliding-doors, so arranged that they can be opened and closed quickly in order to allow the material to enter through the sides of the building, when necessary, and in summer they can be removed entirely, thus very materially adding to the comfort of the employees. The roof trusses are of iron, each truss designed to carry 10,000 pounds at any point along the line of the lower chord.

The whole plant is connected together by standard-gauge tracks in such a way as to admit of the economical discharge of the raw material and the quick and economical loading of the finished product. The standard-gauge tracks extend the whole length of the plant on each side, and at the front of the building, from which the finished product is discharged, there are other spur tracks of standard gauge, one of which enters the building for a distance of 120 feet, so as to admit of iron being loaded inside of the building during wet weather.

All the tracks are controlled at the front of the building by two jib cranes so arranged as to work from a four-drum Mundy hoisting engine, so that one man can operate both cranes at the same time. The loading facilities are of such a nature that 10 cars can be loaded in an ordinary day of 10 hours.

The building itself is served by three lines of narrow-gauge tracks, one on each side and one through the centre, the tracks being connected at each end of the building by transfer-tables, the transfer-tables also connecting these tracks with the tracks in the yard. The raw material is distributed on each side of the main building direct from the cars, and after being sorted is moved by means of the narrow-gauge tracks into the north end of the building—the end shown on the left of the above illustration—where it is laid out from templates, trimmed at the shears and prepared for the punches.

The punches are all arranged with a "drop motion," so that the punch can drop down on the work, and thus the operator is able to find the centre mark and punch the hole exactly in the proper place. From the punches the material goes to the riveting machines, and from the riveters to the planers, drills, etc., and out at the south end of the shop, so that under no circumstances is there any occasion for work to pass except in one direction through the shop, the raw material coming in at one end and the finished product passing out at the other.



The New Factory of the Berlin Iron Bridge Co., East Berlin, Conn.

The building is heated by the well-known Sturtevant system of hot air, and all furnaces both under the boilers and for rivet heating are equipped with fuel air-burners so that crude petroleum is used entirely for fuel through the whole plant, although the boilers are so arranged that coal can be used if desired.

The plant is lighted by a neat Thomson-Houston plant of 500 incandescent lamps run from two machines.

The whole plant is constructed of iron with no wood-work about it, so that there is absolutely no risk from fire, and the company are not obliged to carry any insurance, as there is nothing about the building which can in any way take fire and burn. The construction being of iron, the cost of maintenance consisting only of painting, so that here we have a plant which seems to combine all the requisites of improved shop practice, as certainly with the improved facilities a shop of this kind ought to handle all classes of structural work with the least possible outlay for labor.

In a construction of this kind the cost of maintenance, repairs, insurance, and that class of expenses is reduced to an absolute minimum.

NEW YORK NOTES.

CHAS. A. SCHIEREN & Co. have recently taken an order from the Davenport Gas Co. for about 110 feet of 48-inch double belt, and necessary dynamo belts. They have also received an order from the South Bend Electric Co., South Bend, Ind., for about 110 feet of 48-inch double belt, 100 feet of 20-inch double belt, and all the necessary dynamo belts. They are now introducing their "Electric Leather Belt Stuffing," which closes the pores of the leather, and prevents further stretching.

MR. SIGMUND BERGMANN, the well-known electrical manufacturer, has just returned from a prolonged vacation in Europe, during which he has seen all that there is worth seeing in the newer electrical developments.

J. JONES & SON, of 602 and 604 West 22d street, New York, are very busy on a large order for time stamps.

MR. P. CLAUS has made arrangements with the Germania Electric Company, 53 State street, Boston, to build again the well-known "Continental" dynamo.

NEW ENGLAND NOTES.

THE ELECTRIC GAS LIGHTING COMPANY, of Boston, have made a decided hit with their new style of annunciator, called the "Hub" needle annunciator, designed more especially for the Southern and Western trade. This instrument is designed to take the place of their well-known "Tirrell" gravity drop annunciator; is a thoroughly reliable instrument, and is a first-class device of its kind, and is at the same time of extremely low cost. The drops are all mounted on a metal base, which cannot warp or shrink to throw the mechanism out of adjustment. The Porter motor is also forming a good attraction for their fall trade, and is evidently just what was wanted, being a low-price practical motor. The Samson battery is always a strong "stand-by," and this fall the sales have been something unprecedented. A large cargo of Samson carbons, direct from Paris, is at present only a few miles away from Boston harbor, and if the present high tides hold for a few days more, the ship may be expected to cross the bar safely, notwithstanding its heavy load. The Samson jar has been changed somewhat lately, for the sake of general convenience, the corners of the jar being more rounded and the carbons supported from the top of the jar, so that the carbons do not touch the bottom. This change, however, does not affect the perfect interchange of parts of the old style with the new.

THE EASTERN ELECTRICAL SUPPLY AND CONSTRUCTION COMPANY, of Boston, have recently been reorganized with a new board of directors. The new board is now composed of the following gentlemen: M. W. Brown, president; W. B. Ferguson, vice-president; A. Otis Smith, secretary and treasurer; and L. A. Dean and D. J. Hern. Mr. Ferguson, one of the new members, has for years been identified with electrical interests, and lately has become quite prominent in electrical railway circles. Mr. Hern, the other new member has been for years superintendent of the Mutual Union Telegraph, and is now general manager of the Mutual Union district messenger service. The capital of the company has been increased to $250,000. The business of the company is increasing every day, and they are now amongst the foremost of the electric supply houses in the East. They carry a very complete line of supplies for electric railway work, having made from the start a specialty of this branch of work.

ALBERT & J. M. ANDERSON, of Boston, have recently received orders for large numbers of their bell insulators made out of their new insulating material called "Ætna." They have also supplied the Buffalo Street Railway Company with about 5,000 pieces, and have done a large amount of work for the Brooklyn Street Railway Company. Ætna has been put to several severe tests, among which may be cited a crucial test, consisting of boiling a number of Ætna insulators in water for several hours. When cooled off the material was found to be just as good and as perfect in shape as before the test. The Messrs. Anderson are building at present some very handsome large switchboards of slate and marble, which are well worth seeing, their reputation for this class of work being very high both for electrical and mechanical excellence.

BEATEY & HODGSON, of 209 Washington street, Boston, who commenced a general electrical engineering business this summer, have met with exceedingly good success up to the present. During the summer months they have done a considerable amount of central station work. Mr. Beatey's long connection with the electrical business and thorough knowledge of electrical work make this firm much sought after for good advice and sound construction.

THE RUSSELL ELECTRIC COMPANY, of Boston, at their annual meeting last week in Portland, Me., elected the following gentlemen as directors for the ensuing year: A. W. Rounds, H. E. Chapman, A. N. Reynolds, H. W. Boyd, O. A. Willard, W. F. Robbins, F. H. Carpenter.

THE SAMSON CORDAGE WORKS, of Boston, have recently issued a neat little pamphlet relating to their special cords for hanging arc lamps, bell-cord couplings, trolley cords and various cords for other electrical purposes. This cord is specially waterproof and is well adapted for electrical work, and is well worthy of close investigation by all users of cord.

THE PROVIDENCE CONSTRUCTION COMPANY, of Providence, R. I., of which Mr. H. G. Wright is superintendent, has recently installed 170 Ball arc lights in the Palmer Mills, Three Rivers, Mass., and about 70 Ball arc lights in the Loraine Mills, Woodlawn, R. I.

WESTERN NOTES.

THE ELECTRIC MERCHANDISE COMPANY, Chicago, report for the last week the closing of contracts for the complete equipment of electric roads at Defiance, Ohio, and Negaunee and Ishpeming, Mich. The superiority of the equipment manufactured by this old and reliable company is recognized by both parent electric companies and construction companies, as well as practical street railway managers. They also report during the same period, orders for the Burton electric heater from roads in Amsterdam, N. Y.; Lake Superior, Wis.; Milwaukee, Wis.; Escanaba, Mich.; Defiance, Ohio; Dallas, Texas; Newton, Mass.; Champaign, Ill.; Helena, Mon. and Ann Harbor, Mich.

THE CENTRAL ELECTRIC COMPANY have just completed arrangements for the exclusive handling of the Gladiator Dry Battery. This arrangement was arrived at only after the most exhaustive tests of the Gladiator, and the Central people are confident that they have the very best dry battery now on the market. A series of curve cards showing the characteristics of this battery will shortly appear in these columns.

MR. W. H. APPELGATE 260 S. Clark street, Chicago, has invented a novel form of underground conduit for electric street railways which possesses some important improvements over the ordinary forms. The problem of high insulation, under all conditions, and hence the obviating of leakage, has been worked out in a very thorough and successful manner. The main current is carried in an insulated cable, connection to which is made by the car automatically at certain points by a positive mechanical action. Neither sectional conductors nor electromagnets are employed in this system, and it is exceedingly cheap to install, and can be conveniently put in existing cable conduits. Mr. Appelgate is showing a working model at the Exposition Building.

MR. CHAS. G. ARMSTRONG the electrical expert of the Auditorium Tower, has drawn up the specifications for the plant to be put into the Central Indiana Hospital for the Insane. They cover both the arc and incandescent lights and the needed steam outlet, the whole making a good-sized isolated plant. The bids are to be closed Oct. 9th, and the work will be pushed during the following month. Mr. Armstrong will probably have a chance to introduce a number of his novel devices in connection with this plant.

MR. LUTHER STIERINGER, the well-known authority on electrical illuminations in exhibitions, is in Chicago consulting with the exhibition authorities and with Mr. Frederick Sargent, the electrical engineer of the construction department. Mr. Stieringer is one of the advising committee of electricians specially appointed by the committee on illumination; Prof. F. B. Badt and Mr. Paul Lemaire being the other members.

THE CHAS. MUNSON BELTING CO. are furnishing a goodly number of belts for electric railways and lighting plants. The very large belt, recently noticed in our columns, manufactured by this concern for street railway work in St. Louis, is completed and ready to be placed on the pulleys.

THE SUNBEAM INCANDESCENT LAMP CO. are running their factory day and night and even then find it hard work to keep pace with their orders. The Sunbeam lamp has an enviable reputation for long life with full candle-power, with a constant and small absorption of current.

MR. WILLIAM HOOD, 239 La Salle street, is having a brisk run with the Jewel incandescent lamps, which are giving eminent satisfaction in the numerous plants using them. Mr. Hood is also selling quite a number of storage-battery outfits for various work.

MR. GEORGE CUTTER, 333 The Rookery, is selling a large number of his magnetic cut-outs. They are manufactured in various sizes and different styles for railway motors and stationary motors, and with lightning-arrester attachment.

☞ Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Miscellaneous, etc., will be found in the advertising pages.

THE

Electrical Engineer.

VOL. XII. OCTOBER 7, 1891. No. 179.

REMINISCENCES OF JOHN H. B. LATROBE.

BY

Franklin Leonard Pope

John H. B. Latrobe.

JOHN H. B. LATROBE, lawyer, scholar, historian, engineer and inventor, died at his home in Baltimore on September 11, aged 89 years. His father, an eminent architect, was the original designer of the Capitol at Washington; his mother's family were closely related to the distinguished astronomer Rittenhouse. Mr. Latrobe was the legal and technical counselor of the elder Winans during the work of building and organizing the Baltimore and Ohio railroad, the earliest trunk line from the Atlantic States to the Ohio Valley. When Morse finally reached the point of the realization of his hopes of a commercial electric telegraph, and the Congressional appropriation of $30,000 had been placed at his disposal, his difficulties were, in fact, but scarcely begun. The then president of the Baltimore & Ohio, the only railway line entering the capital, was the Hon. Louis McLane, a man of wide experience, and one of the foremost statesmen of his day. To him Morse appealed for the grant of a right of way for the construction of his experimental line from Washington to Baltimore. The proposed undertaking, so utterly without precedent, and so seemingly chimerical, perplexed the worthy president not a little. Aware of the incomparable aptitude of Latrobe in every emergency, McLane finally referred the troublesome matter to him. "While President McLane and myself were yet speaking of the matter"—once said Mr. Latrobe—"Mr. Morse made his appearance, and when Mr. McLane introduced me, he referred to the fact that, as I had been educated at West Point, I might perhaps the more readily understand the scientific bearings of the invention. The president's office being no place for a prolonged conversation, it was agreed that Mr. Morse should take tea at my home, when we would go over the whole subject. We met accordingly, and it was late in the night before we parted. Mr. Morse went over the history of his invention in detail, from the beginning, with an interest and enthusiasm that had survived the wearying toil of an application to Congress, and with the aid of diagrams, drawn on the instant, made me master of the matter, and wrote for me the telegraphic alphabet which is still in use over the world. Not a small part of what Mr. Morse said on this occasion had reference to the future of his invention—its influence upon communities and individuals—and I remember regarding, as the wild speculation of an active imagination, what he prophesied in this connection, and which I have lived to see more than realized. Of course my first visit next morning was to Mr. McLane to make my report. By this time I had become as enthusiastic almost as Morse himself, and repeating what had passed between us, I soon saw that Mr. McLane was becoming as eager for the construction of the telegraph to Washington as even Mr. Morse could have desired. He entered warmly into the spirit of the thing, and laughed heartily, if not incredulously, when I said to him that, although he had occupied exalted positions as the representative of his country abroad, and of his party at home, his name would be forgotten, while that of Morse would never cease to be remembered with gratitude and praise."

Accordingly at the next monthly meeting of the directors of the road, on April 5, 1843, the formal application of Professor Morse for the privilege of laying his conductors was presented, accompanied with a communication from Chief Engineer B. H. Latrobe, strongly recommending the project as one worthy of every encouragement. After a protracted discussion the following cautiously worded resolution was passed by the board by a nearly unanimous vote:

Resolved, That the President be authorized to afford to Mr. Morse such facilities as may be requisite to give his invention a proper trial upon the Washington road; provided, in his opinion and that of the engineer, it can be done without injury to the road, and without embarrassment to the operations of the company, and provided Mr. Morse will concede to the company the use of the telegraph upon the road without expense, and reserving the right of discontinuing the use, if upon experiment, it should prove in any manner injurious."

Until quite recently Mr. Latrobe, notwithstanding his advanced age, remained in full possession of his faculties, and had acted as counsel in many of the most important patent causes within the past few years, notably those in which the Baltimore & Ohio company were in any way interested. He also bore a prominent part in the litigation over Edison's quadruplex patents, some years since. He was a man of noble and striking personal presence, and of extraordinary and varied ability in many directions. The commercial success of the electric telegraph in the United States has certainly been indebted in no small measure to his early, intelligent and persistent championship of its cause at a critical period in its history.

EARTH CURRENTS IN NEW YORK CITY.

BY

E. W. Stevenson.

THE phenomenon of earth currents in submarine or subterranean cable is explained by all electrical authorities as being the result of different potentials of the earth at different places along the line. Barometric pressure and temperature also have something to do with it; thus the longer the line, the greater the climatic difference of conditions, with a consequent increase in intensity of earth currents.

These currents may be electro-positive or electro-negative. They may be (1) constant, either positive or negative; or (2) they may vary in intensity, either positive or negative; or (3) again they may vary in quick succession from electro-positive to electro-negative, that is to say, not regularly, but spasmodically. Thus, in taking readings on a Thomson reflecting galvanometer, such as is used by electricians in testing high resistances, the deflection, case (1), may remain steadily at 150 divisions +, or 150 —; or again in case (2), it may make a series of jumps from zero to + 10, + 50, + 60, + 100; then fall away again thus, + 30, + 25; then rise to + 40; then perhaps drop to + 5, and so on.

Similarly the currents may have like action on the other side of zero; making all the readings electro-negative. In case (3) where the currents change from electro-positive to electro-negative, I have seen the spot rush rapidly from side to side, producing readings something like this: 10 + to 50 —; 60 + to 20 —; 200 + to 320 —; 10 + to 400 —; 650 + to 45 —; varying sometimes so rapidly that it defies all but the most experienced eye to catch anything like a reading.

With submarine telegraph cables, I have known instances when all communication has been interrupted, and on several occasions, while I was assistant electrician on certain Atlantic cables, I have had to report that I could get no test on account of the intensity of the earth currents.

With reference to earth currents in a city like New York, the reason for their existence of course could not be ascribed to climatic differences of condition of different parts of the line; as, although a circuit may be 20 miles long or more, the area in which such a circuit lies would be so small as to be unaffected by such differences; therefore some other cause must be looked for. It is a fact, although not generally known, that on account of the enormous amount of current generated for electric light, power, etc., for use in the city, the leakage is proportionately large; for instance, if one side of an incandescent circuit is attached to a lamp, and the other side of the lamp grounded, enough current can be obtained to light the lamp. Any one using a telephone with an earth return can hear the peculiar humming noise with short, sharp snaps occasionally. This noise is generally put down to induction, and probably part of it is due to that cause; but a good deal is due to earth currents. Now it can be readily seen what effect these currents would have upon the delicate mirror of a Thomson galvanometer, and from the varying potential of currents in different parts of the city, owing to more or less leakage, would be obtained an effect similar to the difference of barometric conditions mentioned before.

To illustrate the accuracy of this statement, a cable company had to lay a highly insulated wire as an earth return from their office to the cable hut, and there soldered on to the sheathing of the cable running into the sea, so as to eliminate the disturbance due to earth currents in New York city. Since electric cars have been running parallel to the line, the operators in the office have had a good deal of bother with the signals on the recorder, and these were found to be simultaneous with the stopping and starting of the cars.

With reference to earth currents on electric light cables in this city, circuits running from the 29th street station of the United Electric Light and Power Company always contain more than circuits running from any other of this company's stations, and when testing from one end only, the maximum deflection is obtained. By taking both ends, however, it is considerably lessened (Herbert Taylor's method), generally about one quarter. The reason for these excessive currents is probably due to the majority of these circuits running together very closely for ¾ mile.

A peculiarity I have noticed at the Brush station, in Elizabeth street, is that, whereas circuits running down Elizabeth street produce electro-positive currents, circuits running around Prince, and down the Bowery, produce electro-negative currents, readings being more erratic on Elizabeth street.

Authorities on cable-testing briefly mention the subject of earth currents, and dismiss it by stating the cause, but information is very meagre on methods of dealing with it when it occurs in actual testing on submerged or underground cables. Culley has a chapter on the causes, but nothing about illumination. Kempe briefly states that Mr. Herbert Taylor does away with it by taking both ends of the cable to the terminal pole, as before mentioned. This method Mr. Taylor introduced at the testing-room of the Telegraph Construction and Maintenance Company, of London, where the writer was at one time engaged, and dealt only with cables coiled up in tanks, and again he was testing with cables measuring about 1,200 megohms per mile. Munro and Jamieson's small pocket-book has a short paragraph on page 147, Note 3, latter part, which says: "It is usual to add to or subtract from deflections, these earth readings according as they may be against, or with, the battery current." Preece and Sivewright advise taking the positive deflection x, then take the negative y; the reading will be $\frac{x+y}{2}$; that is the mean of the two. This might fail to give an accurate result in the case of an inferior core, as some of these produce a current of themselves which is due neither to earth current nor induction, but from an electrolytic action between the conductor and whatever is used as a ground; in fact, constituting a regular battery combination.

The method I have always used has been to note the earth current before testing, and in the case of testing from a central station, I have frequently got some one to put down the readings as I called them out, when the currents were very erratic, such as + 50, — 10, + 40, + 60, + 90, — 120, — 130, — 5, 0, + 6. Occasionally these will be very rapid and jerky, as I noted in case (3) above; then I add up all the positives, subtract the sum of the negatives and divide the result by the number of readings taken. This result may be negative or positive according to which predominates. In the same way I take my reading when the positive pole of the battery is applied to the cable under test, and again with the opposite pole of the battery to cable, make my additions or subtractions as the case may be. For instance, by taking the earth currents quoted above, the result = — 1.9 divisions, which is nearly zero. By this method I find that my + readings and — readings generally come out about equal. Of course, sometimes an earth current may give + 250 or + 2,500, although the latter case is generally when testing with lamps in circuit, and the insulation is about down to two or three megohms total, giving earth currents the best possible chance of getting in. In these cases, should the reading be + it is subtracted from the + reading of the leakage on the cable, and added to the — reading. Should the currents be —, the reverse is then done. If one has not had much experience on subway wires, all these disturbances might make him suspect that the cable was faulty, but I have known short lengths of even a mile testing up to 600 or 700 megohms show very erratic earth currents; and again I have had cable very poorly insulated show no disturbance at all.

In testing with lamps or converters in circuit, there is always a great deal of leakage, and if an incandescent and an arc circuit run into the same building, sometimes through the same pipe, the converters and cut-out box may be near each other, and the very slightest trace of moisture, although the resistance may be 1,000 megohms, will tend to have considerable effect on the instrument. Multiply this effect 50 times, as is the case with 50 converters in circuit, and that effect will assume a like increase, especially when one takes into consideration the number of times a circuit runs parallel with many others, and the number of times it crosses and recrosses many more.

In conclusion, I do not attempt to prove that excessive earth currents do not show a fault in the cable, but I will maintain that such an effect does not indicate that the cable is faulty.

ELECTRIC MINING IN SOUTH AFRICA.

A PROPOSAL has been made to use electric transmission of power at the Eureka Mine of the Victory Hill Consolidated Mining Company, South Africa. Both mine and mill would be furnished with all the light and power necessary for working. It is proposed to lay down a 100 h. p. plant, 60 h. p. of which would be delivered at the power station at the mine. The power would be obtained from turbines placed near the junction of the Golden Valley stream with the Kaap River. Water enough for the plates of a 25-stamp mill would be available.

THE LOCALIZATION AND REMEDY OF TROUBLES IN DYNAMOS OR MOTORS.—IV.

BY

Francis B. Crocker and S. S. Wheeler.

HEATING OF BEARINGS.

1. Cause.—*Lack of oil.*

Symptom.—Shaft and bearing look dry. Shaft usually turns stiffly. Oil cup or reservoir empty.

REMEDY.—Supply oil, and also make sure that oil passages as well as feeding or self-oiling devices work freely, and that the oil cannot leak out. This last fault sometimes causes oil to fail sooner than attendant expects.

---

2. Cause.—*Grit or other foreign matter in bearings.*

Symptom.—Best detected by removing shaft or bearing and examining both. Any grit can of course easily be felt, and will also scratch the shaft.

FIG. 5.—SHAFT ROUGH OR CUT.

REMEDY.—Remove shaft or bearing, clean both very carefully and see that no grit can get in. Place motor in dustless place or box it in.

---

3. Cause.—*Shaft rough or cut.* (Fig. 5.)

Symptom.—Shaft will show grooves or roughness, and will probably revolve stiffly.

REMEDY.—Turn shaft in lathe or smoothe with fine file and see that bearing is smooth.

---

4. Cause.—*Shaft and bearing fit too tight.*

Symptom.—Shaft hard to revolve by hand.

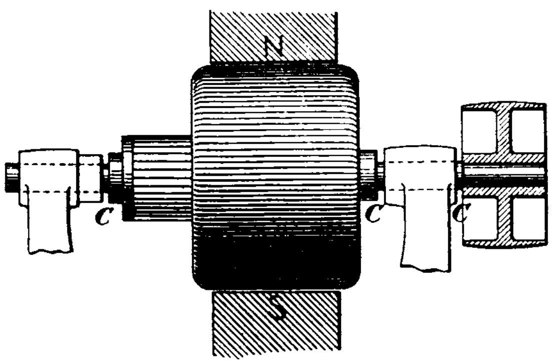


FIG. 6.—ARMATURE WITH GOOD CLEARANCE AT C C.

REMEDY.—Turn or file down shaft in lathe, or scrape or ream out bearings.

---

5. Cause.—*Shaft "sprung" or bent.*

Symptom.—Shaft hard to revolve and usually sticks much more in one part of revolution than in another.

REMEDY.—It is almost impossible to straighten a bent shaft. It might be turned true but probably a new shaft will be necessary.

6. Cause.—*Bearings out of line.*

Symptom.—Shaft hard to revolve, but is much relieved by loosening screws which hold bearings in place. Bearing sometimes moves perceptibly when loosened, even when motor is not running, and belt is off.

REMEDY.—Loosen by partly unscrewing bolts or screws holding bearing in place, and find its easy and true position, which may either require it to be moved sideways or

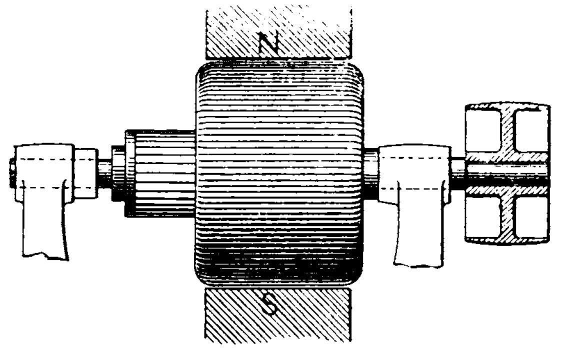

FIG. 7.—ARMATURE FORCED AGAINST BEARING.

up and down; then file the screw holes in the bearings or raise or lower the bearings, as may be necessary, to make them occupy right position when screws are tightened.

---

7. Cause.—*Thrust or pressure of pulley collar or shoulder on shaft against one or both of the bearings.* (Figs. 6 and 7.)

Symptom.—Move shaft, while revolving, back and forth with the finger or a stick applied to the end, and note

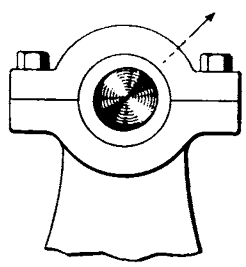

FIG. 8.—BEARING WORN ELLIPTICAL.

if collar or shoulder tends to be pushed or drawn against either bearing. A dynamo or motor shaft should always be capable of moving freely back and forth a sixteenth or eighth of an inch to make commutator and bearings wear smooth (See Sparking, No. 3). If this does not occur it should be relieved in one of the following ways:

REMEDY.—Line up the belt, shift collar or pulley, turn off shoulder on shaft or file off bearing until the shoulder does not touch when running or until pressure is relieved.

---

8. Cause.—*Too great load or strain on the belt.*

Symptom.—Great tension on belt. In this case pulley bearing will probably be very much hotter than the other and also worn elliptical, as indicated in Fig. 8 in which case the shaft may be shaken in the bearing in the direction of the belt pull, provided the machine has been running long enough to wear the bearings.

REMEDY.—Reduce load or belt tension, or use larger pulleys and lighter belt or even gearing so as to relieve side strain on shaft.

---

9. Cause.—*Armature too near one pole-piece, producing much greater magnetic attraction on nearer side.*

Symptom.—Examine the clearance of armature and see if it is uniform on all sides. Charge and discharge the field magnet, the armature being disconnected (by putting paper under one brush), and see if armature seems to be drawn to one side and turns very much less easily when field is magnetized.

REMEDY.—This fault is due to an inherent defect in the original construction, which is difficult to correct, but in cases of necessity the armature can be centered exactly in the field by moving the bearings, which may be done by carefully filing the holes through which the screws pass that hold the bearings in place, or the pole-piece may be filed away where it is too near the armature. It is sometimes possible to spring the pole-piece further away from the armature, but it is difficult and dangerous to attempt.

DEFECTIVE INCANDESCENT LAMPS.

BY

Otis K. Stuart

SAID the manager of a central station to me, not long ago: "I don't know what we are going to do. This incandescent lamp problem is a serious matter. This company spent over $800 last year merely experimenting with different lamps!"

Now, considering the fact that his plant operated only 5,600 lamps, this amount was large and, doubtless, quite exceptional; but the experience of lamp salesmen proves that a large sum of money is annually spent by the various central station companies of the country for the mere "testing" of different makes of lamps. If this expenditure really proved of any permanent or substantial benefit to the consumer, or to the central station itself, there might be good warrant for it; but on it goes month after month, year after year, while the stations still use the lamps of a number of makers, and the station managers are as much in the dark as ever.

A few weeks ago I asked the superintendent of a large station what kind of a lamp he wanted. His answer was, "I want the best lamp that's made!" Now, there are a good many "best" lamps, and not every lamp manufacturer makes the best of every variety, though nearly all of them make nearly every variety of lamp. One maker has high efficiency, with good average life, in the higher voltages, while his low-volt lamps are comparatively poor. He pays special attention to the former, and turns out the latter almost because he must; or his head lamp-maker may be a "crank" on the higher-volt lamps; or *vice versa.* Another manufacturer makes lamps giving very long life and poor efficiency—for the two always go together—and his efficient lamps may not last 300 hours on an average. The incandescent lamp at its best is a somewhat uncertain product, and the fact is that in this line "a man cannot have the penny and the cake, too!" It should be pretty well known now that a 3-watt lamp will not last 2,000 hours, or even very near it.

But the decided expression quoted from the station superintendent was not an exceptional, though it was a random, shot. Let us be frank. Not all central station men, even, know exactly what they do want. And sometimes they are satisfied that what they were sure they *did* want is not what they want in the future. And it *is* rather difficult for the lamp manufacturer to know under what conditions his product has been used. So the manufacturer is forced to bear a considerable part of this expense of "testing," and the question "What is a defective lamp?" frequently remains unsolved, to his loss and his customers' dissatisfaction.

It may be stated in all fairness that nearly every ill with which electric dynamos, and the line and other apparatus, too, for that matter, are afflicted has its bad effect upon the lamps. A "ground," the sudden throwing on and off of loads (especially on motor circuits), changes in speed of generators, bad regulation of transformers, and the ignorance of station men and lamp users, are not the only causes which decrease the life and light of incandescents; yet the manufacturer is often the loser, in the form of defective lamps, from just these very causes. If a lamp burns out within from one second to one hundred hours, it is often classed as "defective," though the voltage of the circuit may be from 20 to 2 volts too high. If a filament burns "yellow" the lamp is said to be defective, though the eye is a notoriously bad photometer, and the voltage may be too low. This question of the voltage of a circuit is so puzzling sometimes that a man might believe the structure of the wire changes with the seasons or the weather! How much the incompetence and dishonesty of constructing engineers has to do with the deplorable condition of hundreds of circuits it would be interesting to know. It was the A B C class, I think, in which we learned the law that a number 10 wire will not carry a thousand amperes with the same "drop" as a number 9!

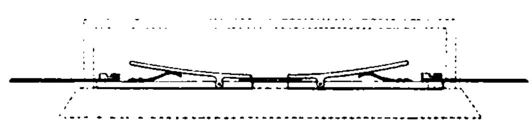
Then, plaster of paris will not often stand a tensile strain of 10 tons to the square inch, though one might be pardoned for thinking so after seeing it resist the pull of lineman Hercules in his endeavor to force lamp from socket sometimes. And glass is brittle, especially very good glass.

The sealing of a carbon filament to platinum wires is a delicate operation, and the joint is "sensitive," no matter how tough the filament itself may be. Incandescent lamps can never be used successfully as base-balls; but they make better plating apparatus, only the color of the "plate" is suggestive; and if lamps do blacken finally, nature must be blamed for not giving us a better substance for filaments than carbon, or man for not finding one.

A reputable lamp manufacturer is certainly as much interested in making the best possible product as the central station manager is in using it, and with the great improvements which have been made within the past three years in incandescent lamp-testing apparatus, it is not a difficult or very expensive operation for him to know accurately the condition of the lamps he is shipping. If central station managers would always accurately state just what sort of lamp they want, and would always be sure beforehand that what they think they want is the best for their purpose, they and the manufacturer would be much better satisfied, and richer by (in the case mentioned above) about $800.00 + a year.

THE HOWELL ELECTRIC SAFETY CUT-OUT.

CONSIDERABLE difficulty has been experienced in the protection of electrical instruments wound with fine wire,



HOWELL ELECTRIC SAFETY CUT-OUT.

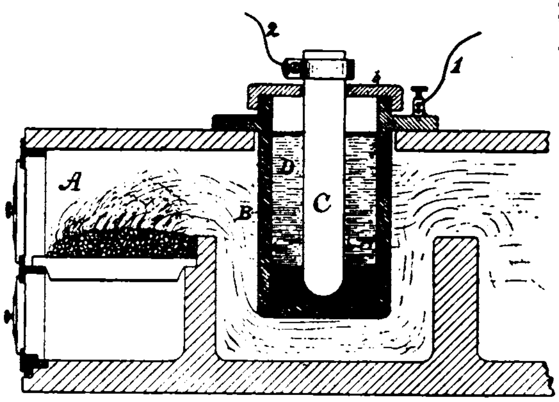
such as comparative indicators, telephones, telegraphic apparatus, etc., since with metal wire of sizes which can be practically made and handled, the instruments will frequently be destroyed or injured before the safety-catch wire is fused, due to the fact that the heat is conserved in the closely-compacted coils.

With a view to correcting this trouble, Mr. John W. Howell, of Newark, N. J., employs for a cut-out a material which, while it is a conductor of electricity, has a high specific resistance compared with the metals, and which is destroyed by chemical action, as distinguished from fusion, when an abnormally large current passes through it.

For this purpose Mr. Howell employs a carbon filament, held in spring clamps, as shown in the accompanying illustration. A cut-out of this character, by reason of the high specific resistance of the material, can be constructed of a large size, compared with one of metal which would respond to the same current. It has been found that these cut-outs can easily be made to open the circuit when a current of one-tenth of an ampere, or even less, is flowing, and still be of an entirely practical size for handling.

EDISON'S DIRECT METHOD OF GENERATING ELECTRICITY FROM CARBON.

A METHOD of generation of electricity directly from carbonaceous material, without the loss caused by the double conversion of heat into mechanical, and thence into electrical, energy, is described in a patent recently issued to Mr. Edison, the application for which was filed May 26, 1882. The method consists in employing carbonaceous material for the soluble electrode of a generating-cell, and using as an active agent oxides, salts, or compounds of elements, by the decomposition of which the carbonaceous material will be acted upon at high temperatures. Heat is applied externally, and the negative electrode of the cell is made of a substance which in the presence of carbon at high temperatures is not attacked to any great extent by the active material employed.



APPARATUS FOR THE DIRECT GENERATION OF ELECTRICITY FROM CARBON.

The accompanying illustration shows the apparatus employed. As will be seen, A represents a furnace for heating the iron melting-pot B, and C is a cylinder of carbonaceous material resting on the fire-clay block *a*. The cover of the pot is also of fire-clay. The circuit connections 1 2 are made with the pot and carbon cylinder.

The heat of the furnace fuses the oxide at the same time that it raises the carbon to a temperature at which it combines rapidly with oxygen. A reduction of the oxide takes place, the oxygen combining with the carbon and forming carbon monoxide, which passes off and may be conducted to the combustion-chamber of the furnace and used for fuel, it being burned to carbonic acid, while the metal is carried to the other electrode and deposited upon the walls of the containing vessel. During the oxidation of the carbon an electric current flows through the circuit of the cell. The product of the reduction of the oxide may be reoxidized and used over again as the active agent of the cell.

ELECTRIC TROLLEY RODS IN EUROPE.

CONSIDERABLE difficulty has been experienced in designing a trolley rod which shall bend up and down, to the right or left, without leaving contact, and at the same time be cheap and simple. Many scores of designs of various principles have been made, but nothing simpler or cheaper, as far as Europe goes, has been proposed than that used on the Schuckert overhead line at the Frankfort Exhibition, which consists simply of an ordinary coiled conical spring (such as is made by slitting a metal tube helically), one end fixed to the roof of the car, and the other bearing a socket for the trolley rod. This arrangement has no need of adjustments, is perfectly flexible, and gives no trouble whatever.

ELEMENTARY GEOMETRICAL THEORY OF THE ALTERNATE-CURRENT TRANSFORMER.—XVI.

BY

Chas. Steinmetz.

WE must leave it to the reader, to go over the changes of the electric and magnetic quantities of the transformer, which are caused by changes of its constants, r_1, r, n n_1;

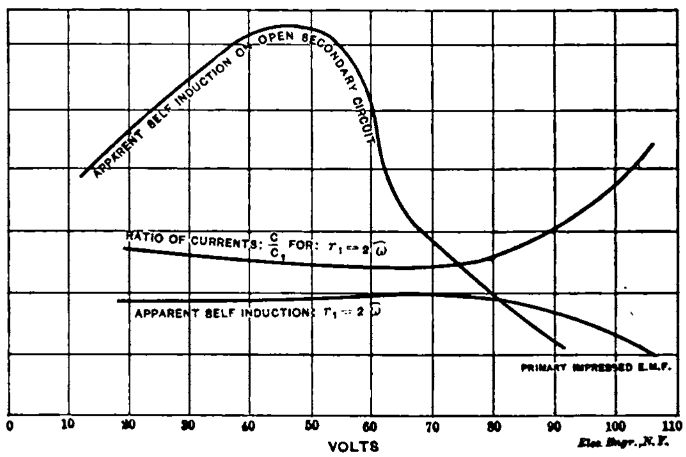


FIG. 29.

N, etc., in the same way as we did—in the simple diagram—in chapter VI., but now with due consideration of the variability of magnetic susceptibility, and give only in Fig. 27 the diagram of the transformer for the secondary resistance, $r_1 = 2$ ohms and in Fig. 28 the diagram of the transformer for open secondary circuit, with the curves of the electric quantities depending upon varying primary impressed E. M. F.

Table II.—Iron-clad transformer, open secondary circuit, $r_1 = \infty$.

Resulting M. M. F., in ampere-turns.	Primary M. M. F. — impressed M. M. F., in ampere-turns.	Resulting, or heating primary E. M. F., in volts.	Impressed primary E. M. F., in volts.	Primary current, in amperes.	Ratio of transformation of E. M. F.'s.	Apparent self induction.		
F	$L^\infty - K$	E^∞	E_0^∞	C^∞	$\frac{E_0^\infty}{E_i}$	$\frac{E_0^\infty}{C^\infty}$	Secondary M. M. F. M. M. F. of eddy-cur-	The same as in Table I.

1520	1540	15.4	79.1	38.5	1.08	2.05	Induced E. M. F.	
3100	3140	31.4	91.0	78.5	1.12	1.16	Magnetization.	

From these Figs. 27 and 28, we derived the values of transformer quantities, corresponding to different resulting M. M. F's, which are given in Tables I. and II. I. for secondary resistance, $r_1 = 2$ ohms, and II. for open secondary circuit.

The ratio of the currents, $\frac{C}{C_1}$ for $r_1 = 2$ ohms, and the apparent self-induction, or the impedance of the primary circuit, for the secondary resistance, $r_1 = 2$ ohms as well as for open secondary circuit, $\frac{E_0}{C}$ and $\frac{E_0^\infty}{C^\infty}$, are shown separately in Fig. 29, as functions of the primary impressed E. M. F., E_0, to show by ocular demonstration, the necessity of considering the variability of magnetic susceptibility.

For, assuming the magnetic susceptibility μ as constant, the three curves in Fig. 29, $\frac{C}{C_1}$, $\frac{E_0}{C}$, $\frac{E_0^\infty}{C^\infty}$, are assumed as three straight horizontal lines.

In reality, in the small range produced in Fig. 29, the different values vary considerably; especially the impedance of the primary coil goes down from 6.42 to 1.16; that is to about one-sixth its maximum value, and decreases for higher impressed E. M. F. still faster, so that for higher impressed E. M. F. the transformer acts as an entire dead short-circuit of apparently no self-induction. This brings up another important point, how far—supposing the insulation will stand it—the impressed primary E. M. F. can be raised, to produce an increase of the induced secondary E. M. F.

As seen from Fig. 29, so soon as the primary impressed E. M. F. oversteps 50 volts, for open circuit, the impedance goes rapidly down, and the primary current increases quite out of proportion to the impressed E. M. F., while the secondary E. M. F. increases only slowly. Near 80 volts the impedance of open circuit goes down even below that of the loaded transformer, and the paradox appears, that the *primary current for open circuit, the so-called "leakage-current," is larger than the primary-current of the loaded transformer—the impressed* E. M. F. *being the same*, so that, by taking current off from the secondary circuit, we actually *decrease* the primary current.

In Table I., the primary current, $C = 58.1$ amperes, corresponds to the impressed E. M. F., $E_0 = 92.4$ volts; in Table II., the impressed E. M. F., $E_0^\infty = 91.0$ volts, corresponds to the primary current, $C^\infty = 78.5$ amperes, and hence, to $E_0^\infty = 92.4$ volts corresponds $C^\infty = 87$ amperes.

Therefore in this transformer at open circuit, a primary E. M. F., $E_0^\infty = 15.4$ causes a primary current, $C^\infty = 3.6$ amperes; 46.9 causes a primary current 7.3 amperes, hence, to double the current we have to increase the E. M. F. threefold. $E_0^\infty = 92.4$ causes a primary current, $C^\infty = 87$ amperes. Doubling now the impressed E. M. F., the current is increased 12 fold. But, taking off now from the secondary circuit, 36.9 amperes, we *decrease* the primary current from 87 to 58.1 amperes.

The reason for this phenomenon is simply, that, by taking secondary current off, we decrease by the secondary counter M. M. F. the resulting M. M. F., and thereby the magnetization, from high saturation to beginning saturation. This curious phenomenon is one of the many paradoxes due to magnetic saturation, into which I cannot enter more deeply now.

Table I.—Iron-clad transformer, secondary resistance, $r_1 = 2$ ohms.

Resulting M. M. F., in ampere-turns.	Secondary M. M. F., in ampere-turns.	Primary M. M. F., in ampere-turns.	M. M. F. of eddy-currents, in ampere-turns.	Ideal M. M. F. of hysteresis, in ampere-turns.	Ideal M. M. F. of the loss of energy in the iron, in ampere-turns.	Impressed M. M. F., in ampere-turns.	Induced E. M. F. in volts.	Resulting, or heating primary E. M. F., in volts. THE USE OF THE MAGNETO IN TESTING.

BY

Chas. Hewitt.

In reading Mr. Ayer's paper read before the National Electric Light Association at Montreal, I notice that he permits the use of the magneto in testing his arc light circuits. The writer is well aware that this practice is quite general in central stations, and submits the following in order to show how useless such tests may be:

Some three years ago I had occasion to place an arc light cable in a creosoted wooden box underground. This cable had an ordinary okonite insulation covered with braid, but no lead or other covering was used. The cable was made under strong guarantees, and I was anxious to see what effect the creosoted wood had upon the insulation. I therefore made tests about every two or three weeks with a galvanometer and bridge, measuring the resistance accurately.

In making one of these tests I noticed a marked decrease in the resistance, and supposed at once that some fault had developed in the cable, but on further investigation I found that my assistant had not disconnected the dynamo from the cable, and in measuring again I found the fault was in the dynamo and not in the cable. Copper dust had accumulated on certain parts of the machines, and was forming an incipient ground. Now, these circuits were regularly tested twice a day with a magneto, and yet this incipient ground was not revealed in the slightest, while it was readily detected with a galvanometer. The dynamo attendant afterwards told me that he could feel a slight shock from the machine when adjusting brushes.

A more recent occurrence happened in Buffalo about three weeks ago, when the writer had occasion to test some electric cars. A certain car had been reported frequently by the motor man as having a ground on the switch. The switch was of the ordinary Sprague type. It had been tested several times by the expert in charge with the magneto, and not the slightest kind of a ring could be obtained. I tried the magneto myself upon the switch, testing every portion of it thoroughly, and could not get a quiver in the bell hammer; I then tried the galvanometer and bridge, using 15 cells of a Barrett battery. The fault was readily located, and was found to be due to the accumulation of some copper dust which was readily removed. Here, then, is a case where a man could feel the shock with 500 volts pressure, and yet absolutely no ring could be obtained from the magneto.

If such cases as the above can occur, how much more liable are faults in the interior wiring of buildings to be overlooked where the magneto is relied upon to test the circuits? There are numerous kinds of bridges and galvanometers that are almost as convenient to use as the magneto, and infinitely more reliable. Why not, then, relegate the magneto to its proper sphere, and use the more accurate and reliable instrument?

ECONOMY IN ELECTRIC POWER DISTRIBUTION.

BY

J. Stanford Brown.

MR. H. WARD LEONARD in his article entitled "Minimum First Cost of Plant and Maximum Economy of Operation in the Electrical Transmission of Power," appearing in THE ELECTRICAL ENGINEER of Sept. 2, has thrown the gauntlet, as is evident from the discussion to which that article has given rise. In all discussions it is necessary to start from given premises to which both sides will agree.

Mr. Sprague's "laws" are based on the familiar formula $C.\ M. = \frac{15.666\ n\ l}{E\ V\ \alpha}$ and using the same abbreviations Mr. Leonard's

$$C.\ M. = \frac{K.\ W. \times D \times 21{,}400}{V\ (E - V)} \text{ becomes } \frac{K.\ W. \times l \times 21{,}000}{E\ V}$$

The difference between them is that in Mr. Leonard's formula α, the motor efficiency is omitted, and that Mr. Sprague uses 10.5 instead of 10.7 for the mil-foot of copper resistance. They can be written as follows:

$$\text{Sprague} \quad - \quad - \quad - \quad \frac{(2\ l)\ (10.5)\ (n \times 746)}{E\ V\ \alpha}$$

$$\text{Leonard} \quad - \quad - \quad - \quad \frac{(2\ l)\ (10.5)\ (1{,}000 \times K.\ W.)}{E\ V}$$

Mr. Leonard, desiring to figure in kilo-watts, reduces his horse-power thereto by dividing by 1,000 and then introduces the factor 1,000 in his constant to get them back again to horse-power.

The question is, *Can the motor efficiency be neglected* in figuring the amount of wire? Perhaps by using a "general formula" Mr. Leonard is dealing with an "ideal machine." Commercial motors under average conditions of practice will not, as a rule, give over 80 per cent. efficiency. Mr. Thomas J. Fay found in 50 stationary motor installations in actual practice an average motor efficiency of 75.1 per cent.

In short, if any given set of conditions with

$\alpha = 100$ require $C.\ M. = x$, then for

$\alpha = 90$ they will " " $= 1.11\ x$ or 11 per cent. more copper.

$\alpha = 80$ " " " $= 1.25\ x$ or 25 per cent. more copper.

$\alpha = 75$ they will require $C.\ M. = 1.33\frac{1}{3}\ x$ or $33\frac{1}{3}$ per cent. more copper.

$\alpha = 70$ " " " $= 1.45\ x$ or 45 per cent. more copper.

Will not a formula yielding such results give an excessive "minimum first cost of plant"?

THE FRANKFORT ELECTRICAL CONGRESS.

BY

L. Gutmann

THE second day's session in Section 2, devoted to Heavy Currents, was opened by the reading of a paper on "Electric Transmission of Power by Means of Alternating Currents," by Mr. v. Dolivo-Dobrowolsky. The subject was inviting and the hall was crowded. Mr. v. Dobrowolsky spoke principally of matters already published, and well known to American readers. On that account the discussion that followed turned to kindred subject-matter. Mr. Déri took the stand that Prof. Ferraris, of Turin, was the original inventor of the rotating field (Drehfeld) system, and had explained the same to him (Déri) in 1885. Engineer Corda, of Paris, called attention to the motor of Mr. Leblanc, who obtained the rotary field by employing a condenser with one winding of a multipolar motor. Prof. S. P. Thompson said in favor of the three-phase motor, that the principal points of advantage over the alternating-current motor are that it starts from a state of rest, has less loss with the same weight of copper, and an exciting field of uniform strength. Of all multi-phase motors those with three wires are the best because three wires are not objectionable. Multiplying the number of phases could still further increase the constancy of the field, but increasing the wires to four, five, or more would complicate matters and would not be a commercial success. Mr. Kapp called attention to the solid construction of motors and dynamos used in the Lauffen-Frankfort stations, and said that not sufficient attention had been called to the fact that generator and motor work with exceedingly low pressure.

On the third day, Sept. 10, several matters of considerable importance were submitted, the first being the "henry." This proposition and some arguments had been printed and distributed to all the members on the day before, so as to give them time for consideration. When the matter came up, however, the president, Dr. von Siemens, who, bye the bye, was of opinion that there were others more entitled to the honor than Prof. Henry, proposed that this matter should be submitted to Section I., and thence to a committee whose resolution should be submitted to the general assembly. The proposition was carried.

M. Hospitalier, of Paris, then rose and spoke of the desirability of the adoption of a universal code of symbols and expressions in electrical matters similar to those used in algebra and geometry. This matter is of more than ordinary importance, and is explained by a few of his arguments. He referred first to the fact that, if we read an algebraic formula or symbol, it explains itself, even if the reader does not understand the language of which the calculation or expression forms a part, as for instance: $(a + b)$ or $\int_o^t$, or $>$, or $=$. Nevertheless, in electrical literature, nearly every writer has his own method of expressions; he gives his meaning in the beginning of his work, and the reader, while fully conversant with the language, is nevertheless compelled to refer constantly to the key, to ascertain the meaning of the expression. For example, Ohm's law is written $C = \frac{E}{R}$, or $I = \frac{E}{R}$, or $I = \frac{E}{W}$, depending on the nationality of the writer; in a similar manner the expressions in various books, as for instance, those of M. Hospitalier, S. P. Thompson, Kapp, Hering and others, for the same thing, have a totally different appearance. M. Hospitalier having proposed his system in 1886, in Paris, and later at the British Association, without success, he therefore called attention once more to such a system at this Congress. This matter was also referred to a committee for consideration.

In the discussion that followed the necessity for such proposed modifications became apparent, as others drew attention to expressions which are continually giving trouble. Mr. Uppenborn proposed the universal adoption of a unit of power instead of the old-fashioned horse-power (H. P.) = 746 watts, which, moreover, has different values in different countries. The German P. S., or (Pferdestärke), the French C. V. (cheval vapeur) is equal to 736 watts. Prof. Kohlrausch proposed as a practical unit 1,000 watts or 1 kilowatt. In reply to this remark, M. Hospitalier said that in France the cheval vapeur of 75 kilogrammetres is about to be abolished and replaced by the "Poncelet," equal to 100 kilogrammetres, which differs from the kilowatt by about 2 per cent.

At the following session of Section 2, Mr. Hummel, electrician of Schuckert & Co., made an address on "The determination of the power absorbed in iron by magnetic and electric action." He described in particular two methods for measuring separately the various losses in the iron. The first consists in constructing two diagrams, when the dynamo operates with constant speed and variable magnetization, or vice versa. This method is suitable only when the mechanical work lost remains constant. If this is not the case, another method must be selected which admits of eliminating this loss. This is done by a supplementary machine, which compensates for the loss by mechanical work by means of a belt. At first the efficiency of this extra machine coupled to the dynamo under test has to be determined. The difference of the measurement found when the latter operates first with the field excited and then unexcited represents the mechanical loss.

The paper read by Dr. C. Heim, regarding "The Examination of Accumulators," did not disclose anything novel. On Sept. 11 Mr. Kapp explained a simple method for determining experimentally the losses by eddy currents and hysteresis independently of one another in dynamo armatures. These losses are different when the dynamo is running empty, and when loaded. Mr. Dobrowolsky stated that the same method is also applicable to transformers.

Mr. Lahmeyer then spoke on "New Constructions of Constant and Rotary Field Machines. The great objection to high-potential continuous-current machines, he claimed, was the sparking at the commutator, which he has overcome by connecting a resistance conductor between armature winding and commutator segments. The discussion disclosed the fact that this method has been used by the Edison Co. for some time.

Mr. Georges, engineer of Siemens & Halske, made some statements on "Experiments with Alternating Currents" made by that firm, and explained them by diagrams, showing that the greater the number of phases used, the more constant does the magnetic excitation remain.

Returning to the General Assembly, Prof. Weber, of Zurich, reported the result of the work done by the committee relative to the propositions of the American Institute of Electrical Engineers and those of Mr. Hospitalier. I would like to mention, however, beforehand the work of the committee more in detail. Mr. Hering, one of the committee, proposed in the name of the American Institute of Electrical Engineers the "henry" for the practical unit of induction, the "gauss" for the practical unit of magnetic intensity (=1,000 lines per square centimetre), and the "weber" was proposed by Mr. Hering personally for the absolute unit of magnetic intensity. Since the work of Prof. Henry, or at any rate, its exact value, seemed to be not generally known among some of the members, the proposed name met with some opposition by some, among them Mr. Uppenborn and Prof. Weber, while Mr. Preece, Prof. S. P. Thompson, and others, speaking for the British Association, advocated the adoption of the name "henry." The members of the committee having had but two sessions, argued that the time had been too short, and that they would not like to rush matters of such importance to a decision without proper investigation. In consideration of these statements, and the non-agreement of the members, the matter was left open to receive proper attention at the next Congress, when a final decision will be given.

Prof. Weber reported that the proposition of naming the practical unit of induction the henry had been withdrawn. This statement was, however, modified by Prof. Kohlrausch, who said that the proposition was not withdrawn in the proper sense of the word, as the Americans were going to continue to use it, and that it would be brought up for reconsideration in the next Congress, held in Chicago. In regard to this matter, as also that regarding the uniform system of symbols proposed by Mr. Hospitalier, he said that every one should familiarize himself with these new matters so that at the next congress they could be settled finally.

In regard to the matter submitted by Mr. Hospitalier, Prof. Weber proposed for the committee that "quantities" should be expressed by letters in italic; "units" by Roman letters; and physical constants and angles by Greek letters. Further, the units of joule and watt, which have been in use since 1889, to be formally adopted, and to abbreviate the names volt, ampere, ohm, coulomb, farad, joule and watt by simply using the initial letter of each.

The final decision in regard to this matter the committee wished to have made by the next Congress.

This report was followed by the paper of Mr. Zipernowsky, who spoke on "Electric Railroads." He described a system contemplated for connecting Vienna with Buda-Pest, in which his company (Ganz & Co.) prefers the use of single cars as against trains, similar to our tramway systems. The speed is to be 250 kilometres per hour. The cars will follow each other every 10 minutes and be capable of carrying 40 passengers each. There are to be two generating stations at suitable distances apart, delivering current to the line at a pressure of 10,000 volts, which are reduced to 1,000 or 500 volts by means of converters placed every two kilometres. The cars will be very large and roomy, and are to be provided with the Westinghouse air-brake. For such a system the rails are made very heavy, and are mounted on brick foundations. In the following general assembly Prof. Heinrich formally invited the delegates to participate in the Chicago Congress of 1893.

Dr. Epstein then spoke about the position to be taken by electric laboratories or institutes making tests. He believed that no certificate should be given to a client sending his apparatus to be tested, which would enable him to use it for the purpose of giving wrong impressions to laymen, especially for apparatus which may be suitable for one special case and totally unsuited to another.

In the last session of Section 2, Mr. Wilking, of Schuckert & Co., spoke on accumulators in alternating-current stations. He pointed out that in cases where water-power or other prime movers are not made use of to their full capacity, the superfluous energy could be stored. To effect this he couples to the shaft of the alternator a continuous-current dynamo, which charges accumulators. This charge is afterward used to drive the dynamo as a motor, which in turn either drives the alternator alone, or helps the prime mover in operating the alternator.

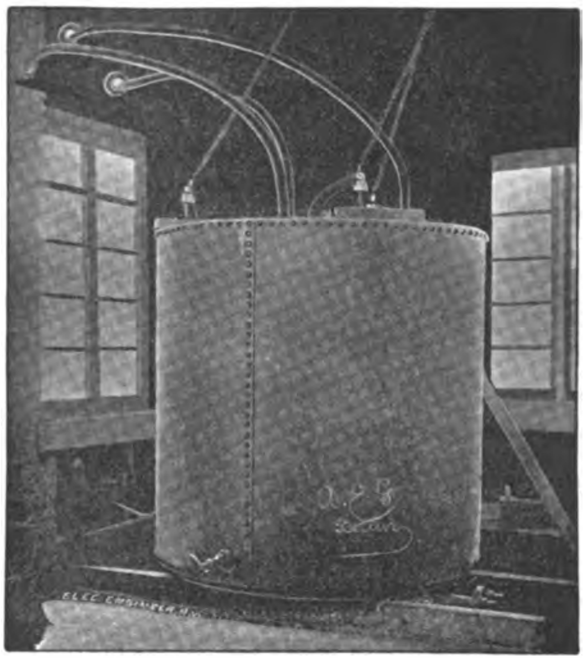
Engineer Baumgardt described graphically the efficiency of the compressed air (Luftdruck) system of power transmission, and showed that under very favorable conditions the system may pay.

Mr. Gutmann, of Pittsburgh, then spoke of the "rotary-field" system in America, and corrected several statements made in German periodicals regarding the non-use of alternating motors in this country, which did not agree with facts. In reply to his remarks on insulation tests of the Lauffen-Frankfort line, which he thought desirable, Mr. Lindley said that such tests were contemplated and would be published.

The Congress concluded with an entertainment in the Zoological Garden and an excursion to Lauffen.

THE LAUFFEN-FRANKFORT OIL TRANSFORMERS.

We have already entered very fully into the description of the transmission of power electrically from Lauffen to Frankfort, a distance of about 112 miles, and have given a number of views and diagrams of the apparatus used. Our readers will still be interested, however, in the accompanying views, which show the transformers as they actually appear. Supplementing our article of last week, which showed the interior of one of the transformers, it may be stated there are three transformers installed at Lauffen, one for actual use and the other two in reserve. At Frankfort there are also three transformers, all being in actual service, and receiving the current at a potential of 15,000 volts and upward. One of these, constructed by the Oerlikon Works (shown in detail last week), reduces the pressure to about 100 volts. This transformer is located on the left of the main entrance of the distribution hall. It furnishes the current for feeding 1,200 glow lamps, partly fixed to a large frame in the transformer-room, partly to a signboard outside the hall. The remainder of the current, corresponding to about 100 h. p., is reduced to



The A. E. G. Transformer at Frankfort.

the requisite E. M. F. of 100 volts by two transformers of the Allgemeine Elektricitäts Gesellschaft. These two transformers are located in a special shed on the right of the hall. The secondary currents furnished by them drive a large rotary-current motor of the Allgemeine Elektricitäts Gesellschaft (shown last week), as well as some other smaller motors of the same company. The large motor makes 600 revolutions per minute, and is coupled direct to a centrifugal pump, built by Messrs. Brodnitz and Seydel, of Berlin, which supplies a waterfall of 10 metres height on the right of the hall. Thus part of the electrically-transmitted energy makes a perfect cycle. A waterfall at Lauffen is the starting point of the energy, and part of

Oerlikon Transformer at Frankfort.

this latter is again seen in the form of a waterfall at Frankfort.

CALLENDAR ELECTRIC PYROMETER.

In a recent number of the *Philosophical Magazine* Mr. H. L. Callendar describes a modified form of the well-known Siemens electric pyrometer. In the Siemens pyrometer the zero is known to change largely and continuously. Mr. Callendar, however, points out that this effect is due to imperfect design, and he claims that if the wire is pure to start with, and is protected while in use from strain and from contamination, its resistance, after having once been annealed, is always very nearly the same at the same temperature. Mr. Callendar's improvements in the platinum resistance thermometer, or pyrometer, consist in the better protection and treatment of the platinum wire. This is differently treated according to the heats to which it is to be exposed. Two recent communications to the Royal Society related to investigations carried out with the aid of the platinum thermometer.

THE FAURE ACCUMULATOR PATENT IN GERMANY.

The action for the annulment of the Faure patent brought against the Joint-Stock Accumulator Company, of Hagen (Westphalia), by the Berlin Accumulator Company, Correns and Co., de Khotinsky, Gelnhausen, and Gottfried Hagen, of Cologne, came before the Imperial Patent Office a short time since. All motions made by the petitioners for annulment, in order to obtain a postponement of the case, the institution of experiments, hearing of witnesses both in this country and abroad, were disallowed, it being decided that sufficient material was already before the court to admit of a decision being arrived at. The Imperial Patent Office granted the demand of the defendant's counsel that the appeal lodged by the petitioners should be disallowed, thereby declaring the validity of Faure's 1881 patent to be unconditional.

THE ELECTRICAL ENGINEER.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XII. NEW YORK, OCTOBER 7, 1891. No. 179.

The people in combination with men of genius—this will be the voltaic pile of civilization.—Lovett.

ELECTRIC RAILWAY SOCIOLOGY.

AMERICANS are a practical people, but that they are no less a people of ideas is shown in the zeal with which they throw themselves, body and soul, into new enterprises. This willingness to assume risks and take chances presupposes a vivid imagination that sees through and over difficulties to the triumphs and successes beyond, and so sane that it can forecast definite results even while the new project is in an embryotic stage. Contradictory as these two qualities of practicality and ideality may be, they present themselves very strikingly in many of the new enterprises that distinguish American growth, and have nowhere been displayed more forcibly than in the rapid advances made by the electric railway, whose realization on a large scale for the public benefit, and as a new source of wealth, is at this present moment almost wholly American.

There are sociological aspects to electric railway work that deserve close study, the more because they show a remarkable interplay of motives, some hard and practical, looking to the mere increase of dollars, others high-pitched, looking to the public welfare and the betterment of social conditions. The street railway man has adopted electricity with such overwhelming unanimity on account of its greater economy and greater earning capacity. The public have welcomed it because it promotes comfort and intercourse, saves time, gives men employment of a refining nature, releases the horse from torturing labor, adds to the value of property, and knits the community closer together.

If this be the case, it should in part at least be demonstrable by statistics, and certainly, so far as the change from horse, steam, and cable to electric locomotion is concerned, no figures could be more notable, while none are easier to obtain. They have often been given in these columns, and of necessity are frequently quoted. But the other figures—those bearing on the gain to the public—are not readily gathered, and for this reason the presentation of them made by Mr. Oscart T. Crosby in our issue this week is very valuable. We have in his address before the Thomson Scientific Club a serious attempt to express in figures the benefit derived by society from the introduction of the electric railway, and it must be said that the analysis is carried forward to a degree, and with a clearness, that one would hardly yet look for. Thus, for example, Mr. Crosby shows that the simple saving in operating expenses of 4 cents per street car mile means a saving to society of $19,600,000 per annum, and at the rate of $1 per day as the average value of a day's work, an array of 53,700 men now engaged in all the departments of street railway work, from first to last, could be re-distributed for other economies in other departments of labor; or, better yet, the gain would count for greater leisure. Next comes the gain from acceleration of speed in travel, and this Mr. Crosby shows to amount per day to 16,000 days of 10 hours each. This added to the other gain represents an economy of 69,700 man-days per day.

Nor is this all, for there are many shiftings of labor to be taken into account. The use of machines instead of horses, the consumption of coal instead of hay and oats, means a great deal as affecting agriculture and mining; and so it goes, all through society and social conditions. to another is not a small matter, especially when it is being The shifting also of 80,000 people from one set of industries done with the rapidity now noticeable in the adoption of electricity. Most of these people have hitherto earned a living by the sweat of their backs; they will now earn it by the sweat of their brow, and will be the better for the change.

INCANDESCENT LAMP ECONOMIES.

A PITHY article by Mr. Otis K. Stuart in this issue deals with light touch, but in a suggestive manner, with one or two points of economy in the purchase and use of incandescent lamps. As Mr. Stuart hints, there is still too much uncertainty in the tests, and indefiniteness in the results, of lamps tried by station managers, and yet the process of trial goes on, and scores of managers are spending thousands of dollars on a game that is not worth sixteen candles. There ought to be a better way of getting at the results they want, and much is to be hoped from the general spread of knowledge on photometry; but the manufacturers and the consumers have hardly yet agreed on the prime essentials of the perfect lamp.

Another point touched on in passing, by Mr. Stuart, is the ill-treatment that lamps receive. We would greatly like to see figures from some large factory, office building or hotel, showing the manner in which lamps have become *hors de combat.* In other words, it would be instructive to know how many lamps fail from natural causes or causes arising from defective manufacture, and how many succumb to careless handling, blows, shocks and "accident." Perhaps if the data were obtainable in some factories, it would be found that the high percentage of lamp breakage complained of was due not to the lamps themselves, but to the people using them. It is a notorious fact that lamps last longer when they have to be renewed by the persons directly using them.

An incident that occurred a week or two ago at Spokane brings to light a new danger for the lamp, and that is, theft. It appears that a place of business in that city lost several of its lamps, and that the place being watched, a "dope fiend" was caught stealing them in order that he might sell them for opium or morphine. It seems to be only a natural precaution that sockets should be watched and lamps counted regularly; but it would be more difficult to keep track of any one who should make a practice of withdrawing good lamps and sticking old ones up in their stead.

LIGHTING CIRCUITS ON ELECTRIC RAILWAYS.

The fact that the electric roads in Cleveland are prepared to do electric lighting, and are negotiating with the city government for the illumination of the 50 miles of streets through which they run and of adjacent thoroughfares, has excited some comment in the newspapers. In Cleveland, it was supposed that even if the railroads were able to utilize their circuits in this way, the terms of ordinances and charters would forbid, but the corporation counsel has decided that they have full legal authority.

The matter is one of interest, and we look for a rapid development of this method of street lighting, for the electric railway should very often be able to take contracts at lower rates than usual, and thus, in outlying districts, if not elsewhere, be able to compete favorably with existing lights, particularly those of oil and gas. The perfection of arc lights for use on incandescent circuits has had much to do with this condition of affairs, and we know of several instances where such lights are giving admirable results of constant potential electric railway lines. Of course it is desirable that the road shall be one of fairly large average load, and also one where the cars run through the night; but it seems to us that in many cases the undertaking of street lighting service will enable the railway companies not only to keep more cars going, but to operate all around the clock. Thus with a service to stationary motors during the day, and to arc lamps at night, the electric railway company will see the curve of its load diagram flattened out at a high level of amperes with an exhilarating increase in the margin of profit.

BIG POWER UNITS IN BOSTON.

Last week the biggest engine in New England was started up at the new power station of the West End Railway Co., of Boston. It is an Allis-Reynolds, of the Corliss type, of 2,000 h. p., triple expansion, the first of thirteen colossi, which will drive Thomson-Houston generators of 500 h. p. each. The whole will constitute a magnificent demonstration, when finished, of mechanical and electrical engineering skill, and they who have been concerned in the work are to be complimented upon their enterprise. This work may be said to mark the highest point yet attained in America in electric current generation, and it will be very interesting to see how much further the tendency towards big units will go. It is, we fancy, hardly expected yet awhile with us to reach what may be called the Ferranti limit. On the contrary, a reaction may in time be looked for, if only as a protest against the "craze" into which every new enthusiasm is destined to grow. There is a craze just now for big units, and while we all hope and look for great strides in this direction, it is not to be forgotten that there is much to be said on the other side, and that the scientific determination of what size these big units ought to be, in view of economic conditions and the present state of the arts, has not been ascertained. What one fears is that while the larger stations are thus wisely striving to get up to as large an economical unit as possible, smaller stations will be carried away by their example, and will be struggling under the depressing influence of units whose full capacity they will be several years in reaching, so that for a long time to come they will be working uneconomically. The tendency is all right, and is one to be encouraged, but a station with a maximum load of 5,000 lights worrying along with 10,000-light units is more a sign of retrogression than of advance. At least, the stockholders will be apt to think so.

Foreign Participation in the Chicago Exposition.

It has been feared by many electricians that there would not be a very active participation by foreigners in the Chicago World's Fair, and certainly our "high tariff' legislation would excuse European manufacturers from worrying themselves much about markets from which they were so severely excluded. But there are not wanting signs of an intention on the part of leading European countries to be well represented, and the welcome news now reaches us from Chicago that England and Germany each want 20,000 square feet in Electricity Hall, 40,000 each in Machinery Hall, and so on. This is not a small block of space, but we may depend upon it that it will be filled with apparatus well worthy of study.

Belts in Europe.

Mr. C. A. Schieren contributes another entertaining article in our columns on belting at the Frankfort Exhibition, and points out that none of the belts there exceed 20 inches in width, showing a preference for shafting over belts in the transmission of power. As he remarks, this is very different from practice in this country, where very large belts are in use in electric light and electric railway plants, and give general satisfaction as to efficiency and economy. Mr. Schieren's remarks on air spaces are also noteworthy.

The Philosophy of Earth Currents.

We commend for careful perusal Mr. Stevenson's article in this issue on earth currents in New York city. Mr. Stevenson has for some time had exceptional opportunities of studying this subject, and gives details of a number of phenomena. His word of caution as to the inferences drawn from the observations made, as bearing on the quality of underground cables, is sagacious and timely.

LEATHER BELTING AT THE FRANKFORT ELECTRICAL EXHIBITION.

BY

Chas. A. Schieren

JUDGING from the exhibition of machinery at the International Electrical Exposition at Frankfort, it is evident that the German engineers (and we may include all Europe) still largely favor the use of gears and direct transmission of power by means of shafting, rather than belting. The widest belt in motion at the Exposition measured about 20 inches, and was single ply. The whole exhibit contained only about a dozen belts over 10 inches wide, in operation; so that to a belt manufacturer interested in leather belting for electric lighting the Exposition was a great disappointment.

Cahn, Leudersdorf & Co., of Muelheim, had a fine example of leather link belting about 16 inches wide in operation, driving a dynamo of 100 h. p. from an engine of R. Wolf, of Magdeburg. This link belt attracted universal attention by its perfect and easy running; it was made on the American patent joint plan. There were two other link belts, 6 and 12 inches in width, respectively, made by Tullis Bros., of Glasgow, running on the engines of Rustan, Proctor & Co., England. These link belts had only one steel bolt and no parallel joint. The advantage of a centre joint was very perceptible in a comparison of these belts, as not 75 per cent. of the surface seemed to touch the face of the pulley in the latter case, while the entire surface touched in the former. However, all of the link belts were very much admired for the graceful curve they made when in motion.

Schuckert & Co., of Nuremberg, exhibited two single belts 12 inches wide, running tandem, or one belt on top of the other, supplying power to two dynamos from one engine pulley. As a novelty in an exhibition, this may do well enough, but cannot be recommended for general use, because in the event of either belt breaking when in motion it would destroy everything within reach. Parkney & Wittekind exhibited a beautiful rope-drive on grooved pulleys, with excellent result.

There is a certain fitness of things which should be observed, especially at an exhibition, and a wide, large, main engine pulley covered with a belt one-half of its width, looks very cheap; such a pulley should have a correspondingly wide belt, or not more than a few inches margin at the most. At Frankfort most of the wide pulleys had narrow belts. One large main engine pulley made by Gebrueder Sultzen, of Switzerland, 38 inches in width, had two crowning centres to allow an 18 inch and 14 inch belt to run alongside of each other and to their respective centres; the belts worked perfectly straight, and ran accurately. This pulley was a fine piece of workmanship.

Most of the belts were single ply, made from heavy leather. Their irregular motion and heavy flapping confirms the experience of American electricians that single belts are unreliable, and not desirable for dynamos. Some of these belts when not in motion were very tight and hollow in the centre, a sure indication of being overstrained, and too weak to transmit the power required of them.

A genuine surprise to an American belt maker was a 14 inch heavy (European) double belt, sewed with eight parallel rows of white lacing, transmitting power to a dynamo, with centres a short distance apart. This clumsy belt ran remarkably easy and noislessly, and apparently without slipping. After watching it closely we came to the conclusion that the thick lacing stitched along the belt allowed considerable air to come between the belt and pulley, thus preventing the formation of an air cushion—another triumph for the idea of allowing air spaces in a belt, which principle is so practically illustrated in America by the perforated belt so extensively used now for dynamos.

Our European cousins who may pay us a visit (perhaps to the World's Fair in Chicago) will be surprised to see the large number of wide main driving belts used in the electric light plants of this country, transmitting immense power with perfect ease and comparative safety, and they will also find that the art of making these belts has almost reached perfection with us.

A SOLUTION OF THE BLOCK SIGNAL PROBLEM.[1]

BY

H. Ward Leonard

THE purpose of this article is to call attention in a cursory manner to the state of the signalling art, and to indicate, if possible, the lines it will be necessary to follow in order to make a thoroughly reliable and practicable block system for railways.

A careful study of the whole subject, with the help of some recent publications too lengthy to be condensed within the limits of a magazine article—including a series of articles in the *Railroad Gazette* compiled in a volume entitled "American Practice in Block Signalling," and a paper read by G. H. Paine before the New York Railway Club on April 16, 1891—leads to the following specification, indicating the desirable features of an automatic block system: 1. There should be signals both on the train and along the track. 2. The signals on the train should give a continuous and positive indication to the engineer. 3. The signals both on the train and along the track should be actuated from a source of energy constantly under the observation and control of the locomotive engineer. 4. The signals should be distinctive both by form and color, and should be audible under certain instances when desired. 5. Any two trains on the same block should each give a danger signal to the other. 6. The power for actuating the signals should be positive, strong enough to operate any desired signal, and should not depreciate and require renewal, as in the case of batteries. 7. The operation of the signal should not depend upon the movements of any mechanism beyond the observation and control of the locomotive engineer while at his post. 8. Any train should have to disregard more than one danger signal before being *able* to reach a preceding train. 9. Any locomotive engineer should be able to communicate with any station or any other train in the same block. 10. There should be a signal constantly before the engineer and in the locomotive cab whose indication will always be "danger" unless *all* his signals are working perfectly. 11. The form and color of the signal should change from "safety" to "danger" under the observation of the engineer as the train passes the signal. 12. The absence of any signal should indicate danger, but there should be a positive danger signal which would only and always give positive and continuous indications to both engineers when two locomotives are in the same block. 13. In case of failure of the train or track signals at any point, means should be provided whereby signals could be instantly sent to a following train. 14. A misplaced switch should set danger signals on any train in that block and also along the track in that block. 15. The signals should be the same by day or night, and any light at the signal should always indicate the presence of a locomotive in that block. 16. Any person should always be able to signal danger to approaching or receding trains in that block while it is out of sight and hearing and without any light or special apparatus.

About three years ago the writer suggested a block system, which, it is believed, would comply with the above specification, and with the hope that it may lead to improvements in practice, the following description of it is offered:

Divide the line of the railway into blocks, say one mile long. Make each block overlap the next one half way. Stretch a bare wire parallel to the track and continuous along each block. Thus a wire one mile long will start from the beginning of each block, and another parallel to the first will start at the centre of the first. There will thus always be two parallel conductors along the track, and a conductor will end, and a new one begin, at each half mile. The forward end of each mile length of conductor will be connected by a wire leading to a green incandescent lamp, and the other terminal of the lamp will connect with the ground. Similarly the rear end of each conductor will connect with a red incandescent lamp.

Upon each locomotive will be placed a generator of electricity of about 100 volts, that is, about the pressure of the incandescent lamps. This generator can be a battery, or, preferably, a small dynamo, driven by a small engine which is operated by steam from the locomotive boiler. One pole of this generator is grounded by making contact with the metal work of the locomotive. A

1. Abstract from *The Engineering Magazine*.

conductor leading from the other pole of the generator passes through an ampere-meter for indicating the current being generated, and thence on through a low-resistance series incandescent lamp, which, when supplied with the current of four of the track signal *lamps*, will operate at a moderate incandescence. After passing through the series lamp which we may call the pilot lamp, the current passes to a trolley carrying a large wheel made after the style of a bicycle wheel, and this wheel makes rolling contact by a concave rim upon the two parallel conductors stretched along the track.

Now it will be evident that if the generator be operated the electric current will pass through the pilot lamp and up the trolley to the two conductors; thence it will divide equally between the four lamps connected to these two conductors, passing through two green lamps ahead of the trolley, and through two red lamps to the rear of the trolley, the green lamps as well as the red being half a mile apart.

As the train moves forward, the trolley will finally roll off the conductor of the block it is leaving, and both the red and green lamp of that block will be extinguished. At the same time the trolley will roll on to a new block and the red lamp at the rear end of this block will light up just as the locomotive reaches it and will then pass to the rear. At the same time the green lamp at the forward end of this new block will light up at a distance of one mile off.

It will be seen that a following train would have to pass the two red lamps of the preceding train before a collision could take place; also that whenever two trains would get within a mile of each other the generators would be acting in concert to divide the combined loads of the two, and whatever the current of each had been previously, it would immediately become different, the generator having the higher pressure taking the larger portion of the combined load. Thus the pilot lamp of one locomotive would flash up, and its ampere-meter would indicate a greater current than usual, and this, by a contact on the ampere-meter needle, would cause an alarm-bell to ring in the cab. Similarly the pilot lamp of the other locomotive would be reduced in candle-power, the ampere-meter would show a reduced current, and the alarm would ring on the lower contact. At the same time the locomotive engineer of the following train would see before him the red lamps of the preceding train in addition to his own green lamps, and a rear guard on the preceding train would see in addition to the red lamps of his own train the green lamps of the following train. On each locomotive a line containing a high resistance is led from the trolley and around the generator to ground, and this circuit in shunt to the generator contains a telephone. It will thus be possible for either locomotive engineer to talk to another engineer preceding or following in the same block, and regardless of whether either, or both, are in motion. If telephones in the various stations be similarly connected from the signal conductors, communication can be carried on between the station-master and passing trains.

Now as regards the signals along the track, the incandescent lamps should be arranged in a proper signal-box, and the green lamp should show a vertical band of green lights whereas the red lamp should show a horizontal band of red light, thus giving a signal defined by both form and color.

Two possible objections which may be raised against this method of signalling are: First, the presence of a car on a track without any accompanying attendant would not give a danger signal as it would with a track-circuit system. This, however, is a rather remote contingency, and, in any event, could not lead to an accident with much loss of life. The unreliability of the track-circuit is so great in other ways, as to make this slight defect almost negligible by comparison.

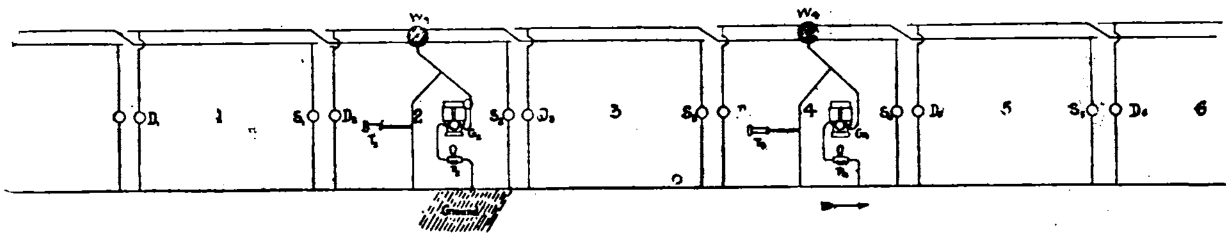
Second. The action of sleet might intefere with the action of the signal by preventing electrical contact between the trolley and wire. This trouble would be rare, in any event, and it is not likely to occur, as the heating effect of the strong current on the wire would tend to eliminate this trouble, just as it does with electric railway systems. If, however, it became necessary to provide against this, it could be done by placing the conductors beneath a semi-circular structure, such as a tube sawed longitudinally and concave downward.

It will be evident, by examining the specification as to the requirements of a safe system, that this plan avoids the defects of the present system.

The next consideration is as to its first cost and maintenance, and it will be evident that the advantages on these points are conspicuously in its favor, for the simplicity of the signals, and the cheapness of the small bare conductor, make its first cost less than that of any existing system. The cost of operation will be almost *nil*, as there will be almost no need of inspecting signals, having no batteries, electromagnets, relays, weights, clockwork, compressed air, oil-lamps, or the various other possible causes of failure of the existing systems.

It will be evident that by connecting along the signal conductors white incandescent lamps, and increasing the size of the generator, the track can be perfectly and uniformly lighted both in advance of and behind the train as it moves forward; and that also all crossings and stations can be lighted while a train is within a mile of them. Two-and-a-half horse-power would in this way be all that would be necessary to keep a track illuminated by 16 c. p. lamp every 200 feet, and for a space of not less than half a mile in both directions from a moving train.

Trains having an electric plant for the illumination of the cars require a plant of about 15 h. p., so that the additional power required in such a case would be hardly worth mentioning, and no special generator beyond that for train lighting would be needed.



D_1, D_2, D_3, etc., are the red lamps connected to rear ends of the sections 1, 2, 3, etc., respectively. S_1, S_2, S_3, etc., are the green lamps connected to the forward ends of the sections 1, 2, 3, etc., respectively. G_2 and G_4 are the generators on trains in sections 2 and 4 respectively. P_2 and P_4 are the Pilot lamps in series with the generators and placed in the locomotive cabs. T_2 and T_4 are the telephones. W_2 and W_4 are the trolley wheels making connection between the signal conductors and the generators.

Under the conditions shown in the diagram the train in section 2 will light its Pilot Lamp P_2, the forward green lamps S_2 and S_3 and the rear red lamps D_2 and D_3. The preceding train in section 4 will light its Pilot Lamp P_4 and the forward green lamps S_4 and S_5 and the rear red lamps D_4 and D_3.

MR. LEONARD'S PROPOSED BLOCK SYSTEM.

THE ELECTRIC RAILWAY FROM A SOCIOLOGICAL POINT OF VIEW.[1]

BY OSCAR T. CROSBY.

ASSUMING $1 to represent the value of "one man-day" as a unit, that being the worth of the labor that could be done, Mr. Crosby said: "There now 33,700 street railway cars of all kinds in operation. They make, per annum, about 490,000,000 miles of service. It will not be far from the mark to assume that four cents per car mile is the economy to be effected by the universal use of electric cars instead of horse cars. The saving to society in such a case is expressed in money at about $19,600,000 per annum. Now, applying our unit of man-days, this means that 19,600,000 of man-days of labor may every year be withdrawn from present industries without diminishing the total product of society in the shape of things desirable to eat, drink and wear or read. Otherwise expressed, it appears that 53,700 men who are now at work, engaged directly or indirectly in street car propulsion, may, every day after the substitution, stop working."

Mr. Crosby then went into a careful and elaborate discussion of the effect of this direct economy, showing it to be valuable for purposes of rest, recreation and greater luxury or comfort for society at large, if not immediately for the individual. So far, the saving in time by invention over old methods had been devoted to increase of production, but there was a tendency to utilize some of it now for increase of leisure. Part of the money benefit inured to the stockholders in electric roads. In Massachusetts there are about 105 stockholders to each of 45 roads. Taking the 1,100 roads, the country over, that would make 115,000 street railway stockholders in the United States, affected favorably in their incomes, ways of life, and ability to promote enterprises, by the higher returns from electric roads.

Having thus seen what may be called the most general effects, let us now glance at the redistribution of some of the social forces connected with this change. To make the car mileage above mentioned, viz., 490,000,000 per annum, there must be burned about 900,000 tons of coal; that is on the basis that one horse-power hour at the station is a close equivalent to 1.25 car mile, of service on the line, and that one horse-power hour of energy may be produced by five pounds of coal. To get out this 900,000 tons of coal per annum will require the constant service of 1,200 miners, besides the services of the men engaged in the commercial handling and transportation of the coal to the power-houses.

1. Abstract of paper read before the Thomson Scientific Club, Lynn, Sept. 24, 1891.

Estimating the coal worth $2.50 per ton as thus laid down, the total supply of labor for coal amounts to 2,250,000 man-days per year, or about 6,200 man-days per day.

Estimating the repairs at 7½ per cent. on the whole cost of machinery, it would appear that something like 30,000 men per day may be occupied in furnishing repairs to engines, dynamos and motors for 33,000 cars. It should, of course, be borne in mind that in covering a general item, such as repairs, we must take into account some miners to furnish the raw material, some engaged in transportation, and some commercial men to direct and co-ordinate the industry.

For producing the steam and electric energy required by these 33,000 cars, there will be daily employed about 1,500 engineers and firemen.

The total of these items—coal, repairs and power-station—shows a demand for about 38,000 man-days per day.

For the manufacture of the original installations of 33,000 cars there must be employed 42,000 people per day, estimating that the work of installation shall extend over 10 years, and understanding that we have covered in this the engines, dynamos, motors and line material, but have not covered new cars, trucks or rails. We thus see that we must divert daily about 80,000 people for the next 10 years from previous occupations to the installation and maintenance of electric railways, just sufficient to replace cars now running. The number will doubtless not diminish after 10 years, on account of the tremendous growth of the country and the extension of car mileage, even for a given population as compared with the present figures.

As to just how this total of 80,000 will be divided among the various occupations, we may judge from the actual distribution of the total population of this country as reported by our census. Not having at hand the figures for 1890, I find from the census of 1880, that out of 17,500,000 people, men and women, engaged in the various occupations, 7,600,000 are reported as agriculturists; 3,800,000 in mechanics and mining; 1,800,000 in trade and transportation; 4,000,000 in professions and other personal services. [This last item covers all individual personal services, from the high-priced lawyer to the humble domestic.] Some such distribution as this would doubtless follow for the 80,000 whom we have discussed above.

The forces which are supplanted we may estimate about as follows: There are 4½ horses per car on all horse railways throughout the United States, or a total of 115,000 horses. The average life of these in service is five years, which requires a supply of 23,000 per year. To feed and groom the total number engaged at the rate of 50 cents per day costs $575,000 daily, while the supply of 23,000 horses per year at the rate of $150 each requires daily $9,500. These 67,000 man-days are then substantially diverted from their original use, of simply maintaining the horse as a motive power.

Some of these, of course, are merely re-engaged to feed and clothe the mechanical workers above mentioned, while also from among them we take the surplus which has been above discussed as resulting when the line of expenditures in the two cases have been compared throughout. It is fair to presume that a very large proportion of these 47,500 thus relieved are at present engaged directly in agricultural pursuits, and the surplus which may be set aside may be taken as supplied directly from the agricultural class. Or it may be put thus: A large part of those engaged in raising grain and horses are now to be drafted into machine shops to make motors, or, on a smaller scale, are drafted into coal mining, etc.

Going more into detail, it will doubtless be found that the transfer is more complicated than this; that the manufacture of electric motors and machinery will absorb a considerable part of the higher class of labor engaged in general mechanical pursuits, while the void thus left will be filled from the agricultural element. After all the changes have been made, it will doubtless be found that the ratio above mentioned between the various occupations will still hold nearly true, with a slight diminution in the numerical value of the agricultural population. In this the United States is considered as a society complete in itself, which is not strictly, but very nearly, true.

Leaving now this redistribution of forces, let us look at some other effects of the change. Supposing the average schedule of speed of horse cars to be six miles and electric cars to be nine miles per hour; the gain in time may be expressed as 3⅓ minutes per mile. During the year ending June 30, 1890, there was a total of 2,000,000,000 of passengers carried. The average distance traveled by each of these may be assumed as about half a mile, hence we have a saving of three and a half billion of man-minutes, equivalent to about 58,000,000 of man-hours, or 5,800,000 man-days; the day of labor taken before as at 10 hours. This for the whole year would amount to 16,000 man-days per day.

We have said this is saved, that is to say, it is saved from the time that would otherwise be spent on a street car in order to cover the same distance. Whether or not this saving will be given to work or to pleasure cannot be determined. If it is taken as of like value to the time which is specifically given to labor, then we may add to the 53,700 man-days, giving a total economy 69,700 man-days per day.

Beside the consideration here presented in figures, we have the indefinite but large value resulting from the more pleasurable sensation with which we are all familiar from riding on the electric cars, this due to the greater speed, which is in itself a satisfaction, and from the relief which comes from seeing that sentient organisms are no longer suffering in our service, and before our eyes.

ON THE RELATION OF THE AIR GAP AND THE SHAPE OF THE POLES TO THE PERFORMANCE OF DYNAMO-ELECTRIC MACHINERY.[1]

BY HARRIS J. RYAN.

(Concluded.)

In Fig. 9 the diagrams show the magnetic action of the armature of a 10 h. p. 110 volt motor, with poles fashioned as in Fig. 6. Measurements of the magnetic leakage were made on this motor, and the results indicate that the shape given to the pole corners avoided saturation in them even at full load. The double angle of lead was almost 60 degrees. The ampere turns embraced by it on the armature were partially compensated for by 9 series turns on each of the consequent fields. The remainder of the armature ampere turns that lie between the double angle of lead ser ed to weaken the field by just the amount required to produce

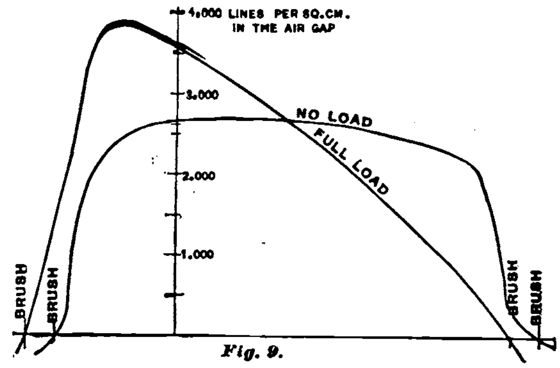


Fig. 9.

a constant speed. The following figures give additional data on this motor:

Diameter of armature core..................	8.33 in.
Diameter over all..................	9. in.
Bore of poles..................	9.38 in.
Double air gap..................	1.05 in.
Shunt turns on field..................	2200.
Shunt current at 110 volts..................	3.55
Ampere turns on field at 110 volts..................	7800.
Ampere turns on armature at full load..................	5750.
Armature sections..................	48.
Turns per section..................	3.
Speed..................	1200.

The ampere turns required to set up 2,600 lines per sq. cm. through a distance of 1.05 in. or 2.64 cms. in open air:

$$\frac{2600 \times 2.64}{1.26} = 5600.$$

This is the number of field ampere turns that exerted their magnetizing force between the pole faces through the armature. The ampere turns acting through the weakened pole corners are, therefore, very near zero, which is entirely corroborated by the fact that the magnetization was observed to be zero at this point. See full load curve in Fig. 9. Through the strong pole corners the ampere turns acting were the 5600 of the shunt ampere turns, + the 720 of the 9 series turns + the armature ampere turns, 5750—twice the ampere turns between the double angle of lead, $2 \times (.3 \times 5750)$, or $3400 = 8670$ which will produce a magnetic density through an air gap of 2.64 cms. depth of

$$\frac{8670 \times 1.26}{2.64} = 4100,$$

while the actual magnetic density measured at this point was 3950, an agreement within the possible limit of error.

In Fig. 10 are given curves showing the magnetic performance of an armature, with its conductors laid in deep, narrow grooves, as shown in Fig. 12. The clearance on each side was one-sixteenth of an inch, making the double air gap one-eighth of an inch. Additional dimensions are as follows:

Diameter of the armature core..................	6. in.
Length of armature core..................	6. in.
Resistance of armature..................	.34

1. A paper read before the American Institute of Electrical Engineers, New York, September 23d, 1891.

Number of sections	64.
Turns per section	3.
Output, amperes	20.
" volts	100.
Speed	1800.

Curve 1, in Fig. 10, shows the distribution of magnetization at 112 volts, no current, a speed of 1800, and a field excitation of 2600 ampere turns. Curve II. shows the magnetic distribution for an output of 97 volts and 24 amperes, at a speed 1800, and a field excitation of 2,600 ampere turns. Curve III shows the magnetic distribution at an output of 40 volts and 20 amperes, at a speed of 1800, with a field excitation of 750 ampere turns. This same excitation when the armature furnished no current, produced an E. M. F. of 48 volts, at a speed of 1800 revolutions. The poles were shaped as in Figs. 11 and 12, but modified as explained below. In making these experiments carbon brushes were used,

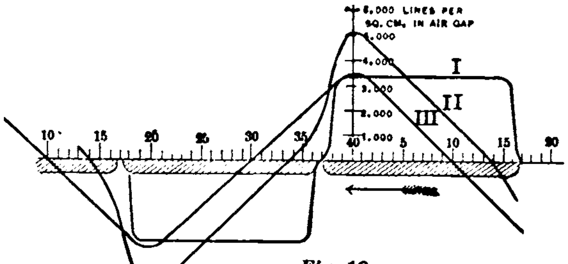

Fig. 10.

and their position maintained at the normal diameter of commutation. An average magnetic density in the air gap of 8400 lines per sq. cm. was required to produce an E. M. F. of 112 volts. The grooves on the armature in which the conductors were placed occupied one-half of the armature surface, so that the actual magnetic density in the air gap was 1.8 times this average magnetic density. The ampere turns required to set up this magnetic density in the air gap were

$$\frac{.125 \times 2.54 \times [3400 \times 1.8]}{1.26} = 1520,$$

which is the number of field ampere turns whose magnetizing force is impressed between the pole surfaces through the armature, when it furnishes 112 volts and no current. The ampere turns on the armature at a current of 24 amperes are

$$\frac{2 \times 64 \times 3 \times 12.}{2.} = 2300,$$

as against 1520 impressed by the field. Under these circumstances the magnetism under the weakened pole corners is reversed, as is also clearly indicated by curve II. in Fig. 10, or the curve C, E, D, F, C, in Fig. 11. This curve also shows that the magnetic density under the strong pole corners was 5,100 lines per sq. cm. Now in building this machine, six longitudinal slots, 1¼ inch deep, were cut in each pole immediately back of the surface, which enables us to be sure of the exact densities in the pole corners for a given distance. For a depth of 1¼ inches immediately back of the pole faces these slots took up one-half of the cross-section of the poles. Then a density, therefore, of 5,100, really means a density of 10,200 or a strong saturation for a distance of 2½ inches in the cast-iron of the poles. The magnetizing force required to produce 10,200 lines per sq. cm. through cast-iron is 200 per centimetre length. Therefore the ampere turns required to establish this density through 2½ inches are

$$\frac{2.5 \times 2.54 \times 200}{1.26} = 1,000.$$

The total number of ampere turns acting to produce magnetization through these strong pole corners was the sum of the field ampere turns that impressed magnetizing force from pole face to pole face through the armature, and the ampere turns on the armature covered by the poles. The poles covered approximately 85 per cent. of the armature surface, making this value: $1500 \times [2300 \times .85] = 3400$. Of this number, as was just shown, 1,000 were utilized in producing the magnetic density of 5,100, through the saturated portion of the poles The remaining 2,400 ampere turns exerted their magnetizing force in producing the average magnetic density of 5,100 through the air gap, and affords another opportunity of checking these ideas of the action of the armature on the field. For the ampere turns required to set up an average magnetic density of 5,100, through the air gap under consideration were:

$$\frac{[1.8 \times 5100] \times .125 \times 2.54}{1.26} = 2300,$$

which checks with the above value as well as could be expected. When the armature furnished 24 amperes, the E. M. F. at the brushes was 97 volts, while with no current it was 112 volts. Of this drop of 15 volts, 8 are accounted for by the resistance of the armature, and the extra seven were caused by the saturated pole corners. By operating this same machine at an E. M. F. at which the pole corners could not saturate with normal output of current, we have demonstrated for us in a very striking manner that the armature ampere turns cannot change the total magnetization established through the armature by the field when the pole corners do not saturate. The E. M. F. with the armature current at zero was brought to 48 volts with a separate field excitation of 750 ampere turns. Then when the armature was allowed to furnish 20 amperes the E. M. F. at the brushes dropped to 40 volts. Of this drop of 8 volts, 7 were produced by the resistance of the armature. Yet the field is powerfully distorted by the armature current, as may be seen by reference to curve III., Fig. 10, or the curve A, D, C, B in Fig 12. Even with this very great rearrangement of the magnetization produced by the armature current, the total magnetization set up by the field is practically unchanged. The difference of potential on the commutator between the points A. B., Fig. 12, was observed to be 72 volts. This excess of E. M. F. over that which was produced at the brushes, the figure shows clearly to be due to the magnetization produced by the armature through itself and the strengthened pole corners. The points where the field is zero are at A. B. They mark the diameter through which the ampere turns encountered on the armature are just equal and opposite in action to the ampere turns of the field that impress a magnetizing force between the pole faces through the armature. A simple computation will show that this is true. The field ampere turns that impress magnetizing force between the poles when the armature produced an external E. M. F. of 48 volts are

$$\frac{1520 \times 48}{112} = 650.$$

The ampere turns on the armature opposed to the magnetization set up by the route A. B. are $\frac{12}{40}$ of the total number of ampere turns on the armature [see Fig 12,] or

$$\frac{12 \times 64 \times 3 \times 20}{40 \times 2} = 576$$

This is a fair agreement when we consider the accuracy with which the original data may be determined.

Mr. Esson in his valuable paper, aboved referred to, discussed the requisite features for a generator for constant current, with closed coil armatures, in which regulation is effected by shifting the brushes. He stated that the field should be uniform at all points, under the poles, and that the armature core should be saturated. These statements are a little misleading. The magnetizing force impressed by the field ampere turns must be uniform at all points between the pole faces. This is accomplished by proportioning the poles so that the strongly magnetized pole-corners will not become saturated when the brushes have their

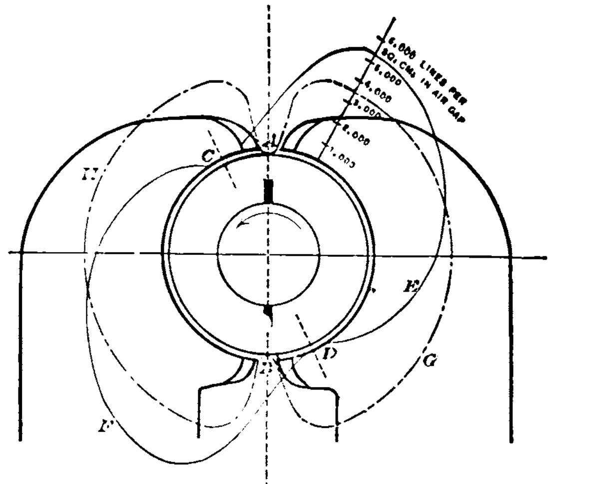

Fig. 11.

extreme position for the development of the highest E. M. F. that the machine is to produce. The air gap is made of such a depth that the ampere turns required to set up the magnetization through the armature, without current, and for the production of the highest E. M. F. that the machine will be called on to give, shall be a little more than the armature ampere turns when it furnishes its normal current. Then as long as the brushes are kept under the pole-faces, the non-sparking point will be whereever the brushes are placed. This will be the case whether the armature is or is not saturated. A practical demonstration is found in the following experiment: A Siemens & Halske dynamo with magnet and armature cores, whose shape and dimensions are shown in Fig. 5, was used.

Length of armature core	7.25 in.
Number of armature sections	56.
Turns per section	6.
Revolutions	1000.
Output in volts	50.
" " amperes	30.

The field was separately excited with 4000 ampere turns on each of the sets of consequent poles. Regulation could then be effected for a constant current in the armature of 22 amperes, by shifting the brushes from no E. M. F. to 35 volts without the slightest sparking even when metallic brushes were used. Within this limit the pole corners did not saturate. The field cores were wrought and the yokes cast iron. When the armature circuit was broken, it was found that the field excitation of 4000 ampere turns produced an E. M. F. of 50 volts. The magnetic density in the field cores, including leakage, was only 11,000 lines per sq. cm. Therefore, of the 4000 ampere turns on the field, not more than 200 were applied in setting up the magnetization from pole face to pole face through the field cores. It is safe to assume, then, that of these 4000 ampere turns, 3800 were active in producing a magnetizing force impressed uniformly over the pole faces through the armature. This same value is obtained by the method adopted in the previous cases. That is by calculating the magnetic density in the air gap when 50 volts were developed, and then deducing the number of ampere turns required to

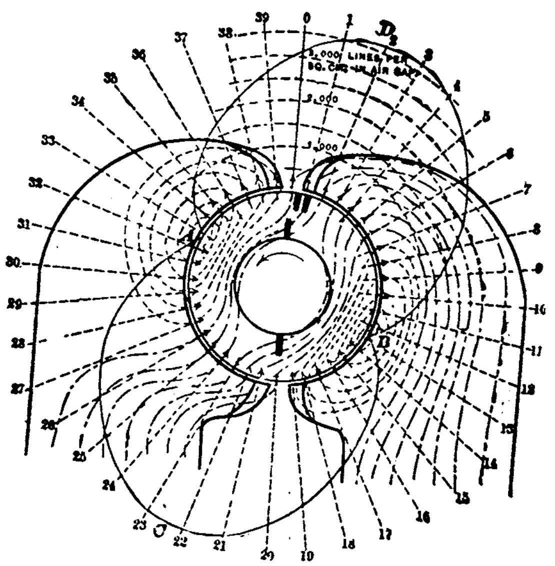

Fig. 12.

establish such a magnetic density through a 1¼ inch air gap. As to the armature, when it produced 22 amperes its ampere turns numbered

$$\frac{2 \times 56 \times 6 \times 11}{2} = 3700,$$

or an excess of 100 ampere turns impressed by the field over and above those on the armature. As long as this same number of ampere turns was maintained on the field it was not possible to regulate for a constant current of a lower or a higher strength without sparking. The impressed field ampere turns are in excess of the armature ampere turns by that amount which is just sufficient to produce a weak positive field that will reverse the current in the coil when its terminal bars at the commutator pass under the brush. When regulation is effected by this means it is seen that all pole corners are alike magnetized and at the centre of the pole faces the magnetization is zero when the machine is short-circuited. At full output, at the highest E. M. F., the magnetization under the one set of pole corners is almost zero, and under the other set it is at the maximum value that is ever obtained. In a generator of this type when the poles are made stout enough at all points, the total amount of magnetization through the armature, at all loads, will remain at a constant value. When used for operating long arc lamps a "drooping characteristic" can better be obtained by saturated field cores than by saturated pole-corners and armature core.

What has been said of dynamos applies equally well to motors. The only difference is that the non-sparking points are on opposite sides of the diameter at which magnetization is zero in the air gap. This is due to a well-known cause. In a motor the armature rotates in an opposite direction when field and armature currents remain the same as in a dynamo. The E. M. F. of self-induction caused by the reversal of the current in a current has not changed, while the E. M. F. developed in the coil by the field has changed sign with the change of the direction of rotation. The result is that the reversal of the current in an armature section must take place in a weak field of an opposite sign in a motor from what it does in a dynamo, when sparking is to be avoided entirely.

The action of the current in the armatures of multipolar dynamos and motors will be the same as that found for two pole machines.

[In view of the importance of the subject treated in this paper, it was voted, on motion of Mr. J. Stanford Brown, that its discussion be continued at a future meeting. Members who may not be able to attend and who are interested in the matter are requested to send to R. W. Pope, secretary, 12 West 61st street, any communications which they may wish to have incorporated in the discussion.]

FAURE'S NEW CARBONATE OF IRON BATTERY.[1]

THE new carbonate of iron battery of M. Camille A. Faure is composed of wooden troughs, say, about 27 ft. long, by three ft. nine in. high and six ft. six in. wide, enclosing some hundred or so double electrodes six ft. six in. wide. These electrodes are constituted of an agglomerate of carbon obtained by grinding up in a mill, drying, and then carbonizing at 1,400 deg. C., a paste composed of quarter by weight of oats, quarter of bituminous coal, and half of very porous, clayey earth. An agglomerate is thus obtained which is extremely porous, with which one side of the electrodes only is covered, the other receiving a coating of tar, rendered entirely impermeable by rebaking. The porous side of the electrode is covered with a large piece of netting or coarse sailcloth. The space between these double electrodes is filled in with granulated iron. The liquid used is salt water led in by tubes. The current is taken from two iron plates at the two extremities; the space between one of the plates and the last electrode is filled in with coke or copper turnings of a sufficient conductivity to carry the current of 1,000 amperes, generated by this battery at a tension of about 1.15 volts.

The elements of iron and carbon immersed in salt water (NaCl) produce chlorate of iron, caustic soda, and hydrogen, with an E. M. F. of about .30 volt; the hydrogen recombining with the oxygen increases this by .40 volt; and the carbonization of the soda by the carbonate of iron adds another .30 volt, which is again increased .15 volt by the use of reduced porous iron instead of solid iron. Thus the total E. M. F., according to M. Faure, is .30 + .40 + .30 + .15 = 1.15 volt.

In the electrolytic reaction the carbonate of iron and the chlorate of iron form carbonate of iron and chlorate of sodium, which is thus regenerated; the battery only uses the iron transformed into carbonate, which, as will be seen, is easily regenerated, as well as the carbonic acid used for this regeneration. The cloth-covered porous surfaces constitute the positive faces of the electrodes; they are depolarized by the gases, which penetrate between the faces of each double electrode, which are arranged in cone shape, by holes placed in the bases of this cone, and of which the inert part—the nitrogen—escapes by the porous face, at the same time agitating the liquid. The reduction of the carbonate of iron takes place in a retort charged with carbonate of iron, and traversed from top to bottom by gas reducers—CO, H, etc.—coming from a gasogene. Passing from the retort, these gases take fire at the contact of air, forming carbonic acid, which passes around the retort to the chimney, whence a portion of the gas is drawn by a pump, which forces it, after washing, into the battery. The air necessary for the combustion of the gasogene arrives, already heated, by a chimney, and the reduced spongy iron passes away cold by a channel placed at the base.

The installation of a Faure primary battery comprises, therefore, besides the battery properly so-called—(1,000 elements)—a pump capable of forcing 1,000 cubic metres of carbonic acid per hour, a machine to agglomerate the carbonate of iron passed out of the channels, into bricks, and the reducing chamber. According to M. Faure, the consumption of fuel in the retort is not more than 0.3 lb. of coal per pound of iron used in the battery, or per h. p. hour at the battery terminals.

ELECTRICAL HEATING.

WE are glad to learn that there will be a complete exhibit of the Burton electric heaters at the Street Railway Convention in Pittsburgh, and also that Dr. W. Leigh Burton, the inventor, will be present, a circumstance which will certainly add largely to the interest of the exhibit. This will be an occasion for street railway men to examine the heaters personally and to determine the comparative value and economy of electric and other heaters. Electric heating, as electric lighting, is of universal interest, and having received its first successful employment upon electric cars, must necessarily be of deep interest to all street railway men.

1. *Bulletin de l'Electricité.*

THE SHORT RAILWAY MOTORS.

OUR readers will recall a description in THE ELECTRICAL ENGINEER, of April 1, 1891, of the Short "gearless" railway motor, then brought before the public for the first time. In view of the improvements already made upon this motor, and the favor with which it has been received, a further account cannot fail to be of interest.

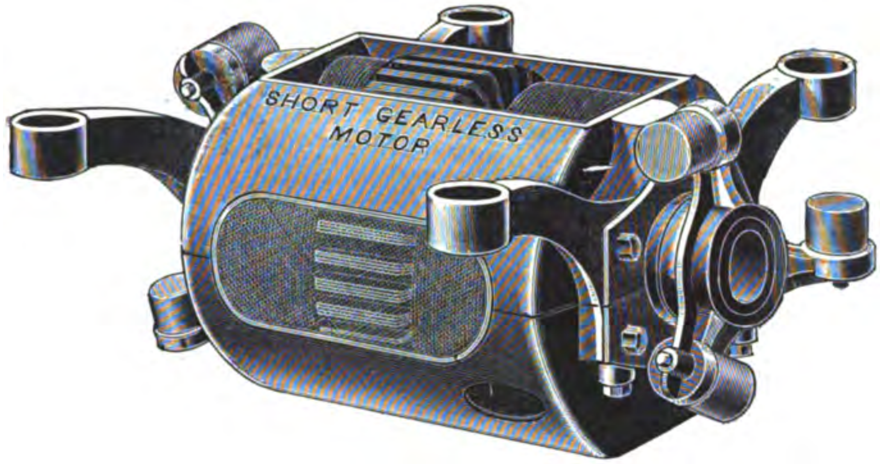

FIG. 1.—SHORT GEARLESS MOTOR.

The motor is shown in Fig. 1 of the accompanying illustrations. As will be seen, all gearing is eliminated from the machine, and the number of bearings is reduced to two on each motor, making four in a car equipment. The armature speed has been reduced to the minimum, viz., that of the car axles in practical operation. The noise of gearing and the "squealing" of commutator brushes are entirely obviated, and there are but three wearing parts on each motor. The armature is of the ring type, of comparatively large diameter and increased "leverage." It is keyed to the hollow steel shaft, which is concentric with the axle of the truck, and an inside clearance of one inch all around is provided for. The coils of the armature are, in this, as in all Short machines, entirely independent and perfectly ventilated. The motor has eight field magnets, four on each side of the armature. They face each other at a distance of only ten inches, and thus form a most intense magnetic field. They are bolted to the frame-work of the motor, in the centre of which are the bearings which carry the hollow armature shaft.

Mounted upon the hollow shaft close to the armature is the commutator, which is protected from injury by the surrounding pole-pieces It is massive in construction, and much larger than any commutator heretofore used, the idea being that, because of its massiveness and slow speed, the wear would be reduced to a minimum. Six months' operation of these motors has proved the correctness of this idea and disclosed other distinct advantages in the use of the enlarged commutator.

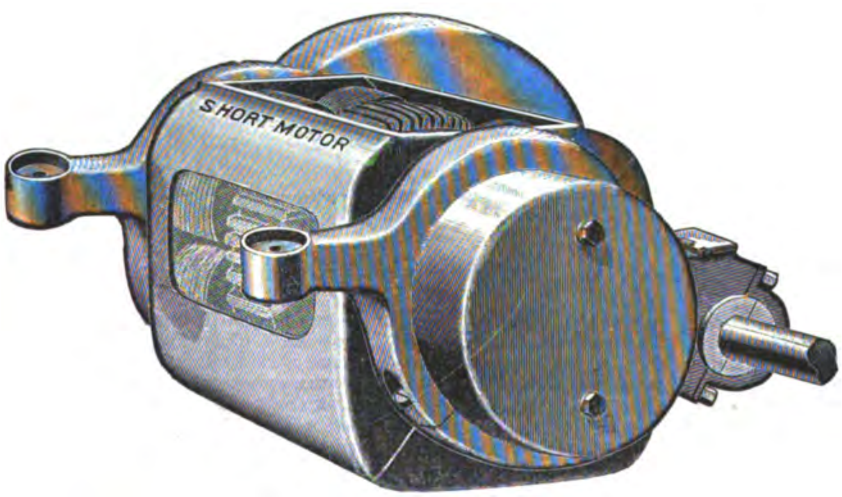

FIG. 3.—SHORT SINGLE-REDUCTION MOTOR.

A glance at Fig. 1 will show the method of mounting this simple machine. A three-armed spider is placed upon each end of the hollow shaft. Each arm is provided at the extremity with a socket to receive a rubber cushion or spring. These cushions bear upon lugs cast on the car wheels, and as the armature shaft and spider revolve the action is imparted to the car wheels. This rubber cushion serves the double purpose of insulation and easy starting.

The electrical output of the motor has been noted with great interest, and all tests have been carefully tabulated. The following result has been obtained from thousands of readings taken on the three electric railway lines in Cleveland:

Average volts.	Amperes.	E. H. P.	Passengers.
480	24	15.44	48

Fig. 2 shows the Short Standard "Double-Reduction" or geared motor, which is already familiar to our readers.

The "Single-Reduction" or "Water-Tight" motor is shown in Fig. 3. One pinion and one gear have been dispensed with, and arrangements made to run the remaining gear in oil. The machines are practically the same, and a series of efficiency tests show that in economy of current and in output of power there is little choice between them. The "W. T." motor however, is smaller than the "Standard" motor, and, it is claimed, is the lightest and smallest street car motor thus far constructed. It weighs something less than 1,800 pounds. It is encased in, and entirely protected by, its iron frame, and can be operated on 30 inch, 33 inch and 36 inch wheels, and on any gauge of track down to 3 feet. It is in great demand for narrow-gauge roads and for mining and other electrical haulage purposes. It is made in two standard sizes, 15 and 20 h. p.

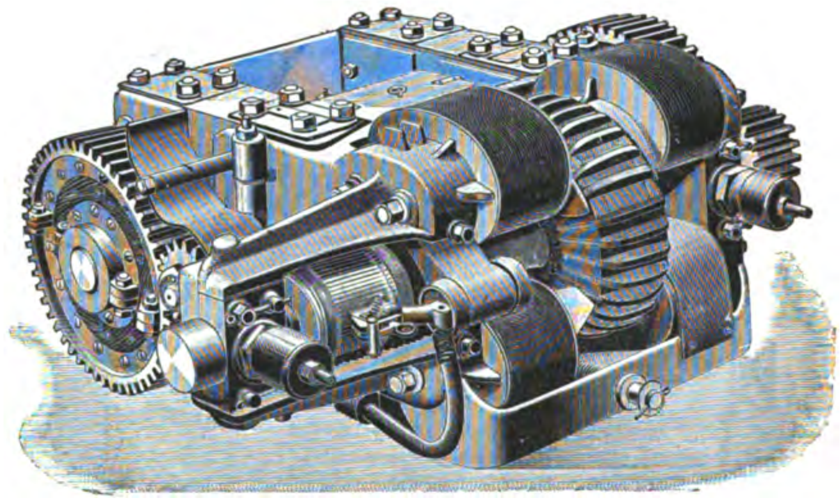

FIG. 2.—SHORT STANDARD MOTOR.

Carefully kept records of the operation of electric cars on the many roads equipped with Short geared motors show that the cost per car mile ranges from two to four mills.

The Jamestown, N. Y., Street Railway operated ten Short cars from June 10 to August 29, a period of 11 weeks, with a total loss of but two car days. On the Rochester, N. Y., Railway, during eight months of operation, the total cost of repairs, including material and repairs to electrical machinery was but four mills per car mile, and the average loss per car was but 4 per cent. of the total mileage.

SOME BIG SCHIEREN BELTS.

ANENT recent statements as to the biggest big belts Charles A. Schieren & Co. write us: "Last spring we supplied the Louisiana Electric Light Co., New Orleans, La., with 160 feet of 72-inch double leather belting ½-inch thick, and up to that time it was the largest belt in the world. Last March we supplied the Tacoma, Wash., Railway & Motor Co. with 158 feet of 54-inch perforated electric leather belting, three ply, ¾ inch thick. We have just supplied the Botany Worsted Mills, Passaic, N. J., with two 60-inch three-ply leather belts, 145 feet long each. We have also just made three 54-inch double leather belts 112 feet long each, for the Denver, Col., Electric Co.; also 150 feet of 50-inch double perforated electric leather belting for the Madison Car Works, Madison, Ill., and 145 feet of 60-inch three ply leather belting to the New

York Biscuit Co., N. Y." These are a few of the company's large belts made recently. To one concern in the South they have shipped 548 feet of 48-inch double leather belting.

THE NEW TRIPLE EXPANSION ENGINE OF THE LAKE ERIE ENGINEERING WORKS, BUFFALO, N. Y.

THIS engine is designed with a view to meeting the continually increasing demand for economy in floor space, in the use of steam, and thorough reliability. It is especially adapted for central station electric lighting and railway work, giving close regulation and economy, and occupying very little floor space, and is one of the first practical solutions of the problem of direct connection or direct bolting for the larger types of generators now being introduced in this country.

The rotative speed is chosen somewhat above the limitations imposed by the releasing valve gear of other engines, but is not what is called high-speed, the engine occupying middle ground in this particular. The pressures per square inch on the bearings, and the rubbing velocities of the journals, form the starting point in establishing the rotative speed, the rate of rotation varying in the different sizes of engines in inverse proportion to the diameters of their shafts; and the pressure per inch of bearing surface is kept below a certain limit in all sizes. This insures uniform results. The piston speed is universally 650 feet per minute, and the stroke is reckoned from the diameter of the shaft and its consequent rate of rotation.

The accompanying illustrations, Figs. 1, 2, and 3, are from scale drawings of triple-expansion engines, and are shown connected directly to two 500 h. p. electric generators. They are intended to work under from 140 pounds to 160 pounds steam pressure when connected with condensers, and from 180 pounds to 200 pounds steam when exhausting into the atmosphere. Their rated power is 1,000 h. p. when most economically loaded, but they are capable of performing 1,200 h. p. or more very easily should they be called on to do so.

It is expected to obtain as good economy with these engines working under from 130 pounds to 200 pounds steam pressure without condensers as with best compound condensing engines under from 30 to 100 pounds of steam. Their adaptability, therefore, to situations where water cannot be obtained for condensation is apparent. It is said that by using triple-expansion engines thoroughly adapted for the service under heavy steam pressure without condensers, not more than one-half the fuel now commonly used will be required.

Figs. 1 and 2 are front and side views of the three-cylinder type; it will be seen that each cylinder acts through an independent set of cranks on a common crank shaft; this is 9¾ inches in diameter, carries at each end an armature, and has two intermediate wheels. In this manner the weight is distributed evenly

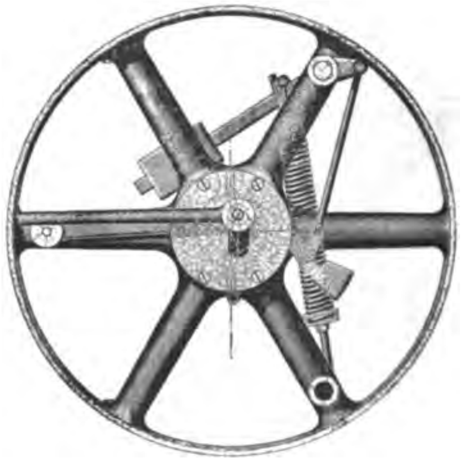

FIG. 3.

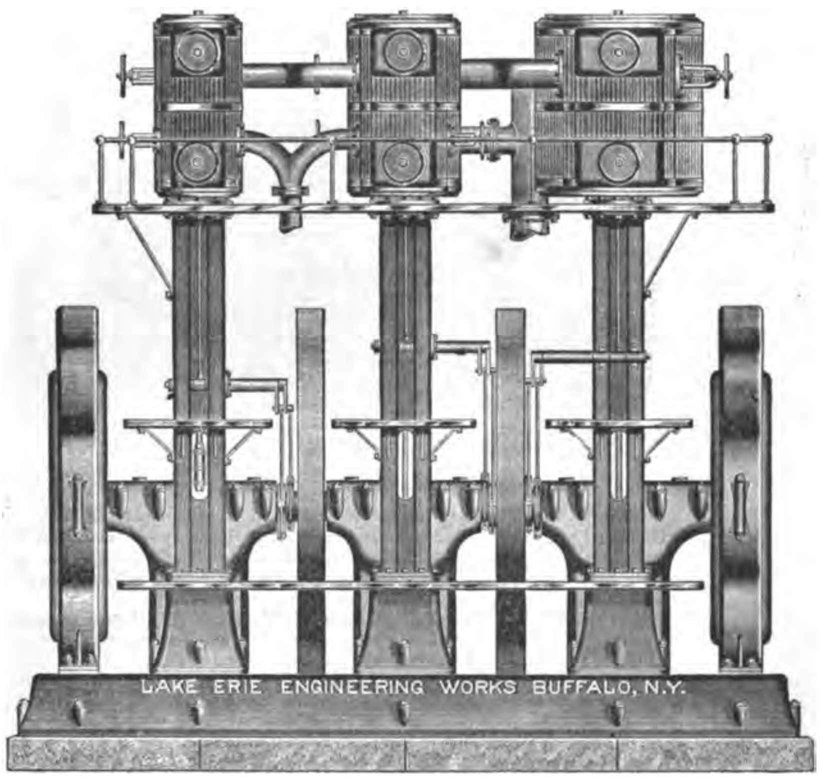
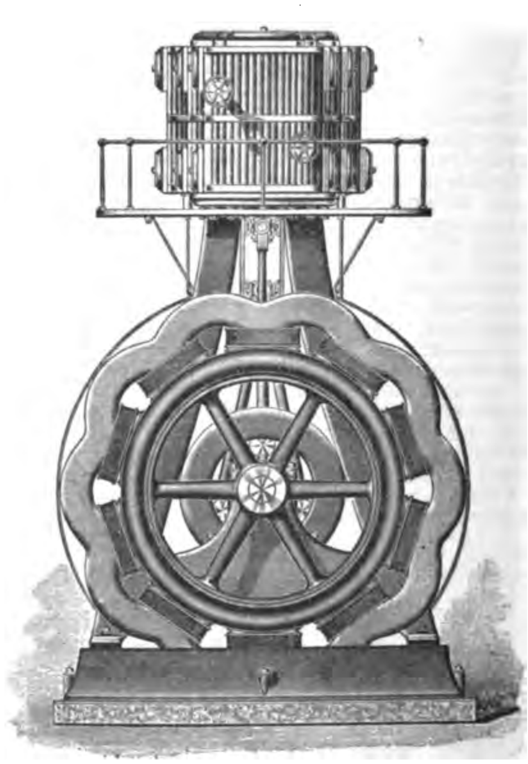
along the shaft upon bearings, tending to bring equal wear upon each journal along its length, and in this manner keeping the shaft straight and free from undue strains.

Each cylinder has an independent framing and pedestal, the whole including the generators standing on a common bed-plate. The columns are "divided," allowing sufficient space between the divided halves for the valve stems and rock arms of the high-prussure and intermediate pressure cylinders, bringing the valve chests at right angles to the crank shaft, where they are perfectly easy of access. These valve chests form the receivers between the cylinders. Four valves are used on each cylinder, the steam and exhaust being independent of each other, and the steam lap and exhaust lap adjustable, so that the admission, lead, closing and opening of exhaust or point of cut-off may be easily altered by adjustment. In this manner the engine is easily adapted to any service, either condensing or non-condensing. In addition to this, the point of cut-off may be changed by hand for the low-pressure cylinders while running, so as to afford that refinement





FIGS. 1 AND 2.—LAKE ERIE ENGINEERING WORKS TRIPLE-EXPANSION ENGINE.

in the management of the receiver pressures required for exceptional economy in the use of steam.

The clearances are small, averaging from 2¼ to 6 per cent. according to sizes of cylinders, and the valves are adjusted to fill the clearance by compression, neutralizing the small loss that would occur in these limited clearance spaces, and at the same time insuring against "knocking" on the rod bearings and main journals.

The valves are four-ported, and therefore small and light, flat-faced and nearly balanced. They press against their seats just sufficiently to keep tight, and are allowed to follow their wear. The engines are of the disconnective type.

By the use of the four valves above mentioned, the engine can be converted into either a small compound engine, by disconnecting the low-pressure cylinder. or it may be made into a large compound by disconnecting the high-pressure cylinder, and the change can be made while the engine is running, the governor being connected to the intermediate steam valves when using the intermediate and low pressure cylinders as a compound. By this arrangement but one governor is used, and its action can be thrown on to the intermediate steam valves either in full or in part, as desired. The main bearings are provided with babbitt-lined shells, and are water-jacketed, a water-jacket being provided in the back of the guides also. The engines are equipped with complete apparatus for grease lubrication. The cranks and shafts are forged and of the built-up pattern, with counterweighted crank arms.

The governor is illustrated in Fig. 3. A similar governor is placed in one of the intermediate wheels in the triple engine shown. The Lake Erie Engineering Works are equipped to build these engines in sizes from 150 h. p. to 10,000 h. p.

The Field Engineering Co., of New York, who are making a specialty of large power station construction, and have built a number of representative stations for railway and lighting work, and who have been looking for an engine which would best fill the requirements of their practice, have concluded arrangements to specially represent this engine in their line of work. They are having the Lake Erie Engineering Works build two large engines of this type, in two cylinder compound, soon to be installed in the power station ofthe Buffalo Railway Co.

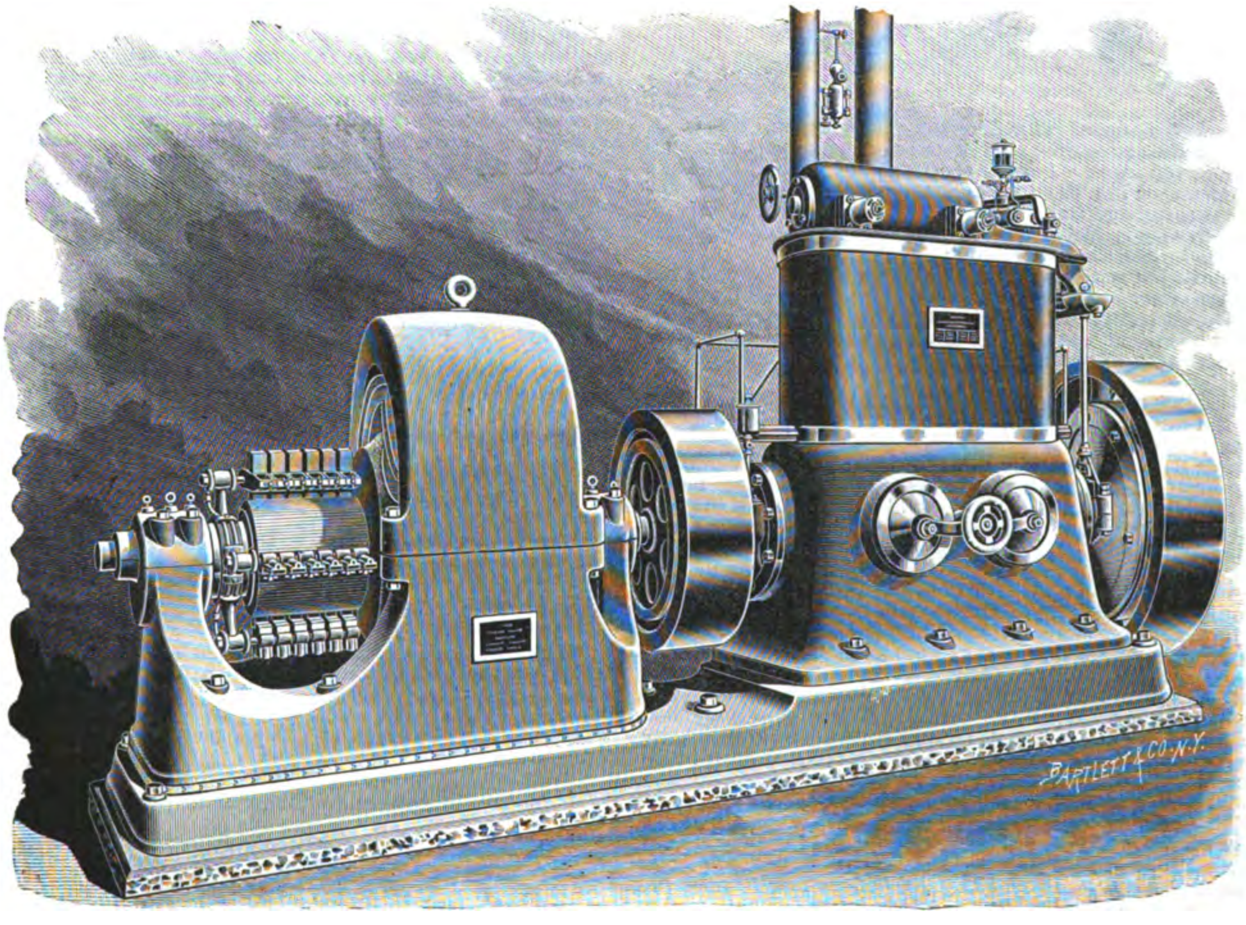
MR. E. W. GOSS has entered upon his duties as superintendent of the Electric Light Co., Amesbury, Mass.

WESTINGHOUSE DIRECT-COUPLED MULTIPOLAR GENERATOR.

THERE is little room for doubt that the generating plant of the future, so immediate as to be almost the present, is to be the direct-coupled, slow-speed, multipolar generator for electric railway stations, and the same system in connection with a dynamo for electric lighting. The advantages are sufficiently apparent. The first cost of a plant on this principle, as compared with a system involving counter-shafting, clutch pulleys, belt tighteners, belts, etc., is enormously in its favor. This is obvious when referring to the machinery alone, but is strongly emphasized when the further value of the reduced cost of real estate and buildings is considered.

Again, every transformation or transmission of energy is a loss of money, and it follows that when the crank shaft of the engine is the armature shaft of the dynamo the loss is reduced to its lowest terms.

Next to the direct saving in power comes the saving in space. As a general statement, fully twice as much generating capacity, with the same accessibility and convenience, can be got into a given floor space with the coupled dynamo as with the direct-belted generator, and from four to eight times as much as with indirect belting through counter-shafting.



WESTINGHOUSE DIRECT-COUPLED MULTIPOLAR GENERATOR AND COMPOUND ENGINE.

In the item of attendance and maintenance the coupled generator possesses manifest advantages in eliminating the belt account wholly, and the oil and babbitt account in large part. Not the least of the recommendations of the coupled generator is that it is strictly noiseless.

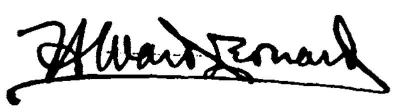
Recognizing the demand for this form of generator and the certainty of its permanent success, Messrs. Westinghouse, Church, Kerr & Co. have, in connection with the Westinghouse Electric and Manufacturing Co., developed it in the form as indicated in the accompanying engraving. The engaving represents a 250 h. p. generator for railway work coupled to a compound engine capable of developing 250 h. p. at 100 lbs. pressure of steam, non-condensing, the speed being 250 revolutions. The design is that of a single machine carried upon a massive bed-plate requiring only moderate foundation. The generator is thoroughly insulated from the bed-plate by a sheeting of tarred plank, the bolts being insulated by bushings and washers of non-conducting material. The insulation is completed at the coupling, in which non-conducting material is interposed to prevent metallic contact. The coupling is further so designed that it will yield fully to any misalignment of the two shafts either as to angle or position of centres. The larger engines are provided with unhooking gear in the valve motion so that they can be handled by a starting bar, and are also fitted with a gallery sole-plate and stairway protected by handrails, so that the throttle valve and lubricator are conveniently accessible.

The same general design is carried out for direct coupling to heavy alternating dynamos. The sizes at present manufactured correspond to 125, 250 and 500 h. p., with 1,000 h. p. to follow. The sizes of engines required for the given power will vary according to the steam pressure carried; 180 lbs. being contemplated as a maximum, and 100 lbs. as a minimum.

The same company has also completed the preliminary work of a design for a third high-pressure cylinder for converting the compound engine into triple expansion.

MINIMUM FIRST COST OF PLANT AND MAXIMUM ECONOMY OF OPERATION IN THE ELECTRICAL TRANSMISSION OF POWER.

BY



In the last issue of THE ELECTRICAL ENGINEER, Mr. C. J. Reed, under the above title, argues that my deductions are radically wrong and says: "I again challenge Mr. Leonard, through the indulgence of THE ELECTRICAL ENGINEER, to show his proofs."

It is not surprising that Mr. Reed feels confident that my results are all wrong, for he claims to have discovered a radical error which he describes as follows:

"He starts out with an arithmetical error and in his reply adheres to the error, insisting that it is correct. I will call his attention to it specifically. In his expression for the weight of the conductor he uses M, the area of 2 D as a factor, and then introduces the factor "2" again giving the weight of a conductor 4 D in length."

I find it difficult to be more explicit than I have been on this point. But perhaps the following statement may point out Mr. Reed's error clearly.

Formula (1) determines the cross-section of the conductor in circular mils. In order to get this cross-section it became necessary to consider the resistance of the total length (2 D) of the conductor both outgoing and returning; this introduces the factor 2 D for the first time. Having now obtained the cross-section M of the conductor, we next get its weight per foot, and then to get the weight of the total length of conductor both ways we must again multiply by 2 D. This introduces 2 D for the second time.

If I have not now made it clear that formula (2) is correct and not 100 per cent. out of the way, I would suggest that the reader, by other formulae available, determine the cross-section and weight for any assumed conditions, and compare the result with that obtained by my formula. A few practical applications will oftentimes change one's views materially and enable one to see exactly the correct application of a formula apparently likely to give incorrect conclusions. If Mr. Reed or any one else interested will take the trouble, after assuming a set of conditions, to get the minimum first cost by gradual approximation he will find that the formulæ given by me are entirely correct. The formulæ are not the result of an abstruse mathematical research, but are exact expressions of conditions which become evident to any one who daily has to deal with estimates in which large sums of money depend upon determining the best possible conditions for operation. I cannot demonstrate the accuracy of the formulæ mathematically any more perfectly than I did in my original article, which led the reader step by step to the conclusion. Hence, I shall not bore your readers with mathematical expressions which can add nothing to the proof.

Mr. Reed cannot understand how it is possible that the conditions of minimum first cost are such that an increased cost of conductor is necessitated by conditions demanding an increased loss. He says of this,—"an absurdity so obvious that it is unworthy of discussion." If Mr. Reed will consider a transmission of say 30,000 feet, with dynamo machinery at $33 per kilowatt at brushes and copper at 20 cents per pound, he will find that with 3,000 volts initial E. M. F. he must, for minimum first cost, operate with 21.5 per cent. loss in conductors and that the cost of conductors will be $15.81 per kilowatt at motor brushes. If he operates with 2,400 volts initial E. M. F. he must, for minimum first cost, have a loss of 25 per cent. in conductor and the cost of conductor will be $22 per kilowatt.

Stated as above, I think Mr. Reed will admit that it is not surprising that my formulæ (12) and (13) show that the conditions which make a minimum first cost with 25 per cent. are such that the cost of conductors will be then more than the cost will be when the conditions are such that 21.5 per cent. gives minimum first cost. I will emphasize again the importance of remembering that we are not discussing the conditions which prevail for *any* loss in conductors, but should confine our attention to the conditions which make minimum first cost for any given set of values.

Mr. Reed has apparently been unable to rid his mind of the impression that under all circumstances an increased percentage of loss in conductors must mean a decreased cost of conductors, which, as is shown by the instance above cited, is not always so, and is never so under conditions of minimum first cost.

Another point which Mr. Reed will not admit is that the condititions of minimum first cost are such that the cost of conductors depend only upon the loss and the cost of dynamo machinery. Yet this is entirely true. If dynamo machinery is worth $33 per kilowatt and copper 20 cents per pound, the conditions making it possible to realize minimum first cost with 21.5 per cent. are such that the cost of copper will be $15.81. This applies to any E. M. F. and distance which make a minimum first cost possible at 21.5 per cent. loss. Also, if our conductors be worth twice as much as before, we will find that the only conditions making it possible to realize a minimum first cost at 21.5 per cent. are those in which the cost of dynamo machinery is also doubled, that is, $66 per kilowatt. In other words, conditions of minimum first cost are such that the cost of conductors depends only upon the percentage of loss and the cost of dynamo and machinery.

Mr. Reed has pointed out that the example I cited to show the inaccuracy of Sir William Thomson's law was not a commercial one. This I admit, but that does not affect the accuracy of the conclusion. I will, however, give a commercial example:

Suppose interest and depreciation to be 15 per cent. and the value of 1 kilowatt per annum as used to be $20, also that we are using 100 volts per 1,000 feet. It will be found (as is shown by my chart No. 3) that the interest and depreciation equals the value of the energy wasted when we lose 31 per cent. in conductors. By Sir Wm. Thomson's law we would then be operating at maximum economy. But we find that in reality we should operate at 12 per cent. loss in conductors, for then we would have an interest and depreciation charge of $9.60 and a value of energy wasted of $2.50, a total of $12.10, against a total of $9 plus $9 or $18, by following Sir Wm. Thomson's law.

I trust that if further criticism regarding my deductions be offered, that practical conditions will be assumed and the resulting figures will be quoted, as I feel that no special gain can be made by merely theoretical discussions of formulæ so easily misinterpreted as those pertaining to this subject are.

Reports of Companies.

TROPICAL AMERICAN TELEPHONE CO.

GENERAL MANAGER HOWARD says the Tropical-American Telephone Company is turning its ready capital about three times a year at a fair profit; that it is enlarging its field and extending its business month by month. The sales for August were over $14,000, and sales in 1890 were 50 per cent. over sales in 1889.

THOMSON-HOUSTON ELECTRIC CO.

THE trustees of Thomson-Houston trust securities, series D, will make a division of the funds in their custody Oct. 10, 1891, by the payment of $1 per share to shareholders of record Oct. 3, 1891. The transfer books will be closed from Oct. 5 to Oct. 10, 1891, both days inclusive. The rush of business at the Thomson-Houston works is caused in part by the established roads giving orders for increased equipment.

EUROPEAN ELECTRIC WELDING CO.

THE European Electric Welding Company has mail advices that at the offering of the stock of the English company, 16,668 shares were sold, and that the English company is prepared to pay the balance of £15,000 due the European company upon transfer of the property. Counsel is preparing to make the transfer. Completion of the deal will give the European company about $425,000 cash, and a dividend upon its $1,500,000 capital will be in order. The European company gave German parties an option on the patents for northern Europe, which lapsed last week; nevertheless, an agent will soon be sent to Germany and another to France, with a view to sell the patents for the territory embraced if satisfactory terms can be secured. The European company can soon pay $20 to $25 per share on its stock if the directors so elect.

Appointments, Etc.

MR. A. H. LYNCH, who has for some time been the superintendent of the Willimantic Electric Light Co.'s plant, has gone to Hartford, where he will take charge of the work of putting in plants of the Waterhouse system.

MR. A. H. BURNETT, who has been superintendent of the Somerville Electric Light Co. for about two years, has resigned, and Mr. J. G. Raymond has succeeded him. Mr. Burnett goes to New Hampton, N. J.

MR. M. J. KEENAN has assumed the office of superintendent of the Galveston City Railroad Co.

MR. HIRAM TERWILLIGER has been made superintendent of the electric light works at Nashville, Tenn.

Literature.

PERIODICALS.

The Engineering Magazine, (World Building, New York City), for October, is very interesting to electrical engineers. One of the articles, on the Keely motor, is by Mr. T. Carpenter Smith, M. E., who is well known in electrical circles. Another article, by Mr. H. Ward Leonard, on Block Signaling, is quoted extensively in this issue of THE ELECTRICAL ENGINEER. A third article by Mr. N. G. Wall deals in an admirable manner with "The New Art, Decorative Electricity." As usual, the *Magazine* is well illustrated and printed, and an improvement has been made by putting the titles of the articles on the front cover in stronger type.

Harper's Weekly for Oct. 3 is quite electrical. It has an unusually able article by Mr. H. L. Webb, on the telephone service of New York, with many illustrations by Mr. H. Dearborn Gardiner. There is also an illustrated article on the electrical fountain in Lincoln Park, Chicago.

Society and Club Notes.

AMERICAN STREET RAILWAY ASSOCIATION.

THE tenth annual meeting of the American Street Railway Association will be held at the Monongahela House, Pittsburgh, Pa., Wednesday, October the 21st, 1891, at 10 o'clock, A. M., and continuing three days. The forthcoming meeting will, from present indications, be much more largely attended than any preceding. The following is a general programme of the meeting:

Reports of Committees.—Special committees will report on the following subjects: "A Perfect Electric Motor;" "A Year'-Progress of Cable Motive Power;" "Public and State Treatment of Corporations, No. 3;" "The Dependent—Overhead or Underground—System of Electric Motive Power," and "The Independent—Storage or Primary Battery—System of Electric Motive Power." Notice has been received by the secretary from the president of one of the member-companies that a special paper will be read, under the following title: "Standards in Machinery and Appliances for Electric Railways."

The Local Committee of Arrangements, of which John G. Holmes, Esq., president of the Citizen's Traction Company, is chairman, has chartered for the week of October 18th-25th a double decked excursion boat, which will be moored to the wharf alongside the Monongahela House, to be used for the exposition. Heavy supplies will be placed on the lower deck and lighter ones on the upper. The boat will be suitably decorated, and lighted in the evening, and will be made a pleasant and interesting place for the exhibition of supplies.

There will be various excursions, etc., and the convention will close with the usual banquet.

FRANKLIN EXPERIMENTAL CLUB, NEWARK, N. J.

THE Franklin Experimental Club, of Newark, held its first regular meeting since the summer vacation on Tuesday evening, Sept. 29th. There was a good attendance and every indication of an increased interest in the society and its work. The club is preparing to move into larger quarters, and, with a view of increasing the membership, it has decided to make the initiation fee for the next three months the small sum of five dollars. The dues are but one dollar and a half per month for active and associate members respectively; and each member is entitled to the use of any and all apparatus, books, papers, use of room by day or night, and other privileges of the society. Parties desiring further information may secure the same by addressing the secretary, Mr. F. W. Hillard, at 153 Mt. Pleasant avenue, Newark, N. J.

After the regular meeting on Tuesday evening, the members were entertained by some remarks by President Hammer upon the Convention and Exhibition of the National Election Light Association at Montreal. Following this, Prof. Geo. C. Sonn gave some interesting and entertaining accounts of his summer tour in Europe, where he visited the Electrical Exhibition at Frankfort. He also described many things of scientific interest which he saw in the large cities of England, France, Germany, Switzerland, Holland and elsewhere. His remarks were listened to with much interest.

NEW YORK TELEGRAPH CLUB.

MR. MARION KERNER, the well-known lecturer, and an equally well-known war telegrapher, is to deliver a lecture for the benefit of the above club, at Chickering Hall, at P. M., on Sunday, October 11, 1891, on the Ober-Ammergau Passion Play. This is one of Mr. Kerner's best illustrated lectures, and on this occasion he may certainly count on an enthusiastic and crowded audience. The music will be under the direction of Prof. Louis Berge.

THE ORDER OF RAILWAY TELEGRAPHERS.

THE Old Telegraphers' Brotherhood has now, it is understood, been practically absorbed by the Order of Railway Telegraphers. The plan has been proposed before, and was recently carried out at St. Louis. The final measures looking to union are expected to go through without delay or friction. The united body should be very strong and influential.

SOCIETY OF OPERATIVE ELECTRICIANS.

THE Boston Society of Operative Electricians, President W. S. Moody, has elected A. T. Chase, second vice-president, and E. Lundin and J. H. Hazlett additional members of the executive committee.

Letters to the Editor.

Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents.
Anonymous communications cannot be noticed.
The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.
In order to facilitate reference, correspondents, when referring to any letter previously inserted, will oblige by mentioning the page on which it appears.
Sketches and drawings for illustrations should be on separate pieces of paper.
All communications should be addressed EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

DR. HUTCHINSON AND MR. LEONARD.

MR. LEONARD'S reply to my paper scarcely calls for answer from me. Mr. Leonard merely repeats his former assertions, adding nothing new. For the present, I have only to say that I have added not an iota to Mr. Sprague's paper; mine was merely an attempt to put the matter in a slightly different view, so as to show directly, instead of by implication, where Mr. Leonard's error lay. Further, although it is a very natural assumption that I spoke for Mr. Sprague from the fact of my being with him in business, yet this is not the case; the views expressed were mine, and I only am responsible for them. Mr. Sprague is out of the city at present, owing to ill health, but on his return will doubtless speak for himself, should he deem it necessary.

CARY T. HUTCHINSON.

NEW YORK, Oct. 3, 1891.

Obituary.

HON. W. L. SCOTT.

FEW men have played so prominent a part in business affairs and in Democratic councils of late years as W. L. Scott, whose death at Newport has just been announced. He was interested in a great many enterprises, and was always ready to lend his aid in the development of valuable new ideas. It was thus that he became connected with the Eureka Tempered Copper Co., of North East, Pa. He was one of the directors of the company and was largely instrumental in enabling that concern to reach its present position and magnitude.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED SEPTEMBER 29, 1891.

Alarms and Signals :—

Electric Alarm, C. H. Shaffer, 460,287. Filed June 20, 1890.
A combined alarm and telephone service.

Automatic Electric Fire-Alarm System, W. S. Cook, M. C. Cook, A. H. Morrow, 460,464. Filed Oct. 18, 1890.
Has for its object to provide an automatic fire-alarm system which shall be at the same time extremely simple and perfectly reliable.

Electric Bell, W. Hay, 460,503. Filed May 11, 1891.
Has for its object a cheap and easy manufacture, installment and care of electric bells.

Electrical Railway Signaling Apparatus, W. F. Z. Desant, 460,524. Filed Sept. 26, 1890.
Improvement in railway block-signaling devices.

Electric Railway Signal, W. F. Z. Desant, 460,525. Filed Sept. 26, 1890.
Similar to 460,524.

Batteries :—

Electrode for Secondary Batteries, J. B. McDonald, 460,235. Filed Feb. 5, 1891.
Claim follows:
In a storage battery a grid for the support of the active material, composed of a metal ribbon having indentations or raised portions upon its surface and bent back and forth upon itself to form the supporting frame.

Distribution :—

System of Electrical Distribution, E. W. Rice, Jr., 460,364. Filed Feb. 18, 1891.
Relates to a novel system of multiple series distribution

Dynamos and Motors :—

Dynamo or Electric Motor, W. M. Fink, 460,125. Filed Oct. 7, 1890.
Has for its object cheapness of manufacture and economy of space.

Dynamo, W. H. Elkins, 460,372. Filed Nov. 28, 1890.
A dynamo containing considerably more turns on one coil than on the other; that having the greater number being connected to one of the main brushes and the other to an auxiliary brush, the coil of the other pole forming part of the main circuit.

Electrolysis :—

Apparatus for Electrolytically Separating Metals from Ores, W. von Siemens, 460,354. Filed June 18, 1890.
Claim 1 follows:
In an electrolytical cell the combination of a revolving cathode, a trough-shaped anode situated below the said cathode, in the trough of which the cathode revolves. A screen permitting the passage of the electrolyte and of electricity and capable of preventing the passage of vibrations of the electrolyte situated between the said cathodes and anode, and means for applying the electrolyte above the screen, and for withdrawing the oxydized liquid from the bottom of the trough of the anode.

Lamps and Appurtenances:—

Hanger for Incandescent Lamps, J. A. Matteson, 460,178. Filed Dec. 24, 1890.
Employs a counterpoise of such weight as to exactly balance the lamp when placed at any height.

Miscellaneous :

Electric Safety-Catch, J. W. Howell, 460,140. Filed Jan. 6, 1891.
Claim 1 follows:
A safety-catch for electric circuits composed of a conductor of electricity, which is destroyed by chemical action (as distinguished from fusion) when an abnormally large current passes through it.

Circuit-Controlling Apparatus, J. P. Cushing & W. J. Kelly, 460,199. Filed Nov. 6, 1890.
Relates to a switchboard designed for use in theatres, etc., whereby independent circuits may be readily and quickly connected.

Switch for Series Dynamo Electric Machines, C. R. Arnold, 460,245. Filed Nov. 10, 1890.
Has for its object to obviate injury to the switch contact and danger of damaging the armature or field-magnet cores of the machine.

Lightning Arrester, J. J. Wood, 460,289. Filed Sept. 25, 1890.
Relates to lightning arresters applicable to the ground connection of electric circuits generally.

Electric Lock, W. S. Hull, 460,391. Filed Dec. 31, 1890.
Claim 1 follows:
The combination of the main latch bolt of an auxiliary bolt suspended to swing into line with, and contact with, the end of said bolt and an armature of an electromagnet connected with said auxiliary locking device by jointed connections.

Push-Button, J. E. White, 460,416. Filed Aug. 21, 1891.
A push-button which may also be used as an automatic alarm in case of fire.

Method of Soldering or Brazing by Electricity, C. L. Coffin, 460,428. Filed Apr. 17, 1890.
Method consists in connecting the material to be soldered to one pole of the generator and the soldering tool to the other pole and passing a current through the two and the material.

Insulator, F. A. Ross, 460,448. Filed Dec. 16, 1890.
An insulator in which the use of binding wires is avoided and upon which the conductor may be securely clamped without injury to the insulation or the wire itself.

Apparatus for Holding and Sewing Carpets, R. M. Hunter, 460,504. Filed June 4, 1890.
A system of holding and sewing carpets by means of electrically operated machinery.

Apparatus for Holding and Sewing Fabrics, R. M. Hunter, 460,505. Filed Sept. 22, 1890.
Similar in its object to 460,504.

Apparatus for Holding and Sewing Fabrics, R. M. Hunter, 460,506. Filed Oct. 13, 1890.
Similar in its object to 460,504.

Apparatus for Holding and Sewing Fabrics, R. M. Hunter, 460,507. Filed Nov. 1, 1890.
Similar in its object to 460,504.

Apparatus for Holding and Sewing Fabrics, R. M. Hunter, 460,508. Filed Nov. 1, 1890.
Similar in its object to 460,504.

Electric Crane, W. A. Stadelman, 460,514. Filed March 11, 1891.
An electric crane in which the current is carried by a flexible cable instead of a trolley.

Thermal Cut-Out, J. O. Phillips, 460,538. Filed Jan., 1891.
A thermal cut-out for pendant incandescent lamps, which may be placed at an intermediate point between the lamp and the ceiling.

Electric Elevator, R. C. Smith, 460,541. Filed Dec. 31, 1890.
Has for its object to provide means whereby the motor connected with the elevator will be automatically cut out of circuit in case of an excessive counter-electromotive force induced.

Railways and Appliances :—

Trolley for Electric Railways, F. F. Smith, 460,163. Filed Dec. 20, 1890.
Intended to prevent the trolley from being thrown off the wire when the car is passing around curves.

Self-Lubricating Trolley, W. Hoen, 460,232. Filed April 13, 1891.
A trolley wheel having internal chambers for receiving dope, these chambers opening into the central bore of the pulley.

Trolley-Switch, H. L. Pierce, 460,488. Filed Oct. 22, 1890.
Relates to switches for the conductors of electric railways, operated by the mere passage of the trolley wheel.

Telegraphs :—

Telegraphic Transmitting-Instrument, C. G. Burke, 460,109. Filed June 17, 1890.
Has for its object to give to the transmitting operator perfect control over the length of actual contact for each impulse and to enable him to vary the potential and relative periods of contact between reversed polarities.

Telegraphic Instrument, C. G. Burke, 460,110. Filed Dec. 26, 1889.
A receiver or relay for long lines or submarine cable circuits of great sensitiveness and delicacy of operation and of simple construction.

Telegraphic Instrument, C. G. Burke, 460,111. Filed Feb. 11, 1891.
A receiver or relay intended to respond rapidly and accurately to signaling circuits and to produce especially clear and distinct records.

Printing-Telegraph, J. E. Wright, 460,328. Filed Dec. 30, 1890.
A printing telegraph in which the impressions are made in line across a web or sheet of paper of the desired width.

Printing Telegraphic Apparatus, G. A. Cassagnes, 460,349. Filed Nov. 28, 1890.
Invention pertains mainly to improvements in the printing receiver.

Printing Telegraph Instrument, J. E. Wright, 460,457. Filed Dec. 31, 1889.
Consists of a rotary type wheel turned by a clock motor and an electromagnetic controlling device regulating the movement of the motor.

Legal Notes.

WESTERN UNION TELEGRAPH CO. vs. LINDDELL—FAILURE TO DELIVER MESSAGE.

In this suit the Supreme Court of Mississippi has decided as follows: In order to sustain an action for damages for failure to deliver a telegram it must be shown that a contract, actual or implied, existed between the sender of the message and the company. Where a man writes a message on a leaf of his note-book, tears the leaf out, and sends it by a messenger to the telegraph office without paying or offering to pay or agreeing to become responsible for the charges for sending it, no contract exists between the parties, and no recovery can be had against the company for failure to deliver.

THE U. S. vs. SOUTHERN PACIFIC R. R., WESTERN UNION, ETC.

A suit has just been brought, in Washington, before Justice Field, of the Supreme Court, sitting as a circuit judge, with the object of canceling the exclusive contracts between the Western Union Co. and various railroads. The parties defendant are the Southern Pacific Railroad Company, the Southern Pacific Company, the Atlantic and Pacific Railroad Company, and the Western Union Telegraph Company. The purpose of the suit is to break the monopoly now possessed by the Western Union Company in the telegraph franchises through the country traversed by the road lines involved, and the instigators of the proceeding on the part of the Government are the same as the instigators of the legislation under which the suit is brought, namely, the old Baltimore and Ohio Telegraph Company and the Postal.

The theory of the Government case is that the grants to the railroads were made by Congress as much for the purpose of having telegraph lines maintained for the public benefit as for having rail transportation facilities; and hence that the railroad companies exceeded their powers when they made leases transferring control of their wires to any other corporation.

Mr. Chas. E. Gregory, general manager of the Hyde Park Electric Light & Power Co., has resigned to take a position as general salesman for the Standard Electric Co., of Chicago.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

"In this age of electricity, any man who advertises can accomplish in two years what formerly took ten."

THE WESTON AUTOMATIC ENGINE.

THE accompanying illustrations, Figs. 1 and 2, show the new automatic engine manufactured by the Weston Engine Co., of Painted Post, N. Y. The bed of this engine is made especially heavy to guard against any springing tendency, and the guides are planed in the bed and accurately scraped. The cross-head shoe is adjustable to accommodate any wear, always leaving the engine in correct alignment. The main bearings have adjustable cheek-pieces to take up the wear, and all bearings are sufficiently generous to satisfy the most radical advocate of large wearing surfaces. The reciprocating parts are balanced by weights in the crank discs. The cylinder and steam chest are in one casting, and made from the best charcoal iron. The piston is made hollow and cast-iron rings are sprung in for packing. The cast-iron jacket allows the cylinder to be covered on the outside with mineral wool to prevent radiation of heat. Interchangeability of parts of these engines forms a valuable feature.

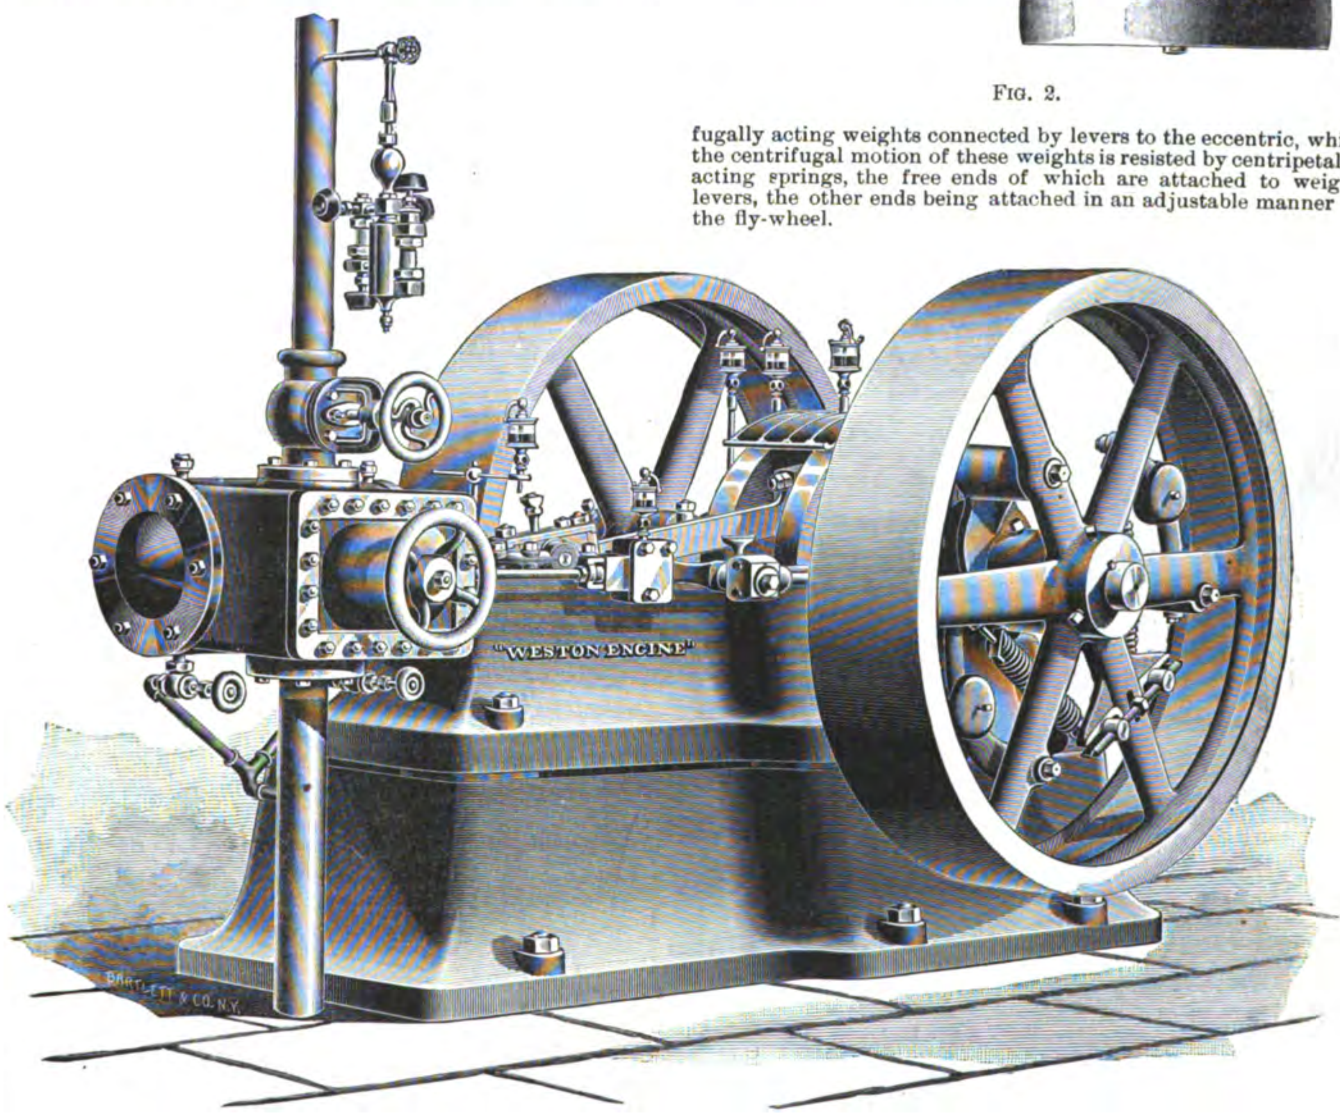


FIG. 1.—THE WESTON AUTOMATIC ENGINE FOR ELECTRIC LIGHTING.

The action of the valve is clearly shown in Fig. 2, and gives four openings for the admission of steam, the length of each equal to the diameter of the cylinder. This, together with a large travel and ample ports, gives, as might be expected, a high steam line and a sharp cut-off. The exhaust is through a double opening, and is attended with the same advantages that characterize the steam admission.

The governor, Fig. 3, has a laterally movable eccentric surrounding the crank-shaft of the engine, by which the admission of steam to the cylinder is regulated through the variation of its throw. This variation is effected by the movements of centrifugally acting weights connected by levers to the eccentric, while the centrifugal motion of these weights is resisted by centripetally acting springs, the free ends of which are attached to weight levers, the other ends being attached in an adjustable manner to the fly-wheel.

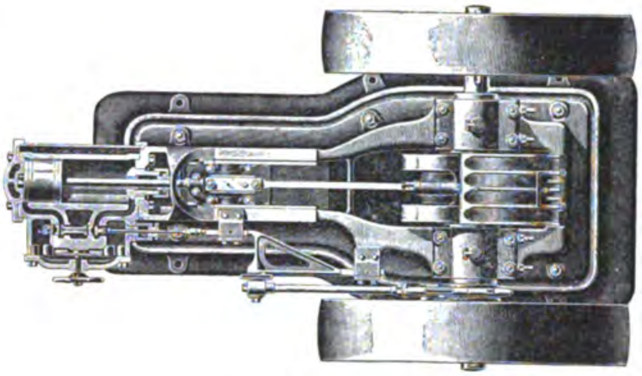

FIG. 2.

With the governor at rest, the tension of the springs will hold the eccentric in position of the greatest throw, but in action the centrifugal force of the weights moves the eccentric across the shaft, reducing its throw as increased rotary motion takes place, until it reaches the point where the valve travel will be in accordance with the amount of steam necessary to drive the load. It is apparent that for any nicety of regulation, the centrifugal force and the centripetal force, as supplied by the weights and springs, should be in equilibrium.

An inspection of Fig. 3 shows how this is accomplished, an arrangement which allows both springs to have their attachment to the wheel on the same side. This admits of a right and left hand screw, with a nut in the centre, being inserted in the two-spring attachment pins, the turning of which moves simultaneously, and an equal distance, the two springs nearer to, or farther from, the pivotal points of levers, thus accomplishing the regulation of the governor to a degree equaling isochronism, if desired.

FIG. 3.

— The New York representatives of the Weston Engine Co. are Messrs. Julian Scholl & Co., with offices at 40 Cortlandt street.

THE BERNSTEIN ACID AND WATERPROOF SOCKET.

Bernstein Socket.

WE illustrate herewith a new form of waterproof socket which has been designed for special use in paper and pulp mills, breweries, marine work, and all places where the use of the ordinary socket is impossible because of the presence of moisture or attacking acid fumes. The body of the socket consists of two hard rubber parts, all the stampings inside being made of phosphor bronze. Rubber gaskets at "A" and "B" protect the lamp cap and the internal parts of the socket, making it perfectly waterproof and gas proof. The socket is adapted for lamps with the Thomson-Houston cap, and is furnished complete with leading wires, as shown, all ready to connect into circuit. These sockets are manufactured exclusively by the Bernstein Electric Company, 620 Atlantic avenue, Boston.

"A FEW ADVANTAGES OF ELECTRIC HEATING."

THE Electric Merchandise Co., 11 Adams street, Chicago, as agents for the Burton Electric Co., have issued a circular entitled as above. It is pithy and pointed, and gives some excellent hints to street railway men on the desirability of heating their cars electrically. On the back are blazoned the five cardinal merits of "convenience," "comfort," "economy," "safety," and "cleanliness."

PAGE BELTING CO.

AMONG the recent orders of the Page Belting Co. is one for a complete outfit for the Derry Electric Light Co., of Derry Depot, N. H., and an outfit for the Concord Gas Light Co.'s new station. Main belts have been furnished as follows:

A 26-in. belt for the Southwestern Electric Light and Water Power Co., at Joplin, Mo.; One 58-in. belt, 127 feet long, for the Reading Electric Light and Power Co., Reading, Pa. This party also had about 800 feet of 12-in. Eureka dynamo slotted belt; a 16-in. belt for Dayton, Ohio, and three 48-in. belts for the Georgia Electric Light Co., at Atlanta, Ga. They have also furnished of their new Eureka dynamo slotted belts as follows:

One 12-in. belt for the Concord Street Railway; one 13-in. belt for New York City; two 18-in. belts for Raleigh, N. C.; four 14-in. belts for the Schuylkill Electric Railway Co., at Pottsville, Pa.; two 8 in. belts for Piqua, Ohio; one 14-in. belt for Boston; one 10 inch belt for Amsterdam Street Railway Co., Amsterdam, N. Y.

Of regular dynamo double belting they have furnished as follows:

One 12-in. belt for the Hyde Park Electric Co., Hyde Park, Mass.; three 13-in. and one 10-in. belt for the Birmingham Railway and Electric Co., Birmingham, Ala.; eight 20-in. belts for Chicago.

A NEW NON-CORROSIVE BATTERY.

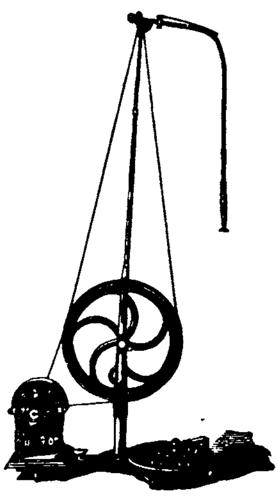
Non-Corrosive Battery.

WE illustrate this week a new form of open circuit battery which bids fair to make a very favorable impression, and which possesses some features quite new and very valuable. A thin plate of zinc is used, instead of a heavy pencil or cylinder of zinc, as in the majority of other batteries, and no corrosion of the zinc takes place. The solution only is destroyed, and it is very cheap. The battery, like others, will polarize, but recuperates very quickly, and there is no local action. The fact that a thin plate of zinc can be used, owing to the increased surface, enables the battery to give out a large current. The zincs are not amalgamated, as there is no necessity for doing so, owing to the fact that the zinc is not consumed. This battery opens up an entirely new field, it being something new to see a battery whose zincs are just the same after months' hard usage, and it is well worthy of consideration. The Consolidated Electric Manufacturing Company, of Boston, are the selling agents and they will cheerfully furnish any information desired.

THE EDISON ELECTRIC DENTAL DRILL.

THAT the practical applications of electricity to useful service are as limitless as electricity itself is evident from the new developments constantly being made.

Of a striking character is the new combination $\frac{1}{16}$ h. p. Edison motor and dental drill, shown in the accompanying illustration.



Edison Electric Dental Drill.

An ordinary dental drill is used, the foot lever and crank being removed. The old pivot is utilized to fix a strip of steel upon which can slide the $\frac{1}{16}$ h. p. Edison motor, arrangement being made to clamp it in any position, so that the belt can be kept at any desired tension. The motor, therefore, occupies one of the legs, and the other two legs are used to support the reversing and resistance switch. The handle of the switch is of a special construction so that the operator can use it as readily as the treadle. It is arranged to project over the edge of the resistance coil, and the operator can, by a slight movement of his foot, switch it over to either side, so that the motor runs in either direction at will.

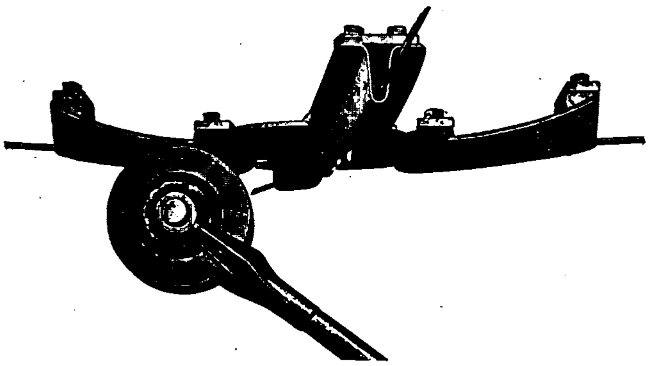
If the arm is in the central position, the current is off. If between the central position and one side, the motor runs in one direction, but not at full speed.

Catch clips are arranged so that the operator can tell immediately he has reached either the "off" position or the "full on" position on either side. He can also obtain four different speeds below full speed. The motor is designed to run on 125-volt circuit, so that it can be used on a local electric light circuit. A wall socket is fixed near the dental chair and a flexible cord led from this to two terminals on the motor.

One advantage of this arrangement is that it insures good and safe work and enables the dentist to concentrate his whole attention and effort upon the work before him.

THE "MINNEAPOLIS" TROLLEY CROSSING.

THE accompanying illustration shows a trolley-wire crossing made by the Minneapolis Brass and Iron Manufacturing Co., of Minneapolis, Minn. It adjusts itself automatically to any desired angle, and is equally efficient with any size of wheel or wire. An



MINNEAPOLIS TROLLEY CROSSING.

important item in regard to these crossings is that they require no soldering, are easily put up, and may be readily shifted or removed. The company state that 1,000 consecutive cars passed one of these crossings in one day, recently, without a single trolley leaving the line.

THE HEISLER CO. AT THE MONTREAL EXHIBITION.

WE are in receipt of the following from Mr. Walter F. Smith, the general manager of the Heisler Electric Light Co., of Philadelphia :

"We wish to enter a mild complaint against the treatment that we received at the hands of the Management of the Exhibition.

"As a matter of course, we did not determine upon making any exhibit until it was rather late. However, before taking any steps in the matter, we communicated with the officials in charge and were assured by them that there was still available sufficient space to enable us to exhibit our apparatus. Upon its arrival there we were very much disappointed at being alloted a space where we could procure no power for the purpose of operating our dynamo. We would, under no circumstances, have made any display had we known it would be impossible to have shown the apparatus in full operation. We regret the circumstances exceedingly, not alone for ourselves, but for the many individuals who visited the exhibition, who were interested in our apparatus, especially in the operation of it. As it was, we were placed in the position of being practically shut out from making any display whatever. You will readily appreciate that the fact of the apparatus standing there to be looked at was not satisfactory to those interested in electric lighting, much less satisfactory to us. We think it was a serious oversight on the part of the management to have shut us out in this manner and given foreign corporations the preference, and would respectfully request that you avail yourself of the first opportunity to make mention of this fact in the columns of your paper, in the form of a notice to your many readers, extending to them our regrets at being unable to show our apparatus in operation; and assure them that it was not our fault, as we made every effort possible to secure the necessary power, but failed."

ALEXANDER, BARNEY & CHAPIN.

ILLUSTRATIONS of remarkable progress by electrical corporations are by no means rare, yet there are few so striking as that furnished by the firm of Alexander, Barney & Chapin, of this city, who, on October 6th, completed the first year of their business life. The supply business is one which has during the past few years drawn to itself a large amount of capital. In the West, particularly, there have been several new organizations started. In the East, however, we know of no example of rapid increase in business more striking than that furnished by the Cortlandt street firm. On October 6th, 1890, they opened their store at 20 Cortlandt street, occupying a space about 30 feet front by 130 feet in depth; their entire force consisted of seven men. The first day, which was given up largely to the hospitalities of house-warming, 25 orders were booked, and those 25 customers still remain on the books of the firm as current buyers. The number of employees has now increased to 28, while the number of customers has reached the astonishing figure of about 2,000, and the floor space occupied has been doubled. When it is considered that the business of this firm has come almost entirely from central electric lighting stations, isolated plants, bell hangers and contruction companies, it is certainly surprising to note the volume of trade which has found its Mecca with the house of "A. B. & C." The electric railway supply business, which has, with some electrical supply companies, compensated for the present competition in the electric lighting field, has not heretofore been sought after by this firm, but encourged by the support they have received from their present customers, they are about to open a department for the manufacture and sale of electric railway specialties, which, as it will be the only one of its kind in the Eastern country, will assuredly be as profitable as their departments for household goods and electric light supplies.

Alexander, Barney & Chapin have just issued several pamphlets regarding their "A. B. C." incandescent lamps, in which they cite various testimonials from customers, certifying to the fact that some lots of their lamps have burned for periods averaging from 2,000 to 6,000 hours. This does not mean that one, two or three lamps have burned that long, but that lots of from 50 upwards have earned this record.

NEW "CENTRAL ELECTRIC" TRADE-MARK.

THE Central Electric Company are out with a new trade-mark. The device represents the Continent of North America faintly outlined on a disc, having the principal cities plainly shown all in connection with Chicago. The words "Central Electric Company" are boldly drawn across the continent, and the well-known trade-mark of the Okonite Company encircles the North and South Poles. We expect this "cannon ball" trade-mark well become as well-known as the famous Okonite sign.

NEW ENGLAND NOTES.

THE CORLISS ENGINE COMPANY, of Providence, have recently started up the engine which they supplied to the Augusta, Hallowell and Gardner Street Railway. The engine is 200 h. p. compound condensing and has cylinders 14 inches and 28 inches by 36 inches stroke. They are also setting up for the Woonsocket Electric Light and Power Company, of Woonsocket, R. I., a twin compound condensing engine of 700 h. p., with cylinders 22 inches and 44 inches by 60 inches stroke. The Connecticut Electric Company, of Waterbury, have recently ordered another compound condensing engine of 400 h. p., with cylinders 18 inches and 32 inches by 48 inches stroke, and two vertical water leg boilers to furnish steam for same. The Corliss company are also furnishing six single non-condensing engines, with cylinders 40 inches by 72 inches stroke, for the Third Avenue Cable Road, in New York, each having a 25-foot balance-wheel, weighing 85,000 pounds. The Chicago West Side Cable Road has ordered a 36 x 72 inch single non-condensing engine, and six of the Corliss company's special boilers. The Corliss Engine Company have also supplied four boilers with an aggregate of 1,000 h. p., to stand 165 pounds pressure, to the California Electric Light Company, of San Francisco.

THE BRADBURY-STONE STORAGE BATTERY COMPANY, of Lowell, Mass., have achieved a success in their recent equipment of electric cars in Sioux City, Iowa, with their system of storage batteries. In this city there are a large number of heavy grades and sharp curves, one of which is a mile long, all of which have been successfully overcome, the cars ascending the hills with ease. The motor in the car is made to act as a dynamo in descending grades and is used to change the batteries, thereby utilizing the energy which would otherwise be lost. The Bradbury-Stone "Ideal" storage battery possesses a number of advantages, the electrode being light and practically indestructible, being braced in every way to make it substantial, and is capable of standing heavy drafts of current. The active material is treated electrically before inserting into the electrode, which is done by cutting it up into strips to fit recesses in the plates. A battery can thus be easily kept in repair as it is an easy matter to withdraw any defective parts.

MR. C. H. HERRICK, of the Wright Electrical Engineering Company, of Boston, has received an order from the Haverhill Electric Light Company, of Haverhill, Mass., to act as their consulting engineer, furnish the complete plans, and take the whole supervision of the work. The station will be designed for 1,500 h. p., and the engines will be furnished by the Corliss Steam Engine Company, of Providence. Return tubular boilers will be provided to furnish the steam.

THE EDISON GENERAL ELECTRIC COMPANY, through their Boston office, have secured the contract for a central station in Penacook, Me., consisting of 1,000 lights, which will be used for general lighting of stores and houses. They have also contracted to put in a central station in Plymouth, N. H., of 1,500 light capacity at present, and will light up about three miles of streets in addition to the general lighting.

THE DAVIDSON VENTILATING FAN COMPANY, of Boston, are making a specialty of manufacturing a very compact and efficient fan for all kinds of ventilating purposes. These fans can be driven by electric or other power, and large numbers of them are in use in mills, mines and buildings of every description. These fans are of strong design with steel blades, babbitted self-oiling boxes, and owing to the peculiar shape of the blades, having both a concave and convex surface on each side of the blade, give a uniform delivery over the whole face of discharge without any reflex action. The Davidson company have their headquarters at 52 Pearl street, Boston, and their factories at Cambridgeport, Mass., and they are thoroughly well equipped to supply fans for every purpose, which will give entire satisfaction.

THE GERMANIA ELECTRIC COMPANY, of Boston, have sold a 350-light Germania incandescent dynamo for the new hotel on Huntington avenue, Boston; a 110-light dynamo for Byrne Brothers, Lodi, N. J., complete with improved Schaefer lamps and sockets, and a 25-volt, 75-ampere dynamo for running special electric engine-turning lathes. The Germania company have also recently secured the contract for the complete installation of a central station for the Portland Electric Light Company, of Portland, Conn. The plant will consist at present of a 30-arc light dynamo, and a 750-light alternating incandescent dynamo, with Freeman transformers. The lamps will be used for both street and commercial purposes. The Germania company have the contract to erect the station and do the whole of the construction work.

CAPTAIN DE KHOTINSKY, of the Electriciteits Maatschappij, of Rotterdam, inventor of the well-known de Khotinsky system of incandescent lighting, has arrived in this country, and has attached himself to the Germania Electric Company, of Boston, who have secured his patents for this country. The Captain will at once commence installing a plant for manufacturing the Khotinsky lamp, which, it is worthy of note, is the only lamp used for lighting the Frankfort Exhibition. The Captain is feeling rather elated at the outcome of the recent decision in France in his favor of the suit brought against his Rotterdam company by the united Edison and Swan companies.

THE RUSSELL ELECTRIC COMPANY, of Boston, have since the first of June installed the Russell disc carbon lamp in 32 central stations, one station, the Suburban Electric Light Company, of Scranton, Pa., having as many as 88 lamps in use, 25 of which are used for inside work, the rest being in use for outside purposes. The Arlington Mills, at Lawrence, Mass., have 25 Russell lamps in service of their regular 12-hour type, burning 23 hours a day, using a special oval carbon, ⅞ x ⅝ inch.

THE EASTERN ELECTRIC SUPPLY COMPANY, of Boston, have sold two electric snow-plows to the Lynn Belt Line Street Railway Company, of Lynn, Mass. This makes 18 snow-plows which they have supplied to electric railways this fall. These plows are of their own construction and were designed by Mr. Wallace, in charge of the electric railway branch of their business.

THE UNION MANUFACTURING COMPANY, of Bridgeport, Conn., are well pleased with the way in which their new socket appears to take with the trade. Orders continue to come in rapidly and the Union Company are desirous of finding agents for them in different cities.

PHILADELPHIA NOTES.

THE IMPERIAL ELECTRIC CO. is the name of a new company just incorporated in this city and located at 1218 Filbert street, for the purpose of manufacturing and selling switches, sockets, cut-outs, branch blocks, fuse blocks, tapes, insulating compound and many other electrical specialties, most of which will be made under their own patents. The incorporators are men of ability, several of whom are well known in electrical circles. The officers of the company are as follows: J. S. Spruance, president; J. C. Corbit, Jr., secretary and treasurer, and John Mustard, general manager.

MR. N. A. WOOD, one of the oldest electricians in this city, has sold his electrical construction and supply business to Messrs. John Cunningham, Jr., and W. S. Ambler, who will conduct the business at the old stand, 1123 Chestnut street, under the firm name of Cunningham & Ambler. The senior member has been connected with the Cornish-Bell Co., of this city, during the first eight years. At present Mr. Wood is connected with the Eastern Pennsylvania Phonograph Co.

MR. ROBERT H. ENGLE, of this city, has just completed a very creditable job of enameled wiring at the new shoe store of E. Ryan, corner of 20th and Christian streets. The combination gas and electric fixtures are finished in antique copper, and are one of the handsomest patterns made by the Thackara Manufacturing Co.

MR. R. W. EDDSON, of the Fowler-Waring Cables Co., North Woolwich, England, is on a short sojourn to this country on business for his company. Mr. Eddson while here is making his headquarters at Messrs. Tatham & Bros.

MR. T. L. TOWNSEND, salesman for the Partrick & Carter Co. left this city last week on his regular fall trip. He will cover the Southern, Western and Northwestern territory pretty thoroughly before his return.

MR. C. W. CARNES, formerly with C. M. Blanchard, has accepted a position as traveling salesman for M. S. Shapleigh.

NEW YORK NOTES.

MR. E. W. LITTLE, the energetic young manager of the Interior Conduit and Insulation Co., has been down with a severe attack of typhoid fever, but has turned the corner and is now convalescing. It will be some few weeks, however, before his physicians will allow him to resume work.

MR. HARRY MADDEN, late manager for the Empire City Electric Co., has been appointed New York agent for the New Haven Insulated Wire Co., with office at 18 Cortlandt street, New York. The agency is in excellent hands.

WESTERN NOTES.

ELECTRIC LIGHTS FOR THE BOULEVARDS.—A new plan for lighting Drexel and Grand boulevards, Chicago, has been proposed by Prof. Barrett, City Electrician, and Ald. Cullerton. The South Park commissioners contemplate erecting a power house in Washington Park to light it by electricity during the World's Fair and thereafter. Prof. Barrett has suggested that the plant be built so as to furnish power not only for the park lights, but also for boulevard lights. If the park commissioners supply power from the Washington Park plant for electric lights along Grand Boulevard as far as 35th St., the city, it is said, will provide power for lights on Michigan Boulevard from its commencement at Jackson st. to 35th and on Douglas to Grand, connecting with the park lights. The Washington Park, as estimated, will cost $70,000. It is understood that the city's appropriation for electric lights this year has already been spent, but probably some arrangement can be arrived at which will enable the new lights to be placed where they are so much to be desired.

THE ELECTRIC GAS LIGHTING CO., of Boston. Mass., have now got their branch office in the Lakeside Building propitiously started off. Mr. Charles E. Lee, well known amongst the Western electrical fraternity, is in charge and will be pleased to see his many friends and furnish them with any supplies they need. A large line of specialties are now being carried in the Chicago office, including electric gas lighting apparatus and supplies, the Tirrell gravity drop and the new "Hub" needle annunciators, the Victor, the Champion, Standard and Success electric bells, and the well-known Samson batteries, and also a large general assortment of electrical supplies.

J. LANG & CO. have just completed a large number of the Lang switches for heavy current work. These switches are great favorites on account of their large and efficient carrying capacity and the entire absence of heating. Mr. Lang attributes his success to the excellent quality of the material employed and the high class of workmanship which is to be found in all his goods.

THE ELECTRIC MERCHANDISE CO., 11 Adams street, Chicago, are very busy filling orders for street railway supplies. They are receiving numerous inquiries from all parts of the world regarding the specialties for electric railways which they manufacture and handle.

THE ILLINOIS ELECTRIC MATERIAL CO. report the demand for "Canvas Jacket" line wire, Bishop india-rubber wires and cables as very brisk. In general supplies for electric lighting, power and railway work they are doing a flourishing trade.

THE CENTRAL ELECTRIC COMPANY report that eight of the large buildings now being constructed in Chicago, to contain in the aggregate 14,200 incandescent lamps and 650 arc lamps, are being wired with Okonite wire.

MR. FRANK N. WATERMAN, who has had charge of the construction work on the new Westinghouse railway at Burlington, Iowa, was in Chicago last week.

MR. JAMES A. LOUNSBURY, a well-known electrician in the West, has associated himself with the Chicago office of the Westinghouse Electric and Manufacturing Co.

☞ ***Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Miscellaneous, etc., will be found in the advertising pages.***

THE

Electrical Engineer.

VOL. XII. OCTOBER 14, 1891. No. 180.

THE FRANKFORT INTERNATIONAL ELECTRICAL EXHIBITION.—IX.

BY

L. Gutmann.

The Lauffen-Frankfort Transmission.

ALL electrical engineers have been interested in the famous transmission of power from Lauffen to Frankfort, and while this is the topic of the day, other transmissions of less gigantic a nature have hitherto been overlooked. The saying is, when the sun shines, the stars are invisible. Before calling your readers' attention to other interesting exhibits, however, it may be said that the current sent from Lauffen has a pressure of 16,000 to 18,000 volts, and 30 to 35 periods of alternation per second. One of the reasons for the reduction in pressure has to be looked for in the fact that the large style or compound insulators of the Johnson & Philipp type, which were to be used, could not be obtained in sufficient number, so that the rest are of the simple type of fluid insulators. Another is the carrying capacity of the conductor, which, with high potential, would cause excessive heating, especially as the oil prevents the radiation, unless choking devices are employed. After the Exhibition is over it is contemplated to raise the pressure to 30,000 volts or more for carrying on the examination of this system by government and other officials.

The Lahmeyer Exhibit.

Pending these experiments, I wish to draw attention to the neat exhibit of Lahmeyer & Co., whose system, as will be seen, is thoroughly worked out. In the Central Machine Hall, shown in Fig. 1 of the accompanying illustrations, there is exhibited in operation a dynamo generating 110 amperes continuous current at a pressure of 660 volts, driven by an engine of the Nurnburger Maschinenbau Aktiengesellschaft, formerly Klett & Co., and another dynamo with the same pressure, but only 70 amperes, driven by a Westinghouse engine of the firm of Garrett, Smith & Co., Magdeburg-Buckau. The general appearance of the compact dynamo is shown in Fig. 1. It is of the four-pole type, the magnets of which project inward towards the armature. The latter is provided with a commutator and but two brushes. In this case the inter-

FIG. 1.—THE LAHMEYER EXHIBIT AT THE FRANKFORT ELECTRICAL EXHIBITION.

nal grouping of the armature winding is not made, as is often done, by cross-connection or coupling in parallel, but the windings or coils having similar positions in the magnetic field, are wound in succession, and therefore are in series with one another. In spite of the pressure, which in these separately-excited dynamos is above the average as regards machines with ordinary commutators, the sparking is quite negligible.

Another dynamo, having a capacity of 150 amperes at 110 volts, is operated by a triple-expansion engine of Gebr. Sachenberg, of Rosslau am E. The current of this dynamo is used for lighting the central station and the surrounding exhibits, and, furthermore, to excite the fields of the two first-named generators, which in turn are connected to busbars common to both, energizing a direct current transformer and a motor of 60 h. p., also shown in Fig. 1, which drives a large pump for supplying water from the River Main to the waterfall in the Exhibition grounds. The transformer and motor are of similar construction, with the difference that in the transformer there are wrought iron pole-pieces, which in the motor are of cast iron, and the armature windings are evidently different with regard to length and cross-section, depending on the use to which the device has to be put. In one case all the energy is transformed from high tension to low, while in the other most of the power is used to do mechanical work, and one-seventh or eighth is used for lighting, and at the same time energizing the field magnets. All other arrangements being identical, the transformer may be described by reference to Fig. 1 which shows the motor, the pump in front, and the switchboard to the right.

The transformer has an external appearance similar to the generator with the difference of having two commutators and two sets of brushes. The capacity of the one exhibited is 300 lamps, and the ratio of transformation is 6 : 1. The current with a pressure of 660 volts is transformed to one of 110 volts. Some of the station instrument readings are : Primary, volt, 682, amp. 14.5 ; secondary, volt, 110.5, amp. 72.5; primary, volt, 670, amp. 20; secondary, volt, 108, amp. 10.5; primary, volt, 670, amp. 14 ; secondary, volt, 110, amp. 72. The efficiency of these first machines, as these figures show, is between 81 and 85 per cent. at one-third or one-half load of total capacity of 200 amperes. The armature is provided with two separate sets of windings, one capable of developing or receiving currents under a pressure of 660 volts, while the second produces currents at 110 volts. The field winding consists of four coils, the first layers of which are separable from the rest, and are connected to the terminals of the rheostat, and also to a two-way switch on the switchboard.

This board is clearly shown in detail in Fig. 1. In the upper row are located the line terminals and others for connection behind the switchboard. The two central and circular instruments are the voltmeters for the high and low tension circuits ; to the left is the high-pressure ampere meter, and to the right, one for the low-tension circuit, the indices of which are steadied by moving in mercury. To the right of these is the main primary double pole, double break switch, while to the extreme left is a similar one for the low-tension circuit. The two handles to the left of these main switches are releasing levers for opening the circuits manually, while the relays below the ammeters are for the purpose of effecting this operation automatically in case of abnormal circuit conditions. The device below the voltmeters consists of a rheostat and an electromagnet, whose armature is shown released. The two-way switch at the lower central part of the switchboard is that one to which the extra layers of the field windings are connected for joining them to, or cutting them out of, the low-tension circuit. In the right-hand corner we observe further the main fuses enclosed in glass tubes.

We are now ready to start the operation, and close the high and low pressure circuits while the two-way switch is touching the lower two points, and the resistances of the rheostat are all in the circuit. In this position the transformer acts as a series motor, in which the armature and the separate field winding receive the 660 volt current. The armature begins to turn with very little sparking indeed, increasing in speed as the resistances are gradually cut out. Depending on the load of the circuit, the secondary may be closed after the secondary armature winding has picked up, which takes place in about 10 to 15 seconds. The rheostat lever is turned to the last point, in which position the extra field winding is cut out, and the high pressure current then circulates through only one of the armature windings. Meanwhile, the low-pressure winding has established its current, and supplies or excites its field magnets which are in shunt to the 110 volt brushes. The excitation has reached its normal condition after all resistances are cut out, and by turning the two-way switch into the second position, the extra or separate field winding is placed in series with the other layers.

In constructing this and similar devices, safety in handling was one of the principal objects, and the inventor has therefore decided to have no high-pressure winding on the field at all when the apparatus is in normal working condition. As a further safeguard, an automatic device is mounted on the switchboard, consisting of an electromagnet, situated over a rheostat, by which, when energized by the high-tension circuit, the armature is attracted. The switchboard is now in normal working condition.

The system when explained in detail seems to be rather complicated, but this is by no means the case. After the two main switches are closed, there are but three motions to carry out, viz., cutting out the resistances, grouping the field winding, and placing the armature of the electro-magnet, and it will be attempted to reduce these separate movements into two or one.

The ingenious part in designing these devices is the automatic action and the impossibility of doing harm by wrong connection or failure to turn a switch. The rheostat can be moved only in one direction and not backwards, and the electromagnet above it is in the primary circuit and releases its armature when there is a short circuit or a break on the line. The electromagnet, which in such a case is thrown out of circuit, can no longer hold the heavy iron armature, which drops back and opens the line by removing the rheostat lever from the last contact point, operating at the same time, by means of a special arrangement behind the switchboard, the primary main switch, while the transformer armature gradually comes to rest. It will be noticed that the rheostat contact arm is provided with a metallic sector, which is in the path of the two-way switch, and moves it to its original position. If this operation should not be complete, and the generator were started again at a distant station, after the fault had been removed, the consequence would be evident ; the generator would be short-circuited, as the transformer armature is at rest, and there would be no resistance in circuit. Such a mistake is impossible in this case, because the rheostat switch could not go back to the original position without first changing the position of the two-way switch.

All devices are thoroughly worked out, and the manipulation of the switchboard is as simple as that of any other system. When the transformer is in normal working operation the 660 volt current circulates through the armature only while the field in all all its parts is excited by the second armature winding, whose main current is used for lighting the lamps at a pressure of 110 volts. In the motor the high-tension commutator has a greater prominence than in the transformer, while the one for the low-tension circuit is smaller on account of the reasons given above.

This system of transformation is not the only one shown within the grounds of the Exhibition. Another one especially modified is carried out, bringing the energy from Offenbach to Frankfort, a distance of six miles. In Offenbach a separately excited dynamo produces 22 amperes under a pressure of 2,000 volts, which tension is kept contant. This current is conducted by means of bare overhead wires supported on fluid insulators, to Frankfort. This type of transformer is self-regulating, that is to say, if the tension of the 2,000 volts current is kept constant in the main station, the transformer maintains the pressure constant in the low-tension circuits at all loads, of course within a certain limit for which it is designed, in spite of increased drop on the line. This result can be obtained by coupling a motor to a compound dynamo which has so many more additional turns as to compensate for the difference of speed of the motor between no load and maximum. In this case there would be constant pressure

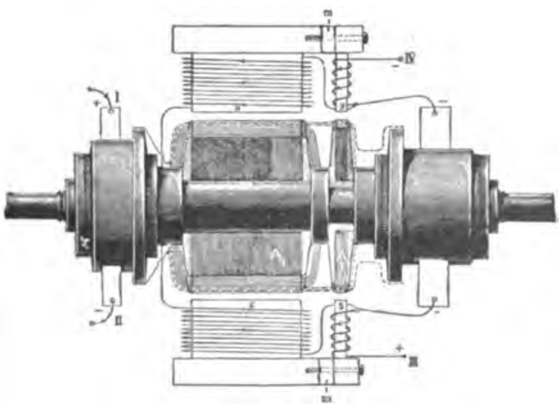


FIG. 2.

in the secondary circuit, but the efficiency of this combination would be less, and the expense of manufacture, and therefore, first cost price greater, than if both could be combined in one machine. If this latter is attempted, it will be found difficult to obtain constant pressure in the secondary circuit. The regulation of the two armature windings cannot be effected by the same means, because at increasing loads and constant speed, the motor winding requires a compensation of opposite character from that of the secondary winding.

Mr. Lahmeyer, however, has solved this question in the following manner : Fig. 2 represents the transformer in diagram. The armature, which is made for larger sizes of the Gramme ring type, is shown in here of the drum type. The high-tension winding is connected to the commutator to the left, on which rest brushes I and II connecting this winding with the high-tension source. These armature coils are wound around the main core, marked A_1. The secondary winding also surrounds the core A_1, but in addition a supplementary core A_2. Its terminals are finally led to the commutator to the right, on which rest brushes III and IV. The main field magnet is energized from brushes III and IV, and forms, therefore, a shunt to the low-pressure winding.

Separated from this field structure by non-magnetic metal *m*, is a small supplementary electro magnet, whose energizing winding takes the full secondary current. The regulation of this machine is similar to a compound wound dynamo, with the difference that the series winding is applied to a separate core and so arranged as not to influence the whole winding. Only the secondary coils are included in this small field. The current in these energizing field coils is proportional to the drop in pressure in the primary circuit, and in the same proportion the pressure is increased in the armature A_2. That is to say, if the pressure is kept constant in the central station, and the transformer is doing a certain amount of work, say for instance, one-half, and suddenly the load is increased to three-quarters, a greater current would be used in the secondary circuit, and a greater current would have to be supplied from the station. The drop on the line would be greater than on half load, and, if there were no compensation, the pressure in the low-tension circuit would drop also, but the supplementary field, carrying a series winding, has now an increased number of ampere turns, and creates a stronger field, while the secondary armature winding cuts a greater number of lines, which enables it to maintain the same pressure as before.

The apparatus is very carefully constructed, compact and well-balanced, and no sparking, or very little indeed, is visible between commutator and brushes on starting or shutting down the machine. Some readings taken on station instruments will give an idea of its efficiency. Primary, volts, 1845, amp. 7.6, secondary volts, 110 ; amp. 100; primary, volts, 1830, amp. 7.55, secondary volts, 109.5, amp. 100; that is, between 78 and 79 per cent. at half load, the transformer being designed to deliver 200 amperes at 10 volts.

THE LOCALIZATION AND REMEDY OF TROUBLES IN DYNAMOS OR MOTORS.—V.

(*Copyright.*)

BY

Francis B. Crocker and S. S. Wheeler.

NOISE.

1. Cause.— *Vibration due to armature or pulley being out of balance.*

Symptom.—Strong vibration felt when hand is placed on machine while running. Vibration changes greatly if speed is changed, and sometimes almost disappears at certain speeds.

REMEDY.—Armature or pulley must be perfectly balanced by securely attaching lead or other weight on light side, which can be found by trial. The easiest method of finding in which direction the armature is out of balance is to take it out and rest the shaft on two parallel and horizontal A-shaped metallic tracks sufficiently far apart to allow armature to go between them (Fig. 9.) If the armature is then slowly rolled back and forth, the heavy side will, of course, tend to turn downwards. The armature and pulley should always be balanced separately. An excess of weight on one side of pulley and an equal excess of weight on opposite side of armature will not produce a balance while running, though it may appear to when standing still; on the contrary, it will give the shaft a strong tendency to "wobble."

FIG. 9.—METHOD OF BALANCING ARMATURE.

2. Cause.—*Armature striking pole-pieces.*

Symptom.—Easily detected by placing the ear near the pole-pieces or by examining armature to see if its surface is abraided at any point, or by examining each part of the space between armature and field, as armature is slowly revolved, to see if at any point it touches or is so close as to be likely to touch when the machine is running. It is unwise to have a clearance of less than one-sixteenth inch full. Also turn armature by hand when no current is on and note if it sticks at any point.

REMEDY.—Bind down any wire or other part of armature that may project abnormally, or file out pole-pieces where armature strikes.

3. Cause.—*Shaft collars, shoulders, hub or edges of pulley or belt rattling against bearings.*

Symptom.—Noise stops when shaft is pushed lengthwise away from one or the other of the bearings. (See Heating of the Bearings, No. 7.)

REMEDY.—Shift collar or pulley, turn off shoulder on shaft, file or turn off the bearing, move pulley on shaft or straighten belt until they do not touch and noise ceases.

4. Cause.—*Rattling due to looseness of screws or other parts.*

Symptom.—Close examination of the bearings, shaft, pulley, screws, nuts, binding posts, &c., or touching the machine while running, or shaking its parts while standing still, will usually show the particular parts which are loose.

REMEDY.—Tighten up the loose parts, and be careful to keep them all in place and properly set up. It is very easy to guard against the occurrence of this trouble, which is very common, by simply examining the various screws and other parts each day before the machine is started.

5. Cause.—*Singing or hissing of brushes on commutator,* usually occasioned by rough or eccentric commutator (see Sparking at Commutator, No. 3), or by tips of brushes not being smooth, or the layers of a copper brush not being held together and in place; with carbon brushes, hissing will be caused by the use of carbon which is gritty or too hard. Vertical carbon brushes or inclined brushes running backward are apt to squeak or sing.

Symptom.—Sound of high pitch and easily located by putting the ear near the commutator while it is running, and by lifting off the brushes one at a time.

REMEDY.—Apply a very little oil to the commutator with the finger or a rag. Adjust brushes or smooth commutator by turning, filing or fine sandpaper. Carbon brushes are apt to squeak in starting up or at slow speed. This decreases at full speed, and can usually be reduced by moistening carbon brush with oil, care being taken not to have any drops or excess of oil.

6. Cause.—*Flapping or pounding of belt joint or lacing against pulley.* (Fig. 10.)

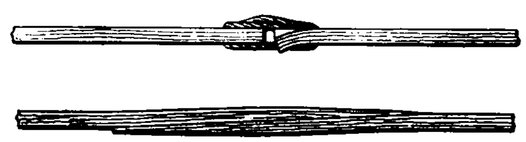

Fig. 10.—Bad Joints in Belt.

Symptom.—Sound repeated once for each complete revolution of the belt, which is much less frequent than any other dynamo or motor sound, and can be seen or easily counted.

REMEDY.—Endless belt or smoother joint in belt. A perfect joint and a straight, smooth belt are always very desirable for dynamos and motors.

7. Cause.—*Slipping of belt or pulley due to over load.*

Symptom.—Intermittent squeaking noise.

REMEDY.—Tighten the belt, or reduce the load. A wider belt may be required.

8. Cause.—*Humming of armature core teeth (if any) as they pass pole-pieces.*

Symptom.—Pure humming sound less metallic than No. 5.

REMEDY.—Slope ends of pole-pieces so that armature tooth does not pass edge of pole-piece all at once. Decrease the magnetization of the fields. Increase the cross section or capacity of the teeth, or reduce that of the body of the armature.

THE AVERAGE LIFE OF INCANDESCENT LAMPS.

BY

Horatio A. Foster

In the majority of central electric lighting stations, and in many isolated incandescent plants, considerable care is taken to determine the average life of the incandescent lamp.

While this is a comparatively easy matter in the smaller isolated plants for factory use, where all the lamps are started at once and stopped at the same time, it is by no means so easy for larger isolated plants, such as those in office buildings; and it is especially difficult in central stations.

In many places an exact record is kept of each and every lamp; it is dated and recorded when sent out, and entered again on the same books when the collar is returned. While this gives excellent data for learning which installations use the larger proportion of lamps, and thus for locating possible faults in distribution, it has not the slightest bearing on the point in question, *i. e., the average life of all the lamps.*

The fact that a lamp was sent out to a place on a certain date and returned a certain date, the circuits being started and stopped at set times during that period, gives no data of value for the purpose, as, in the first place, no allowance can be made for the fact that this lamp may not have been in use at all during that time; and, secondly, it makes no allowance for lamps which, being structurally weak, burn out almost immediately.

There seems to be no way that is perfectly and positively accurate and will apply alike to all situations, but probably the nearest approach to it is by keeping an accurate station record of ampere-hour loads and the number of lamps for renewals. Ampere-hours must first be reduced to lamp-hours; then a proper percentage of reduction must be made for the predetermined average loss in distribution. This leaves the net amount of burning in lamp-hours.

It would be unfair to try to make an average on a station where the lamps had just been installed in lump, as only those lamps which were weak would come out for a long period, and, when that time arrived, the breakage would be much above the normal. It is only after the plant has been in operation for some time, and there are only occasional additions, and the lamp renewals have become a settled and steady number, and vary very little week by week, that a proper test can be made. As long a period as possible should be taken in order to give a fair average all around. The average lamp-hours per day should be found, as well as the average number of lamps connected to the circuit, also the average hours per day for each lamp connected. Then the average lamp renewals per day must be found for the same period, and the average number of lamps connected, divided by the average renewals per day, will give the number of days' life per lamp, and this multiplied by the hours per day per lamp, as found above, will give the average life in hours.

While the above method is not new, and may be in more or less constant use, it is thought well to call attention away from the old methods, which cannot possibly give accurate data.

It is well to bear in mind also that *great length of life is not the only requisite* of a good incandescent lamp.

THE LIFE WORK OF RANKIN KENNEDY.

BY

Franklin Leonard Pope

IT gives me much pleasure to present the readers of THE ELECTRICAL ENGINEER with an excellent portrait of the Scotch electrical engineer, Mr. Rankin Kennedy, who has become well known in this country by reason of his important work in connection with alternating current distribution. Mr. Kennedy is one of those men who have won success in life almost solely through their own industry and perseverance, a class of which perhaps fewer examples are to be found in Europe at the present day than in our own country.

At the age of 14, young Kennedy entered upon an apprenticeship of six years in the works of Andrew Barclay, the well-known Scotch engine builder, during which time he was employed mainly in the construction of machinery of a heavy character, such as mine pumps, blowing-engines and locomotives. During his apprenticeship he diligently improved his spare hours by attending one of the Government science schools, intending ultimately to qualify himself as a science teacher. At the expiration of his apprenticeship he was fortunate enough to be awarded a scholarship worth £75 per year, under the Government Science and Art Department, which enabled him to attend the classes at South Kensington, London. Here he improved his enlarged opportunities with the diligence and industry characteristic of his nation, and succeeded in carrying off first-class honors in the department of Electricity and Magnetism. He also obtained high certificates in Applied Mechanics, Steam and Physical Science at the Science and Art examinations on these subjects.

Rankin Kennedy

In 1872 Mr. Kennedy received an appointment as teacher in his favorite branches of physics, in the New Academy and in the Kay schools, in Kilmarnock, Scotland, which position he filled most acceptably for eight years. He first became especially interested in the dynamo-electric machine while attending the celebrated exhibition of the Loan Collection of Scientific Instruments at South Kensington, in 1874. This exhibition was particularly valuable to students, as it embraced the original experimental apparatus of many of the founders of modern science; the apparatus used by Faraday in his "Experimental Researches," including his historical ring-transformer, together with the appliances made and used by Volta, Galileo, Galvani, Davy and many others. There were also Gramme and Siemens dynamos, the latter working a large arc lamp. The Science and Art Department, with commendable forethought, invited a number of its most successful teachers from different parts of the kingdom to spend a week at this exhibition, paying their expenses meanwhile. Mr. Kennedy was one of the fortunate recipients of this honor, and it is scarcely necessary to say that he made the most of the unusual though well-deserved opportunity which had fallen in his way. Almost the first thing after his return from this exhibition, he constructed a dynamo-electric machine of the Siemens type, and also a model electric tram-locomotive with a Gramme armature.

Resigning his occupation as a science teacher, in 1880, and commencing business on a moderate scale in Glasgow, in the commercial manufacture of dynamos, motors and arc lamps, Mr. Kennedy soon began to acquire a reputation for the structural excellence and good working qualities of his productions.

Mr. Kennedy's commercial work has always been very largely in the line of isolated plants, of which he has constructed a great number, especially for marine purposes. One of the most successful of his direct-current machines was introduced in 1887, under the name of the "Single Bobbin Constant Pressure Dynamo," of which a very large number have been installed. The inherent excellence of the design of this machine is perhaps sufficiently attested by the extent to which its substantial features have since been adopted by other manufacturers, both in Europe and America. During the past five years Mr. Kennedy has executed contracts for the electric lighting of more than 120 steamers. The first large factory building in which both the lighting and the power are electrical, was engineered by Mr. Kennedy at Leeds, and his establishment is at present engaged on the largest contract yet undertaken in Scotland—the new lunatic asylum at Harwood, near Glasgow.

The most important and permanently valuable line of work in which Mr. Kennedy has been engaged is that which relates to the development of alternating inductive systems of distribution and apparatus, to which he has devoted a large share of attention since 1881. An extended series of original researches was begun by him in that year, which resulted in establishing beyond controversy, many facts and principles having a most important bearing upon the reactions involved in the transfer of energy by induction between primary and secondary conductors, which had hitherto been enveloped in obscurity. He showed among other things that the counter-electromotive force set up in a coil traversed by an alternating current and surrounding any iron core is proportionate both to the mass of the core within determinate limits, and to the length of the wire; that under such conditions a counter-electromotive force is set up in the primary wire of an inductor, and that the alternating currents induced in the secondary tend to oppose and delay this counter-electromotive force. Mr. Kennedy also demonstrated for the first time, that in the case of an endless core of sufficient mass the necessary loss of energy in conversion was very small; and most important of all, he discovered and pointed out that a system of inductors with their primaries arranged in parallel and with translating devices in their secondaries, constitute a theoretically perfect self-regulating system for the distribution of electrical energy. It is not too much to affirm, that the commercial practicability of the modern system of electrical distribution by alternating currents and transformers, is founded almost wholly upon principles discovered by Kennedy in these investigations, and first made known by him in the columns of a technical journal in the summer of 1883.[1] Prior to this time, the efforts which had been made to effect the commercial distribution of electricity by inductive apparatus, had been successful but to a very limited extent, owing to the imperfect understanding which prevailed among electricians of the nature of the reactions of periodic currents.

Shortly after this time, a protracted and serious illness for a considerable time interrupted Mr. Kennedy's work, but in 1886 he again resumed his alternating current investigations by designing the original of the well-known type of alternating machines, known as the "iron-clad," a name which, by the way, was of his own coinage. He also originated the important system of distribution by alternating currents over long distances, employed in the Frankfort-Lauffen plant, in which main transformers are employed to raise to any required extent the potential of an induced current originated by a low-pressure dynamo. Other inventions made by him during this period are subdivided transformers, and a method of measuring alternating currents by low pressure voltmeters combined with transformers having an accurately known ratio of conversion.

Mr. Kennedy is now engaged in working out the details of a new method of electrical distribution by two independent pulsating currents alternating in quadrature, which is a radical departure from present practice, and bids fair to have an extended field of future usefulness. He has also recently designed a new type of alternator, having only two exciting and two generating coils, and being without any moving coils whatever. This apparatus is capable of producing alternating currents of any required pressure and frequency however great. Another important recent invention of Mr. Kennedy is a special type of alternator for lighthouse and marine use, which has neither commutators, brushes nor sliding contacts of any description; he thus expects to eliminate nearly all the troubles that beset the dynamo under these most exacting conditions.

Mr. Kennedy has during the past ten years contributed numerous articles to the technical and scientific press of Great Britain, mainly having reference to periodic and alternating current work. A little treatise on "Electrical Distribution by Alternate Currents and Transformers," which he published in 1887, and was the earliest work on this subject, met with an extraordinary sale, the whole edition having been disposed of within a few months. A second edition is now in preparation. He has also made inventions of much merit in the line of alternating motors, meters and heating apparatus, which lack of space compels us dismiss with mere mention.

Mr. Kennedy has recently greatly enlarged his manufacturing facilities, having established himself at the Carntyne Electric Works, at Shettleston, Glasgow, which bids fair to become one of the leading electrical manufactories of Great Britain.

A NEW BATTERY FROM BAVARIA.

A Munich inventor has produced a modified battery cell resembling an ordinary Leclanché in which the carbon of the latter is replaced by copper in sulphate of copper, the zinc rod being in salammoniac. There is a special modification in the porous pot itself, which is prepared by dipping it, to one-third of its height, into melted paraffine wax, and then filling it with an aqueous solution of ammonia. The ammonia solution is then poured out and replaced by copper sulphate, which is in its turn poured away, and, finally, the pot is allowed to drain dry. The object of this successive dipping into ammonia and copper sulphate solutions is the formation of a double sulphate of copper and ammonium which fills up the pores of the cell, and being insoluble in either of the solutions used in the battery, prevents them from mixing.

1. London *Electrical Review*, June 9, 1883; ibid; June 16, 1883.

THE ACCUMULATORS AT THE FRANKFORT ELECTRICAL EXHIBITION.—I.

BY

Paul Schoop

The electrical accumulator is considered on the European continent and in the United States of America from widely different standpoints. Since the storage-battery has been introduced into this country its biography has been an uninterrupted tale of woe and sorrow. This has been not only in the United States; the English electricians have also had the most discouraging experiences. It is, nevertheless, a fact that in Germany, Austria and Switzerland quite the reverse is the case, the most celebrated electricians there favoring accumulators, and as a consequence using storage batteries for central station lighting to a large extent. We may state that the well-known Siemens & Halske Co., of Berlin, have not erected central stations without a storage-battery plant for some time past, and that the two most important accumulator factories, at the Oerlkon Works, in Switzerland, and at Hagen, in Germany, have filled very large orders during the last two years. The exhibition at Frankfort impresses the fact upon one that the accumulator business is being pushed in Europe.

It may be interesting to look at the reasons of this very different state of affairs between the two continents. Consider first the fact that in Europe, and especially in Germany, the lead accumulator has been mainly adapted to lighting purposes, while in America it has been tested principally with a view to street car work. A great many people here are already of the opinion that accumulator cells are out of question for the economical working of street cars. Probably there are a lot of people of the same opinion in Europe, too, but there are in Germany more electricians who consider the leaden storage battery

Fig. 1.

of to-day a necessary and practical apparatus for central stations, and perhaps a smaller number who look forward to accumulator cars also. It seems doubtful at present which is right. Let me first state that, dealing with the storage batteries exhibited at Frankfort, one receives the general impression that the manufacture of the cells, as well as the erection of the whole plant, is performed in an infinitely more careful manner than was the case only two years ago. The manner of connecting the electrodes, binding the cells together, and the complete arrangements for automatically avoiding overcharging, etc., are of the greatest perfection, and, though the chemical part of the lead cell has been pretty well cleared up in regard to the conditions of the longest possible life of the electrodes, it is well known that the careful erection and handling of a plant are even more important with storage stations than with dynamos or motors. In some places the opinion prevails that the failure of storage batteries in this country depends partly upon the lack of these conditions. In each case, if a prediction is allowed here, we may be bold to say that after some time the accumulator will again be introduced here, and, let us hope, in a more favorable way than formerly.

It seems that of the two original types of lead accumulators, to wit, the Planté type and the Faure type, the Faure type alone has been developed of late, as no cells without paste or mechanical application of active material are to be found at the exhibition, and no secondary batteries of other material than lead are present there. There is enough variety among these leaden batteries, however, and in trying to give as exact an account of them as possible we shall here classify them according to the method of manufacture of the electrodes.

We find that the supports for the lead oxides are made by casting, by hydraulic pressure, and by rolling sheet lead, and that either dilute sulphuric acid or gelatinized acid is used as an electrolyte. Cast lead grids are exhibited by G. Hagen, Köln, Germany, Correns & Co., Berlin, and the Deutsche-Accumulator Actien-Gesellschaft.

Usually the grids are cast by means of iron or brass moulds, and this plan has been continued by Correns & Co. and the Actren-Gesellschaft, while G. Hagen casts in

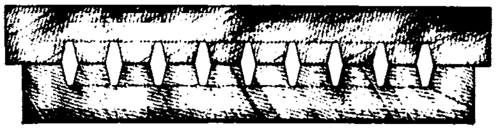

FIG. 2.

the same or a similar material. Considering the old type of plates, as manufactured by the well-known accumulator companies in this country, we find a grid forming a network of lead bars, which have a cross-section, as indicated by Fig. 1.

Fig. 2 shows the metallic mould used in casting such a grid. The form of the plugs of active material is shown at *b*, Fig. 1, and if such a plug splits, as occasionally happens, the two halves are liable to fall out of the grid.

WHO SHALL DO THE WIRING?

BY

A. E. BRADDELL.

I HAVE read the article bearing the above title by Mr. C. A. Harris in the August 26th issue of THE ELECTRICAL ENGINEER with a great deal of interest. As my duties consist in inspecting electric wiring, I feel that I should have something to say on this subject.

The question can be answered with many pros and cons from both sides, but as far as my experience goes, it depends altogether on the location of the city or town, who shall do the work. By this, I mean that in nearly all the large cities the contractors are, for the greater part, responsible men, and as an inspector is generally employed, he can weed out the good from the bad. Now, take the case of a small town at a distance from a large centre of population, and where it will not pay to have one of these contractors wire for, say, a dozen lights at a time. Now, if the local lighting company does not do any work, not even repairing, it follows that the amateur electricians (cheap Johns) see a "bonanza" in sight, and are not slow to "catch on." This is where I find the work, as Mr. Harris puts it, "fearfully and wonderfully done," not only jeopardizing property, but casting a blot (and that a very black one) on the name of the electric lighting company.

These men know little about this class of work, and if asked how they learned the business, I think the answer would be like unto the Irishman's "Sure I did it by my own penetration." Of course, this work is principally found where the electric company does not give any supervision to it, but simply furnishes current wherever and whenever asked.

Next with regard to companies that make the wiring a "secondary consideration." Of course, there were many who had to make some inducement in the early days of the business, and therefore wired numerous places without charge. This method of getting customers is, I think, or at least hope, being abandoned, as people see that electricity is getting on such a firm basis that it can hold its own with any other illumination without free wiring.

Apropos of this, I heard the manager of a large central station state to one of his customers not very long ago, when speaking about rewiring a risk, that he "used to run a free lunch counter, but now all the soup was gone," and that the customer would have to pay for what he got. But, as stated before, the worst trouble is found where local contractors do the work. I contend that the electric light companies, especially those in the small towns, should do their own wiring. By getting a good man and paying him a decent salary, I am certain it is money in their pockets. Take a building wired by an outside person in a small town, and let there be a fire caused from defective wiring. The owner of this building is not going to trouble himself about the exact why and wherefore of the fire, as he expected and paid for "a first-class job," but he immediately pours out his wrath in the form of violent execrations against the electric company. Now, why should they suffer for another person's sins? The owner of the building simply thinks that the electric current cannot be properly controlled, and therefore dispenses with the light.

I do not wish it to be understood that no work should be done outside of electric light companies. Far from it. I am a believer in the motto "Live and let live," and my object is simply to keep out incompetent and irresponsible men. With this object in view, it may be of interest to state the method adopted by the Association with which I am connected. The different electric light companies are asked to sign an agreement stating that "all work will be made in accordance with the rules and requirements of the Association, and that any defects found will be corrected in accordance with same." Another clause which we look upon as very essential is as follows: "That the electric current will not be supplied for any work done by other parties unless such parties have made a similar agreement, or furnished a certificate from the electrical inspector that it is approved." I would state that sixty-seven of these agreements have been signed by lighting companies, and eighteen by contractors, in our territory. By this means we know the people who are, or should be, doing the work, and are able to keep track of them. This appears to be a good method of working where there is a large territory to cover, as it is impossible to inspect every little "shanty" as it is wired. Of course, that is what should be done, but expense is the great drawback, at least if it has all to be borne by the insurance companies. Mr. Harris speaks of a town where "the wiring was given over entirely to local contractors." I venture to state that the work done was as bad as, if not worse than, that by the electric light company before the appointment of the city electrician. I will conclude by seconding the motion of Mr. Harris, that a general expression of opinion on this subject be given through these columns as affording the best means for a thorough ventilation of this important subject.

TROUVÉ SEA-WATER BATTERY.

THE indefatigable M. Trouvé has been astonishing the French Academy of Sciences by his design for an electric boat propelled by a sea-water battery. The plates are sunk in the sea under the boat by way of a kind of keel, and drive a large rotary wheel by means of a motor. Pulleys raise or lower the plates of zinc or copper, as required. Thomas Davenport, the Vermont blacksmith, whose career was recently set forth in the pages of THE ELECTRICAL ENGINEER, made a similar suggestion or design fifty years ago.

THE ROBERTS CHROME ARC LIGHT PENCIL.

BY

Isaiah L. Roberts

IN the history of the electric arc pencil, begun with Sir Humphry Davy and his charcoal points, it was soon discovered that the carbon deposited on the inside of gas retorts in the process of manufacturing coal gas by the destructive distillation of coal, was a conductor of electricity, and made better points than charcoal for experimental purposes. Later, when it was proposed to use the electric arc commercially, it became necessary to manufacture pencils which would be capable of "feeding," and this gas coke was employed as the best material. It was pulverized and mixed with some substance containing a large amount of carbonizable material, which would become plastic when heated, and thus a mass could be made which could be moulded into the desired form and size.

These pencils must be baked in a retort until enough hydrogen and water has been driven off to make the remaining carbon a conductor, and bind together the original coke. In the early state of the art they were very poor conductors because of the great heat needed to completely carbonize the binder, generally asphalt or bitumen, which are fine insulators. They were also soft and not homogeneous.

These defects caused them to burn rapidly, and, with the poor lamps used in the early days of the arc light, to give a sort of winking, jumping light that was most trying to the eye. Thanks, however, to the inventor, both the mechanism of the lamp and the pencil have been so improved that a brilliant and steady light can now be produced.

Very soon after the introduction of the arc light it was found to be impracticable to make pencils of such a length that one pair would burn all night. This resulted in the use of the double arc lamp, so that now all-night lighting is possible.

The double lamp is about twice as expensive as the single lamp, and constitutes no small item in the cost of the plant. To avoid this expense many inventors have busied themselves for several years with the problem of finding something which could be mixed with carbon that would prolong the life of the pencil. Others have tried "tipping" the pencils with some refractory compound. Others still have tried making them of metals, combinations of metals, or oxides of metals, but nothing has been produced which did not have some objections fatal to its utility.

The initial letter of this article shows a pencil which is free from all serious objections and promises to revolutionize the art of electric arc lighting.

This pencil is composed of nothing but the simple elements of iron, chromium and oxygen. If a piece of iron wire be coated or a tube be filled with a chromate of any kind it becomes at once a suitable electric arc pencil. Probably the best form is that shown in the illustration. This is a piece of wire cloth rolled into a cylinder of any size or length, the meshes holding the chromate firmly in position.

The principle on which the pencil burns is as simple to understand as its construction. The chromates are non-conducting bodies, but the metal starts the arc when the pencil separates, and the intense heat thus generated reduces the chromate in presence of molten metal to the chromite of the metal used. These chromites are good conductors when hot, and fair when cold. This enables the pencils to relight.

One of the chief difficulties of using any metallic compound was the relighting. For instance, if an iron tube be filled with lime a good light will be maintained so long as the ends are hot, but when once cold they cannot be relighted, because the slag of iron oxide and lime is a non-conductor. But with chromium oxide and a metal, a slag is formed which will conduct when cold. A little carbon mixed with the chromate helps to reduce it.

The light from these pencils is normally pure white, like the calcium light, but it may be made of any color by introducing various coloring ingredients into the chromate. The actinic rays are more powerful than in a carbon light, while the most delicate colors are brought out fully as clearly as by sunlight. The faintest yellow, which cannot be distinguished from white by carbon light, is readily discernible. These pencils burn about $\frac{1}{8}$ of an inch per hour when properly proportioned to the current. Thus a pencil consuming one and a half inches will burn all night. The light is very steady; so much so that it very much resembles the incandescent light, which in fact it really is to a great extent. This steadiness is due partly to the fact that the mechanism of the lamp is required to operate so seldom that this factor of disturbance does not count.

Another marked peculiarity of these pencils is that the arc with 45 volts is about $\frac{3}{4}$ inch long, while the same E. M. F. with carbons makes an arc of only about $\frac{1}{8}$ inch. When the arc made with carbons exceeds $\frac{1}{8}$ inch, or when it reaches so much as $\frac{1}{4}$ inch, the light is very unsatisfactory, and is called a "flaming" arc. With the chrome pencils the light comes principally from the flame. This is due largely to the small particles of ehromite volatilizing in the intense heat of the arc. The length of the arc and its flame-like nature resembles the flame of a candle, and like it, cannot stand any strong air currents, and hence must be enclosed in a globe as nearly closed as is necessary to prevent draughts.

One of the greatest points of difference between chrome and carbon pencil lights is that with carbon no practical lighting has been accomplished with less than five amperes. The reason for this is that the size of the carbon pencil must not be reduced beyond a certain size, or it will consume too rapidly. If it is not reduced, currents of two or three amperes will not heat the point sufficiently to centre the arc. With chrome, however, the pencils can be made so small as to reach the heat intensity necessary with almost as great economy with a current of one or two amperes as is obtained with ten. As much as 100 actual candle-power, or 300 as commonly rated, can be obtained with two amperes and 50 volts with a consumption of $\frac{1}{4}$ inch per hour, the consumption being about double that of a pencil suitable for a current of six amperes. There is no gain in using large currents and large lights when a greater number of smaller lights break up the shadows more effectually, and make a more acceptable arc light, especially for inside lighting.

Like all revolutionizing inventions, some changes must be made in the present form of this pencil before it can be properly used. The lamp must accommodate at least a half-inch arc, and the arc must be in a globe tight enough to prevent air draughts sidewise. Any lamp using this pencil must be provided with a retarding device, so that when the circuit is broken or the current stopped the pencil will not be allowed to touch for a space of four or five seconds, for if allowed to drop together they will weld, the points being in a plastic condition. If, however, a short space of time be allowed, the ends harden sufficiently by cooling. The lamps used for these pencils must be provided with a shunt of a few ohms resistance, as it takes from 6 to 12 volts to start sufficient current through the feebly conducting ends to heat them. The instant they warm up, however, they have practically no resistance. Carbons have high resistance at the incandescent ends when burning, but no resistance when cold. The chrome pencils are just the reverse.

THE EFFECT OF ELECTRIC LIGHT ON PLANTS.

THE experiments at Cornell University, on the effect of the arc light upon the growth of plants under varied conditions, have developed results sufficiently remarkable to attract the attention of horticulturists and electricians alike, and proved that the subject was one demanding careful investigation.

FIG. 1.—EFFECT UPON VERBENAS.

The forcing house used in the Cornell experiments was 20 x 60 feet, with a low, flat roof, ventilated by windows at the peak, and heated by steam. This was divided by a board partition, one-half being subjected to natural conditions of light and darkness, and the other receiving sunlight by day and electric light during the whole, or a part, of the night, the arc being 2½ feet above the soil of the bench. The lamp used was a 45 volt 10 ampere Brush, of 2,000 candle power.

The general effect of the naked light running all night was to hasten maturity, especially in the case of leaf plants, such as lettuce, spinach, etc., which ran to seed before edible leaves were formed. For five feet either side of the lamp the plants died soon after coming up. Two varieties of cress acted in the same way, and the surviving plants were in full bloom seven weeks after sowing, while those in the dark house were still in good leaf.

Radishes were injured by the light in direct proportion to their proximity to the lamp, those within three to six feet being nearly dead at the end of six weeks.

In regard to entire crops, it was found that those obtained in the normal house were about twice as great as those from the light compartment.

Tests were then made with a view to discovering whether the injury to the plants resulted from the electric light itself or from the fact that they received light during the whole twenty-four hours. The plants were covered during the day in such a manner as to entirely exclude the light, while permitting a free circulation of air. Radishes, subjected to this treatment, were slender and sickly, assumed a faint green color, and died in three or four weeks.

FIG. 2.—EFFECT UPON PETUNIAS.

The fact that the light hastened seed-bearing suggested that a modification might, under certain conditions, be profitable, and to this end the lamp was enclosed in a white "opal" glass globe. The results were very much the same, but in a less degree, with the exception of the lettuce, which was decidedly better in the electric light house.

The influence of the light upon productiveness and color of flowers was found to vary with different species and with different colors within the same species. Several varieties of tulips gave interesting results. Careful observations were made upon Proserpine, light-cherry color; Wourseman, maroon; Vander Neer, light cherry; Yellow Pottebakker, bright yellow; Belle Alliance, scarlet; and Cerise gris delin, cherry and white. When these came into full flower it was found that in every case the colors were deeper and richer in the light house; but the colors lost their intensity after four or five days, and were indistinguishable from those in the dark house. The plants in the light compartment had longer stems and larger leaves than the others; and there was a greater number of floriferous plants in the light.

Verbena flowers growing near the electric light were uniformly injured. All plants within six feet of the light were stunted; the leaves were small and curled, and the flowers were short lived. The flowers were small, and those on the lower part of the clusters turned brown and died before those on the top opened. The buds within two or three feet of the lamp curled up and shrunk and became discolored before opening, but the discoloration did not extend to the inside of the flower until it had opened. Scarlet, dark red, blue and pink flowers within three feet of the light soon turned to a grayish-white, and this discoloration was noticeable to a distance of six or seven feet. The plant shown on the left in Fig. 1 of the accompanying illustrations was subjected to the electric light, while the other was raised under normal conditions, and it will be seen that the former is past flowering, while the latter is in good condition.

Petunias were much affected by the light, as is shown in Fig. 2. The plants were much taller and slenderer, and bloomed earlier and more profusely. Those marked A B C grew 14 feet from the light, and D E F in the normal house. The flowers faded from the effect of the light, however, and became thin and flabby.

From these and other experiments, it seems highly probable that while, in a variety of instances, the effect of the arc light is injurious to the proper growth of plants, yet under certain conditions the judicious use of the electric light will prove particularly helpful. The study is an instructive one, and will, doubtless, be productive of important results.

ELEMENTARY GEOMETRICAL THEORY OF THE ALTERNATE-CURRENT TRANSFORMER.—XVI.

BY

Chas. Steinmetz.

THIS is of less importance for parallel transformers because all the commercial transformers must, on account of the heat generated otherwise in the iron, work with a magnetization, shown in Fig. 28 by the dotted line *I*, considerably below the maximum point of impedance, so that still a considerable increase of impressed E. M. F. could be allowed, without fear of magnetic breakdown.

Only under abnormal conditions this phenomenon becomes of dangerous importance. For instance, if by mistake a 100-volt converter is connected "upside-down," that is, with its coarse wire terminals, to a 1,000-volt circuit, then the leakage current will not only be increased ten-fold, as constancy of magnetic susceptibility would lead us to expect, but the converter will short-circuit the dynamo.

If the frequency is decreased considerably, and the impressed E. M. F. kept the same, with a certain frequency, the danger point, marked on the diagram, Fig. 28, will cross and b_1, that is, b_s, will be reached. This point corresponds to the turn in the magnetic characteristic.

But this phenomenon has a reverse, which might be made useful in constant current transformers. If in Table I, corresponding to Fig. 27, the primary current is kept constant at 58.1 amperes, for a secondary current of 36.9 amperes the transformer consumes 92.4 volts primary E. M. F. But, when breaking the secondary circuit, the E. M. F. consumed by the transformer goes from 92.4 volts down to 85 volts. Hence in constant current transformers this phenomenon could be used to guard against too great an increase of impressed E. M. F. at open circuit.

X. Non-Sinusoidal Waves.

Having considered in the foregoing the harmonic or sine-wave in its action upon the closed-iron transformer, we need to add only a few remarks on non-sinusoidal waves, because these currents have not found until now any extensive application in electrical practice. The waves of all the alternating dynamo electric machines under almost any circumstances are either so nearly harmonic or sine-waves, that they can be considered as such without hesitation, or, even if they differ very considerably in their shape from true sine-waves, nevertheless the assumption of sinusoidal shape generally gives a remarkably fair approximation.

For instance, in the Westinghouse transformer, treated in the next chapter, the primary current, especially for open secondary circuit, differs very considerably from a harmonic wave. Nevertheless we shall see how closely the phenomena observed with this transformer are represented by the polar-diagram of sine-waves. But, if we represent electric waves of different shapes by sine functions, we shall have to define first what is meant by the *phase* of the wave.

As the phase φ of the wave we consider the angle—that is, the time—which divides the wave into two halves of equal *effective* strength, so that the average value of the *square* of the current, etc., from its zero value up to the value corresponding to its angle of phase, equals the mean *square* of the values from the angle of phase down to zero again. That is, *the phase of the current, etc., is that angle φ, which divides the area of the curve of the electric wave in the polar-diagram into two equal parts.* This generally does *not* divide the area of its representation in *rectangular* co-ordinates into two equal parts.

As *maximum value* of the electric wave is used in the diagram, the product of the effective value, that is, $\sqrt{\text{mean}^2}$ into $\sqrt{2}$, or the diagram is produced directly by using the *effective values* of the electric quantities as the diameters of the polar-circles, instead of the *maximum values*, which gives the same result, only that then, if we want to take *instantaneous values* from the diagram, we have to multiply the radii vectores by $\sqrt{2} = 1.4142$.

In the following chapter, in the diagrams of some commercial transformers, we shall proceed in this way.

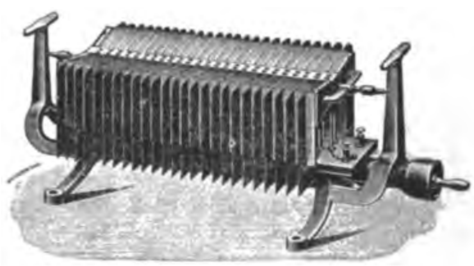
GULCHER'S THERMOPILE AT THE FRANKFORT EXHIBITION.[1]

THE Gülcher thermopile is now constructed by the well-known firm of Julius Pintsch, of Berlin, in two sizes. The accompanying illustration represents the larger model of the latest type manufactured. It has a weight of about 10 kilogrammes, and consists of 50 elements, mounted in two parallel rows on a slate plate. The slate plate forms the cover of the gas reservoir place beneath it, which is provided on the right-hand side with a Bunsen supply pipe. Each element consists, in the first place, of a small nickel tube, forming the negative electrode, and at the same time serving as a supply tube for the Bunsen flame. To the upper end of the nickel tube, into which a simple jet burner of serpentine is screwed, a tubular connection-piece, also made of nickel, is strongly soldered. About this latter the positive electrode, consisting of an antimony alloy, difficultly fusible and very durable, is cast. As a protection against mechanical changes of the alloy (rent, cracks, etc.) which might arise from the expansion of the heated junction tube, and would increase the internal resistance of the element, two steel rings are laid round the junction pipe. At the external extremity of the positive electrode copper sheets for cooling purposes are soldered, serving at the same time for the connection of the elements. All the elements are insulated from one another by asbestos, and the space between the heated places of the elements is lined with the same material.

The remarkable feature of this thermopile is, in addition to its great durability, its great efficiency, greater than has hitherto been obtained by any similar apparatus. The model represented in the figure gives an electromotive force of 4 volts. Its mean internal resistance is .04 ohm, so that (with an equal external resistance) a thermopile of this kind gives a current of 5 amperes.

The working expenses of the larger type, therefore, amount to about 3 pfennigs (a little more than ½ cent) per hour. It further follows from this that the Gülcher thermopile, per cubic meter of gas, gives a total electrical energy of 100 watts, whilst the best instruments of this kind hitherto constructed only give about 24 watts per cubic meter of gas.

A still higher efficiency than the batteries heated by gas is shown by the batteries intended for the production of



GULCHER'S THERMOPILE.

large electrical energies, and arranged for *heating with coke.* In these, the elements are grouped round a common stove, and other improvements have been adopted, increasing the efficiency. One of these improvements is as follows: The terminals of each element are joined in such a way, by an intermediary contact replacing the solder, and are so arranged that the difficultly fusible electrode (nickel) is heated much more than the more easily fusible electrode (antimony alloy). The advantage obtained by this arrangement is, in the first instance, that the elements themselves cannot fuse by excessive heating; on the other hand, that the internal resistance is reduced by more than one-half. From this it follows that the elements (at equal temperature and E. M. F.) generate a current twice as large as those of the old-fashioned type. The second essential improvement permits the perfect utilization of the heat of the common stove for the purpose of conversion into electricity. This object is obtained by making constant in each row of elements built up to form the battery the ratio of the external resistance of the element to the E. M. F., it reaches at a certain part of the stove.

A thermopile consuming 2 kilogrammes of coke per hour gave 80 volts and (at equal external and internal resistance) a current of 10 amperes. The useful output of such a battery would thus amount to 400 watts and suffice for feeding 8 glow lamps of 14 to 16 candles continually, or (with the help of accumulators) 30 of these lamps for six hours per day.

MR. E. R. MITCHELL, of the Thomson Houston factory, Lynn has gone to Minneapolis to take charge of the repair department of the Northwestern Thomson-Houston Co.

THE "JOULE," "746" AND THE "WATT."

BY

G. T. Evans.

Unfortunately, to adequately discuss this subject, it seems necessary to pass over ground which bears the footprints of many a worker, and which would, it almost seems, be wholly gleaned and devoid of any remaining material. The main excuse I have to offer for turning over this soil again is that a majority of "electricians" are still not conversant with the subject; many do not know the definite relations which exist between the above units and other units of Power and Work, and not a few are unaware of how easily these relations may be traced to a common root.

The joule, the watt and the constant, 746, are terms common enough in these days, but there are very shady ideas abroad concerning them. Even the more common volt is sadly misrepresented, and only recently the superintendent of a large station refused to connect a motor because the fuse looked "too small to carry 220 volts."

The utility of the knowledge of the "stuff these different units are made of" and their connection with each other for any but the theoretical electrician may be questioned. A man without this knowledge can squirt oil on a bearing or splice a wire as well as one who possesses it. This may be so, but squirting oil, splicing wire and such necessary work should not form the sum total of his knowledge. He ought at least to have enough respect for his business to be able to converse sensibly on it. A poor carpenter would he be who would not tell what an inch is, or a tin-smith who was ignorant of the size of a quart. Yet there are hundreds of "electricians" who cannot state the difference between an ampere and an ohm.

As a reference to what will be said of the joule, watt and 746, the following familiar formulæ are inserted:

$$W = P \times T = \frac{E^2 \times T}{R} = E \times Q = R + Q^2$$

$$P = \frac{W}{T} = \frac{E^2}{R} = E \times C = R \times C^2$$

Where W = Work; P = Power; E = Electro Motive Force; T = Time; R = Resistance; Q = Quantity; C = Current.

Unit	of	W	in	electro	magnetic	measure	Joule.
"	"	P	"	"	"	"	Watt
"	"	C	"	"	"	"	Ampere
"	"	Q	"	"	"	"	Coulomb
"	"	R	"	"	"	"	Ohm
"	"	E	"	"	"	"	Volt

Horse-Power = 550 foot pounds per sec.; 746 joules = amount of *work* done by 1 h. p. in *one second*; 746 Watts = 1 h. p.

Units of the same dimensions but of different denominations must be reduced to a common denomination to determine what part one is of the other. According to the formulæ, the joule being the product of volts and coulombs, and supposing for simplicity that each of these factors is equal to unity, the next step is to reduce these factors to absolute or C. G. S. units. One coulomb = .1 of the absolute unit of quantity. One volt = 10^8 times the absolute unit of electromotive force. The product of 1 coulomb and one volt thus reduced 1×10^7 absolute units of work = 10^7 ergs. A mass of 1 gramme raised against a force of 1 dyne through a distance of one centimetre has 1 erg of work done upon it. Since the force of gravity is, in round numbers, equal to 981 dynes, a gramme mass will, when raised 1 centimetre, have 1×981 = 981 ergs done on it. One gramme centimetre is thus equal to 981 ergs. In a foot there are 30.48 centimetres, a centimetre being equal to .3937 inches.

In one pound there are 453.6 grammes, there being 15.432 grains in a gramme and 7,000 grains in a pound. Multiplying the factors of the foot-pound thus reduced, the product of 13,825.82 gramme centimetres is obtained. As 1 gramme centimetre = 981 erg, 13,825.82 gramme centimetres is equivalent to 13,563,125.88 ergs. The number of ergs in one joule, divided by the number of ergs in 1 foot pound will give a result of .7373, showing that 1 joule is .7373 of a foot-pound. If the foot pound be increased to 550 foot pounds, work of 7,459,719,245 ergs will be done, which is approximately 746 times the number of ergs in 1 joule. If this work is done in 1 second, it would be at the rate of 1 h. p., and the work done by the joule would be at the rate of $\frac{1}{746}$ of a horse-power, or at the rate of 1 watt.

Perhaps the most interesting way of tracing out the relation between the joule and foot pound is by a process derived from the well-known "Joule" experiment of heating water by a revolving paddle-wheel. It was found that the wheel being revolved in a pound of water by a falling weight equal to 772 foot pounds, would raise the temperature of the water 1° Fahrenheit; 550 foot-pounds acting upon the water would raise the temperature .7124° F.

A current of electricity delivering 1 joule to the water would raise the temperature .00095508° F, which is $\frac{1}{746}$ of the increase caused by the expenditure of 550 foot-pounds.

A little investigation given to all the electrical units would be wonderfully beneficial, and their mystery, which in so many minds, surrounds them, would be shown to be pure, simple common sense.

ELECTROLYTIC DEPOSITION OF ORE IN FRANCE.

The French Société des Ingenieurs Civils have lately had before them a discussion upon plants supplied by power from the falls of Valloirette at Saint-Michel, Savoy, which are being established by M. Adolphe Minet. The Saint-Michel works will be specially arranged for the working on a large scale of M. Minet's electrolytic processes. The power at present at disposal is 6,000 h. p., of which 4,000 h. p. is capable of being utilized. This can be raised to 30,000 h. p. Besides aluminum, M. Adolphe Minet intends to carry out the electrical extraction of other metals and metalloids, particularly those elements of which the oxides are irreducible by carbon, and for which the processes of electrolysis by high-temperature fusion, of which M. Minet is the orginator, is suitable. He intends to also develop the applications of electricity to chemistry and the refinement of metals.

GUTTA-PERCHA FORESTS.

The valley of the Orinoco, which is connected in such a peculiar manner to the River Negro by the Casicuiare, has been found to contain not only immense virgin india-rubber forests, the trees of which are said to yield a rubber superior to the best Para, but also trees of the order Sapotaceæ. Amongst the various gums obtained by explorers in the upper reaches of the river, some have been found by experts to be very similar, if not identical, with the products of the Malay Archipelago.

THE BANDSEPT ACCUMULATOR.

The accumulator invented by M. Bandsept is being introduced by the Franco-Belgian Lighting Apparatus Company. The electrodes are formed of a compressed powder, which is saturated during the process of compression by substances reduced to a gaseous state. The powder is thus impregnated, and becomes solid under continued pressure. The company is about to carry out a system of electric lighting on the smaller lines of railway by means of this accumulator.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XII. NEW YORK, OCTOBER 14, 1891. No. 180.

Science is a growth of time, and though man's cultivation of the field is an essential condition of that growth, the development steadily progresses, independently of any individual investigator, however great his mental power.—Josiah Parsons Cooke.

THE NEW YORK UNDERGROUND ROAD.

FURTHER reports have been made to the New York Rapid Transit Commission by its engineers and others, but in nowise do they bring nearer the end to which all the inhabitants of this city are so anxiously looking. On the contrary, they are a disappointment. The plan proposed does contemplate an underground road, it is true, but the road would come so near the surface that it brings back into the problem all the old difficulties that rendered a solution impossible. The extraordinary feature of these reports, however, is that they make no mention of the Greathead system, although that is to-day the only one known and shown to be operative. In other words, the reports filed would give New York, practically, such an underground system as London has found imperfect and inadequate, and would debar us from the new methods that London has been progressive enough to try and is pleased enough with to extend and push. There has yet to be published any data or information that would condemn the Greathead tunnels and the electrical apparatus they use, and while it may be quite feasible to improve on both, little doubt can be entertained as to the enormous advance they have made in underground travel.

It has been hinted, nay, expressed loudly, that the reason why the deep-tunnel plans have been put in the background is that "there is nothing in it for Tammany," for the reason that such tunnels burrowing far below buildings, pipes and streets would avoid all the vested rights in the readjustment of which, with the plans now favored, a great many politicians would be given an opportunity to rise in world. If this be so, it would be a measure of economy to ascertain who these politicians are, get their price, buy them off, and add the money thus spent to the cost of deep-tunnel work. This would be a paying investment for the city, and far less costly than leaving these politicians to an unholy scramble for two or three years. What New Yorkers want is rapid transit, and one of the saving virtues of the World's Fair that we missed would have been the fact that sheer necessity would have brought such a boon among the Fair's developments. That the city should first be deprived of the Fair by Republican bosses, and then be robbed of rapid transit by Tammany heelers is nothing short of intolerable. But perhaps a better fate awaits the city as to rapid transit than current rumors imply.

ELECTRIC LIGHT AND PLANT LIFE.

THERE has been not a little said on the subject of the effect of the electric light on plant life; but we confess to feeling little confidence in any results obtained prior to those of the Cornell Agricultural Station, of which note is made in our columns this week. One cannot arrive, even now, at any very definite conclusion, yet it is safe to adopt the opinion of the experimenters, who say that the light promotes assimilation, helps growth and maturity, can produce natural flavors and colors in fruits, will intensify the colors of flowers and sometimes increase the number of blooms. It would follow that the light can be used with commercial profit. Yet, evidently there are some vegetables and flowers that the light is hurtful to, just as there are some human races that modern civilization acts upon as a curse.

COMMON SENSE AT FALL RIVER.

WE are glad to see that the sound common sense for which New England has a well-deserved reputation has made itself felt in the deliberations at Fall River, Mass., over the proposition to establish a municipal lighting plant. The committee on street lights have carefully investigated the subject, and have come to the conclusion that the local company can give a better and cheaper service. Moreover, they say that the scheme "rests upon no adequate public demand; it will inevitably work great injury and injustice to an industry which should be fostered and not discouraged; it is contrary to sound precedent; it is impolitic because it will necessitate a vast enlargement of public service, and may lead to a great official neglect and corruption; it is inexpedient because as a business venture it will not prove of financial advantage to the city." All of which are very good reasons for not embarking on what is neatly objected to as "an experiment so vast in its proportions and so uncertain in its results." The committee are not misled by the wild figures that have been afloat as to municipal lights costing only 20 or 25 cents a night, but say that with a 200-light plant they would not be able to give service for less than 55 and 65 cents per light per night. They quote, too, the figure of 52 cents per night recently given as the cost per lamp for a proposed 1,000-light municipal plant for Boston. As the report will probably be adopted, one New England city at least may be congratulated on having the judgment not to run itself into heavy debt for the sake of engaging in commercial and industrial pursuits.

THE CHICAGO ELECTRICAL CONGRESS OF 1893.

We print elsewhere in this issue a suggestive communication from Professor H. S. Carhart, touching arrangements for the International Electrical Congress to be held at Chicago during the World's Fair of 1893. The situation of the matter is clear. It only remains, before official notices or invitations are sent out in the name of the Columbian Exposition and of the Government, to include in such invitation a proper recognition of the work already done in the same regard by the American Institute of Electrical Engineers. That body undoubtedly embraces in its membership so large a number of the most distinguished electricians and electrical engineers of the country, as to make its official recognition by the Exposition authorities and by the Government in connection with the Electrical Congress an element of strength in securing an adequate and representative attendance of electricians from abroad in 1893. We speak advisedly when we say that since first agitating the matter two years ago, the only aim of the Institute has been to make such a Congress in this country a success, and that its best efforts will be given to the authorities in Chicago. There was a time, not many months ago, when it was proposed to make the Electrical Congress an insignificant portion of a Civil Engineering Congress. This the Institute opposed resolutely. Affairs are now, however, in just such shape as will best fulfill the wishes of the Institute, and this was clearly stated at Montreal, when one of the members of the Institute committee urged the National Electric Light Association to join with the Institute in supporting the Chicago authorities and in making the Congress there a memorable event in electrical history. We are glad to receive word, just as we go to press, that Dr. Elisha Gray has accepted the chairmanship of the Committee on Electrical Congress of the World's Fair authorities. This appointment will meet the hearty approval of electricians, both at home and abroad.

Electrical Talent in the Navy.

An officer in the army or navy expects to go wherever duty calls, and hence there is nothing out of the way in the fact that Lieut. Bradley A. Fiske has been ordered to the South Pacific in the old tub "Yorktown;" but it does seem to us that such ability and experience as his in the field of electricity might be better availed of than by thus sending him to the far ends of the earth where his electrical aptitudes will have no opportunity of utilization. The United States Navy, with all its new work, needs such men at home, and it is impossible not to feel that the place for such trained electrical experts as Lieuts. Fiske and Murdock is near to headquarters and not in dim corners of the world. Moreover, in the case of Lieut. Fiske, there are one or two very important inventions that home, but have elicited very favorable comment in naval have not only excited the admiration of electricians at circles abroad. Surely it would have been easy to assign him to a ship where these inventions could have been put thoroughly to the test. What is the use of building fine men-of-war unless they have all the appliances that enable them to save themselves and smash the enemy?

"Let There Be Light."

During the past ten or twelve years we have had the pleasure of noting the installation of a good many central station plants. We are glad that the work goes on, and that part of our duty still lies in keeping up the record; but the pleasure would be very greatly enhanced if our esteemed contemporaries of the secular press would kindly stop heading their articles on the subject with "Let there be light." As there are to-day pretty well 2,000 central stations, and as each of these has had, on an average, about five articles so headed written in its honor, it follows that we have had to dally with that text about four times a day for the last ten years. We have stood this monotonous repetition of a once brilliant remark with all the strength that Christian fortitude and Jewish resignation combined could afford, but we trust it will not be thought impertinent if we ask for something fresh and novel. It is now emphatically unsafe for any man to express his belief, in a company of electricians, that "electricity is still in its infancy;" and it is also to be hoped that the hour is approaching when no self-respecting newspaper will thus preface its rich, nineteenth century American with threadbare, first century Genesis.

Baked and Boiled Criminals.

A report has now been published by the physicians who conducted the recent electrical executions at Sing Sing. It is a very unsatisfactory kind of document, but is pretty clear on the point that the current was quite successful in baking the skin and boiling the blood of the four criminals who were intercalated in the circuit to gratify the humane instincts of Mr. Gerry. The doctors assume quite gratuitously that there was neither consciousness nor pain, but it appears that in one case two doses of current of 27 and 26½ seconds' duration were necessary; in another, three of 10 and one of 19; in the third, three of 20 seconds; in the fourth, three of 15 seconds. Still "no organ was shattered or much out of order," and therefore electrical execution is all it is cracked up to be.

Electric Railway Conduits.

Interest in systems of electric railroading that shall take the current from below instead of from above has been revived by the comments of many of the papers on the Broadway cable road, and the statement by Mr. Edison that he has devised a plan for picking up the current in some way from the rails. The use of the rails is an old and oft tried idea, but if Mr. Edison has hit upon a way of rendering it available in large cities, he will have conferred a decided benefit upon the public and the electrical community.

THE INTERNATIONAL CONGRESS OF ELECTRICIANS.

BY

H. S. Carhart.

VARIOUS movements have been set on foot with the object of securing the attendance of foreign electricians of note at the International Congress of Electricians to be held in Chicago, in 1893. The American Institute of Electrical Engineers extended an invitation to the Paris Congress in 1889, and to the late Frankfort Congress, to be present in Chicago, a year from next summer; and the National Electric Light Association, at its recent meeting in Montreal, appointed a committee in the interest of the proposed International Congress of 1893.

The discussion of the subject in the electrical journals discloses the fact that much uncertainty exists relative to the auspices under which this Congress is to be held. Our report from the Frankfort Electrotechnical Congress says that the members in attendance were invited to Chicago, in 1893 to take part in a conference to be held under the auspices of the American Institute of Electrical Engineers. While such auspices would undoubtedly command respect abroad, they would not connect the undertaking officially with the World's Columbian Exposition, nor secure the recognition of the Government.

It is well known that the World's Congress Auxiliary is an organization authorized and supported by the Exposition corporation. It "has also been recognized and approved by the Government of the United States. Its general announcement has been sent to foreign governments by the Department of State, and an appropriation on account of its expenses has been made by act of Congress."

This organization will provide places of meeting and other appropriate facilities for various conventions or congresses to be held in Chicago at a convenient time in the Exposition season of 1893. It has already appointed a number of general committees to organize such congresses, to enlist the interest and co-operation of eminent men at home and abroad, and to secure if possible the attendance of the most distinguished representatives of each department of knowledge and activity at its respective congress or convention. These committees are necessarily resident in or near Chicago, but they are expected to procure the co-operation and aid of as many able men as possible, who will constitute an advisory council. The advisory councils are invited to aid the local committees by correspondence and by personal conference as opportunity may offer.

The chairmanship of the local committee on an electrical congress has been offered by the World's Congress Auxiliary to Professor Elisha Gray (who has signified his acceptance), and the vice-chairmanship to Col. Clowry. Mr. B. E. Sunny, the chairman of the Montreal Committee, is one of the committee of the Auxiliary; so also is the writer.

Since the movement for an International Congress of Electricians has now been inaugurated by the properly constituted authorities, and under auspices recognized by the World's Fair Directory and by the United States Government, it is intended that plans shall be rapidly matured, and that nothing practicable shall be left undone to secure co-operation both at home and aboad. The only electrical congress of great importance, thus far held, was the congress at Paris in 1881. Its decisions have been universally accepted, and its influence on the progress of the science of electricity has been plainly apparent ever since. If this supreme opportunity, presented by the World's Fair in 1893, can be rightly laid hold of, the gathering of electricians in congress at that time may prove no less fruitful in results than that at Paris ten years ago.

EARLY WORK IN INSULATION.

IN one of our English contemporaries, and more recently in one of our American, the desire has been expressed for information as to early work in insulating wires. As a matter of fact, such information is not far to seek, but since the matter is of general interest, it may not be amiss to recall the facts. The first recorded instance of the use of an electric conductor suspended in the air upon insulating supports was by Stephen Gray, a pensioner of the Charter-house London, who on July 2, 1729, transmitted an electric impulse through a pack-thread eighty feet in a horizontal direction, supported by threads of silk. In August, 1730, Gray transmitted a charge of elecritcity through 886 feet of wire supported in the same manner.

"C. M.," the unknown correspondent of the *Scot's Magazine*, who, in a letter dated at Renfrew, February 1, 1753, made the first definite proposal to employ electricity for the transmission of intelligence, appears also to have been the first to make the suggestion of enveloping the conductor in an insulating coating. Referring to the anticipated objection that the "electric fire" would become dissipated, or, as he quaintly phrases it, "entirely drained off in a few miles by the surrounding air," he says:

> "To prevent this objection and save longer argument, lay over the wires from one end to the other a thin coat of jeweler's cement. This may be done for a trifle of additional expense, and, as it is an electric *per se* [in modern parlance, an insulator] will effectually secure any part of the fire from mixing with the atmosphere."

Tiberius Cavallo's *Complete Treatise on Electricity, etc.*, published in London, 4th ed., 1795, pp 285-96, contains an account of certain experiments which the author says he "made some years ago" with the object of firing gunpowder and other explosives from a distance by electricity. His well-considered directions for insulating the conductors are minutely given as follows:

> "A piece of annealed copper or brass wire being stretched from one side of a room to the other, heat it by means of a flame of a candle, or a red-hot piece of iron, and as you proceed, rub a lump of pitch over the part just heated. When the wire has been thus covered, a slip of linen rag must be put round it, which can easily be made to adhere, and over this rag another coat of melted pitch must be laid with a brush. This second layer must be covered with a slip of woolen cloth, which must be fastened by means of a needle and thread. Lastly, the cloth must be covered with a thick coat of oil paint."

On the 29th of August, 1809, Dr. Samuel Thomas von Sömmerring read a paper before the Munich Academy of Sciences, descriptive of an electro-chemical telegraph which he had recently devised having 35 insulated wires.[1] Estimating the cost of such a telegraph; he says:

> "One line, consisting of thirty-five wires, laid in glass or earthen pipes, each wire insulated with silk, and measuring 32,827 Prussian feet, might be made for less than 2,000 florins."

In a letter dated July 30, 1810, written by Sömmerring to his friend Baron Larrey, in Paris, in reference to a model which he had sent thither from Munich for exhibition to the French Academy, he says:

> "The old conducting wires are somewhat damaged, and as it was entirely to avoid delay that I did not rearrange them before despatching the apparatus, I would be glad if they could be replaced by new wires, of the sort used in harpsichords, *covered with silk thread*, as the material of which these are composed is more durable than the old copper wires." * * * * "I am very much afraid that, besides the fragility of the copper wires, the rough usage to which they have been subjected in the course of experiment may have rubbed the silk off in places, and so may cause intermediate contacts of the metal, whence must result a derangement of the whole system."[2]

One of Sömmerring's original models is still preserved in the family of one of his descendants in Frankfort. It was exhibited at the Loan Exhibition at South Kensington in 1876, and may very probably be seen in the present Electrical Exhibition in Frankfort.

1. Über einen elektrischen Telegraphen. *Denkschr. Münch. Akad* 1811.
2. J. J. Fahie; *History of Electric Telegraphy, etc.*, p. 240.

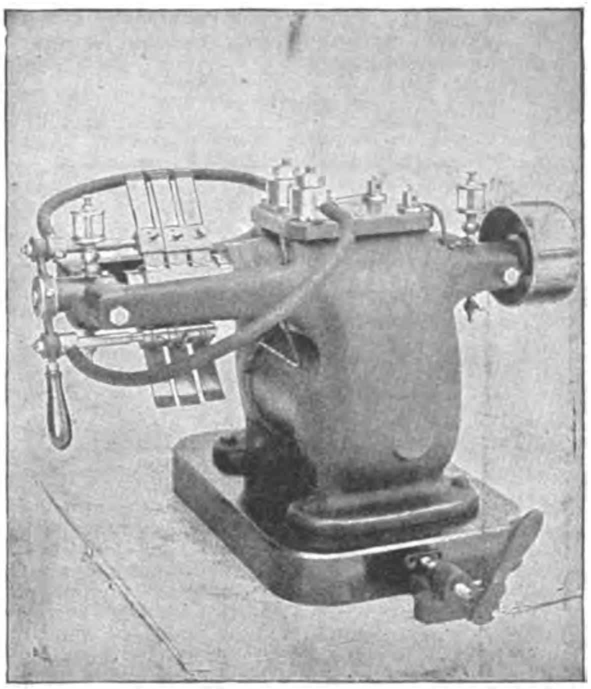
To Dr. Sömmerring, therefore, appears to be due the credit of being first to use conductors wrapped with silk; the first to employ a multiple cable of insulated conductors, and the first to use such an insulated wire for the transmission of voltaic currents.

It is not so generally known as it deserves to be that the first submarine wire insulated with gutta-percha ever laid in the world was constructed by Dr. John J. Craven, of Newark, N. J. With the assistance of his wife, he covered a piece of No. 16 copper wire by hand with gutta-percha. This insulated wire, which was about 15 feet in length, he experimentally submerged in the water of Bound Creek, a small tidal stream crossing the present line of the Pennsylvania Railroad midway between Newark and Elizabeth, N. J., and connected it in the circuit of the Morse line between New York and Philadelphia. This experiment, which was entirely successful, was made about the middle of September, 1847. Dr. Craven afterwards submerged a similar wire for the Magnetic Telegraph Company at the Passaic draw, near Newark, which was followed by the manufacture and laying of a cable a mile long across the Hudson River by the same company in the line of the Cortlandt street ferry. This was a No. 12 iron wire with three coats of gutta-percha. The first telegraphic communication sent through it was on the 15th of June, 1848.

The result of this undertaking led directly to the laying of a cable between England and France, which was successfully accomplished on the 27th of August, 1850.

COLBURN'S NEW DYNAMOS AND MOTORS.

Among the very first to go into the business of the practical manufacture of electric motors and dynamos, was Mr. I. W. Colburn, of Fitchburg, Mass., who has in the course of the past few years brought out many different designs and types of electric machines, all of which have found a successful field. Lately Mr. Colburn has organized his business into a company, now known as the Colburn Electric Manufacturing Company, and about the same time brought out a new design of motor, which probably excels all his previous designs in beauty, finish and efficiency. We illustrate in the accompanying engraving one his new machines, which are all more or less similar in design, but of varied purpose and capacity. The armature of this type of machine is built up of laminated Norway iron, insulated from the shaft by a wooden bushing, and having wooden blocks on the end, the whole being covered with asbestos and canvas before winding. The armatures are carefully balanced both before and after winding, and every bearing is carefully ground. The commutator, which is made of tempered copper, is on a solid steel shell, which is keyed to the shaft, and which is very easily removed, and is insulated by an asbestos bushing with laminated fibre at the ends. The bars of the commutator are insulated by sheet mica. All the bearings are self-oiling with an oil-well underneath, in which there is a revolving chain. The field-magnet is of wrought iron tapered at either end with a key slot, and fitting snugly into recesses in the cast-iron pole-pieces, which are secured to the field-magnet by one large bolt or stud. The carriers for the bearings are cast on the pole-pieces, and are bored out at the same time as the pole-pieces where the armature fits, thus securing a correct line. The bearings are turned and bored separately, and require only to be bolted in their places. This method of building the field-magnet and pole-pieces, secures a very short, intense magnetic field, has all the advantages of a wrought-iron core, and by means of the tapered ends, secures an excellent magnetic contact between the core and the pole-pieces. The bobbins of the field are made of tin insulated on the inside, and having leatheroid ends. All the bobbins are interchangeable, so that if a field should burn out at any time, all that has to be done is to take out the large bolt, the bolts of the bearings, draw back the pole-piece and slip on a new bobbin. The base of the machine is of wood, with a V-shaped groove and bar to slide on, and is supplied with a ratchet. The figure shows a 5 h. p. motor. The same types of machine are made for lighting, deposition, &c. The machines are all well finished and are well made throughout, and have given universal satisfaction wherever used. The dynamos are made in sizes of from four lights to 300, the motors from ¼ to 5 h. p., and the plating machines with a capacity of four to 400 ounces of silver per hour.



Colburn Five H. P. Motor.

THE MEASUREMENT OF LIQUID RESISTANCES.[1]

BY J. SWINBURNE.

The great difficulties in measuring liquid resistances arise from the polarization at the electrodes. Various methods of eliminating the errrors arising from polarization, and from variations of surface resistance due to bubbles, have come into use; the most usual being to employ an alternating current and a telephone. The following are some methods of avoiding polarization errors in a manner analogous to that employed by Sir William Thomson, Mr. Heaviside and others, in measuring low resistances. In measuring low resistances, the resistances of the contacts are high in comparison, and have to be eliminated. Fig. 1 shows the vessel employed. It consists of a glass tube, with cups, A and B, at the ends, for the main electrodes. Near the ends are feeler cups, C, D, and it is the difference of potential of these feeler cups that is measured. Tbey are connected by means of parchmented siphon tubes, such as those used in Raoult's cell, with vessels containing electrodes in a suitable electrolyte. For instance, suppose the resistance of sulphuric acid is to be measured. The main electrodes are platinum or lead. The siphon tubes are filled with acid, and connected to vessels filled with sulphate of zinc. The electrodes in these are zinc amalgam. The apparatus may be arranged either so that there is no current from C to D, or so that there is a current which may polarize the amalgams a little. In this case the polarization can be observed. Fig. 2 shows a method with no current. The main circuit from the battery E is

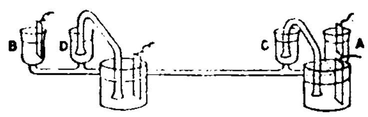


Fig. 1.

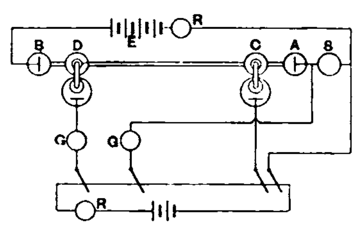

Fig. 2.

1. Abstract of a paper read before the British Association, in Section A, at Cardiff, August, 1891.

through a resistance, R, which is fairly large, so that variations of resistance or back pressure elsewhere in the circuit do not affect the current much. Then it passes through a standard resistance, S, to the main electrode, then through the tube back to the battery. The fall of pressure between the feelers C and D is compared with that over the standard resistance S by means of the potentiometer arrangement shown diagrammatically. For accurate work a resistance box is used; the wire is only shown for clearness. In this case there is no current in the feeler circuit, and, therefore, no polarization. A deflection can be taken on each side of zero, if desired, so as actually to reverse the current. Polarization of the feeler electrodes can also be detected instantly by breaking both the cell circuits. There should then be no deflection. The drawback to this method is that successive readings have to be taken, and if bubbles are coming off the main electrodes, the main current can never be quite constant. Fig. 3

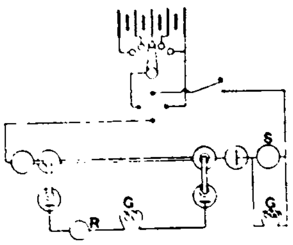

FIG. 3.

shows another disposition with a differential galvanometer, whose coils are lettered G G. In this case there is a current in the feeler circuit. To make sure that it produces no error the direction of the main current is commuted quickly at K. Any polarization then gives a double deflection. The apparatus may also be coupled up as a Thomson low-resistance bridge. By varying the number of cells, Ohm's law can be checked. As Prof. Stroud has pointed out to me, the resistances of the siphon tubes must be taken into account. They can, however, be made inappreciable in comparison with that of the galvanometer circuits.

Amalgamated zinc does polarize slightly, or some other action takes place which produces an equivalent result. Unless the time of contact is long, however, it does not give rise to trouble. Polarization shows at once by the deflection on lifting the main key.

The main tube is calibrated by filling it with mercury. Mine is straight, but it would be better to coil it up to go into a water bath easily. If one siphon tube is not enough, a second intermediate tube with a vessel can be used. I think one is generally enough, however. For instance, for measuring caustic sulphate of soda would be used in the siphon tubes, and so on. I have not experimented on various electrodes yet. Amalgams of silver or copper in suitable solutions, or mercury in mercurous nitrate, may be better than zinc amalgam in zinc sulphate.

THE TELEPHONING OF GREAT CITIES.[1]

BY A. R. BENNETT.

MR. BENNETT said that the establishment of an effective and popular telephone exchange in a large town, and one that can be added to and extended freely and economically, without pulling down what has already been done, involves the fulfillment of several indispensable conditions.

First—Speech must be loud and distinct, and privacy of communication complete. There must, furthermore, be an absence of all disturbing sounds.

Second—The arrangements must be so complete that eight or 10 seconds should be the maximum time occupied in calling and connecting within the compass of the largest town.

Third—The rates should not exceed $40 per annum.

Fourth—New subscribers in every direction and to any extent must be able to be added without interfering with the work already done.

What is necessary can be broadly indicated.

(1) The universal use of metallic circuits, and the absence from the line of intermediate electromagnets and other signaling devices.

(2) The provision of means by which certain and instantaneous communication can be secured.

(3) The division of the town into small sections, each worked from a switch-room placed at or near its centre.

It has always been a bugbear that telephonists have to fix their wires, not where they want them, but where they may.

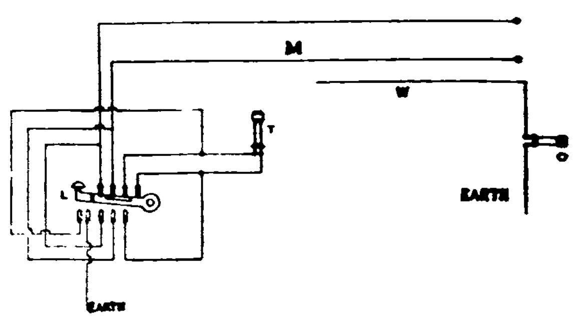
Without legislative assistance, which cannot consistently be withheld, efficient telephoning of great cities verges so near to the impossible that the author assumed that it will be forthcoming at the proper time. He said:

"All subscribers' lines will be metallic circuits. So long ago as 1883 I warned the National Telephone Company of the error they were committing in persisting in the use of the single-wire system. The opportunity was lost, and now cannot be regained without sacrificing the greater part of the capital they have expended. In Manchester my advice was taken, and universal commendation has resulted. The 'Mann' system enables connections to be obtained with certainty and celerity; it renders easy the task of getting rid of one connection and obtaining another. It simplifies and cheapens switching apparatus to an almost incredible degree, and it permits of connections being made through many switch-rooms without the intervention of intermediate electromagnets, so that no retardation and indistinctness of speech result.

"The main feature of the system is the service wire. One such wire is allotted to every 60 to 100 subscribers, according to the amount of traffic passing. During the busy hours of the day operators are always listening on the service wires, so that subscribers may speak and be heard without any premonitory signals. The subscriber, on his part, can at any moment place himself in communication with the operator by depressing a small lever, which has the effect of changing his instrument temporarily from his main line to the service wire."

It occured to Mr. Bennett that, on the "Mann" system, it might be possible to convey the service messages between subscribers and operators by means of electrostatic induction between the subscriber's metallic loop and a special single wire run out for a sufficient distance from the exchange amongst each group of metallic circuits.

On arranging the wires and apparatus in the manner indicated in the accompanying diagram it was found that such a plan was really practicable. Here M is the subscriber's metallic circuit, forming, when the lever is depressed, the subscriber's side of the condenser; L is the subscriber's lever changing his phone T from metallic circuit to earth; W is the insulated wire forming operator's side of the condenser, and O is the operator's phone. The connections of the subscriber's instrument were altered in such a way that, on depressing the lever, the metallic circuit M was put to earth through the telephone. The metallic circuit then acted as a single wire of double area, and, whether insulated at the switchboard or connected through to another circuit, practically formed one plate of a condenser, the other plate or plates of which were any of the adjacent wires that happened to be earthed at their extremities.



TELEPHONING BY ELECTROSTATIC INDUCTION.

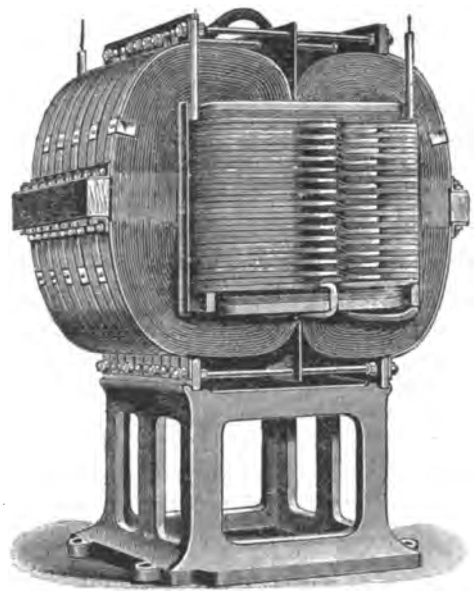
It was, therefore, only necessary to put the operator's instrument in permanent connection with one or more wires running parallel to the subscriber's metallic circuit for a short distance, to enable any of the subscribers, whose instruments were so fitted, to communicate with the operator by depressing their levers. When the levers were not depressed, the telephones were looped in the metallic circuits as usual, and the operators could neither hear or be heard. When cables were used containing 36 or even 72 metallic circuits, it was only necessary to connect the operator's instrument to a single wire placed in the centre of the cable, or to the metallic sheathing of the cable, to obtain perfectly good speaking when the metallic loops were earthed by the subscribers depressing their levers. When a connection has to be obtained through more than one switch-room, it is asked for by each operator in succession by depressing a lever which puts the required operator in communication with the service wire to which the operator at the next switch-room is giving attention.

The Mann system is specially applicable to large cities, and Mr. Bennett, therefore, proposes to supply a town like London, which ought to have tens of thousands of subscribers, by arranging numerous small local exchanges on the Mann system. The small exchanges would call through to one another. In this way a city of any size may be easily, efficiently, and economically served.

1. Abstract of a paper read before the British Association at Cardiff.

THE FERRANTI SUB-STATION TRANSFORMER.[1]

THE accompanying figure shows one of the Ferranti 150 h. p. transformers, specially designed as a sub-station instrument for reducing pressure from 10,000 or 5,000 to 2,400 or 2,000 volts. The transformer consists of three coils—viz., of one high-pressure coil, which is sandwiched in between two low-pressure coils. Each of these coils is composed of a copper strip separated by a strip of vulcanized fibre and wound over with shellaced cloth and vulcanized fibre. In forming these coils a number of separate



FERRANTI TRANSFORMER.

flat coils are built up one over the other, and connected together in series, insulating material being placed between every elementary coil. The high-pressure and low-pressure coils are separated from one another by sheets of ebonite, with a considerable air-space between. The iron cores are exceedingly massive, and formed of flat bands bent over in opposite directions to form closed magnetic circuits; the various layers of iron bands are separated from one another by an air-space of a half inch, to provide for ventilation, or, in cases where the transformer is placed in oil, to allow a free circulation to the oil. It is advantageous to immerse these high-tension transformers under the surface of an insulating fluid, diminishing thereby the liability to electrical discharge between the high-pressure coil and the iron frame, or the low-pressure coil, which exists by virtue of the powerful electrostatic field in the neighborhood of the high potential end of the high-pressure coil.

THE LIGHTING OF THE EMPIRE THEATRE, PHILADELPHIA.

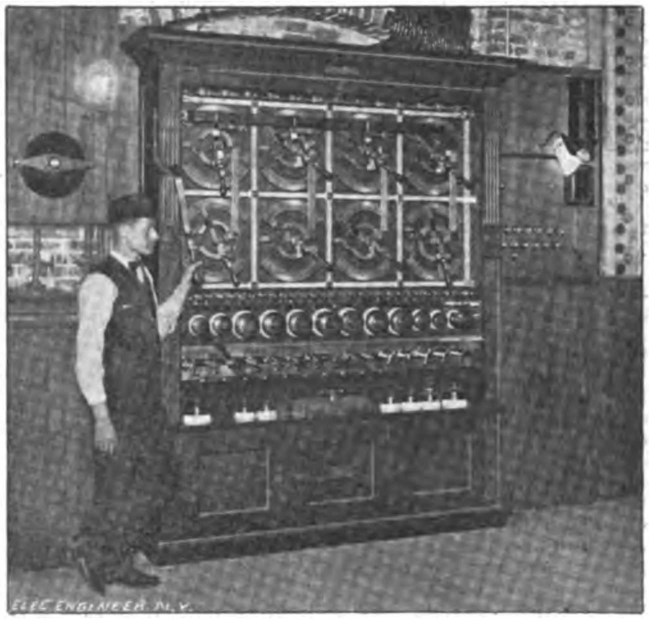
THE new Empire Theatre, opened in Philadelphia on August 29th, is the most beautiful of all the Philadelphia playhouses, and has attracted a great deal of attention both on account of its picturesque and well-lighted interior, and its original and striking exterior. Mr. Angus S. Wade, the architect, has designed a structure theatrical in appearance from foundation to roof, and, in departing from many old-established forms, has created a place of amusement which is a model of excellence and convenience. The theatre is lighted by electricity by a plant of its own, the electrical work all being done under the personal supervision of Dr. W. A. Drysdale, consulting electrical engineer, and, it is said, excels anything of the kind heretofore attempted.

The façade of the theatre is of light buff brick, trimmed with Indiana limestone. Turrets flank either side of the main entrance, entirely detached from the auditorium, containing the stairways from the lobby to the balcony, and between them in the second and third stories extend open balconies with balustrades and arches of copper, designed after the Moorish. On the keystone of each of these arches is hung a large incandescent lamp covered by an antique twisted globe. These lamps, hung under the eaves of the balconies, and partially concealed from the street, casting a glow over the dull copper work, and, outlining the building with its Moorish forms, produce a truly beautiful effect, making the façade look like the entrance to a Moorish castle, and giving the building a general effect from the street which surpasses anything hitherto attempted in outside lighting; an effect in which the arc lamp plays no part, and which would be destroyed by its use.

There is an absence of fixtures in the lobby, the lights being in crystal globes between the projecting rafter ends of papier-maché, beneath the roofs of the vestibule and box-office. In the broad stairways leading from the lobby to the balcony are side brackets of brass, bearing lamps, and one noticeable feature in the lighting is that no shadows are cast on the stairways.

The lighting of the auditorium is a radical departure from anything that has hitherto been attempted in theatre illumination. Fixtures of Moorish design, forming capitals for the columns supporting the balcony and gallery, contain the lamps which are usually placed on the face of the balcony and gallery themselves, and this arrangement gives the audience in these parts of the house an unobstructed view of the stage. The box lighting is so arranged that the lamps are out of sight of the audience. A novel effect of lighting is in the box canopies, the roofs of the boxes forming great lanterns of stained glass, giving a soft light, that harmonizes with the draperies of the boxes below.

Looking toward the stage, the attention is arrested by the lowness of the footlight apron, it being only a few inches above the stage floor, although the lights are entirely concealed from the audience. The footlights are 150 in number, fifty each of green, red and white. The border lights are so hung that all the light is cast upon the stage, and not lost in the rigging loft, as is too often the case. Ground rows or additional footlights, beside the customary bunch lights, assist in furnishing a perfect illumination for the stage.



SWITCHBOARD, EMPIRE THEATRE, PHILADELPHIA.

Every provision has been made on the stage for spectacular and striking effects. Special arc lamps are used throughout the house instead of the time-honored calcium light. The switchboard, constructed by John P. Cushing & Co., of Boston, is an excellent piece of work in all its details. It is made of quartered oak 6 feet 6 inches high by 8 feet 3 inches wide, and stands on a cabinet 17 inches high by 8 feet 6 inches wide, containing the cut-outs and bus bars. The whole board is protected by a roll-top cover. The board, which is shown in the accompanying engraving, controls 200 lights for the borders, 150 footlights, 240 bunch-lights, and 1,000 lights for the house, which are controlled by 34 different circuits, these circuits being again subdivided after leaving the board. Ten circuits are on gang snap switches, which can be worked one at a time, or all together, by means of a lever. The whole is controlled by one break-down, reciprocally-acting switch.

The greatest care has been taken with the wiring of the building, interior conduit being used throughout. A distinctive feature of the arrangement of the circuits is that no cut-outs are located in the auditorium, these all being placed on the stage, so that a blowing fuse can in no way alarm the audience, and can be replaced at once without confusion. The auditorium lighting is divided into two circuits controlled by separate rheostats. This arrangement has been provided to permit of the darkening of the body of the house, leaving the sidewalls lighted to permit the convenient ingress of the audience in case of there being a dark scene in the early part of the play.

The plant for the lighting of the theatre and Hotel Metropole,

1. London *Electrician*.

adjoining, is in a separate building, and consists of one 150 h. p. Gill tubular boiler, 100 h. p. Woodbury engine, and two 240 ampere Edison dynamos. The entire plant when completed will consist of four 240 ampere dynamos, two 100 h. p. Woodbury engines, and 450 h. p. of boilers, the switchboard being so arranged that either engine can take charge of either the lighting of the theatre or Hotel Metropole, or the buildings can be lighted by the current from the street in case of the remote possibility of a break-down of the plant. Only enough gas is used in the theatre to dismiss the audience in case of accident, no gas being used on the stage. The Hotel Metropole will be erected in the spring on the site next to the theatre, and the lighting of this building will also be under the supervision of Dr. Drysdale.

In the theatre every device and precaution known to the art has been used to make the installation absolutely safe and free from danger of fire, and through the liberality of Mr. John M. Sharp, the owner, no expense has been spared to make the entire theatre and plant perfect in every detail. The contractors for the electrical equipment were Messrs. Walker & Kepler, who have very successfully carried out the specifications of the consulting engineer.

SOME FIGURES OF THE MINNEAPOLIS ELECTRIC RAILWAY.

THE July report of the street railway systems of Minneapolis and St. Paul is the first of the monthly returns in which no horse account appears, and as such, is of especial interest to the advocates of the electrical car and the overhead system of propulsion. It appears from the report that the gross earnings for the month were $107,571, the expenses $52,585 and the net earnings $54,985. More than ordinary interest has been taken generally in the success of the St. Paul and Minneapolis system because it represented the largest electric system in the world, and furnished a perfect test of the overhead trolley as furnished by the Thomson-Houston Co. With a view to getting at the facts respecting the satisfaction with which the system in vogue is regarded by the management, Mr. Thomas Lowry, who is at the head of the business, was interviewed while on a brief visit in Boston recently, and expressed himself as perfectly satisfied with its operation.

"We hear nothing but praise," said Mr. Lowry. "Here are to-day nearly 350,000 people and not a horse car in either city. Minneapolis has 120 miles of street railway all equipped with the overhead electric system, with posts set in the middle of the street and arms for the wires extending over the track on either side. St. Paul has 90 miles of street railway; 75 miles of it are in the electric system and 15 miles in cable, but we shall take up part of the cable road and supplant it by electricity, except where we have to mount a 17 per cent. grade. Here we must keep the cable in. One can now travel by our electric line from the north side of Minneapolis to St. Paul parks, over 20 miles, upon a transfer check.

"The expenses for operating during July," continued Mr. Lowry, "were less than 49 per cent., and I feel perfectly sure that within two years we shall be operating our entire electric system of 215 miles in two cities for less than 40 per cent. for expenses. A year ago our Minneapolis lines were earning about $70,000 a month. We have increased our gross earnings 50 per cent. by the improved facilities which the electric lines afford to the traveling public. All the people in the Northwest are enthusiastically in favor of the electric system. We have had every kind of power, and find in the winter the overhead electric is better to work through snow drifts than either steam, horse or cables, and we have tried them all. We have used electricity now for two years, and we think we know something about motor repairs and the general repair account, and we expect this account to diminish instead of increase. The principal item is the burning out of the armatures, but this becomes less as the employees become more experienced, and operations become systematized."

Lima oil is used principally for fuel. This is brought from Ohio and costs, landed there, $1 per barrel. Experts figure that it takes three barrels to make the equivalent of a ton of coal, and Mr. Lowry estimates that it costs only $1 for power a day to run an electric car where 150 cars are being operated in the system as at present. Horses used to cost the company $3.85 to $4 a day per car, with the low-priced grain. The cars now make a greater number of trips per day, and transport a correspondingly larger number of passengers.

During the interview Mr. Lowry made some interesting comparisons between his own lines and those of other cities operated similarly by the overhead system. Among these was the West End Street Railway Co., of Boston. As an expert his opinion regarding its possibilities is worthy of consideration. He had just been looking over the June monthly statement of the West End Co. and stated, as his opinion, that, with the volume of traffic which it had to deal with, it will operate with a good deal less than 50 per cent. for expenses when the horse cars shall have been dispensed with. He thought that with these out of the way, nearly a third more trips could be made with the same equipment. He believed that Boston expenses for the electric system, with its immense traffic, could be gotten down to 35 or 40 per cent., and he predicted that with the great volume of street traffic there, West End will operate for 40 per cent. of its gross receipts when its electric system is completed, for as the traffic grows, the ratio of expense diminishes.

"The ratio of operating expenses on the electric system," Mr. Lowry concluded, "is downward, not upward. My report for July covers 11 electric lines for the month. The line of our heaviest traffic, 9½ miles between Minneapolis and St. Paul, shows only 35 per cent. of a 5-cent fare as cost of operating. We run trains of two cars on this line, and we are going to run three cars as the traffic increases. The principal increase in expense will be the cost of a conductor, as we have a man on each car. Two years ago when we started to introduce electricity, the street railway gross earnings in St. Paul and Minneapolis were only about $800,000. We are now earning, and shall earn this calendar year, $2,000,000 gross. Next year we expect $2,500,000, and 1893 should give us $3,000,000 of gross earnings, or half what the West End earns."

Rochester, N. Y., was cited as a place where an overhead system of 60 miles is being operated for 44 per cent. of its gross receipts.

ELECTRICAL UNITS AT THE BRITISH ASSOCIATION.

OUR London correspondent, under a recent date, writes us as follows in regard to the late interesting discussion at the British Association meeting, on electrical units.

The joint discussion with the Mechanical Science Section on "Units and Their Nomenclature" was opened by Professor Oliver Lodge. He said it would probably be best to divide the subject into two parts, taking the electrical units first, as far as possible, and leaving the discussion on mechanical units, which was of a less practical, and more academical, character, to a later stage. One practical unit which had not yet received an officially recognized name, and which is, nevertheless, very largely used, is that of self-induction. Two names have been proposed for it, secohm and quadrant. The first of these is open to the objection that it regards the unit of self-induction as one derived from the ohm, whereas in reality the former is the more fundamental unit, and in ascertaining the value of the ohm the determination of self-induction is necessary. Again, the term quadrant was objectionable, because it led to the idea that the unit of self induction was a length, thus ignoring the dimensions of magnetic permeability. There is moreover, some question as to whether the present unit of self-induction is not too large, and it might be advisable to attach a name to a unit whose value is one hundreth or one-thousandth of the secohm. Again, the present unit of magnetic field is too small, and was introduced from reference to magnetic poles, whereas now it is used almost exclusively in connection with induced currents. Professor Lodge showed also that it would be convenient to have a unit in terms of which the whole number of lines of force passing through any circuit can be measured.

Mr. W. H. Preece thought the idea of naming the unit after deceased physicists a very good one, and he hoped, therefore, that the unit of self-induction should be connected with the name of Henry. Although advocating a strict conservatism with regard to the present absolute system of units, he desired to suggest that the unit of electromotive force be increased tenfold, seeing that the present value of the volt is rather too small for practical use, and was originally chosen simply because it happens to be nearly equal to the electromotive force of a Daniell cell. Moreover, the proposed change would get rid of the existing discrepancy between the ampere and coulomb and the corresponding absolute units. Mr. Preece also suggested that physicists should devote themselves to a closer determination of the absolute dimensions of specific inductive capacity and magnetic permeability.

Professor W. Stroud read a paper, as a contribution to the discussion, in which he advocated the adoption of an earth quadrant as the unit of length for the practical system, and the one thousand millionth of a gramme as the unit of mass, the unit of time being one second, as at present. This would lead really to Mr. Preece's suggestion. The unit of power would be a hundred times greater than at present, and would be, therefore, about one-seventh horse power. He deprecated any interference with a clear distinction which is at present preserved between the practical and the absolute systems of electric units, but thought a unit of force or value equal to a million, or even a thousand million, dynes would be useful in connection with both systems.

Mr. J. Swinburne thought a unit of self-induction was not used in practice as often as was supposed, and he hardly thought it necessary to give a name to it.

Dr. D. J. Stoney said that in 1874, while sitting on the committee which fixed the present units, he objected to making the dyne and erg so small at that time. Siemens objected also to using the centimetre as the unit of length, but no system could be devised in which some of the units were not awkwardly large or small. It was then suggested to use multiples and sub-multiples of the fundamental units, each physicist selecting those which would be most useful for his work. The notation suggested was to use powers of 10. Dr. Stoney also hoped that some method could be found of getting rid of the word "force" in terms such as "electromotive force." He suggested, to this end, that this should be called energy, the factors being energy per unit quantity. The corresponding forces would be force-factors or potencies, and would be spaced variations of the energy-factors.

Professor Carey Foster hoped that if any new unit of electromotive force were agreed upon, it would be provided with a new name. It would be exceedingly awkward if any one referred to a volt not to know whether the old or the new value was meant.

Professor Rucker insisted upon the recognition of the factor's specific inductive capacity and magnetic permeability in dimensional equations, and objected to our assuming any absolute dimensions for electrical constants.

Professor S. P. Thompson thought that in a certain way analogous to that used by Sir Wm. Thomson in the case of electrical resistance, the self-induction of a wire or coil might be represented by a length. He also thought some clue to the dimensions of permeability and inductive capacity might be obtained by ascertaining what dimensions of them would clear all the equations of fractional indices. He also asked for the recognition of vector quantities in dimensional equations, and showed how it might be secured.

Mr. T. H. Blakesley wanted a new unit representing the square of a current. The angular deflection of a dynamometer would directly measure such units.

Professor Lodge, in reply, called upon the members to take every opportunity of abusing the present electrostatic and electromagnetic systems of units, but to retain them until our increased knowledge enabled us to bring forward a better and more scientific system. He hoped that the discussion would be continued in the scientific papers during the year, and that something definite might result.

At last we have a report of the committee who were appointed on the question of electrical measurement. You may remember that at the end of last year a committee was appointed by the Board of Trade to consider and report whether any, and if so, what, action should be taken by the board under the Weights and Measures Act, 1889, with a view of causing new denominations of standards for the measurement of electricity for use for trade to be made and verified. The committee to which Sir T. Blomefield acted as secretary consisted of Mr. Courtney Boyle and Major Cardew, representing the Board of Trade; Mr. Graves and Mr. Preece, the Post Office; Sir W. Thomson and Lord Rayleigh, the Royal Society; Professor Carey Foster and Mr. Glazebrook, the British Association; and Dr. Hopkinson and Professor Ayrton, the Institution of Electrical Engineers.

The report published recently, to which are appended the specifications referred to in resolution 10 and the draft order to Council, is as follows:

In compliance with the instructions contained in your minute of the 16th December last, that we should consider and report whether any, and if so, what, action should be taken by the Board of Trade under Section 6 of the Weights and Measures Act, 1889, with a view to causing new denominations of standards for the measurement of electricity for use for trade to be made and duly verified, we have the honor to submit the following report:

1. Before coming to a decision as to the points referred to us, we were anxious to obtain evidence as to the wishes and views of those practically interested in the question, as well as local authorities, who are concerned in the administration of the Weights and Measures Act.
2. With this view we prepared draft resolutions embodying the proposals which, subject to further consideration, appeared to us desirable, and forwarded copies to the representatives of various interests for criticism. Copies were also forwarded to the press. The following bodies were also invited to nominate witnesses to give evidence before us; The Association of Chamber of Commerce of the United Kingdom, the Association of Municipal Corporations, the London County Council, and the London Chamber of Commerce.
3. In response to this invitation the following gentlemen attended and gave evidence: On behalf of the Association of Chambers of Commerce, Mr. Thomas Parker and Mr. Hugh Erat Harrison; Professor Silvanus Thompson, on behalf of the London County Council; Mr. R. E. Crompton, on behalf of the London Chamber of Commerce.

The committee state that they were assisted by Dr. J. A. Fleming and Dr. Alexander Muirhead. After careful consideration of the questions submitted to us and the evidence given by the various witnesses, we have agreed to the following resolutions:

1. That it is desirable that new denominations of standards for the measurement of electricity should be made and approved by Her Majesty in Council as Board of Trade standards.
2. That the magnitudes of these standards should be determined on the electromagnetic system of measurement with reference to the centimetre as unit of length, the gramme as unit of mass, and the second as unit of time, and that by the terms centimetre of gramme are meant the standards of those denominations deposited with the Board of Trade.
3. That the standard of electrical resistance should be denominated the ohm and should have the value of 1,000,000,000, in terms of the centimetre and second.
4. That the resistance offered to an unvarying electric current by a column of mercury of a constant cross-section, of an area of one square millimetre, and of a length of 106.3 centimetres, at the temperature of melting ice, may be adopted as one ohm.
5. That the value of the standard of resistance constructed by a committee of the British Association for the Advancement of Science, in the years 1863 and 1864, and known as the British Association unit, may be taken as point .9866 of the ohm.
6. That a material standard, constructed in solid metal, and verified by comparison with the British Association unit, should be adopted as the standard ohm.
7. That for the purpose of replacing the standard if lost, destroyed or damaged, and for ordinary use, a limited number of copies should be constructed, which should be periodically compared with the standard ohm and with the British Association unit.
8. That resistances constructed in solid metal should be adopted as Board of Trade standards for multiples and sub-multiples of the ohm.
9. That the standard of electrical current should be denominated the ampere, and should have the value of one-tenth, in terms of the centimetre, gramme, and second.
10. That an unvarying current which, when passed through a solution of nitrate of silver in water, in accordance with specification attached to this report, deposits silver at the rate 0.001118 of a gramme per second, may be taken as a current of one ampere.
11. That alternating current of one ampere shall mean a current such that the square root of the time average of the square of its strength at each instant in amperes, is unity.
12. That instruments constructed on the principle of the balance in which by the proper disposition of the conductors, forces of attraction and repulsion are produced, which depend upon the amount of current passing, and are balanced by known weights, should be adopted as the Board of Trade standards for the measurement of current, whether unvarying or alternating.
13. That the standard of electrical pressure should be denominated the volt, being the pressure which, if steadily applied to a conductor whose resistance is one ohm, will produce a current of one ampere.
14. That the electrical pressure at a temperature of 62° F., between the poles or electrodes of the voltaic cell known as Clark's cell, may be taken as not differing from a pressure of 1.433 volts by more than an amount which will be determined by a sub-committee appointed to investigate the question, who will prepare a specification for the construction and use of the cell.
15. That an alternating pressure of one volt shall mean a pressure such that the square root of the time average of the square of its value at each instant in volts is unity.
16. That instruments constructed on the principle of Sir W. Thomson's quadrant electrometer used idiostatically, and for high-pressure instruments on the principle of the balance, electrostatic forces being balanced against a known weight, should be adopted as Board of Trade standards for the measurement of pressure, whether unvarying or alternating.

The committee further state that they have adopted the system of electrical units originally defined by the British Association for the Advancement of Science; and have found in its recent researches, as well as in the deliberations of the International Congress on electrical units, held in Paris, valuable guidance for determining the exact magnitudes of the several units of electrical measurement, as well as for the verification of the material standards.

It appears to the committee to be necessary that in transactions between buyer and seller a legal character should henceforth be assigned to the units of electrical measurements now suggested, and with this view recommend the issue of an Order in Council.

THE PHOTOCHRONOGRAPH.

REV. GEO. A. FARGIS, S. J., of the Georgetown College Observatory. Georgetown, D. C., has recently invented an instrument called the photochronograph, by means of which a star is caused to record with absolute accuracy the time of its own transit across the meridian, thus eliminating all personal errors. The apparatus is thus described: In a small camera, attached to the eye-piece of the transit instrument, a highly sensitive plate is inserted. Electric connection is made with a sidereal clock in such a manner that a narrow shutter or bar is moved up and down before the plate, cutting off and admitting the light of the star at stated intervals during its passage across the field. The image of the spider line is afterward impressed upon the plate by the light of a lamp held for a few moments before the object glass of the telescope. By means of the shutter or bar this light is prevented from interfering with the star trail on the plate, which may be subjected at any time to repeated examinations and measurements with a microscope.

Letters to the Editor.

Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents.
Anonymous communications cannot be noticed.
The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.
In order to facilitate reference, correspondents, when referring to any letter previously inserted, will oblige by mentioning the page on which it appears.
Sketches and drawings for illustrations should be on separate pieces of paper.
All communications should be addressed EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

ABSOLUTE UNIT OF MAGNETIC INTENSITY.

IN your issue of Oct. 7th there is a mistake which should be corrected. In Mr. Gutmann's article on the Frankfort Electrical Congress, page 398, first column, bottom of page, I am reported as having proposed the name "weber" for the "absolute unit of magnetic intensity." This was *not* what I proposed, nor was it the way my proposition was understood by the committee to whom it was referred.

In what might be termed "canvassing" for the adoption of the name "gauss," as proposed by the delegates of the American Institute of Electrical Engineers, I found in my conversation with a number of prominent electricians that there would be considerable opposition, because some wanted this name given to the practical unit for the *number* of magnetic lines of force as distinguished from the *intensity* (i. e., number of lines per square centimetre also called "density of lines"), as proposed by the American delegates. In order to meet this objection, and thereby to accomplish our object by obtaining unanimity of opinion among some of the prominent members of the Congress, I proposed as an amendment that *both* of these magnetic units be named, and that the former be named "weber." The name "weber" would then be the name of the practical unit of the *whole number of magnetic lines*, also called *magnetic flux*, and often represented by the letter **N**; while the name "gauss" would be, as originally proposed, the name of the practical unit of magnetic *intensity* or *density of lines*, or *number of lines per square centimetre*, and often represented by the letters **B** or **H**.

This had the desired effect, and the proposition in this form appeared to meet with general favor. The disagreement was as to the *numerical values* to be given these units and their *relative values*.

I trust you will publish this in your next number, as Mr. Gutmann's article unintentionally represents me as having proposed "an absolute unit of magnetic intensity" on the one hand, and on the other hand the name "weber" for the same thing for which we had proposed the name "gauss." I was not guilty of having done either of these, nor was my proposition so understood by the committee of which I was secretary, and therefore have reason to know.

CARL HERING.

PHILADELPHIA, PA., Oct. 7.

ECONOMY IN ELECTRIC POWER DISTRIBUTION.

I HAVE read the article in your issue of Oct. 7th, entitled, "Economy in Electric Power Distribution," by J. Stanford Brown, in which he endeavors to show that in my paper on this subject I made an error by neglecting to take consideration of the efficiency of the motor.

All of my formulæ refer to electric energy in kilowatts at the end of the conductor, that is, at the brushes of the motor, while Mr. Sprague's formula is for mechanical power at the pulley of the motor, making it necessary, in his case, to take into consideration the motor efficiency.

I judge from Mr. Brown's article that he thinks my formulæ refer to horse-power at the pulley, as he says: "Mr. Leonard, desiring to figure in kilowatts, reduces his horse-power thereto by dividing by 1,000 and then introduces the factor 1,000 in his constant to get them back again to horse-power."

I beg to correct this impression by calling attention to the fact that in no part of my paper did I consider horse-power, hence I did not "reduce" from any such unit to kilowatts, nor did I get my kilowatts "back again to horse-power."

Since my formulæ refer to kilowatts at the end of the conductor, it is evident that the motor efficiency is not a factor. My formulæ were intentionally put in such shape as to apply whether the energy be used for motors, incandescent lamps, storage batteries, electric heaters, electro-deposition, or any other use.

H. WARD LEONARD.

NEW YORK, Oct. 7, 1891.

Reports of Companies.

THE WESTINGHOUSE ELECTRIC AND MFG. CO.

SUBSCRIPTIONS for $3,000,000 7 per cent. cumulative preferred stock of the Westinghouse Electric and Mfg. Co. will be received at par by August Belmont & Co., New York, and Lee, Higginson & Co., Boston. The company's authorized capital is $10,000,000, of which $4,000,000 is preferred. The balance, $1,000,000, of the preferred stock above the amount offered for subscription will remain in the treasury to meet future requirements of the business. The statement of the company, embodied in the prospectus on another page, presents a notable growth of business, which is again likely to be increased by the general introduction of electric lighting and electric power. The factories now have a capacity of caring for an annual business of over $7,500,000. An official examination of the assets shows that after making liberal deductions for contingencies, the assets will furnish ample security for the total issue of preference stock without taking into consideration the value of the company's patents, and that the working capital will be sufficient to conduct the business on an economical basis, the saving in the interest account alone being sufficient to pay full dividends on this issue. The subscription books will be opened at 10 a. m. on Wednesday, Oct. 14, and close at 3 p. m. Oct. 16.

STANLEY & HALL.

THOMAS F. STEVENSON has been appointed receiver for Stanley & Hall, manufacturers of electrical supplies, at 34 Frankfort street, New York City. The business was started about ten years ago by E. W. Hazazer, who was joined by Arthur F. Stanley in October, 1886, and Harry Hall became a partner in March, 1890. The business was turned into a stock company in April, 1890, with a capital stock of $20,000, which was afterwards increased to $30,000, the new stock being taken, it is said, by Sheldon H. Bassett, of Birmingham, Conn., who became vice-president. Royal M. Bassett, the latter's father, it is said, loaned the company money, which was secured by a chattel mortgage for $10,000 in August last. The receivership, it is said, is in the interest of Mr. Bassett. The company, it is reported, has about $12,000 unsecured debts, and there is due it about $14,000 from customers, besides some stock and plant on hand. The firm has many friends, and is expected soon to be in shape again to do a large trade.

THE WILLSON ALUMINUM CO.

THE Willson Aluminum Co. has been organized with a capital stock of $45,000 to manufacture aluminum under the patents of Thos. L. Willson, of Brooklyn, N. Y. The works will be at Spray, Rockingham county, N. C., and will have a capacity of 400 pounds per day. The company has had built a dynamo of 1,000 h. p. A large water-power is at the command of the company. The works will be in operation in the early part of next year. The aluminum will, it is said, be produced from corundum and bauxite.

DIVIDENDS.

NEW YORK CITY.—The Edison Electric Illuminating Co., of New York, has declared its twenty-sixth quarterly dividend of 1 per cent.

WASHINGTON, PA.—The Washington Electric Light & Power Co. has declared a dividend of 3 per cent. It is doing an increasing business.

NEW BEDFORD, MASS.—The New Bedford Gas and Electric Light Co. has declared a dividend of 1½ per cent.

Appointments, Etc.

MR. A. H. HYDE has joined the forces of the Minnesota Brush Electric Light Co., of Minneapolis, with charge of its underground work lately installed by the Standard Underground Cable Co.

MR. FRANK DRULINER, who has for some time been connected with the South Bend Electric Co., has resigned his position, and will enter upon studies at Cornell, taking the electrical engineering course.

MR. H. A. SAWYER, late superintendent of the electric light company at Amesbury, Mass., has gone into the electrical supply and wiring business in that town.

MR. F. N. PRUYN has assumed the management of the Thomson-Houston Light, Heat and Power Co., of Binghamton, N. Y., taking the place of Mr. C. J. Morehouse.

MR. C. E. HUGHES has been elected superintendent of the fire alarm system of St. Paul, Minn. He was formerly manager of the Western Union office.

MR. E. H. WALDO, of Lynn, has been appointed superintendent and electrician of the Milford, Mass., Electric Light and Power Co.

MR. A. MARTIN, late of the Lynn Belt Line Electric Railway, has taken charge of the Gloucester, Mass., Electric Street Railway.

MR. H. M. UNDERWOOD has severed his connection with the Interior Conduit & Insulation Co., of this city.

MR. G. B. COLEMAN has resigned his position as superintendent of the Milford Electric Light and Power Co.

DR. P. E. MURRAY has been appointed manager of the Western Union office at Atlanta, Ga.

Legal Notes.

ELECTRICITY NOT A MANUFACTURED ARTICLE.

JUDGE SIMONTON'S decision in the case of the Commonwealth against the Northern Electric Light and Power Company having been affirmed by the Supreme Court of Pennsylvania, the question as to whether electricity is a manufactured article is pretty definitely settled in the negative. This was a test case, and was the result of a combination of electric light companies to determine their liability to taxation.

They claimed to be exempt under the act exempting manufacturing corporations. The State will receive a large amount in taxes as the result of this decision.

THE GOVERNMENT TELEPHONE SUIT.

THE suit of the United States of America against the Bell Telephone Company and Alexander Graham Bell to try the question as to whether the patents of the latter were obtained from the Patent Office at Washinton by fraud is now before Mr. Henry L. Hallett, who is taking testimony.

College Notes.

RENSSELAER POLYTECHNIC INSTITUTE.

MR. C. C. MARTIN, of the Brooklyn Bridge Company, has, it is understood, declined the offered directorship of the Rensselaer Polytechnic Institute. It is said that the Bridge Company have increased his salary considerably, which, if true, would account for his declining the honor of the office tendered him by this celebrated school.

Society and Club Notes.

BUFFALO ELECTRICAL SOCIETY.

THE annual meeting of the Buffalo Electrical Society was held on Oct. 5th. In the President's report he took occasion to congratulate the members on the prosperous condition of the society's affairs, and on the success which had attended their efforts during the past year. The secretary's report showed an increase of 25 per cent. in membership, and the treasurer's report, a respectable balance on hand. The society now has one of the best electrical libraries in the country. The following officers were elected: President, F. P. Jones; vice-president, Madison Buell; secretary, Astley C. Terry; treasurer, Samuel Stewart; librarian, Wm. C. Lewin; executive committee, Frank Kitton, Wm. H. Dopp, M. Beecher Marvin and the elected officers.

BROOKLYN INSTITUTE.

MR. F. B. HENSHAW, electrical engineer of the C. & C. Motor Co., is to read an illustrated paper before the electrical section of the Institute, Friday, Oct. 16, at the Y. M. C. A. Building. His subject is "The Designing of Electric Motors."

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

OWING to the fact that many members of the Institute will be in attendance at the Pitsburgh Street Railway Convention, the regular monthly meeting will be postponed until Oct. 27.

Obituary.

C. R. DINSMORE.

MR. C. R. DINSMORE, superintendent of the Marblehead Gas and Electric Co., died on Oct. 4, at Marblehead, aged 29 years. He had resigned his position as superintendent of the gas works, to take effect Oct. 15.

NEW YORK SUBWAYS.

AT the meeting of the New York Board of Electrical Control, last week, permission was given for the building of subsidiary subways through 45 streets in various parts of the city. There was a protracted contention between ex-Judge W. H. Kelly for the East River Company and Edward Lauterbach for the Consolidated Telegraph and Electrical Subway Company as to the payment of rent in advance by the former to the latter company. Judge Kelly said that the latter company was overcharging for rent and inspection, and he did not think his company ought to be compelled to pay a year's rent in advance and thus forced to lose interest on the money.

It was decided that the East River Company should pay one-fourth of its rent before October 10, and that the board would hold a special meeting within a few days to consider the question of modifying the rule to pay a year's rent in advance. The alleged overcharging for rent will be considered at the same meeting. A map was exhibited showing that the telegraph poles, except those of the Fire Department, have been taken down between Eighth and Fifty-ninth streets, and Third and Eighth avenues.

ELECTRIC LIGHTING IN PENNSYLVANIA COAL MINES.

THE H. C. Frick Coal and Coke Company, of Pittsburgh, Pa., the largest coal operators in the world, have just completed arrangements for the illumination of their many mines by electricity; in fact, the plans have already so far advanced that the lighting of two mining plants has been successfully accomplished. The contract for the work has been awarded to the Westinghouse Electric and Manufacturing Company, under whose supervision the work of installing the lighting plants was conducted. The first two mines to be lit by electric lights were the Leisenring No. 1 and Leisenring No. 2. The operation of the lights was commenced a few days ago. Everthing turned out to the greatest satisfaction of the Westinghouse and the Frick Companies.

The mines of the company are mostly situated in the Connellsville region, in Westmoreland and Cambria counties, Pennsylvania, and a number of them are shaft mines, varying in depth from one hundred to nearly one thousand feet. Owing to the accumulation of fire-damp and gas in many of these mines the lighting has always been a very grave problem, because almost every known method of illumination included the danger of causing the mine to catch fire. This led at last to the attempt of utilizing the electric current for lighting purposes. The wonderful success which was immediately established upon the first experiments is causing a rapid superseding of all other methods of lighting by electric illumination.

The Frick Company has adopted the method of lighting each mine independently, and at every mine is installed Westinghouse direct-current apparatus of sufficient capacity to light up the mine below and above the ground. The lamps are distributed underground throughout the main walks leading to the shaft. In addition, the tipple above ground, the engine house and other surface buildings are also lighted. The lamps vary from 16 to 50 c. p.

Electric light plants are now being put up at Leisenring No. 3, Trotter and Standard mine—the latter, by the way, is said to be the largest coal mine in the world—but it will probably take a whole year before the plants for all the mines are installed.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED OCTOBER 6, 1891.

Accumulators :—

Electrode for Secondary Batteries, W. A. Rosenbaum, 460,599. Filed Dec. 31, 1890.
Electrode consists of an envelope, a separate metallic frame within the same, and tablets of active material held in the frame.

Alarms and Signals :—

Central Station Apparatus for Call-Boxes, E. R. Wilder, 460,767. Filed Jan. 2, 1891.
Adapted for district messenger service and similar purposes.

Electrical Alarm, H. P. Smith, 460,895. Filed March 24, 1891.
For use in connection with lubricators, and designed to indicate the consumption of oil.

Conductors, Conduits and Insulators :—

Electric Conductor, W. Vogler, 460,606. Filed Nov. 9, 1889.
A double conductor; each wire embedded in an independent semi-cylindrical insulation; a reinforcing strip is interposed between the two insulations; an outer covering encloses the whole and binds it together.

Conduit for Electric Wires, W. Vogler, 460,607. Filed Feb. 25, 1891.
Sections are abutted together end-to-end and surrounded by a series of shields held in place by clamps.

Insulation for Electric Wires, J. R. Markle, 460,725. Filed Nov. 24, 1890.
Adapted especially for interior wiring, and relates especially to the means of junction between the conductors embedded in successive strips of insulating material.

Composition for Insulating Material, E. Thomson, 460,765. Filed Aug. 5, 1889.
Intended as a material which can be molded into form and to be fire or heat-resisting and to have great strength so that it can be drilled, tapped or otherwise mechanically worked.
Claim 1 follows:
An electrical insulating composition consisting of a fibrous mineral insulator as a base, a cementing insulating substance, such as rubber, and a lubricator consisting of an insulating material, as and for the purpose described.

Dynamos and Motors :—

Regulating the Speed of Electric Motors, M. J. Wightman, 460,614. Filed Feb. 28, 1891.
Adapted for constant potential motors; and consists in variably opposing the flow of current to the motor by coupling storage battery cells in the circuit leading through the motor, in various combinations.

Lamps and Appurtenances:—

Electric Arc Lamp, H. W. Libbey, 460,587. Filed Jan 12, 1891.
Relates to the class of lamps in which a disc carbon is employed for the positive electrode and a pencil carbon for the negative electrode. Relates to the manner of operating the electrodes.

Arc-Lamp Pencil, I. L. Roberts, 460,595. Filed March 10, 1890.
Employs a substance including chromium in its composition, in connection with a metal; the metal being either in the form of a tube enclosing the chromium compound or in the form a wire or rod surrounded or coated with the chromium compound. Upon the establishment of an arc between two such pencils the metal and the chromium compound fuse together and form smooth and highly infusible points.
Claim 1 follows:
A pencil for arc lamps, composed a of metal associated with a substance containing chromium, as set forth.

Electrode for Arc Lamps, I. L. Roberts, 460,596. Filed March 6, 1891.
Similar to the next above, but includes carbon with the chromium compound.

Electrode for Arc Lamps, I. L. Roberts, 460,597. Filed March 18, 1891.
Claim 1 follows:
In an arc lamp, the combination of an electrode composed of a conducting substance and a refractory non-conducting substance, substantially as described, and an electrode of carbon, as set forth.

Globe-Protector for Electric Arc Lamps, E. J. Openlander, 460,652. Filed Mar. 14, 1891.

Arc Lamp Electrode, H. W. Libbey, 460,680. Filed Oct. 17, 1890.
The positive carbon electrode is in the form of a hollow cylinder the lower end being cut in a spiral form; this positive carbon is rotated while fed downward.

Measurement :—

Millampere-Meter, L. D. McIntosh, 460,650. Filed Sept. 5, 1890.
Adapted especially for indicating currents employed in medical practice.

Metallurgical :—

Apparatus for Washing and Separating Gold and Silver from their Ores. W. J. Tanner, 460,722. Filed Sept. 24, 1884.

Miscellaneous :

Safety-Plug, H. P. Ball, 460,548. Filed Dec. 1, 1890.

Electric Switch, C. Wirt, 460,618. Filed Jan. 10, 1891.

Illuminating-Balloon for Advertising Purposes at Night, A. Gross, 460,674. Filed Apr. 25, 1891.

Electrically Controlled Cutting Device, LeR. S. White, 460,695. Filed Jan. 16, 1891.
An electro-magnetic device for controlling the application of a cutting-tool to the material to be cut at predetermined distances while fed through the cutting machine.

Automatic Safety Cut-Out, W. B. Cleveland, 460,701. Filed June 8, 1891.
Particularly applicable to circuits carrying large currents, such as light or power circuits.

Core for Electric Solenoids, J. T. Williams, 460,923. Filed Dec. 18, 1890.
Core is composed of a series of members of differing lengths and varying diameter, fitted one within the other in metallic contact.

Railways and Appliances :—

Turn-Out or Switch for Trolley Wires, D. W. Edwards, 460,571. Filed Oct. 2, 1890.

Ball Connection for Electric Railways, M. J. Wightman, 460,615. Filed May 15, 1891.
Designed to improve certainty of contact and to provide for the ready location of faults.

Trolley Wire Support, T. Fricker, 460,634. Filed Dec. 15, 1890.

Trolley Wire Support, N. Weeks, Jr., 460,735. Filed April 1, 1891.

Telegraph Block System of Railway Traffic Control, D. C. Coombes and W. Rowe, 460,771. Filed June 19, 1891.
Provides an automatic alarm at either end of a block section whenever a train or engine erroneously advances "against the block."

System of Electrical Signaling for Railroads, S. de Jager and A. Zoutman, 460,779. Filed April 25, 1891.
Designed to preclude collision between trains, whether moving in the same or opposite directions.

Underground Railway Conduit, E. E. Keller, 460,780. Filed April 13, 1891.
A conduit and devices providing for sectional or successive contacts between the working conductors and a continuous supply conductor.

Electric Railway Trolley, E. E. Keller, 460,781. Filed April 21, 1891.
Trolley includes a series of rolling parts so disposed that two or more of them will engage simultaneously with the trolley wire.

Automatic Electric Switch-Indicator, E. W. Hadley, 460,864. Filed Jan. 7, 1891.
Adapted for giving audible signals in case of a misplaced switch.

Electric Railroad, I. Robbins, 460,887. Filed Jan 19, 1891.
Employs a continuous main conductor and a series of resilient or self-returning wires connected to the main conductor, and which are successively picked up and let go by a drag connection attached to the moving car.

Telegraphs :—

Printing Telegraph, M. G. Farmer, 460,572. Filed May 15, 1891.
Primarily an improvement upon the same inventor's telegraph patented July 22, 1856, No. 15,378. The present system, however, employs induction coils, secondary currents only being employed upon the main line.

Steno-Telegraphic Apparatus, A. Wood, 460,619. Filed Dec. 7, 1886.
For the telegraphic transmission of phonographic symbols.

Message-Recording Instrument, A. Storer, 460,676. Filed Jan. 27, 1891.
A signal register or recorder.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

The Advertiser as well as the Farmer may reap great harvests if he will.

HALE & ADAMS.

THIS firm, composed of Willis G. Hale and Samuel F. Adams, formerly with the Edgemoor Iron Company, of Wilmington, Del., has recently been organized, with headquarters in New York and Philadelphia. They will carry on the business, not only of architects but also of consulting and constructing electrical, mechanical and civil engineers. Mr. Hale's work in Philadelphia, architecturally, is well known, such buildings as the Widener mansion, the Bingham House, the Union Trust Building, the Hale Building (formerly the Keystone Bank), and many others having been designed and built by him. Mr. Adams is perhaps best known in connection with his work on the Chicago Edison Central Station, the Rookery Building, the Omaha *Bee* Building, the St. Paul *Pioneer Press* Building, and the Chamber of Commerce Safety Vaults in Chicago, although his more recent operations have been in the South. This firm already have on their books the plans for a 14-story building on lower Broadway, New York, to cost $1,500,000, besides plans for numerous other buildings. They expect to make quite a feature of the electrical business, and are perhaps the first firm of architects to make this departure. The 14-story building, before referred to, is to be heated exclusively by an electric system of heating designed by Mr. Adams, and is to have 6,000 incandescent lights and 40 arcs. This will be the first building in the world heated throughout by electricity.

WIRING OF THE MASONIC HOME, UTICA, N. Y.

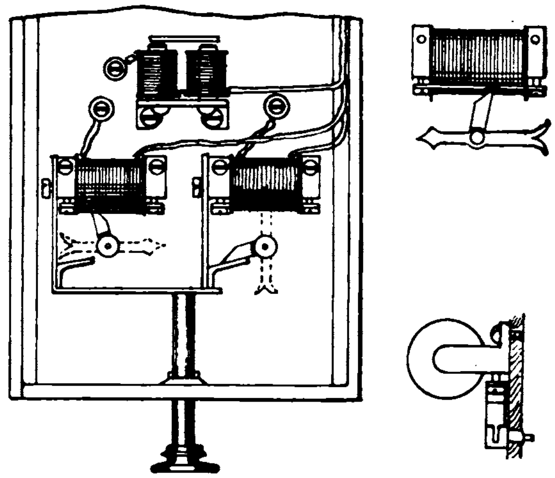
MR. W. H. HUME, of this city, the architect of the new Masonic Home, at Utica, N. Y., has designed a building 250 feet front by 200 feet deep, which, in point of completness and thoroughness of detail, is a credit even to one of his eminence in the profession. The building is, of course, electrically lighted throughout, the contract having been awarded to the Utica Electric Light Co., who propose to make their work correspond in excellence with that of the architect. Grimshaw white core wire is to be used, and will be placed in "Vulca" ducts, but one wire being contained in each tube.

The success of the "Vulca" ducts has been remarkable since their introduction a short time ago, and orders are now being received from all parts of the country. "Vulca" is also being used quite extensively as a substitute for hard rubber, and a large amount has already been sold for that purpose.

THE UNION GRAVITY ANNUNCIATOR.

DURING the past six months the Union Electric Works, of Chicago, have been experimenting upon annunciators with a view to producing one which should be perfectly accurate, require very little current, would not be likely to get out of order, and that could be furnished at a low price.

The accompanying illustration shows the results finally arrived at, and will be readily understood. The armature suspended from the poles of the single magnet rests upon the heads of the screws which pierce it. Drawn to the poles by the action of the electric



UNION GRAVITY ANNUNCIATOR.

current, it at once falls back to its normal position when the pressure upon the push ceases. The latch which is connected with the needle falls immediately when the armature is drawn up, and is caught upon the projection from the replacing mechanism. This mechanism is operated by pushing upward upon the knob below the case, and it also drops back into place by its own weight. There are no springs to get out of order, and nothing is liable to to wear out for years. These annunciators are handsomely encased in oak, walnut, Georgia pine and cherry.

THE ALEXANDER-CHAMBERLAIN ELECTRIC CO.

MR. HARRY ALEXANDER, well known to the electrical fraternity through his connections with the Thomson-Houston Electric Co., as well as with other companies, has found his business increasing to such an extent that he has taken a partner in Mr. Rufus N. Chamberlain. They will do business under the firm name of the Alexander-Chamberlain Electric Co. Mr. Chamberlain has also had great experience through his connection with the Sawyer-Man Electric, Julien Electric Traction, and other companies. This company intends to make a specialty of automatic isolated plants for private houses, as well as inspection of all kinds of electric plants. All kinds of electric work will receive their prompt attention. Mr. Alexander has been doing a good deal of this work. Both members, having had much experience with storage batteries, will be in a position to install most thorough and complete accumulator plants for light and power for launches as well as buildings. The new field of electro-deposition will receive their special attention.

MR. W. A. GILES.

MR. W. A. GILES, electrical and mechanical engineer, recently with the Edison General Electrical Co. in the Marine and Mining Department, will in the future conduct an engineering and equipment business with headquarters at Pittsburgh, Pa.

Mr. Giles is also an expert in ventilating and drying in all its applications. He has been appointed selling agent for the J. T. Case Engine Co., of New Britain, Conn., makers of the Case automatic high-speed engine ; L. J. Wing Co,, New York, disc exhaust fans,engines and motors fans, etc. ; and the Exeter Machine Co., Exeter, N. H., blowers, exhausts, etc.

H. WARD LEONARD & CO.

A VERY neat little phamphlet has been issued by the above firm on the value of the services of a consulting electrical engineer to persons investing in electrical plants. It is full of good points and useful hints.

THE ELIESON SYSTEM AT NEWARK, N. J.

MR. C. P. ELIESON is to put his system of storage battery traction in operation at Newark, N. J., and has let the contract for motors, &c., to the Detroit Electrical Works, of Detroit, as he considers the Rae motor the best for such work.

J. H. BUNNELL & CO.'S POCKET GALVANOMETER BATTERY GAUGE.

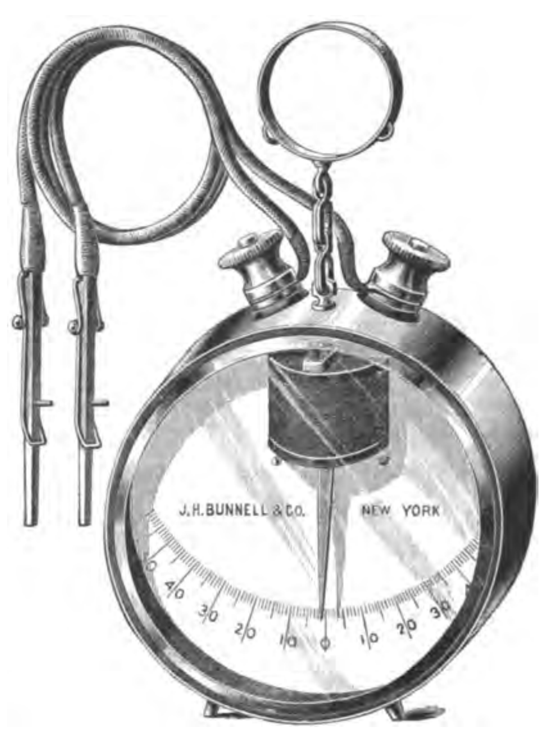
THIS consists of a pocket galvanometer of such construction and calibration as to furnish a reliable standard for practical measurement of current strengths, in testing from one to five cells of ordinary batteries, such as the various forms of sal-ammoniac, sulphate of copper and acid batteries. The reading is such that a good Leclanché cell indicates about 9°; Burnley dry battery, 14°; Lockwood American District (blue vitriol) 6°; Crowfoot Western Union form, 8°.

As these gauges are all calibrated to a single standard, and are made exactly alike, their introduction furnishes an accurate instrument for comparisons, or condition tests, of from one to five cells. The gauge being a true galvanometer, and not dependent for its action on springs or electromagnetic devices, its indication is always the same for a given force.

The "Galvanometer Gauge" is arranged for use either standing upright on instrument, table or desk, or as when used for miscellaneous testing in a battery room, etc. It is held suspended by the chain and ring, in which position, without current, the needle hangs at zero, the same as it would if the galvanometer were standing on a table.

These gauges are especially advantageous for use as permanent circuit indicators for fire-alarms, burglar-alarms, district telegraphs, etc., on account of their presenting the face of the instrument in upright position. For all the purposes for which it is available, one particular feature of its practical merit consists in the fact that the action of the needle is perfectly "dead beat" (that is, the needle moves at once to whatever indication the current calls for and remains there without oscillation as long as the current continues). The dead-beat movement is usually to be found only on the most expensive galvanometers.

Two silk-covered conducting cords are attached to each gauge, and these cords are provided with a very convenient form of im-



BUNNELL POCKET GALVANOMETER BATTERY GAUGE.

proved "tip," which is so made that it can enter any ordinary binding post and be held by the binding screw in the usual way, or, being a square-end tip, is suitable for English binding posts. Also having a spring clamp, it can be hooked firmly to bare wire (office wire size or less) at any exposed point. This form of tip is extremely handy in all experimental temporary wire connecting, and by its use with the gauge the condition of any one to five cells in the middle of the series can be instantly ascertained without making breaks and reconnecting.

NOVEL FORMS OF MINIATURE SOMOFF INCANDESCENT LAMPS.

THE illustrations herewith present some of the novel and useful forms of miniature incandescent electric lamps which have just been placed on the market by J. L. Somoff, of No. 1 Ann street, New York City, who makes a specialty of their manufacture.

Fig. 1.–Grain Lamp.

Fig. 1 is a "Grain lamp"—the smallest incandescent lamp ever made. Compared with the well-known "Pea"—the next larger size lamp to it—the "Grain" is smaller than its rival by 1/16 inch in diameter and 1/8 inch in length. The exact dimensions are: 3 mm. diameter and 5 mm. long.

In medical practice, where electricity is acquiring an ever-growing application, this lamp, thanks to its very small size, has made it possible to thoroughly inspect the bladder and the stomach, principally the former, into which it is introduced. The use to which such a lamp can be put was illustrated at the Centennial Exhibition by a fish, swimming in an aquarium with a lamp brightly glowing in his stomach. The electromotive force required by those lamps is high, the filament being exceedingly thin. Twelve volts, with a current of but 2 amperes, gives a light of about 1 c. p., and the little globe heats up to no more than the temperature of the body. The very low current required by the lamp makes it suitable for use with Prof. Barrett's well-known chloride of silver medical batteries.

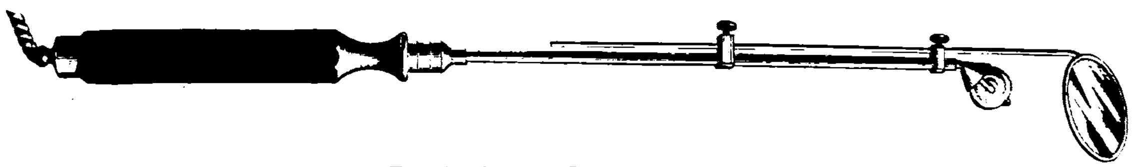


FIG. 2.—SOMOFF LARYNGOSCOPE.

Fig. 2 presents the same lamp mounted in a laryngoscope, which, likewise possesses some novel features, inasmuch as, excepting the hard rubber handle, and the glass of the lamp and of the mirror, the entire instrument is electro-plated with platinum. This feature is of much value in treatment of infectious diseases. The lower half of the lamp is encased in a platinum cup, to which the glass is fused, the cup being screwed on to the instrument.

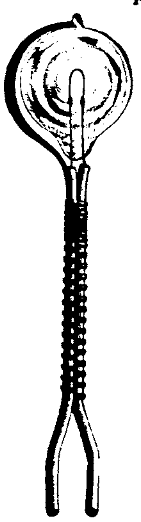

Fig. 3.—Tulip.

Fig. 3 is a "Tulip lamp" mounted upon two bare copper rods, wound over with a thread of silk. The thread serves to insulate the rods from each other as well as to keep them firmly together. A spring attached to one of the rods loops over the "tip" of the lamp and holds it in position.

The copper rods fit the handles or sockets now almost universally employed in connection with electric cauterizing knives, and a doctor working with a cauterizing knife, can in an instant replace it by a lamp, should this become necessary, for instance, in cases of diseases of the mouth. The lamps are of 3.6 volts, to suit the battery employed in electro-cauterization—usually two cells of plunge bichromate pattern.

Fig. 4 is a unique form of lamp, combining a lamp globe of "German" or "Bohemian" glass with a bull's eye or concavo-convex lens, hence called the "Bull's Eye" lamp. On the side of the globe opposite the lens is a platinum mirror, which is formed by precipitating this metal from its chloride at a red heat. The finely divided metal united with the glass by fusion presents a beautiful reflector, which remains always clean and bright.

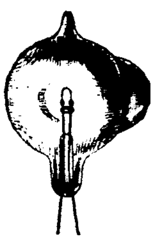

Fig. 4.—Bull's Eye.

The advantages of such a lamp over any other in an electric lantern are evident. The luminous filament is in the focus of both the lens and the reflector, which arrangement greatly increases the amount of effective light, notwithstanding the imperfections of the lens which, of course, is neither cast in a mould nor ground. And, moreover, if made of very heavy glass, it renders useless the glass dome (serving the double purpose of protecting the lamp and as a lens) with which all English miners' lanterns are equipped.

MR. J. C. KEEFE has resigned as secretary of the Syracuse, N. Y., Electric Light Co. Mr. Manning C. Palmer is acting in his stead.

A LIST OF THE SHORT SYSTEM ELECTRIC ROADS.

WE give below a list of roads equipped entirely or in part by the Short Electric Railway Company:

Watervliet Turnpike and Railway Co., Albany, N. Y., 2 motors; Battle Creek Street Railway Co., Battle Creek, Mich., 2 dynamos, 12 motors; Braddock Electric Railway Co., Braddock, Pa., 6 motors; Bristol Belt Line Railway Co., Bristol, Tenn., 1 dynamo, 6 motors; Coney Island & Brooklyn R. R. Co., Brooklyn, N. Y., 2 motors; Broadway & Newburg Street R. R. Co., Cleveland, O., 23 motors; Brooklyn Street R. R. Co., 2 motors; So. Covington & Cincinnati Street R. R. Co., Covington, Ky., 5 dynamos, 36 motors, 10 miles; Georgetown & Tennallytown Railway Co., Georgetown, D. C., 4 motors; Harvey Transit Company, Harvey, Ill., 6 motors; Fred. T. Evans, Hot Springs, S. Dak., 1 dynamo, 4 motors, 1.25 miles; Huntington Electric Light & Street Railway Co., Huntington, W. Va., 1 dynamo, 6 motors, 3.5 miles; Citizens' Street Railway R. R. Co., Indianapolis, Ind., 12 motors; Jamestown Street Railway Co., Jamestown, N. Y., 3 dynamos, 30 motors, 12 miles; Johnstown Passenger Railway Company, Johnstown, Pa., 3 dynamos, 20 motors; Lincoln Street Railway Co., Lincoln, Neb., 40 motors; Central Passenger Railway Co., Louisville, Ky., 4 motors; Muskegon Railway Co., Muskegon, Mich., 5 dynamos, 36 motors, 13.5 miles; Pittsburgh & Birmingham Traction Co., Pittsburgh, Pa., 40 motors; Pittsburgh Traction Company, Pittsburgh, Pa., 1 dynamo, 4 motors, 2 miles; Schuylkill Electric Railway Company, Pottsville, Pa., 4 dynamos, 20 motors, 6 miles; Rochester Electric Railway Co., Rochester, N. Y., 4 motors; Rochester Railway Co., Rochester, N. Y., 11 dynamos, 100 motors, 55 miles; West End Street Railway Co., Rockford, Ill., 1 dynamo, 6 motors, 4.5 miles; Lindell Railway Company, St. Louis, Mo., 4 motors; Wilkesbarre & Wyoming Valley Traction Co., Wilkesbarre, Pa, 2 dynamos, 36 motors, 16 miles.

AMERICAN INSTITUTE FAIR NOTES.

THE Sixtieth Annual Fair of the American Institute opened in their building on Third avenue, Sept. 30th. Among the interesting exhibits are the following:

JOSEPH MEIER, 34 Ferry street, New York, patent friction pulley and means of transmitting power.

UNITED STATES ELECTRIC ILLUMINATING CO., dynamos running 102 arc lamps for lighting the hall.

THE MATHER ELECTRIC CO., dynamos, incandescent, running 600 16 c. p. and 32 c. p. for lighting the hall.

THE C. & C. ELECTRIC MOTOR CO. exhibit a generator running Blackman fan motors.

VOLNEY W. MASON, Providence, R. I., exhibits a large assortment of friction clutches.

THE BLACKMAN FAN and Solano steam engine combined are exhibited by Howard & Morse, 45 Fulton street, New York.

A. J. WEED & CO., 106 Liberty street, New York, exhibit model dynamos designed for students and amateurs.

THE TANITE EMERY CO., Stroudsburg, Pa., exhibit a large assortment of emery wheels, &c.

THE BRISTOL RECORDING STEAM GAUGE is exhibited by the Bristol Mfg. Co., of Waterbury, Conn.

THE COLWELL LEAD CO., 63 Centre street, New York, exhibit a number of their specialties.

THE H. W. JOHNS CO. have a large exhibit of their Vulcabeston specialties.

THE STANDARD PAINT CO. have in place their exhibit lately at the Montreal Convention, showing their P. & B. paints, &c.

CHARLES A. SCHIEREN & CO. exhibit leather link belting, &c., and a sample of the largest belt in the world.

THE NEW YORK LEATHER BELTING CO., 86 Gold street, New York, exhibit leather belting, &c.

THE DAVIS ELECTRIC TRACK SCALES are exhibited on the eastern platform, &c. They were described in THE ELECTRICAL ENGINEER of Sept. 30.

FRANK W. GATES, 39 Dey street, New York, exhibits a large variety of sectional ladders adapted for linemen, wiremen, &c.

ST. LOUIS NOTES.

THE HAZELTINE ELECTRIC COMPANY was represented at the recent exhibition at St. Louis, by its general manager, Mr. C. W. Hazeltine—one of the many naval officers who have drifted into the electrical business. Mr. Hazeltine had on exhibition his carbon protector, the claim for which is the doubling of the life of carbons in ordinary arc lamps. By this device, without any change whatever in the lamp, and without any attention during the interval, a single arc lamp can be made to burn for fourteen hours, and a double lamp for from 28 to 30 hours. The central station men at the Convention showed much interest in this device, which bids fair to save them much money.

THE EMERSON ELECTRIC MANUFACTURING CO. are bringing out an alternating current motor for driving sewing machines. By a simple attachment to the regular foot treadle the speed of the motor is regulated from the slowest speed required for intricate work up to the highest speed permissible for straight seam work. The machine responds almost instantaneously to the action of the regulator; the operator has more thorough control over the speed of the machine than is possible with foot power. The regulating device is operated by simply pressing the foot treadle down against the action of a retractile spring; the farther it is depressed the greater the speed.

MR. G. PANTELEONI, representing the Westinghouse Electric Co., reports the sale of two 400,000 watt alternating generators to the Missouri Electric Light & Power Co., St. Louis. These generators are compound wound and self-regulating, and are the largest in the United States, the two having a combined capacity of 20,000 lights. Contracts have also been closed for 1,500 lights for Hot Springs, Ark., and 1,500 lights for San Luis Potosi, Mexico. The 650 light plant at Venice, Ill., has been put into operation; also the electric railway at Cairo, Ill., consisting of six cars with an 80 h. p. generating plant.

W. D. BOYCE & CO., 1234 Clark Ave., have taken the agency for the Porter-Allen engines manufactured by the Southwark Foundry and Machine Co., Philadelphia, and have made the following sales: The Lindell Railway Co., one 400 h. p. and four 250 h. p.; the Missouri Railway Company one 100 h. p. They will have one of their 100 h. p. engines on exhibition in the exposition building during the annual exposition which opened Wednesday, Sept. 2d.

WESTERN NOTES.

THE SPERRY ELECTRIC MINING MACHINE CO., 39th street and Stewart avenue, Chicago, are placing on the market a superior fuse wire which is meeting with most excellent success on account of its many good qualities. The company's extended experience in adapting electrical machinery to mining and railroad work, and furnishing supplies for arc and incandescent lighting, convinced them that there was a pressing demand for a more accurate system of fuse wire. As fuse wire is directly in the line of electrical supplies and specialties, they decided to go into its manufacture extensively, and have now prepared, after a series of careful tests, a full and complete supply, which may be relied on absolutely for correctness of carrying capacity and uniformity of sizes and alloy. This wire is calculated for all classes of work, being just the thing in small sizes for ceiling rosettes and fuse boxes, while the heavier grades will insure against burn-outs in mining and railroad service. All sizes are kept constantly on hand in large and small quantities to suit the requirements of all classes of buyers.

JEFFERSON CITY, MO.—At the last session of the Missouri State Legislature, provision was made for the establishment of a Manual Training School, or Industrial Department, in connection with the Lincoln Institute, at Jefferson City, Mo. The necessary buildings are nearing completion, and the power plant, tools, etc., will be installed in a short time. The board has contracted with the Pond Engineering Company, of St. Louis, for a thoroughly first-class power plant, designed in accordance with the best principles of modern steam engineering, as the educational value of such a plant will be an important consideration. The order covers an Armington & Sims engine, horizontal tublular steam boiler, with rocking grates, Lowe feed-water heater and purifier, and Blake boiler feed pump. The Pond Engineering Company are to deliver and erect this machinery at the institute complete and ready for regular service

THE ELECTRIC MERCHANDISE CO., No. 11 Adams st., Chicago, dealers in electric railway supplies exclusively, report business as very brisk, and are filling large orders for equipment of all kinds right along. Their catalogue of street railway apparatus, together with the supplement, just issued, form a most valuable work on the details of equipment for electric roads, and show all the latest and most improved devices. The Burton Electric Heater, for which the company are the general agents, is being very largely introduced, and is attracting universal attention.

THE HANDSOME EXHIBITION at the Institute of Building Arts 65 Washington Street, Chicago, of Kohler Bros. & Grier, the Western representatives of H. T. Paiste and the Eddy Electric Mfg. Co., has been greatly admired by the architects of Chicago. The offices of this firm are at 341 "The Rookery." They also have a large wareroom on the West Side, and a stockroom in the immediate vicinity of their office. They carry a large assortment of motors, and a full stock of sockets and switches, and are a main distributing house for the factories which they represent.

THE KNAPP ELECTRICAL WORKS are having a large demand for their Thomson-Houston and Sawyer-Man sockets. This socket is very simple in design, and there is absolutely no danger of a short-circuit. One of their salesmen recently booked an order for five thousand before they were ready for the market. The firm are now having a large supply made up, and can fill all orders promptly. They have laid in a large and complete stock of Perkins lamps of all candle-powers and voltages for the fall trade.

ERIE BALL ENGINES.—The Bloomington Electric Light Co., Bloomington, Ind., are about to install a 150 h. p. Ball engine, manufactured by the Ball Engine Company, Erie, Pa. This company are also installing an 80 h. p. engine in the Hebrew Institute, New York City, through their representative, E. T. Copeland, 106 Liberty street, New York City. The Dubois Traction Passenger Railway Co., Dubois, Pa., are likewise installing a 100 h. p. Erie Ball engine, and sold them by Dravo & Black, Pittsburgh, representatives of the Ball Engine Company, in that district.

THE KNAPP ELECTRICAL WORKS, 54 Franklin street, Chicago, report an increasing demand for "Safety Seamless" rubber wire. They have laid in a large stock of Perkins lamps to meet the fall trade, and from all indications their lamp trade will be larger than ever the coming year. They have also recently placed upon the market a new socket. This socket is very simple in design and complete in construction, and it is said there is absolutely no danger of a short circuit.

NEW WESTINGHOUSE ELECTRIC ROAD.—The Westinghouse Company have just completed the equipment of the Windsor & Sandwich Street Railway, at Windsor, Canada. Six closed cars and four open ones are now in operation. Two of the closed cars are equipped with double motors and the others with single. The road is a great success and every one is delighted with the advent of rapid transit.

THE ILLINOIS ELECTRIC MATERIAL CO., through Mr. E. L. Clark, secretary of the company, have secured an order for the line material for an extension of 150 arc lights to be added to the plant of the Jenney Electric Light and Power Co., of Peoria, Ill. The electric road which this company has been constructing at Cairo, Ill., was started on the first of the month and is a great success.

THE FALLS RIVET & MACHINE CO., of Cuyahoga Falls, Ohio, have just issued a most extensive and complete catalogue of their power transmission machinery and other products. It is beautifully gotten up, replete with handsome illustrations and contains a fund of the most useful and valuable information. This company manufacture shafting, pulleys and clutches, and are doing a large business with the central stations everywhere.

THE CHICAGO ELECTRIC MOTOR CO., Springer Building, Chicago, are making a specialty of repair work at reasonable prices. This will interest street railway men and other operators of electrical machinery who require armatures and fields rewound. They have made a special department for this work, which is done by experienced men, and satisfaction is guaranteed.

THE BURTON ELECTRIC COMPANY, through their selling agents, the Electric Merchandise Company, of Chicago, report sales of the Burton Electric Heater to the West End Road of Boston (20 cars) Jamestown, N. Y., Newburyport, Mass., Spokane Falls, Wash., New Albany, Ind. and Sioux City, Iowa. These heaters have passed satisfactorily the expertmental stage, and are to-day a fully demonstrated practical and commercial success.

THE ELECTRIC MERCHANDISE COMPANY, Chicago, report a very large business during the last month, both in orders for complete equipments of new roads, and also for a large number of extensions. The well-known standing of this company is a guarantee to would-be purchasers that material offered by them will be found satisfactory in every respect.

THE UNION ELECTRICAL WORKS, Springer Building, Chicago, are turning out a very large number of their new bells, which are meeting with a ready sale and the approval of both dealers and buyers wherever they have been used. They will shortly put on the market a new form of annunciator, possessing some important advantages.

MR. GEORGE CUTTER is sending out large batches of Simplex wire, most of it going to places where a number of prominent wires had been carefully tested.

THE SIOUX CITY ENGINE WORKS, of Sioux City, Ia., have issued a large "reminder" to hang upon the wall, illustrating the engines and boilers manufactured by them. Among these are the Sioux City Corliss, Gidding's automatic and compound engines, and the Stirling water-tube safety boiler. The factory of this company has a capacity for turning out 20,000 h. p. annually, and is the largest west of the Mississippi.

MR. J. C. LIGGETT, who has been for some years past associated with the Westinghouse Co. and later with the Edison Illuminating Co. in Milwaukee, Wis., and is well known in electrical circles in the West, has accepted a position with the Standard Electric Co., of Detroit, as general superintendent of the company, who are manufacturing a new storage battery for all classes of work.

THE CHICAGO OFFICE of the Pond Engineering Company has just contracted to furnish two 60 h. p. Armington & Sims engines with foundation boxes to the gas works of Chicago. One of them goes into the north station of the Peoples' Gas Light & Coke Co., and the other into the south station of the Chicago Gas Light Co. Both will be used for driving blowers.

JOHN R. MARKLE, of the Electrical Fibre Carbon Co., Detroit, spent a week, recently, in Chicago, and made several large contracts for carbons for battery and other purposes. Mr. Markle is a pioneer, one of the best-known men in the electrical business, and under his management the Electrical Fibre Carbon Company will achieve success in a high degree.

MR. THOMAS C. RAFFERTY, the assistant general manager of the Great Western Electric Supply Co., reports business as very flourishing with his company. In some of his recent trips in the interest of his house he states that he secured several large orders for railway line material and general supplies for construction work.

THE GLEASON & BAILEY MANUFACTURING CO., 233 Lake street, Chicago, manufacturers of gas and electric light fixtures and supplies, have recently added a full line of electric supplies, in which department they propose doing considerable business. They are also taking hold of good specialties, amongst others, the Steuben incandescent lamp, for which they are finding a ready sale.

MR. ARCHER TURNER, a young English electrical engineer, is making Chicago a visit. He has been connected for some time with the Brush Company, in London. Mr. Turner will probably ally himself with some of the parent companies in this country, where he proposes remaining for some time.

J. LANG & CO., 44 Michigan street, Chicago, are busy turning out switches for large and small currents. They have acquired quite a reputation for the excellence and beauty of their goods, which never show any signs of heating or arcing, even under the severest conditions.

MR. GILBERT G. M. MCDUFF, who for the past year and a half has been the general Western representative of the Fred. H. Whipple Co., with offices at 407 "The Rookery," Chicago, has severed his connection, and will probably take hold of some other electrical journal.

MR. GEORGE D. SHEPARDSON, whose appointment as Professor of Electrical Engineering at the University of Minnesota was recently noted in THE ELECTRICAL ENGINEER, stopped in Chicago recently, and inspected some of the local electrical works on the way.

THE ELECTRIC MERCHANDISE CO. are very busy shipping orders for electric street railway equipment. This well-known company are furnishing supplies to almost every street railway plant in the country, and also shipping goods abroad.

THE SALT LAKE CITY POWER LIGHT & HEATING CO. have found it necessary to make a large increase in their power plant, and have ordered two additional Armington & Sims engines from the Pond Engineering Company, St. Louis.

THE CENTRAL ELECTRIC CO. are doing their usual large amount of business, and orders for Okonite, Packard lamps, and other specialties for which they are agents are coming in all the time.

MR. EARNEST HOEFER, of the Illinois Electric Material Co., has returned from his trip East, and is pushing for business in his wonted energetic manner.

MR. C. E. LEE, formerly with the Great Western Electric Supply Co., will open an office in Chicago as representative of the Electric Gas Lighting Co., of Boston.

CHARLES A. BENTON, the manager of the railway department of the Detroit Electrical Works, spent a day in Chicago recently.

PHILADELPHIA NOTES.

THE THOMSON-HOUSTON ELECTRIC LIGHT CO., 509 Arch street, report recent installations from their office as follows: Conneaut Electric Co., Conneaut, O., 650 incandescent; Columbia Electric Light Co., Columbia, Pa., 50 arc and 650 incandescent; Shamokin Street Ry. Co., Shamokin, Pa., 50 arc and 650 incandescent; Frackville & Gilberton Electric Co., Frackville, Pa., 50 arc and 650 incandescent; Butler Electric Co., Butler, Pa., 1,300 incandescent (local company, new); Indiana Electric Co., Indiana, Pa., 80 arc and 650 incandescent; Pencoyd Iron Works, Pencoyd, Pa., 450 incandescent: A. B. Farquhar & Co., York, Pa., 300 incandescent; Bethlehem Electric Co., Bethlehem, Pa., 50 arc; Bethlehem Iron Co., Bethlehem, Pa., 50 arc; Baltimore & Ohio R. R. Baltimore, Md., 50 arc; Hughesville Electric Co., Hughesville, Pa., 20 arc and 500 incandescent; Bala & Merion Electric Co., Bala, Pa., 1,300 incandescent; Atlantic City Gas & Water Co., Atlantic City, N. J., 50 arc; Home Electric Co., Tyrone, Pa., 100 arc: Camden Electric Co., Camden, N. J., 50 arc; Milton Electric Co., Milton, Pa., 100 arc; Schuylkill Haven Electric Co, Schuylkill Haven, Pa., 50 arc and 650 incandescent; Jermyn Electric Co., Jermyn, Pa., 30 arc and 650 incandescent. The company also reports the sale of 45 motors ranging from ¼ to 5 h. p.

THE ARNOLD ELECTRIC MANUFACTURING CO., of Chester, Pa., has secured a contract from the U. S. Government for four electric fan blowers, and four motors to be used on the new cruisers "Texas" and "Main." They also supply these vessels with the new Navy standard sockets and special waterproof junction boxes.

MR. C. F. COLE, who for some time past has been a salesman in the isolated lighting department of the Thomson-Houston Electric Lighting Co., of this city, has severed his connection with that company, and accepted the position as general agent for the La Roche Electric Works.

NEW YORK NOTES.

TRUEX & VAIL, of 136 Liberty street, New York City, received a large order from the Pittsburg Gas Light and Coke Company, of Pittsburg, Kansas, on the 24th inst., for their "Swinging Ball" lighnting arrester, and were informed that the company had suffered to the extent of five hundred dollars during the month of July from lightning, and had now decided to equip the plant with this lightning protector, in order to be on the safe side hereafter.

THE T. & L. R. R. are still hampered in extending their lines by the non-arrival of material. They have now put a few men at work, and those are principally engaged in setting poles along the new routes. Unless the switches and curves reach Troy very soon the work will necessarily be delayed until spring.

THE INTERIOR CONDUIT AND INSULATION CO. will be represented at the street railway convention, at Pittsburgh, by President E. H. Johnson and Mr. E. T. Greenfield, its electrician. The company will show its improved method of burying the feeder wires of electric railways; also its new junction box.

HON. CHARLES CLEMINSHAW has resigned the presidency of the Troy City Railroad. Reasons alleged are that his private business and the presidency of the Troy & Lansingburg R. R. Co. demand all his attention. The vacancy will probably be filled at the October meeting of the trustees.

THE WENSTROM CONSOLIDATED DYNAMO AND MOTOR CO., through their New York agents, have shipped a 450 light direct-current dynamo for an isolated plant in Montreal.

THE W. S. HILL ELECTRIC COMPANY.

THE W. S Hill Electric Company of Boston, have purchased from Mr. W. S. Hill all of his electrical inventions for electric motors, dynamos, lamps, switches, etc., and will at once enter largely into the manufacture of these goods.

The new men coming into the company are Geo. A. Denham, of Sioux Falls; Geo. H. Poor, of Chicago, Geo. F. Gould, of Portland, Me., and Louis F. Busiel, of Laconia, N. H.

These, with Mr. Hill and his son, Louis E. Hill, will constitute the board of directors. Mr. Denham will be treasurer, and Mr. Poor general manager. W. S. Hill is president of the company, and Louis E. Hill will attend to the manufacturing department.

The office of the company will for the present be located at No. 54 Devonshire street. The present factory will be enlarged, and the company will enter at once into the manufacture of small dynamos, for which Mr. Hill has acquired an extended reputation.

Hill's double pole switches, station switch, arc lamp and switchboard apparatus, with various other electrical apparatus, will constitute the electrical goods handled by the new company.

☞ Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Miscellaneous, etc., will be found in the advertising pages.

THE

Electrical Engineer.

VOL. XII. OCTOBER 21, 1891. No. 181.

THE CENTRAL POWER STATION OF THE WEST END STREET RAILWAY COMPANY, OF BOSTON.

BY

A. C. Shaw.

I.—INTRODUCTORY.

MUCH has already been written about the wonderfully rapid development of the electric street railway since it first began to attract commercial attention by its practical successes. It is not my purpose in the present article to follow the history of the electric car from the beginning of the year 1888, the year in which it may be said the electric car first became a commercial success, when there were barely a dozen roads in the United States, having an aggregate mileage of about 50 miles, being operated by electricity, with about 100 cars, down to the present day, when there are over 350 roads, operating nearly 3,000 miles, with over 4,500 cars. A visit to any of these roads will prove that electric cars are being run sucessfully, but nothing will bring home to the mind of the inquirer so forcibly the vast hold that the electric railway has upon the people of this country, and the immense prospects of its universal adoption for street railway purposes as a visit to one or other of the enormous central stations being erected in various cities for street railway work. To a certain extent electric lighting has reached its limit, in the way of new franchises, though not in the way of new work. Almost every town of any size in the United States has one or more central stations, lighting up the streets and providing commercial and house lighting. There are, however, very many street railway companies who have as yet not adopted electricity as a motive power, and it is to this branch of the business that most attention is being given by electrical engineers at the present day. A description of the largest central power station in the world will therefore, it is believed, prove interesting to every one connected with the electrical business, and it is my purpose in the following article, to describe in detail the station which is now being built by the West End Street Railway Company, of Boston, a station the immensity of which can hardly be appreciated without an actual visit, and which certainly places Boston in the front rank as a city electrically equipped with street railways.

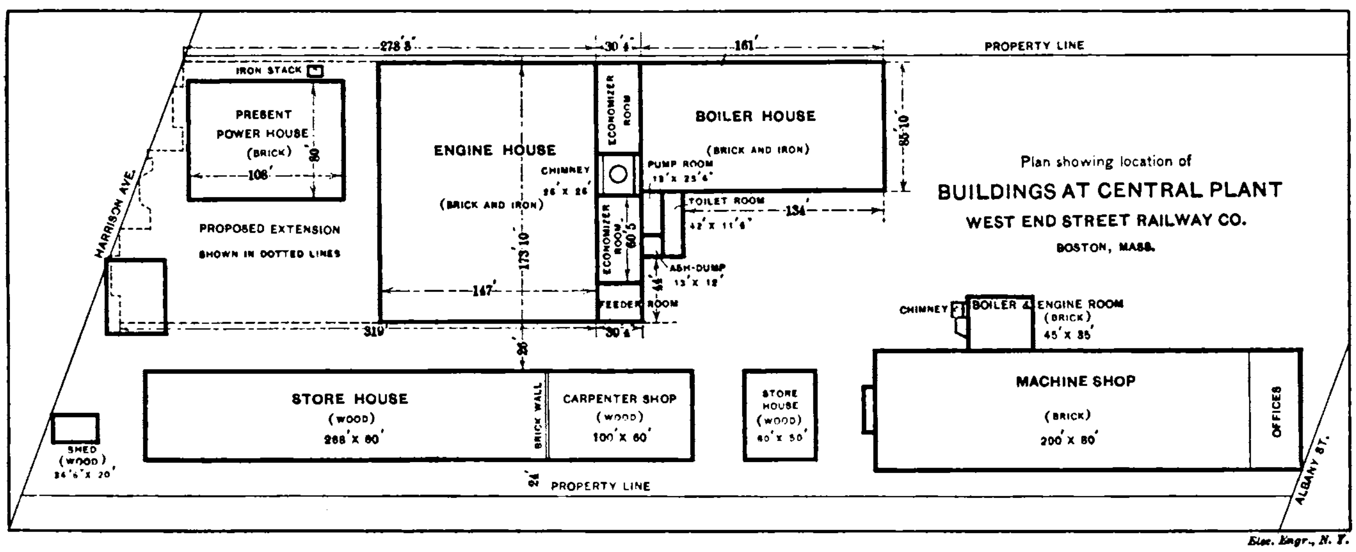

FIG. 1.—GENERAL PLAN OF THE BUILDINGS.

II.—THE HISTORY OF THE ROAD.

A few words as to the history of the company may be found interesting. The West End Street Railway Company was organized November 12th, 1887, with a capital of $80,000, and with Mr. H. M. Whitney as president, for the purpose of building a short line to Brookline, so as to develop the land of the West End Land Company, there being at that time several other street railway companies operating in Boston. Soon after the franchise was granted, before any construction was done, consolidation of the several companies was talked of, and in 1888, finally, a consolidation was effected, the companies consolidating being the West End Company, the Metropolitan, the Cambridge, the Boston Consolidated, South Boston, the Charles River and the Somerville, the only one left out being the Lynn and Boston Railroad, which still exists. At the time of the consolidation there were required about 7,816 horses and 1,480 cars, and the company was started with a capital of $6,000,000 preferred stock, $1,500,000 common stock, and $1,500,000 outstanding bonds which the West End Company assumed. Business increased so rapidly that a year later there were as many as 9,000 horses and 2,000 cars, and some other form of motive power was investigated, and much time and money was spent in making complete plans and estimates for equipping Boston with cable roads. About that time Mr. H. M. Whitney was invited by the Sprague Company to go to Richmond, Va., and investigate the merits of the electric road in that city, and so impressed was he with the great possibilities of the electric car, as foreshadowed in Richmond, that it was at once decided to abandon the cable project and equip a portion of the road with electricity as a practical experiment. In the summer of 1888 a contract was made with the Sprague Company, and on January 1st, 1889, 20 cars were started, running from Park Square to Chestnut Hill and Allston, with the overhead system, the line from West Chester Park to Park Square being operated by the Bentley-Knight underground conduit, this underground part of the work being afterwards abandoned. A month or so later the Thomson-Houston Electric Company started 20 cars of their manufacture from Bowdoin Square to Harvard Square, these being operated by themselves for the first six months until their success was fairly demonstrated, and they secured from the West End Company an order for 600 motors. This was really the commencement of the large Thomson-Houston system now in operation by the West End Company in Boston. It is worthy of note that so well pleased were the citizens with the electric cars that when the West End Company went before the Board of Aldermen for a franchise for pole rights for 180 miles of track all through the city and suburbs, not a single man was present to offer an objection. The power at this time was furnished from the power house at Allston, and from the Cambridge Electric Light Company, but it was soon seen that this was insufficient, and the old Hinckley Locomotive Works, with their extensive grounds, extending from Harrison avenue to Albany street, were purchased with the view to building a large permanent station, another temporary station being installed meantime in the old foundry building, and equipped with MacIntosh & Seymour engines and Thomson-Houston generators, which have done yeoman service. On June 1st, 1889, Mr. F. S. Pearson entered the service of the West End Company, under whose immediate charge the whole work has gone on, and ground was eventually broken for the foundations of the central power station in August, 1889. Since then the capital of the company has been increased twice, the first time by $4,000,000, and the second time by $4,500,000.

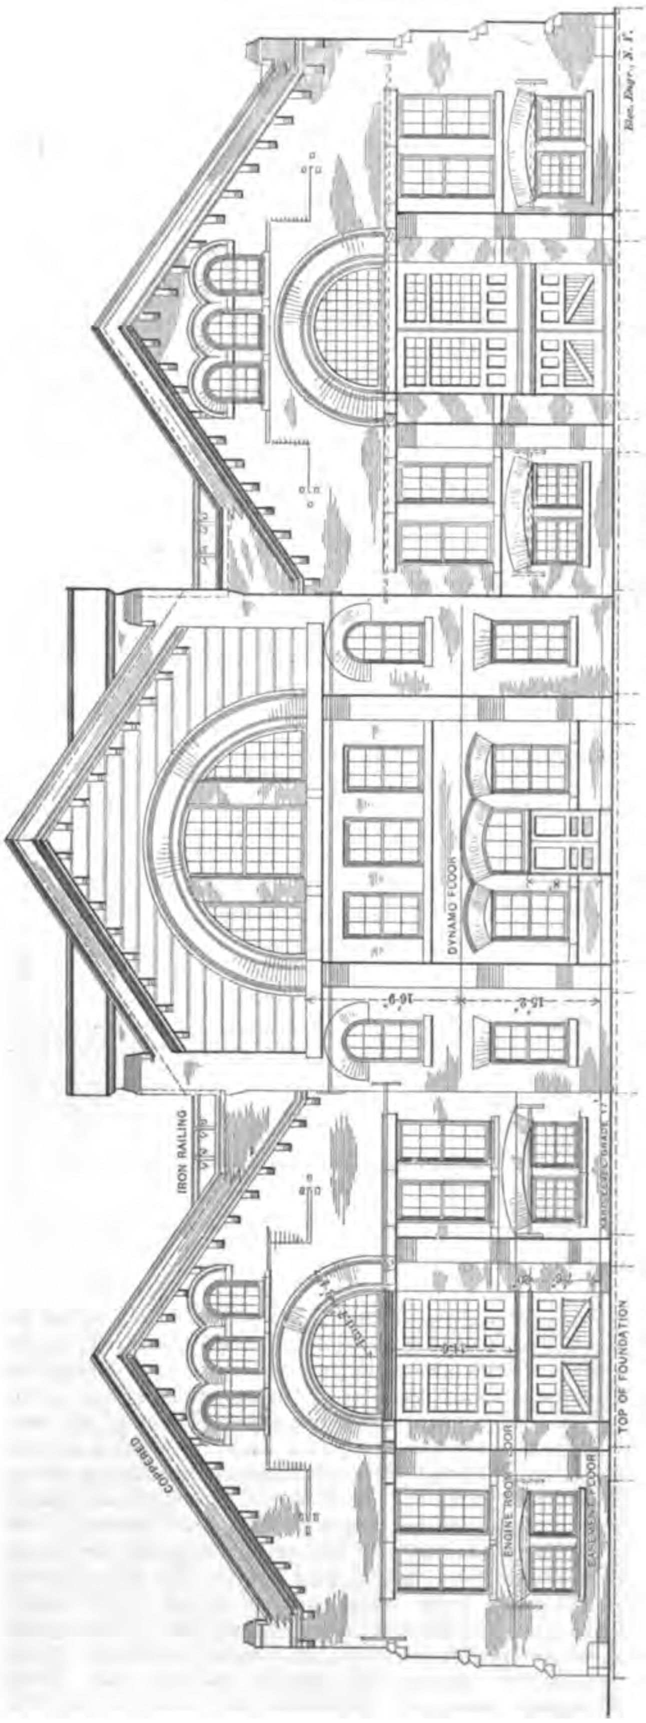

FIG. 2.—WEST FRONT OF THE POWER HOUSE.

III—THE BUILDINGS IN GENERAL.

The space secured in the lot, as shown in Fig. 1, measures about 830 feet long by 290 feet wide, extending from Harrison avenue to Albany street, and with a valuable wharf frontage of about 300 feet on the South Bay. This wharf will be equipped with a coal pocket, traveling cranes and all necessary appliances for the prompt unloading of coal, and it will be connected by a track with electric fittings to the boiler house. The station proper when complete will extend 510 feet from Harrison avenue, and will be 175 feet wide, excepting at the boiler house, where it is only about 86 feet wide. The plan of the ground shows distinctly its location, the dotted part showing the extension, with the temporary station occupying part of it; it shows also the machine shop and car shop, the carpenter shop, store house and offices. Taking the plan of building in detail, the boiler house occupies a space 161 feet long by 85 ft. 10 in. Adjacent to the boiler house is a space 30′ 4″, occupied by the economizers and smoke stack, feeder room, etc., and then comes the main engine and dynamo room, 147 feet long by 174 feet wide. The extension when completed will measure 172 feet long by the same width, making the total length of the station when finished 319 feet. On the site of the extension the old power house is situated, occupying 108 feet by 80 feet, and having 2,000 horse power capacity. This building will be torn down just as soon as the present half of the Main Building is all equipped and in running order. At present also one-half of the large boiler house is being used as a temporary station, being equipped with 2,500 horse power.

The fact that this immense station with its enormous weight of engines and machinery is situated on reclaimed land makes the foundation work of supreme importance and particularly interesting, and worthy of a few details of description. The surface of the ground is 17 feet above

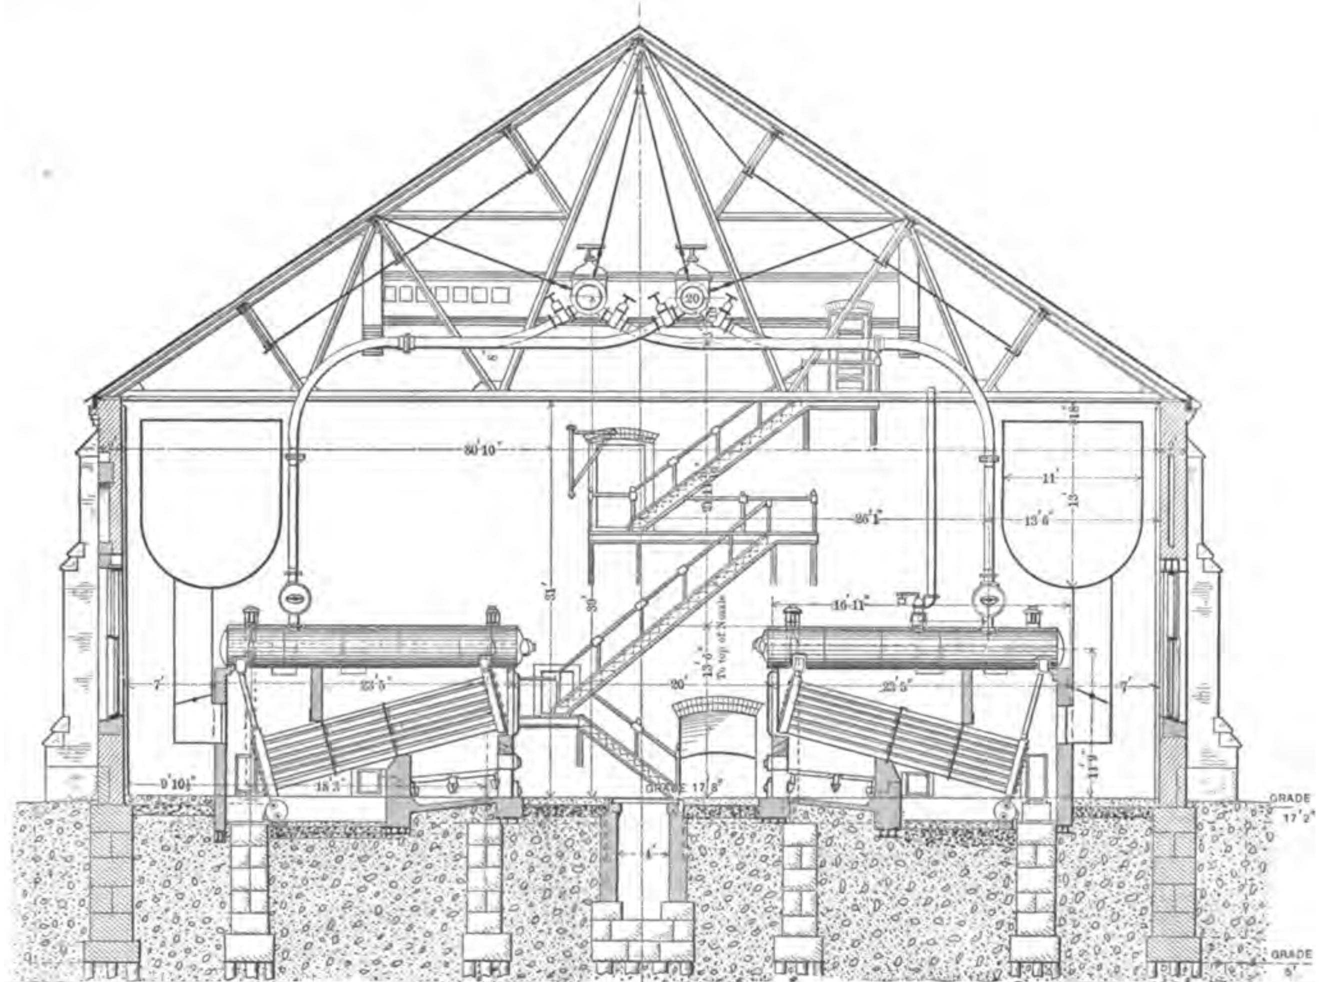

FIG. 3.—SECTIONAL VIEW OF BOILER HOUSE.

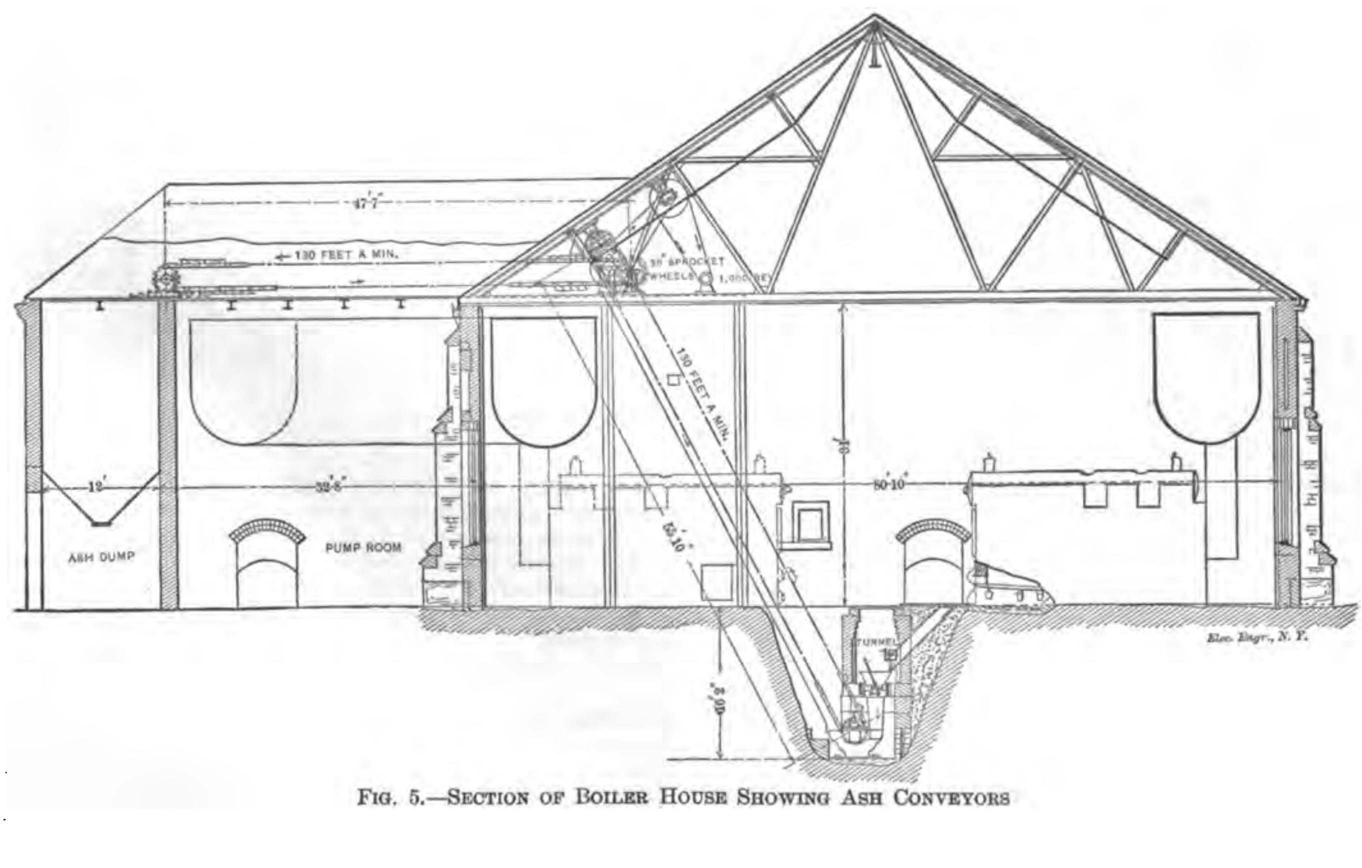

FIG. 5.—SECTION OF BOILER HOUSE SHOWING ASH CONVEYORS

mean low-tide water, and the whole space occupied by the buildings was excavated to a depth of just 17 feet, that is, to mean low-water mark. The whole square taken in by the engine room, the economizers and smokestack was then literally covered with piles 45 feet long and about 12 inches in diameter, they being driven at intervals of about 30 inches apart. Close piling is also underneath all the walls of the buildings. The piles in the engine room were cut off at 5 feet from low-water mark, while under the smoke-stack the piles were cut off just at low-water mark. Under the chimney alone there are 810 piles, and under the engines and machinery 6,000 piles have been driven. After the piles were driven, the whole excavation, extending across the engine and machinery room, was filled in with six feet of solid concrete, consisting of five parts of broken stone, two parts of sand and one of Portland cement, upon which the necessary masonry foundations rested. In the boiler house each battery of boilers is supported on six stone piers, each resting on five piles, but no concrete was used. It may be interesting to note that the total foundations, including the excavations, piling, concreting and masonry cost in the neighborhood of about $300,000.

The buildings are of brick, with brown stone trimmings, having slate roofs of graceful design, and well finished. The walls are about two feet thick throughout. The boiler house has a single-span roof, and the engine room a triple-span, the centre span being supported on latticed columns. The whole design, as shown in Fig. 2, is tasteful and compact, and the whole building presents a pleasing picture to the eye, and is well balanced in design.

IV.—THE BOILERS.

With this general description of the plan of the ground and the buildings, and their general design, it is now my purpose to describe more particularly each detail of the building, and naturally the boiler house, being the actual source of the power, attracts attention first. This is shown in section in Fig. 3, and in plan in Fig. 4. Entering this building the vastness of the work at once becomes apparent. On either side are arranged six batteries of boilers, manufactured by Babcox & Wilcox, of New York. These are the well-known water-tube type, and are of the latest pattern, each battery being capable of furnishing 2,000 horse power, making a total for the boiler room of 24,000 horse power. Only six batteries are used at present, enough for the first half of the station, which is now nearing completion. The shells are of steel and are designed to withstand a working pressure of about 200 pounds to the square inch.

Each battery consists of two distinct boilers, 23 ft. 5 in. long by 21 ft. 10. in wide, and about 15 ft. high, each boiler having three 36 inch horizontal drums, shown in Fig. 6, running length-wise of the boilers, made of steel and capable of withstanding a steam pressure of 200 pounds to the square inch. The boilers are all faced with white glazed bricks, specially imported, and present a very attractive and clean appear-

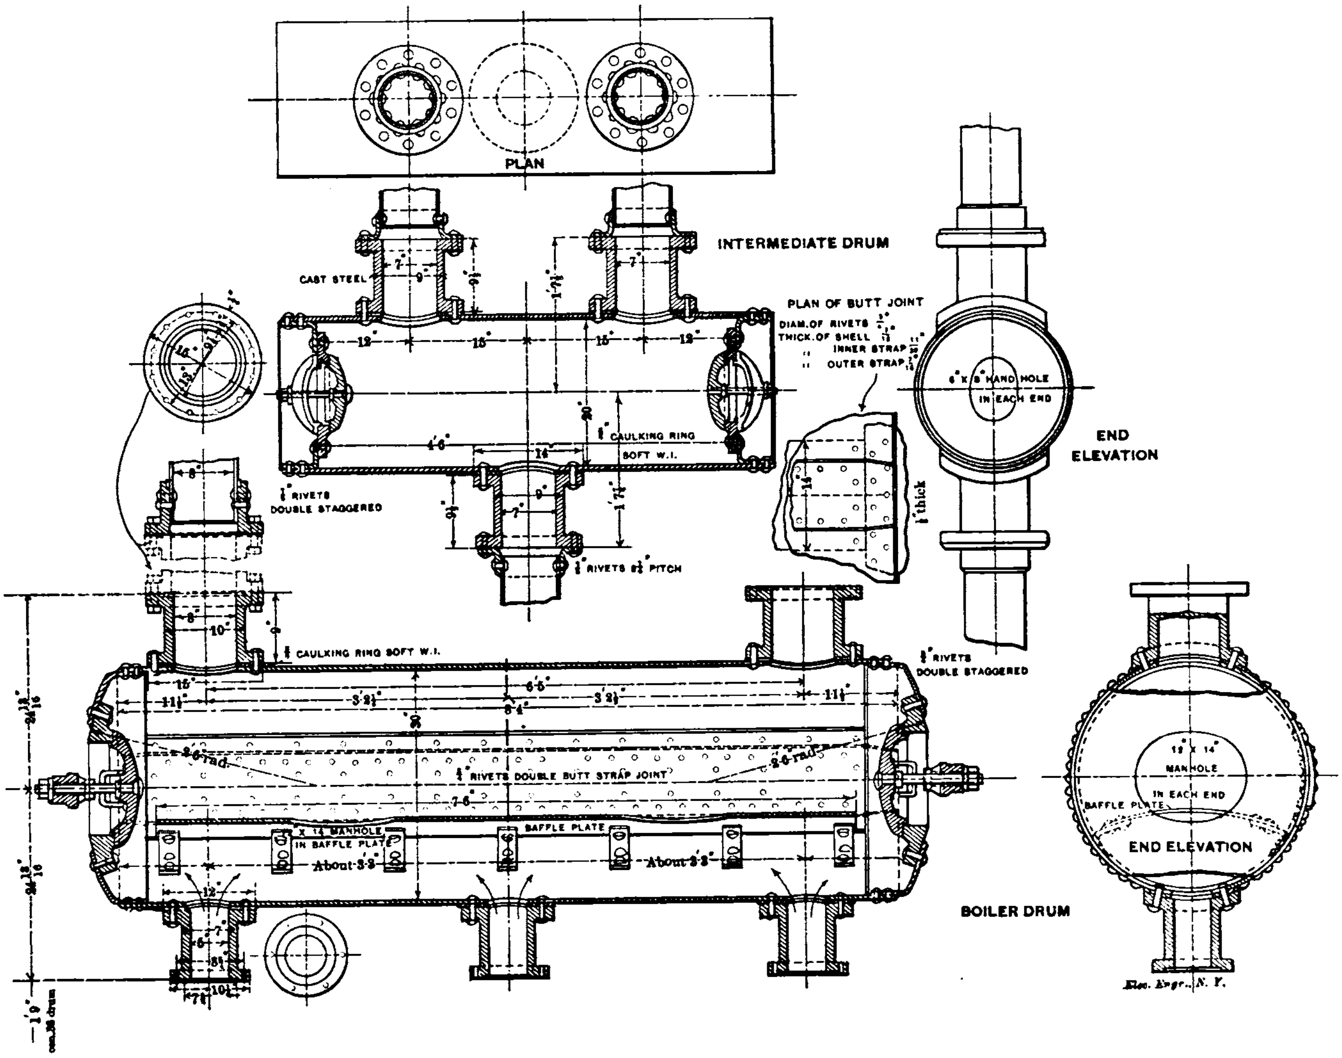

Fig. 6.—Drums for Steam Piping.

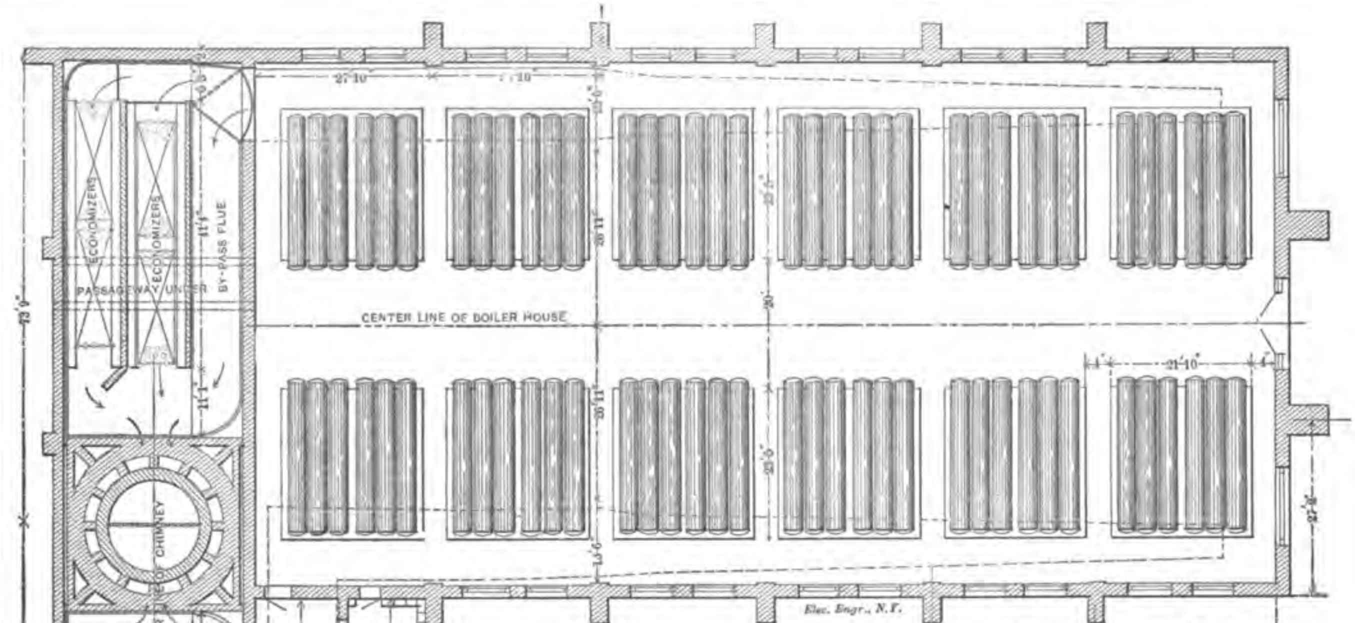

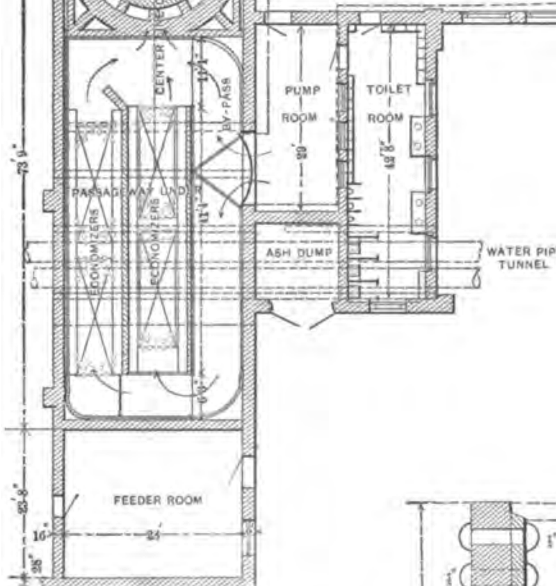

FIG. 4.—PLAN OF BOILER HOUSE AND ECONOMIZERS.

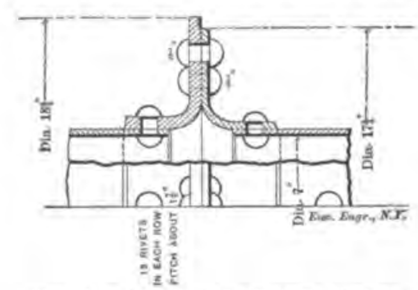

FIG. 9.—DETAIL OF FLANGE JOINTS.

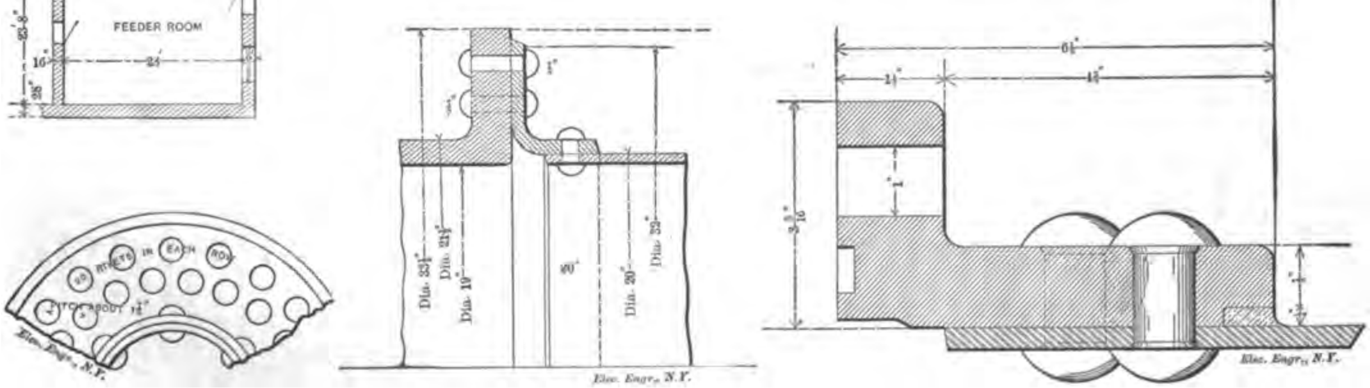

FIGS. 8, 10 AND 11.—DETAILS OF FLANGE JOINTS.

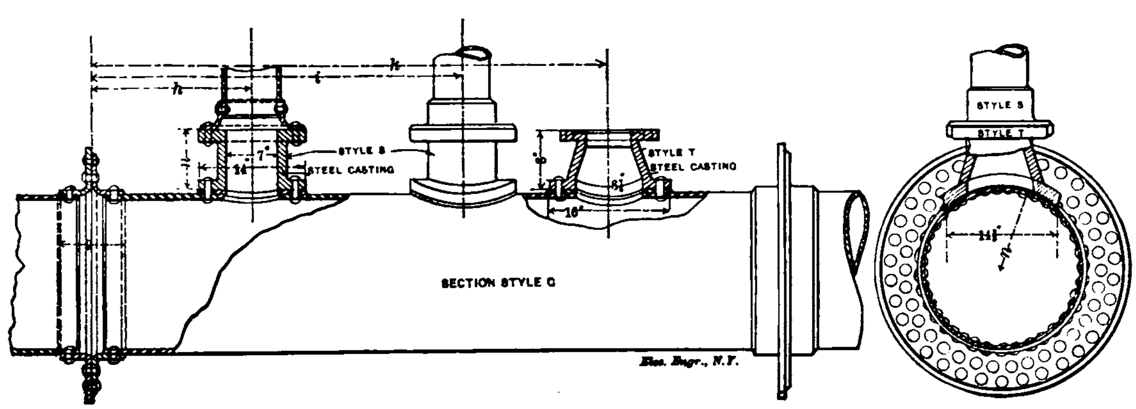

FIG. 7.—DETAILS OF STEAM PIPING.

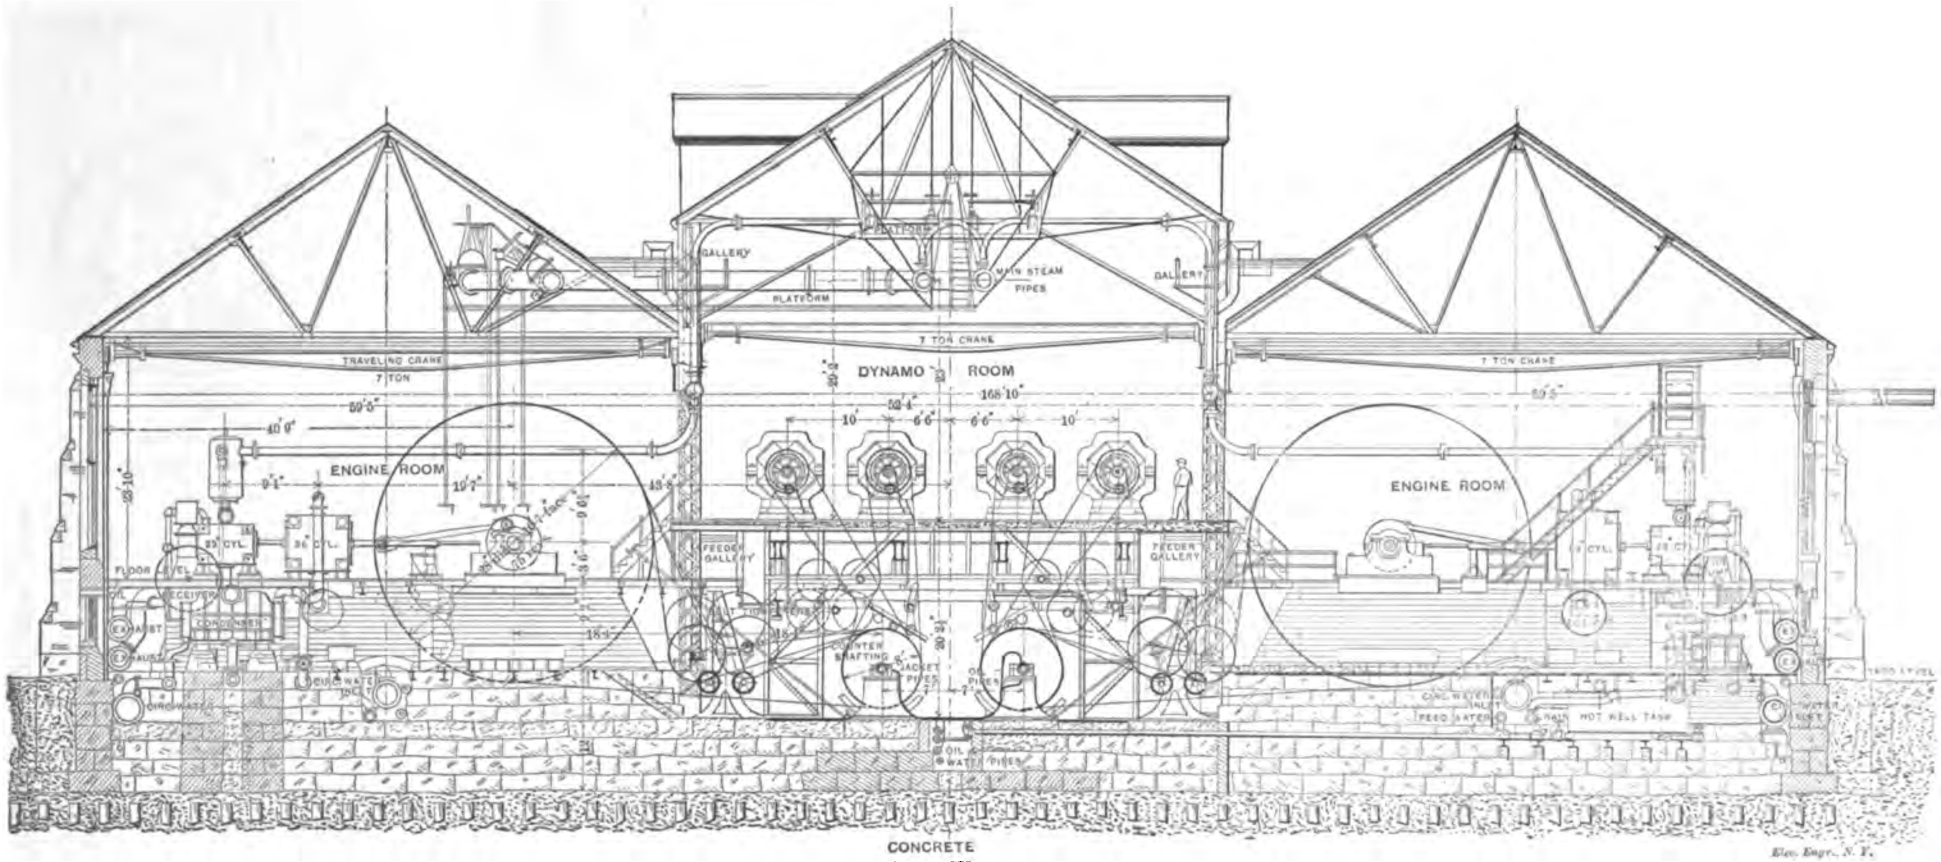
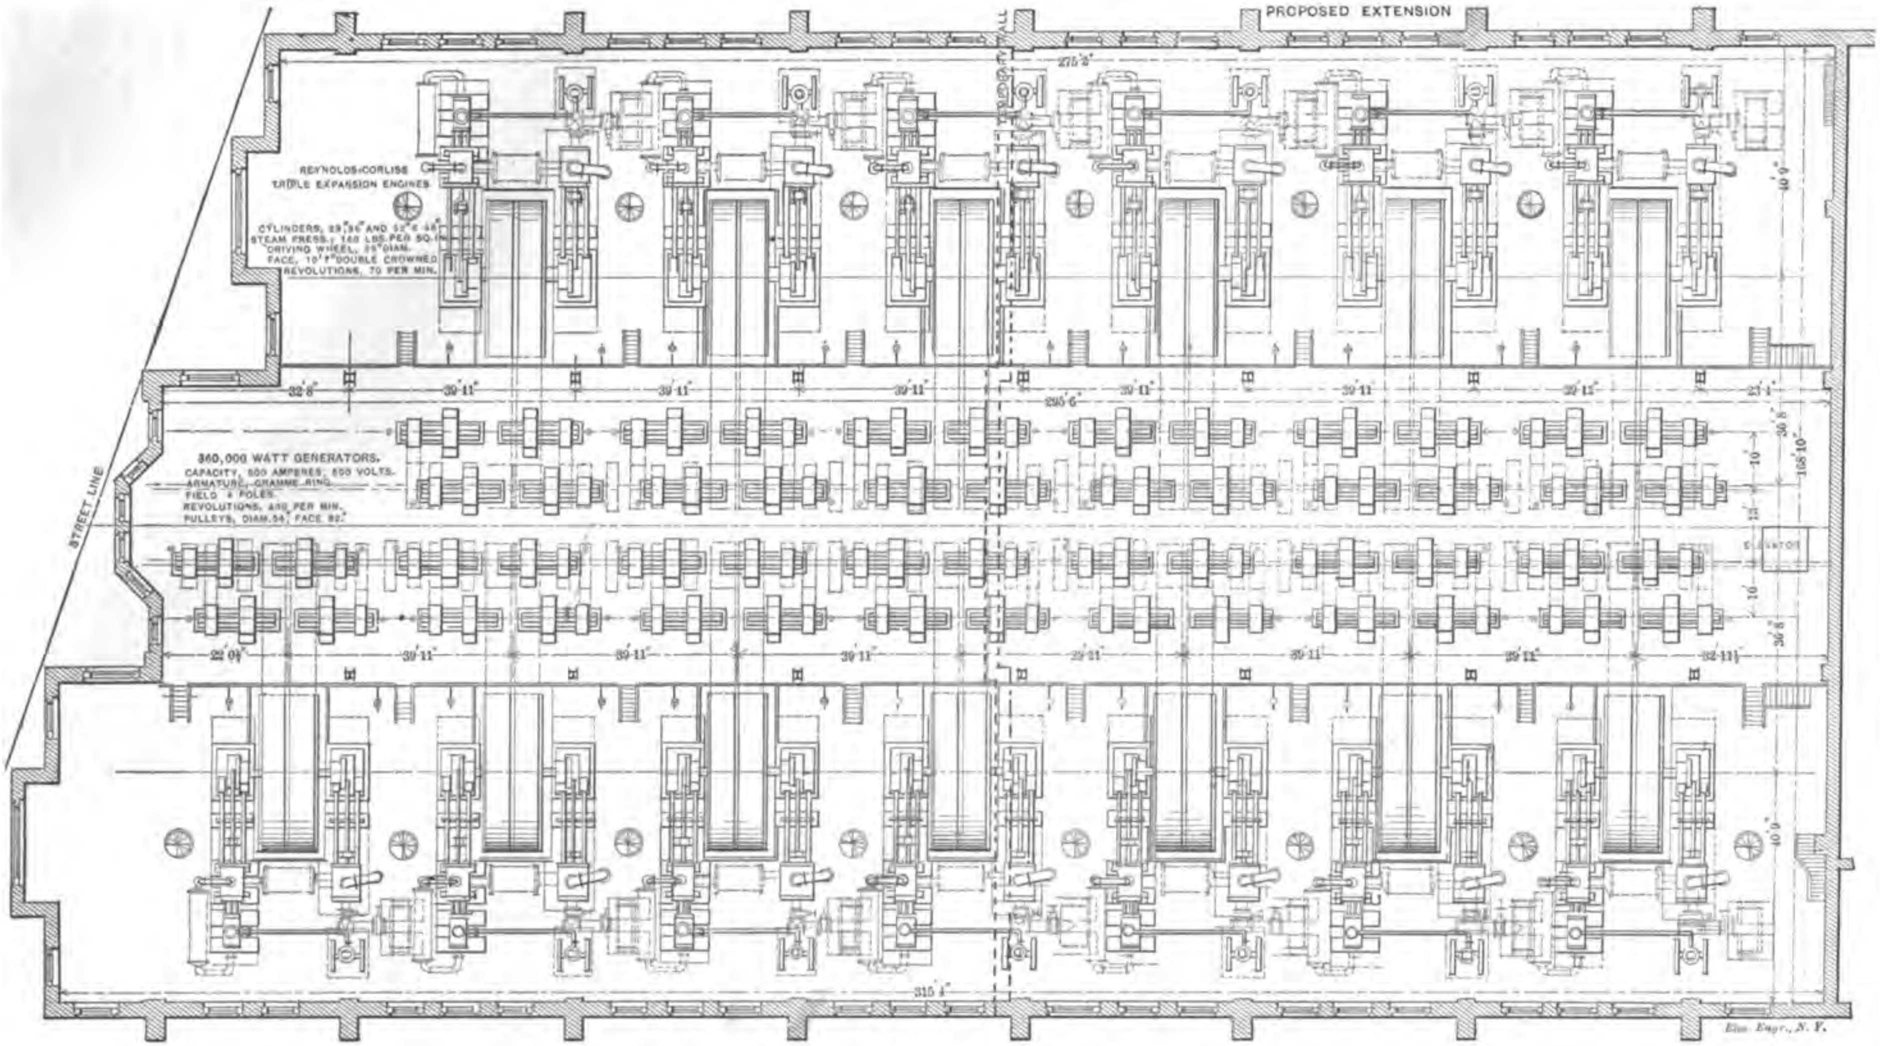


ance. A duplicate system of brass piping, tapering from 5 to 3 inches, runs along the walls of the boiler house with branches to each side of each battery, with valves, etc., complete, adding materially to the appearance of the boilers. The usual gauges, test cocks, etc., etc., are provided complete. Although only one side of the boiler house is at present equipped, the other side being used as a temporary station, one can get a very good idea of how the boiler house will look when completed. Between the two rows of boilers will be a space for firing and handling the coal, 20 feet wide, and in the centre of this space there will be a track for hand trucks for handling the coal. Underneath the centre of this space is located a very complete system of mechanism for handling and removing the ashes, as shown in Fig. 5. Opposite each fire door is a chute leading directly into this pit, through which the ashes are dumped into a series of hand cars and transported on rails to the

THE WEST END ELECTRIC RAILWAY, BOSTON, MASS.

Fig. 12.—Sectional View of Power House.

end of the pit at the end of the boiler house. Here the ashes are emptied into another recess, in which is constantly moving an endless chain gear attached to pan conveyors, which convey the ashes in an oblique direction to the top of the boiler house, whence another endless chain with pans conveys them in a horizontal direction to a large ash dump, whence they are hauled away at convenience by cartage. It is also intended to equip the boiler house with a complete system of automatic coal-handling apparatus. The smoke flues, supported from the roof truss, are shown at either side of the section of the boiler house behind the boilers, and are, at the end nearest the smokestack, 11 ft. wide by 13 ft. high, rounded on the bottom, and tapering down to about five feet by five feet at the further end. These flues will connect the boilers with the economizers, and will be covered by some insulating compound to prevent radiation of heat.



THE WEST END ELECTRIC RAILWAY, BOSTON, MASS.

FIG. 18.—PLAN OF POWER HOUSE.

The roofs of the boiler-house and dynamo and engine house, the general design of which has already been described and illustrated in a number of the accompanying engravings, have been built to meet the following requirements, and were built and erected by the Boston Bridge Works, of Boston.

The load provided for, in addition to the weight of all the material in the roof, is, first, a snow load of 20 pounds on every square foot of all the slopes and other surfaces, and at the same time provision has been made for a horizontal wind-storm of forty pounds blowing in either direction against every square foot. Provision has also been made to withstand the greatest stress possible from any combination of these loads. The strain allowed in the iron work nowhere exceeds 12,000 pounds per square inch in tension, and the strains in compression do not exceed 10,000 pounds per square inch, properly reduced in cases of posts, according to the most scientific formula for that kind of member.

The maximum strain on rivets is confined to 9,000 lbs. per square inch, and in rolled beams or channels the maximum strain allowed under the greatest load possible is 15,000 pounds per square inch. Bearing plates are provided under all the trusses, so that the pressure due to the greatest weight possible from the trusses on the masonry is not greater than 200 pounds on every square inch.

All material in these roofs is wrought iron, and it was tested during the process of construction of the work. All plates of iron were obliged to show in the tests a strength of 48,000 pounds for every square inch of area. All rolled forms of iron were obliged to show under test a tensile strength of 50,000 pounds per square inch. All plates and angles and other forms of iron were subjected to a test of sharply bending them to a right angle at a working heat without showing any sign of fracture. All rivets in the structure were subject to the test of bending double, either hot or cold, so that the sides came into close contact without showing any sign of fracture, and all iron was subject to the test of being bent cold 90 degrees around a small curve without showing any signs of fracture. All workmanship was subject to inspection, and conformed to the best practice and modern demands for high-class product.

V.—THE STEAM PIPING.

The steam-pipe arrangement and details possess a number of interesting specialties, which are shown in several of our figures. Steam is taken in the usual way from the drums of each boiler, and passes first into an auxiliary drum of 30 in. diameter, which connects all three drums of each boiler, and which is shown in Fig. 6. From each of these auxiliary drums two 8 in. pipes lead upward by means of a long graceful sweep to two 20 in. main steam pipes, leading into the power house. These main steam pipes are tapered down to 16 in. at the first battery, and are supported by a series of straps from the truss roof. The whole steam-pipe system is duplicate throughout, one system being capable of alone furnishing steam for the whole plant. The steam pipes are all wrought iron, lap welded, and the joints are all riveted throughout the entire station, the elbows also being made of wrought iron bent to the proper shape. The extreme high pressure of the

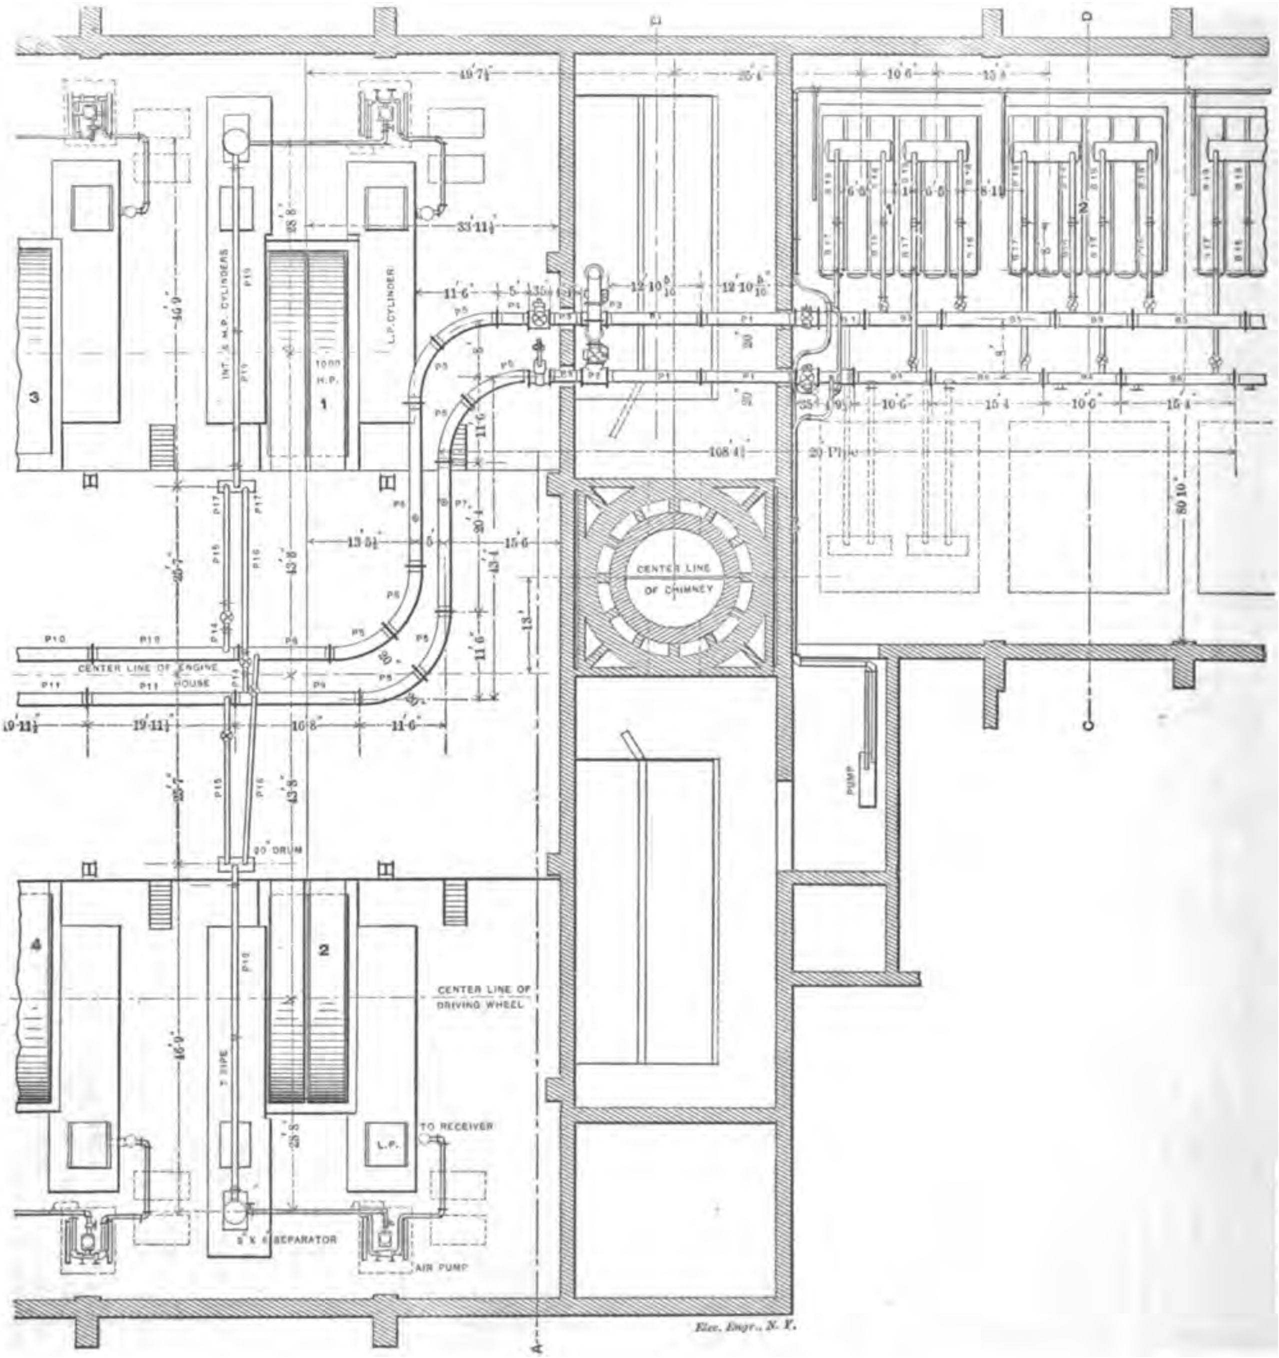


FIG. 15.—PLAN OF STEAM PIPING.

steam necessitates special care in the design of the joints. The joints are made with pressed steel flanges, single riveted to the pipe, and double riveted to each other, and are all caulked outside and inside, as shown in Figs. 7, 8, 9 and 10. All connection from the branch steam pipes to the main steam pipes are made with steel castings of a very heavy pattern, and the long sweep from the auxiliary drum to the mains allows for free expansion and contraction. These steel castings are riveted to the main pipes and have a soft iron caulking ring between them and the pipe, as shown in Figs. 7, 8 and 11. All joints at the valves are bolted

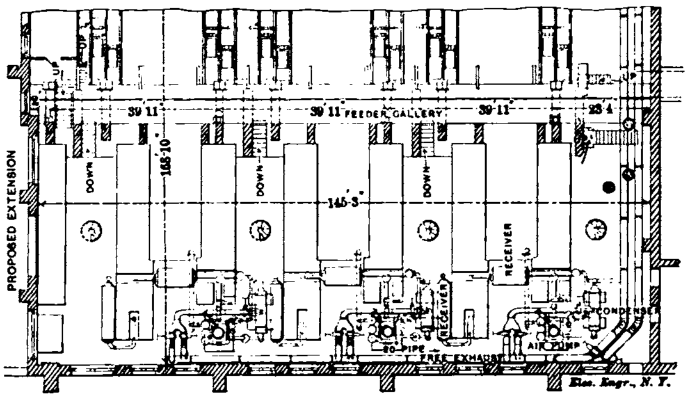

FIG. 13 A.—PLAN OF BASEMENT, SHOWING AIR PUMP, CONDENSERS, ETC.

and are made with tongue and groove, the groove being fitted with a packing ring. In each branch pipe is an automatic check valve of special design, and a Chapman gate valve, also of special design, being extra heavy and provided with a by-pass. Under the main pipe is suspended an iron gallery, to which access is had by a flight of iron steps at the end of the boiler house. The boiler-room roof is of iron, built by the Boston Bridge Works, as stated, and is a single-span truss roof, with two large cupola ventilators on the ridge, and three tastefully designed dormer windows on each side for light. The roof design is very solid and substantial, consisting first of 2 inch planking, then $\frac{7}{8}$ inch boarding, then $\frac{3}{4}$ inch of plaster, held in place by screeds, to which are fastened the slate. The under side of the planking is covered by wire, lath and plaster, so that the structure is thoroughly waterproof. The roof of the power house is of similar design, making the entire building unique in this respect.

VI.—THE ECONOMIZERS.

Following the path of the flues we come to the complete system of economizers, where the feed water for the boilers is heated by the waste gases from the boiler furnaces before passing up the smokestack. These economizers are of the Lowcock type, made in England, and consist of a series of vertical cast iron tubes 10 feet high and 4 inches in diameter. They are arranged in pairs, as shown in Fig. 4, each pair consisting of 600 tubes, 2,400 tubes in all, with connections top and bottom, through which the circulation of the feed water is maintained. The economizers are situated on each side of the smokestack, being situated in large brick chambers, occupying a space about 30 feet wide, 30 feet high by 174 feet long, including the chimney. The outer end of each chamber is open to the flues from the boilers, and the inner end open to the smokestack, so that the gases from the boilers must pass through these chambers before being allowed to escape. Each chamber is divided longitudinally into two by a brick wall, so that any economizer can be shut off by dampers, and repaired when necessary, and each chamber is also provided with a by-pass flue. The economizers themselves are situated on brick foundations, are 38 feet long by 7 feet wide, by 10 feet high, and each one of the 2,400 tubes is provided with a mechanical scraper which is kept constantly moving up and down the tube to prevent the collection of soot.

VII.—THE CHIMNEY.

Such a large steam plant requires a capacious smokestack, and a few details may be found interesting. Above the concrete foundation, already described, was built a granite foundation, seventeen feet in depth, 60 feet square at the base, tapering to 30 feet square at the top, solid throughout with the exception of three or four courses at the top, in which allowance was made for a soot chamber. The chimney is 28 feet square at the base, extending to a height of about 30 feet, the level of top of boiler house, from which point it is circular in section, 26 feet in diameter, tapering to 17 feet near the top, where it bulges out in a neat design to 22 feet in diameter at the extreme top. It is 252 feet high over all. The flue is 13 feet 8 inches in diameter, and is parallel all the way up, extending to within a few feet of the top. The chimney consists of an outer shell 32 inches thick at the bottom, tapering to 16 inches at the head, and has 12 internal buttresses extending the whole length, but not touching the inside core or shell, which is left free to expand by the heat of the gases. The inside shell is 21 inches thick at the base, and tapers to 8 inches at the top. The top of the chimney is provided with a tastefully designed cap of cast iron, made in 24 sections, and weighing 8,400 pounds. To this cap is attached a system of lightning rods, consisting of six 5 foot copper rods with spreading platinum tips, connected to each other by a copper ribbon, and to the water pipes in the ground by two copper ribbons cleated to the side of the chimney. Inside of the chimney and near the top is a means for taking the temperature of the escaping gases. This consists simply of an iron bracket and pulley with a wire rope, by means of which a thermometer can be raised to the top and the heat registered. It is worthy of note that the chimney was built entirely from the inside by means of an elevator.

VIII.—THE POWER HOUSE ARRANGEMENT.

Fig. 12 gives in general a section of the power house, showing the position of the engines, condensers, circulating pumps,

FIG. 14.—VIEW IN THE ENGINE ROOM.

counter-shafting, belt tighteners and generators, while Figs. 13 and 13 A show plans of the same building, giving the arrangement of engines and generators. The sectional view gives an excellent idea of the piling and concrete foundations already described, on which rest the masonry foundations for the engines and other purposes. Each engine requires two separate foundations, with a wheel pit between, each of which consists of a substructure of seven courses of granite, 12 feet high and about nine feet wide at the top. Upon this is built the superstructure of brick nine feet high and eight feet wide, into which are set the capstones on which the cylinders and engine beds rest. The air pumps and condensers have independent foundations of granite, as also the engine belt tighteners and two rows of counter-shafting. Looking at the plan as shown in Fig. 13 it will be seen that the station will consist of 13 units when complete, six of which are now being put in, the wall at the end furthest from the boiler house being temporary, as shown by dotted lines. It is the purpose of the West End Street Railway Company, as soon as the load can be withdrawn from the small temporary station, as shown in the plan of the lot already described, to tear it down and commence excavations for the extension. It may be said that the steam piping, circulating pipes, and exhaust pipes, etc., etc., are all made large enough for the capacity of the 13 units. Each of the above units consists of a Reynolds Corliss triple-expansion condensing engine, a Reynolds Corliss circulating vacuum and feed pump, Wheeler condenser, a forty foot section of counter-shafting and four electric generators, and the accompanying belts and belt tighteners. Each unit is therefore entirely independent of each other, and can be connected only through the shafting by means of clutches.

IX.—THE REYNOLDS CORLISS ENGINES.

The engines were built by Messrs. E. P. Allis & Co. of Milwaukee, Wis., and can develop 2,000 horsepower at their maximum, being made of massive proportions and very strong throughout. An excellent photographic view is shown herewith in Fig. 14 which is taken from the boiler house end, showing the vertical independent circulating and air pump in the foreground. The high pressure and intermediate cylinders are tandem, on one foundation, being twenty-three in. and thirty-six in. in diameter respectively, with a forty-eight in. stroke. The low-pressure cylinder is on the other foundation, and is fifty-two in. diameter by forty-eight in. stroke. The intermediate receivers, of which there are two for each engine, are placed between the cylinders just beneath the floor, and with the steam pipe connections are all covered with magnesia to retain the heat. The cylinders are all steam-jacketed and are also completely surrounded with magnesia. The fly-wheel is of mammoth design, being twenty-eight ft. in diameter, 10 ft. 7 in. face, and weighs eighty tons. It is double in its structure, being divided in the middle of its circumference, and built up of two rows of ten sections each, with two sets of ten arms of elliptical section, bolted to the rim of the fly-wheel at the intersections, and also bolted to the hub, which was cast independent of the arms. The flywheel is double-crowned, and carries two enormous double-ply leather belts, each fifty-four in. wide and 150 ft. long, to drive the counter-shafting in the basement, the belts being carried under the floor by means of a mammoth belt tightener, also situated in the basement.

Steam is supplied to these engines from the two mains, as shown in Fig. 15, as well as in Fig. 12, there being a connection to both mains, though only a single pipe comes to the engines, the two branches being connected by valves half way between the mains and the engines. This one steam pipe then enters a separator of special design, as shown, about thirty-six in. diameter by six ft. high, located over the throttle valve of the high-pressure cylinder. Similar connections are made to each engine. The main steam pipes, which are duplicate throughout, just as in the boiler house, are twenty in. diameter at end nearest the boilers, tapering to eighteen in. at the further end, and, as explained, have capacity enough for the complete station. Directly behind the low-pressure cylinder is situated the Corliss vertical circulating engine, also built by E. P. Allis & Co., which performs three distinct functions, namely, circulates the salt condensing water, operates the air pump for the condensers, and acts as a feed pump for the boilers. Each engine is provided with a Wheeler surface condenser, the cold water for which is provided by two lines of cast-iron pipes, drawing water from the South Bay. These pipes, which are entirely underground, start from the South Bay with a diameter of thirty-six in., one being the inlet and the other the outlet, and retain this diameter till they enter the basement of the power house, where each pipe branches into two, one for each side of the house, each branch being twenty-nine in. in diameter at the first engine, tapering to eleven in. at the furthest engine, with ten in. branches to each pump and condenser. These pipes are also designed large enough for the whole station, and will be sufficient to supply 20,000,000 gallons of condensing water per day. From the condenser the condensed or hot water is pumped into the hot well, which is situated in the wheel pit, and consists of a wrought-iron tank, there being one for each engine. From there it is pumped by a plunger on the same engine to the boilers, passing through the economizers, and being controlled by a complete set of valves in the pump room, described later on in this article. A duplicate system of piping twenty in. diameter has been erected, and shown in Fig. 12, next the walls of the building, to be used in cases of emergency as a free exhaust. These pipes having short rigid connections to the engines, are fitted with Wainwright patent corrugated expansion joints, manufactured by the Wainwright Manufacturing Company of Boston. No expense has thus been spared to make the steam part of the station absolutely reliable and capable of taking care of any possible emergency.

X.—THE COUNTERSHAFTING.

In such a station the counter-shafting is a most important factor, and much time was spent in elaborating the system now to be described, in order to get it compact and complete. One section of this shaft is shown in Fig. 16, and represents probably part of the largest counter-shaft for electrical purposes in the world. The design is unique and perfect, and embodies the latest improvements in the way of clutch connections and devices for disconnecting the power speedily and safely. It presents a solid and compact appearance, and is provided with all the latest appliances for reducing the amount of useless friction and wear and liability to accidents. Each section consists of a ten in. steel shaft, forty ft. long with four nine in. bearings. At the centre of the shaft, and supported on a steel quill or hollow sleeve, with independent bearings, is the main pulley eight ft. diameter by ten ft. seven in. face, cast in two circumferentially, and bolted together, and carrying the main driving belts, as described. This quill allows the shaft to pass freely through without touching the pulley, so that the shaft can move, if clutched to another engine, without moving the pulley, and allowing each engine to be started and stopped independently of the others. It also allows the weight of this large pulley with the heavy belt strain to be borne independent of the shaft, and when running, the strain on the shaft is taken outside and close to the bearings instead of between the bearings. To this sleeve is attached the clutch ring, as shown, and on the shaft adjoining the ring is keyed an eighty-four in. Hill friction clutch, specially designed for this purpose. Over the whole clutch there is a casing finished on the outside, so that there are no revolving arms or projections in view, and thus preventing much liability to accident. Each shaft is provided at one end with a clutch ring and at the other end with a clutch proper, so that it can be connected at any moment with the adjoining shafts. On either side of the main pulley are two dynamo pulleys, thirty-two in. face by eight ft. in diameter, driving the generators on the floor above by means of a thirty in. double-ply belt. All the boxes of the counter-shafting are jacketed for the purpose of having a cold-water circulation, to prevent any danger of becoming overheated. Each dynamo belt can be released from the driving pulley and

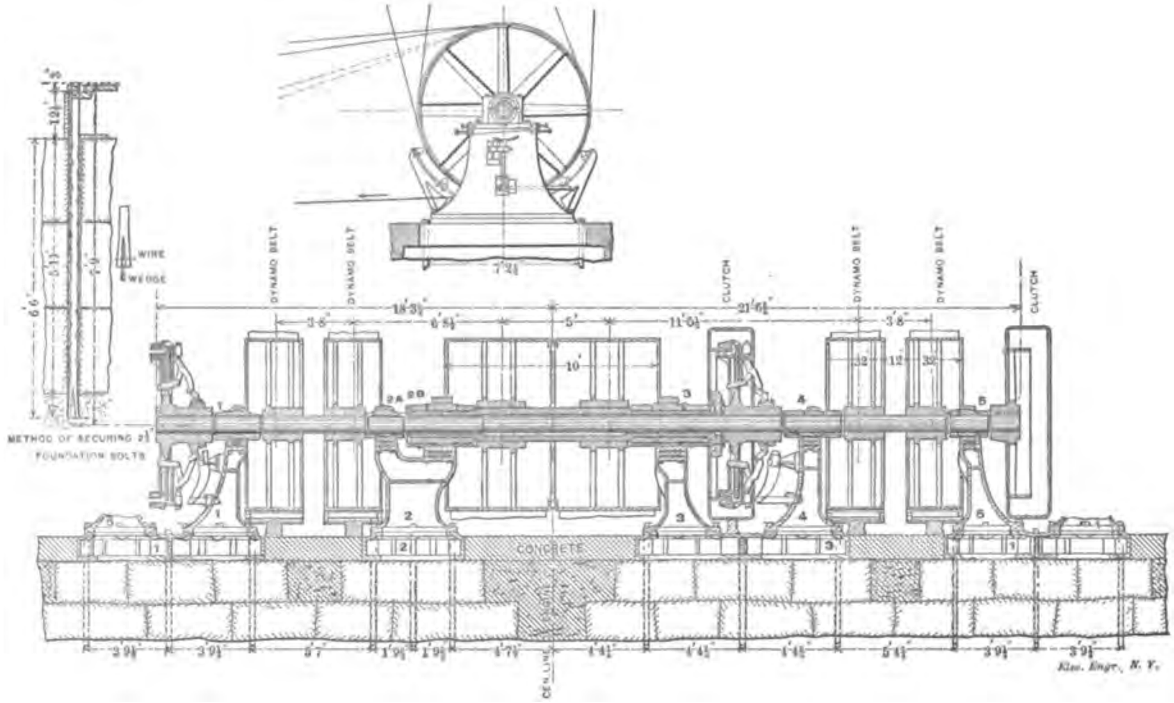

Fig. 16.—Shaft for 2,000 H. P. Engine.

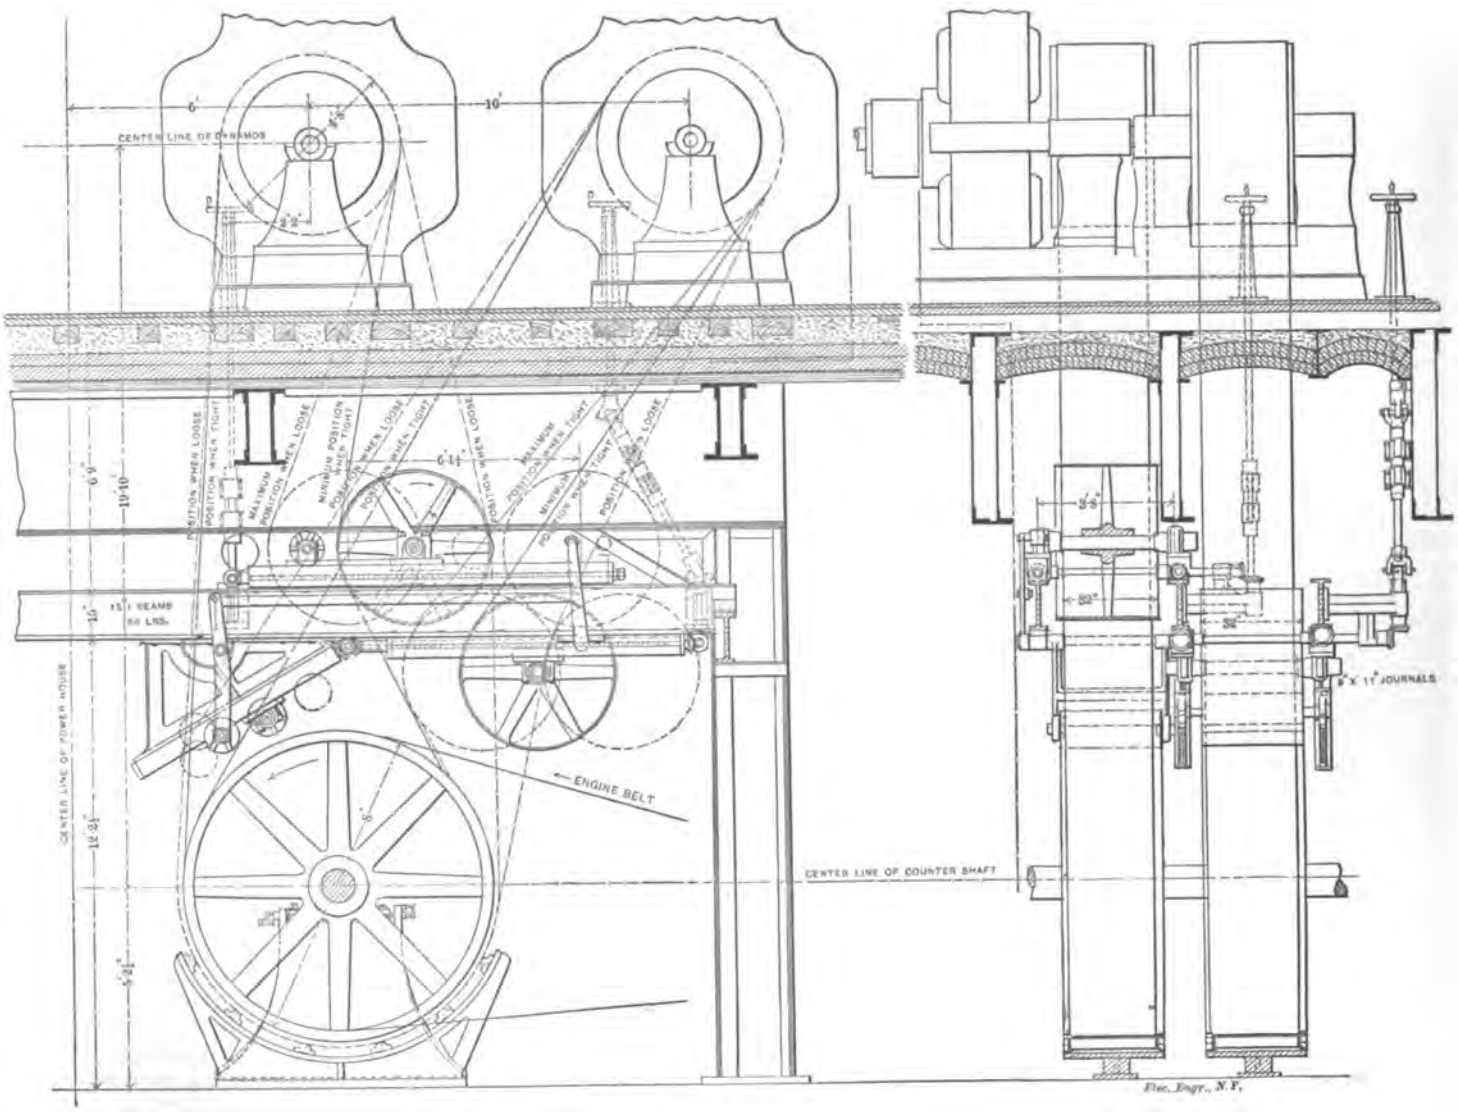

Fig. 17.—Dynamo Belt Tighteners.

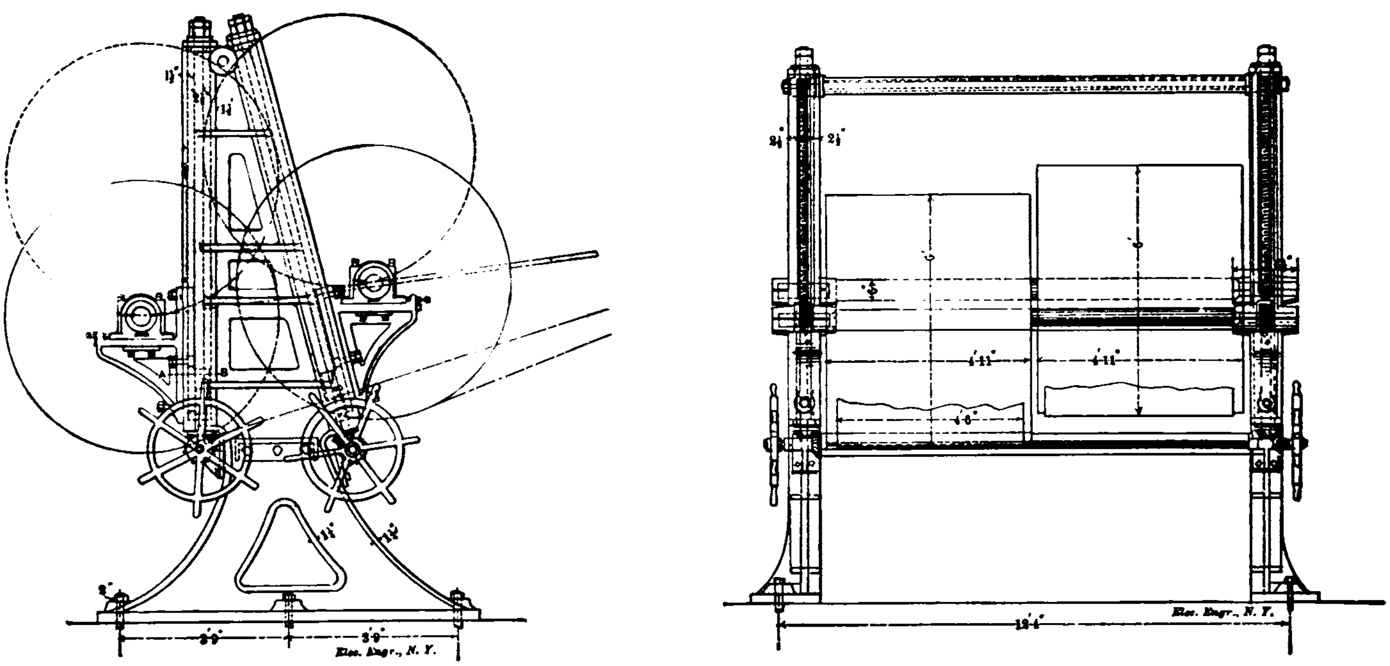
supported on a cradle, shown in the figure and also in Fig. 17 carrying rollers beneath each pulley, so that any dynamo can be stopped while the engine is still running. The mechanism for releasing the belts is shown in Fig. 17, which shows the dynamo belt tighteners, and is operated by wheel-stands on the dynamo floor. The tightening pulley moves horizontally, and the frame is supported on horizontal beams. These pulleys are moved by means of a screw passing through the box on which the pulley is mounted, which screw is operated by bevel gears from the vertical shaft leading from the hand wheels on the dynamo floor above. The counter-shafting pulleys and belt-tighteners, including the main engine belt-tighteners, were all supplied by E. P. Allis & Co., while the clutches were manufactured by the Hill Clutch Works, of Cleveland, Ohio. The main engine belt-tighteners shown in Figs. 18 and 19 are the largest that have ever been built, and were specially designed. They are of massive design, and their location is shown in Fig. 12. Each belt tightener consists of a heavy upright cast iron frame, supporting two independent pulleys 6 feet in diameter and 5 feet face, which are situated on vertical sliding carriages, controlled by a heavy worm shaft operated in the basement by four 30 inch hand wheels.

and one span over the generator or dynamo room, supported on vertical latticed columns. Under each span is a seven-ton traveling crane, worked by hand power, for the convenient handling of any part of the machinery. These cranes, along with the whole roof construction, were supplied by the Boston Bridge Works. Under the middle span and suspended from it are the main steam pipes directly over the middle of the dynamo room and about six feet apart. Between these pipes and at a slightly lower level is an iron gallery which runs all the way through the dynamo room. At intervals opposite each engine, and above this gallery, are suspended elevated platforms, for the convenient handling of the branch steam pipe valves. Along either side of the dynamo room, above the ends of the traveling crane, are placed iron observation galleries, running the entire length of the building. All along the roof of the engine room have been placed skylights, and in addition there are a number of dormer windows, so that the dynamo room is thoroughly well provided with light. Under the floor of the dynamo room, at either side, is a feeder gallery four ft. wide by five ft. deep, for the accommodation of all the wires leading from the dynamos to the switch house, which has not yet been commenced.



FIGS. 18 AND 19.—ENGINE BELT TIGHTENER.

XI.—THE SELF-OILING SYSTEM.

Fig. 20 shows a very interesting detail of construction, consisting of a complete self-oiling system for all the machinery. Over the economizer room is loctated the distributing room for this device, containing receiving, mixing and service tanks and filters. The crude petroleum oil is received in tanks located in a basement just outside the boiler house, whence it is pumped into the distributing room, where it is refined and mixed for the various purposes for which it is to be used. In the engine house, at a very low point, are placed discharging tanks, into which the oil from the machinery after use is drained, and from which it is pumped back into the distributing room, carefully filtered, and used over again. There is a complete system of service pipes made of brass, and duplicate throughout, leading from the tanks to all parts of the machinery, and streams of oil can readily be procured at any point should any part become heated. The elevation of the tanks gives the necessary head to force the oil to any point.

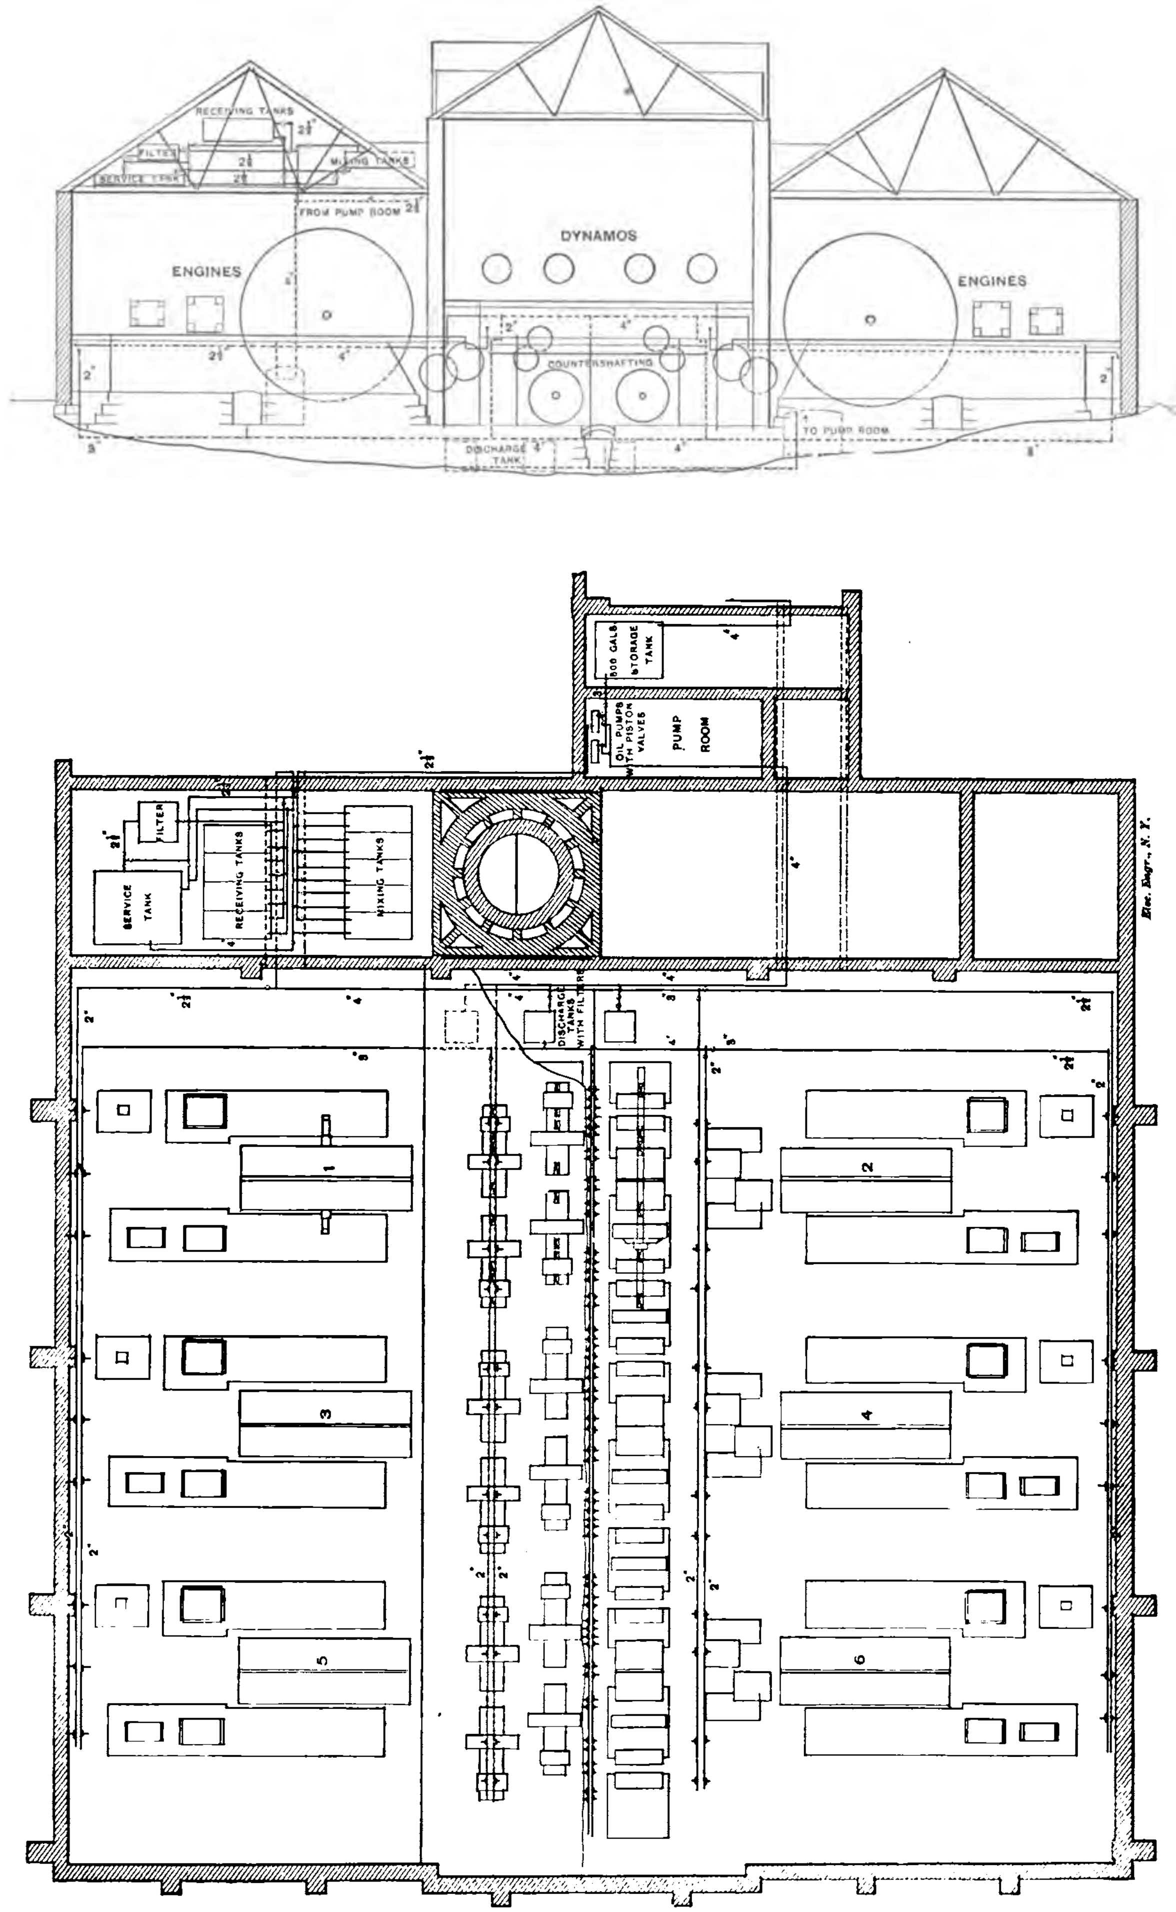
XII.—THE CRANES.

The roof of the power house is, as shown, a triple iron truss roof, one span being over each of the engine rooms,

XIII.—THE DYNAMO FLOOR.

The dynamo floor has been carefully designed, and is of unique structure, everything having been done to make it as solid as possible, and is supported on hollow iron girders and posts. These structures span the counter-shafting room, and are about seven feet apart, and rest upon the foundations already described. The posts are 6 ft. x 1 ft. cross section, and the horizontal girders 5 ft. deep by 10 inches wide. These form the tranverse girders and are all filled solid with concrete, being also braced with longitudinal girders 2 ft. by 18 inches cross section. Between the transverse girders and over the longitudinal girders were placed brick arches 8 inches in depth, the whole upper surface being then covered over with 18 in. of concrete, in which were embedded the spiking pieces for the finished flooring, which consisted of two inch planking and one inch hardwood boarding. So massive and solid is the whole structure that it is believed that there will be absolutely no vibration. The dynamo room floor measures at present 55 feet wide by 147 feet long, though when completed it will be considerably over 300 feet long.

The generators are arranged in four parallel rows running the whole length of the floor, four dynamos being



Elec. Engr., N. Y.

FIG. 20.—GENERAL SYSTEM OF OIL DISTRIBUTION.

driven from each engine. These generators will sit right on the floor, and are not intended to be moved from their position after alignment, the adjustment of the belts being made by the belt tighteners. They measure approximately nine feet high, eight feet wide, are 16 feet long and weigh each about 35 tons.

Figs. 12 and 13 show the general arrangement of the generators on the floor, and they are each driven by means of a 30 inch belt from the counter-shafting below. Fig. 21 shows the general design of the generator, which possesses apart from its electrical properties many interesting and novel mechanical features. It will be seen that each generator has four bearings, and that the pulley has a self-contained double jaw clutch, which adds materially to the flexibility of the whole system. The armature shaft is provided with two bearings, and is entirely independent of the pulley shaft, but extends into the pulley passing through the pulley quill without touching it, far enough to support a clutch ring, by which the power is communicated to the armature. The pulley is 56 inches in diameter and 32 inch face, and is split on the circumference and bolted together, each half being supported on a separate quill, having one bearing each. The outer quill carries the clutch mechanism of special design with levers extending outside to a controlling hand wheel, as shown.

inches in diameter and 25 inches long, and is wound in 180 sections; the conductors of which have a capacity of 800 square mils per ampere at 600 amperes; consequently a load of 1,000 amperes could safely be carried in case of an emergency. It is mounted on a shaft 7 inches in diameter, and with the commutator weighs about 9 tons. The armature core is built up of the best quality of sheet iron 46 inches in diameter, each sheet being punched in two sections, the joints of the one layer being so arranged that they do not come opposite the joints of the next layer. The depth of the ring is about 8 inches, and the whole core is carried on two spiders of gun metal, each spider having six arms which are carefully forced on to the shaft by immense pressure and then keyed. The insulation of the armature from the core has received special attention, and is made to withstand a test of 3,000 volts alternating. The commutator is 24⅝ inches in diameter, with a brush surface of 15 inches, and when completed will weigh about 1,900 pounds. The sections, of which there are 180, are made of hard drawn copper, separated by the usual mica insulation, the copper bars having a depth of about 3 inches. These bars alone weigh in the neighborhood of about 1,000 pounds. The shell on which the commutator is built and the caps which hold the sections in position, are made of gun metal. The manner

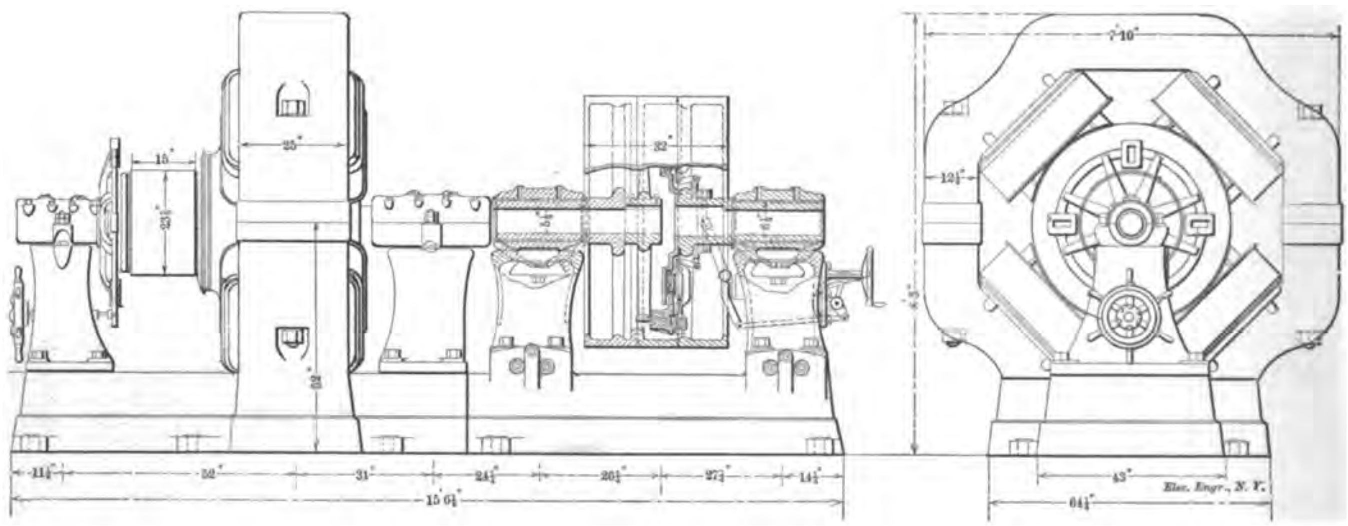


FIG. 21.—THOMSON-HOUSTON MULTIPOLAR DYNAMO IN WEST END STATION.

The pulley of the generator can thus be run independently of the armature, and the generator cannot be started up, even though the engine and counter-shafting are running, without throwing in gear this clutch. It will thus be seen that a perfect control of each and every generator is attained, and any generator can instantaneously be stopped from the generator floor without waiting for engine or counter-shaft or generator pulley to stop. The stands which support the pulley-shaft bearings have a wedge adjustment for purposes of alignment, and all four boxes are also capable of adjustment, being of the ball-and-socket pattern.

XIV.—THE GENERATORS.

HAVING thus described the general mechanical construction of the generator, a few words regarding its electrical construction will be found interesting. The generator is of the Thomson-Houston multipolar type, known as the M. P. 360, having 4 poles, with a maximum capacity of 600 amperes at 600 volts, or equal to 360,000 watts when running at its normal speed of 400 revolutions per minute. Each generator, therefore, reckoned in mechanical units, is capable of giving out about 500 h. p., four of them being therefore a full load for each of the 2,000 h. p. engines. The armature is of the Gramme type, about 48

of connecting the conductors of the armature to the commutator is precisely the same as in other Thomson-Houston generators. In order to meet all the varying conditions of load, specially incidental to electric railway work, each generator has been made with compound winding, the series winding being so arranged that the amount of over compounding can be varied to give different arrangements of compounding for various loads. The field winding is on spools, easily removable, as is usual in this type of machine, built up of special insulation, the field magnets having to stand the same crucial test as the armature. Each generator is built to stand a continuous run of 24 hours with the maximum load, the temperature at the end of the run to be within specified limits. The current is to be taken from the commutator by four sets of carbon brushes, each set consisting of five double carbons. The yoke carrying the brushes is arranged so that they can be moved by means of a spur wheel and gear, as shown in the figure. These generators are not as yet completed, but are well forward in course of construction. The station at present is being equipped with "M. P. 80" generators, each having a capacity of 80,000 watts, 12 of these generators being driven by each engine. As there are only four driving pulleys on each section of counter-shaft, two of these generators have been connected end to end through a common pulley. This pulley is made in halves, one-half being keyed to the shaft of each generator, and the two halves then bolted together, being driven by one belt.

XV.—THE VALVE ROOM.

A station of the magnitude of the central power house, requires an immense amount of piping for feed-water purposes, and it is just as necessary to have a central distribut-

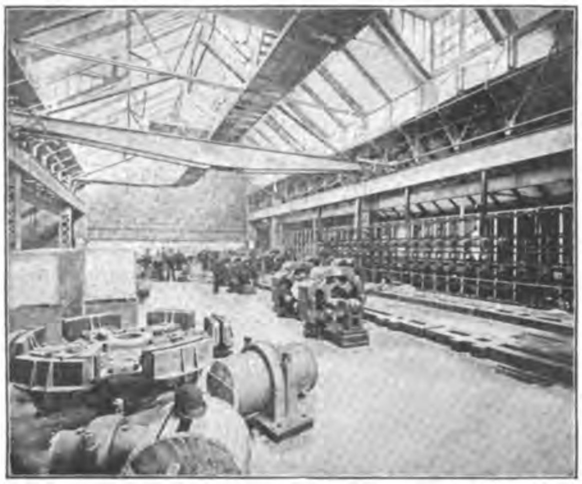

FIG. 23.—VIEW IN THE DYNAMO ROOM.

ing room for this purpose as it is to have a switch room for the distribution of the electric circuits. Accordingly a pump room, or really a valve room, has been provided for this purpose, not shown in any drawing, as it is impossible to distinctly show it to such a small scale as could be used, from which room the whole system of pumping is controlled. To this room, which is situated in the angle between the power-house and the boiler-house, lead all the feed-water pipes from the boilers, pumps, economizers, city water pipes, and also pipes from the salt, circulating water supply. Thus, any combination of effects can be produced, and water of almost any description sent to the boilers. Ordinarily the feed-water is pumped by the circulating pump direct from the hot well to this room, whence it is sent to the economizers, and then again returns to the room, and is then distributed to the boilers. Valves are so arranged, however, that the water from the hot well can be sent direct to the boilers without passing through the economizers. City water can also be used, and by a combination of valves, can be sent either to the hot well or direct to the boilers, or through the economizers to the boilers. Salt water can also be utilized in the same way in cases of extreme emergency. An auxiliary pump is also situated in this room, together with Hancock inspirators, for feeding the boilers in case of emergency, and for distributing water through the building in case of fire. In this way any possible chance of dearth of feed water is entirely overcome, and every possible emergency fairly met. Special meters and a full testing equipment are also provided in this room for carefully measuring, when testing, every pound of water fed to the boilers. Valves are also provided for this purpose, so that the water in passing through the testing instruments can be fed to the boilers in the various ways described.

All the hot-water piping in this room is of brass, as it is throughout the station, and some idea of the completeness of this system may be given when it is stated that there are over 100 Chapman valves in the room of various sizes.

XVI.—A WORD ABOUT THE BELTS.

In describing the engines, the counter-shafting and the generators mention has several times been made of the belts, but these are of such exceptionally large dimensions, and involve such an enormous amount of belting, that a few further particulars will be found quite interesting. Much attention has already been attracted by these belts, owing to their magnitude, and the important part they play in the transmission of the power. Our cut, Fig. 22, represents the belting used for the first three of the large engines and their accompanying generators, as packed ready for delivery. The belting was all built by Mr. Charles L. Ireson, of 97 High street, Boston, who now has the honor of having made the largest amount of leather belting in one order ever given out in this country. The large belts are each 54 inches wide and about 150 feet long, there being two of these belts to each engine, making a total of 1,800 feet of 54-inch belting for the present capacity of the station. Their approximate breaking strain is 64,800 pounds. They are made exclusively from the centres of extra heavy hides of pure oak-tanned leather, carefully selected and double throughout. On the side next the pulley it is made of two 27-inch widths, and on the outside there is one 20-inch width in the middle and a 17-inch width on each side. The centre of five hides is thus required for one width of belt, and it took 165 hides for each belt, or 1,980 hides for the twelve belts, weighing 79,200 pounds of leather. Two belts being used on each pulley, the width of belt surface on the pulley is therefore 108 inches, supposed to be the largest belt surface ever used on a single fly-wheel, and is wider by 34 inches than anything known in this country. The belts for the generators, numbering 24, are 30 inches in width, and are made of the same high quality of stock. These will consume 625 hides, or 27,000 pounds of leather, making a grand total for the six engines and 24 generators of 2,600 hides,

FIG. 22.—IRESON BELTING FOR THE WEST END RAILWAY CO.

or 104,200 pounds of leather. Each pair of the large belts will transmit 2,000 horse-power at a speed of 6,000 feet per minute. All the belts are endless, made of very carefully-selected stock and of the heaviest leather, and are cemented only, there being neither pegs nor rivets nor sewing.

XVII.—HANDLING THE CURRENT.

Though the electric equipment of the station is not yet very far advanced, it is interesting to note the arrangements that will be made for handling so great a volume of current with safety and precision. Adjoining the economizers already described, will be situated two rooms, the switch or controlling-room on top, and, directly underneath, the feeder-room. These rooms are both the same size, 26 x 28 feet. The wires from the generators will be carried in the feeder galleries, already mentioned, and brought up through the feeder-room on the walls (the floors of this room and the switch-room being a few inches away from the walls) up to the switch-room. In this room, ranged all around the four walls, will be the governing instruments for controlling and regulating the generators. These will comprise voltmeters, ammeters or current indicators, automatic circuit-breakers, polarity indicators, lightning arresters and make and break switches. These instruments are all of special design and are being made specially for this work, many of them embodying entirely new principles, and everything will be done to have this room as complete as the present state of the art admits.

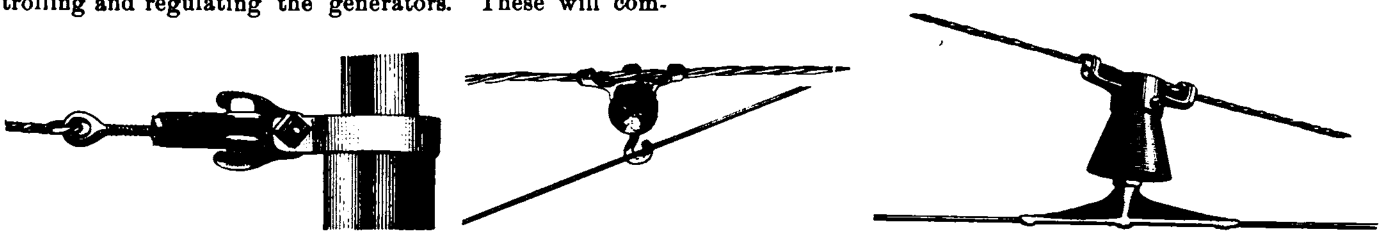
The control of the generators will thus be entirely away from the generator-room, similar in many respects to the controlling-room in large railway depots.

From this room the wires will all pass down again to the feeder-room, where they are all subdivided into the different feeder circuits, each feeder being provided with a switch, current indicator and lightning arrester. From here it is the intention of the company to run the feeders into underground conduits, which will reach to various centres all over the city. At present the feeders are carried on poles. As shown in our photographic view of the dynamo-room, Fig. 23, there has been erected a temporary switchboard, 50 feet long by 12 feet high, merely for the control of the generators now being used, the main bus wires of this board being connected with the main bus wires in the adjoining temporary station, and distributed from two feeder boards in that station to the various feeders already existing. It is worthy of notice that all the inside wiring above described has been done with Okonite wire furnished by the Pettingell-Andrews Company, of Boston.

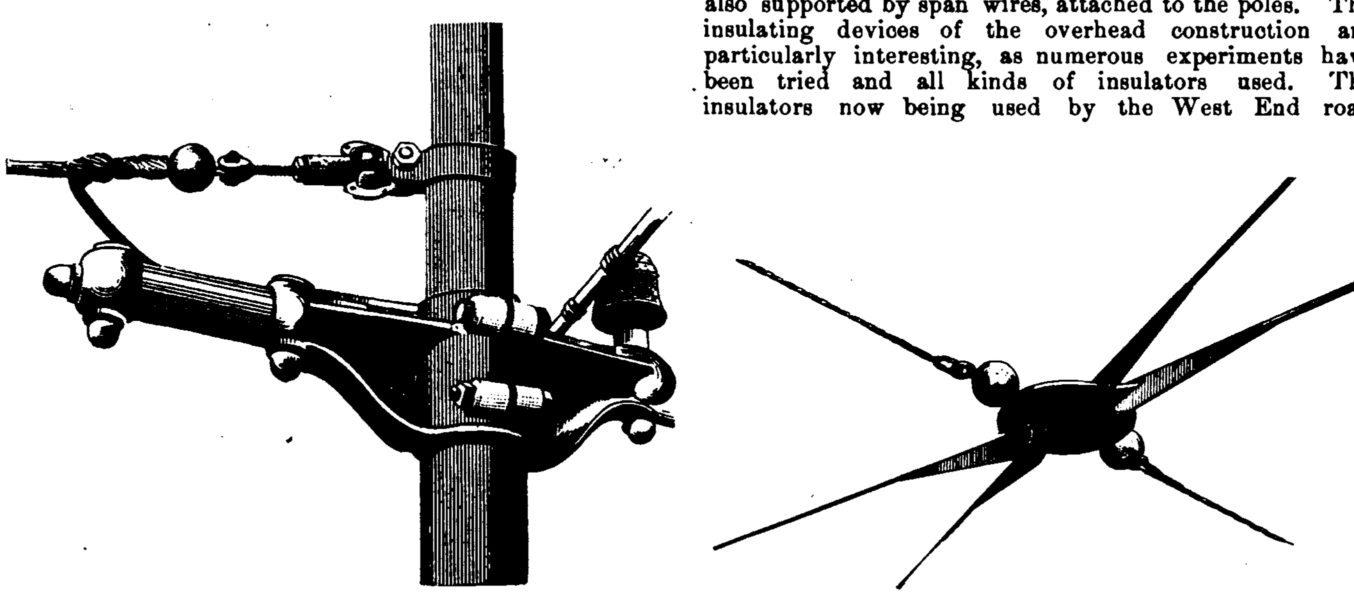
XVIII.—DETAILS OF LINE CONSTRUCTION.

While not strictly within the province of this article, the outside construction for the complete equipment of an electric railway system forms so important a feature that it is expedient to give some idea of the details, together with a few particulars of the track and the cars. At present there are about thirty-five feeders, varying in size from 200,000 to 500,000 circular mils, and amounting in all to about 180 miles of circuit. Some of these feeders run without being tapped direct to centres of distribution, frequently located in the car stations, from which the sub-feeders can be controlled. Other feeders are tapped all the way along, making connection with the trolley wire at frequent intervals.

The poles for supporting the span wires and also the feeders are all of the Walworth type, manufactured by the Walworth Manufacturing Company, of Boston. These poles support the span wire, consisting of three No. 9 twisted iron wires, insulated from the pole and insulated from the trolley wire, which is of No. 1 B & S hard drawn copper, over which are stretched iron guard wires, also supported by span wires, attached to the poles. The insulating devices of the overhead construction are particularly interesting, as numerous experiments have been tried and all kinds of insulators used. The insulators now being used by the West End road almost exclusively are made of moulded mica, manufactured by the Gould and Watson Company, of Boston, who were the first to develop the field of combining metal with insulation for such devices. A few of the most important devices are shown in the accompanying cuts, taken from actual photographs of the construction on the road, and for which I am indebted to Mr. Lee, of The Gould and Watson Company. Fig. 24 represents the Brooklyn strain insulator in position for insulating the span wire, and at the same time for tightening it up easily without much manipulation. Fig. 25 shows a similar device where the



FIGS. 24, 26 AND 27.—DETAILS OF WEST END LINE CONSTRUCTION



FIGS 25 AND 28.—DETAILS OF WEST END LINE CONSTRUCTION.

side feeder itself acts as the span wire, requiring the insertion of the extra Globe insulator for double insulation. This cut also shows a Walworth bracket for carrying the feeder, to which the side feeder is attached. Fig. 26 shows the regular and latest type of trolley insulator, with a metal sheathing or covering, enabling the insulation to be totally independent of the weather. Fig. 27 shows a guard wire insulator, an extra precaution in case of electric light or other wires falling on them. These spherical insulators consist of brass rings strung through one another, being cast in this way and surrounded with, and separated by, insulation. These globes are also occasionally inserted in the guard wires, so that should any portion of a guard wire come in contact with a line wire, the current cannot travel very far. Fig. 28 shows a switch suspended by insulating globes, the switch being in contact with the trolley wire.

A view of the general construction of the overhead system is given in Fig. 29, showing Tremont street, looking from the Park Street Church. The Ætna insulators, 35 feet over all, and all the new cars are long ones. These long cars may be divided into two distinct types, the eight-wheel cars and the six-wheel Robinson radial cars. The eight-wheel cars, of the most recent type, are the design of Mr. Louis Pfingst, master mechanic of the road, and the trucks are built by the well-known Bemis Car Box Company, of Springfield, Mass., and embody all the latest improvments. One or two other trucks are also used, one being made by the Tripp Manufacturing Company, of Boston, and one by the Taunton Locomotive Works, of Taunton, Mass. These cars measure 25 feet long over the body, and 35 feet over the dashboards; are 7 ft. 6 in. wide, with a height of 8 ft. 6 in inside, and have a comfortable seating capacity for 34. The interior of the cars is finished in cherry, with three-ply oak-veneered ceilings, stained antique. Bronze trimmings are used throughout, handsomely polished and lacquered, and in addition to single lights distributed through the car, have a Smith combination electric and kerosene lamp in the centre. The trucks

FIG. 29.—OVERHEAD CONSTRUCTION ON TREMONT STREET.

manufactured by A. & J. M. Anderson, of Boston, are also used by the West End road, and have given good satisfaction.

The track construction has been made very solid, and is designed for smooth riding and good wearing qualities. The rails are all of the girder type, set on chairs or stringers, and weigh 75 pounds to the yard, and there are at present over 100 miles of double track equipped electrically. Between each track in the earth is a No. 1 B & S soft-tinned bare copper wire, connected to each rail on either side by a No. 4 B & S copper wire, soldered to the main wire and riveted to the rail. Where the traffic is very heavy there are three No. 1 wires between each track, the ground return not being depended upon to any extent.

XIX.—THE CARS ON THE ROAD.

At present there are 300 electric cars actually equipped, and there are 250 in course of construction, all of which will doubtless be in service within the next few months. The ordinary short 16-foot cars are rapidly being replaced, probably more than half of the present equipment being long cars, averaging 25 feet inside measurement, and of the Bemis swivel type have 14 ft. centres, and the wheel base of each truck is 5 ft. 2 in. Each truck is fitted with a swinging bolster beam, to take up the lateral motion of the car. After a thorough and careful investigation of the best method of applying the motors, the system adopted now is to apply the propelling power, consisting of two 15 h. p. motors, to one truck only, the other truck being idle. The Robinson radial car, Fig. 30, of which there are about 50 on the West End road, and of which we present a cut, has also given remarkably good satisfaction, and is built by the Robinson Electric Truck and Supply Company, of Boston. These cars are 36 ft. 4 in. over all, 28 ft. length of body, 15 ft. wheel base, and have a seating capacity of from 42 to 44. They are all fitted with Robinson's standard electric radial steel trucks, the axles of which become radial to any curve which they may be on, and pass around curves with ease and smoothness. In the case of the Robinson car, one 15 h. p. motor is attached to each of the end axles, the middle axle being idle, and helping simply to guide the other axles, and support a small part of the weight. These cars also are of elegant design, and are beautifully finished both outside and inside.

XX.—THE CAR MOTORS.

The motors of all the cars are of the Thomson-Houston type, and have given wonderful results, working now every day with perfect uniformity and giving a minimum of trouble. At first all the cars were equipped with the "F 30" type, having the ordinary double reduction gear, but now the "S. R. G.," or single reduction motor is rapidly taking their place, and giving better satisfaction. This motor has a Gramme armature, and as it does not require to run at so high a speed, and has only one set of gearing, it is much more quiet and is also much more efficient. As has been said, each car is equipped with two motors, and each motor has a reversing switch, so that each armature acts upon its own field, thereby maintaining an even distribution of power between the two motors. In the nature of things it is not unlikely that even greater improvements will yet be

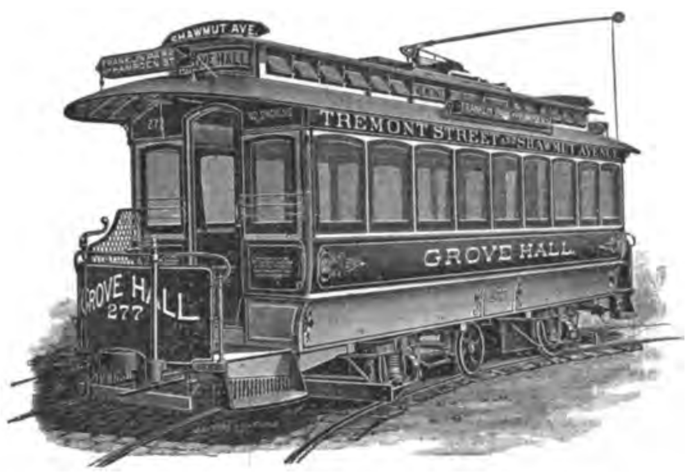


FIG. 30.—ROBINSON RADIAL CAR.

made in the motive power, continuous experiments in this direction being vigorously carried on by an efficient corps in search of further knowledge.

XXI.—PERSONAL.

By way of conclusion a word is due to the men who have put into execution this great work, and have carried out all the details of the enterprise. First and foremost, of course, is Mr. Henry M. Whitney, the leading spirit of the whole undertaking. He was born in Conway, Franklin county, Mass., in 1841, on October 22, exactly 40 years ago. The public schools furnished him with his early educational training, supplemented by one year at Easthampton Seminary.

His entrance upon a business career was as a clerk in the Conway Bank, where he remained three years. He then went to the Bank of Mutual Redemption, Boston; was afterwards clerk in the navy agent's office for one year (1860), and was then engaged in New York City in the shipping business.

In 1866 he became Boston agent, and in 1879 president, of the Metropolitan Steamship Co., Boston, which position he still holds. In 1887 he was elected president of the West End Street Railway Co., the largest street railway in the world, and a corporation controlling all the street car lines now running in the city of Boston. He is also president of the Hancock Inspirator Co. Mr. Whitney has brought to the presidency of the West End Street Railway thorough business experience, financial integrity and inventive genius. Before him and his associates lies the task of solving the problem of rapid transit in the city of Boston. The movements so far made toward bringing order out of chaos have been eminently successful.

While Mr. H. M. Whitney, the general manager of the West End Company, has been the prime mover in equipping Boston so thoroughly with electric street railroads, the details of the station and the outside construction have been admirably designed and carried out by Mr. F. S. Pearson, the chief engineer, Mr. L. J. Hirt, his assistant in the mechanical department, and Mr. L. S. Dumoulin, in the electrical department, who, by their united efforts, have produced a system of electric railways, with the adequate power houses, which leads the civilized world to-day. Mr. F. S. Pearson was born in 1861, and graduated at Tufft's College as a chemist and mining engineer, afterwards graduating in 1883 in the course of civil engineering. He also pursued the studies of electrical and mechanical engineering and graduated in these branches later.

F. S. Pearson.

Mr. Pearson was employed in Virginia, Texas, and South America as a mining engineer, and was later employed as an instructor in chemistry at the Boston Institute of Technology in 1879-80. Afterwards he became instructor in mechanical engineering and higher mathematics at Tufft's College, which position he held for three years. About that time also he formed business connections, becoming general manager of the Somerville Electric Light Company and treasurer of the Somerville and Woburn Electric Light Companies. He was also the treasurer and manager of the Halifax Illuminating Company, of Halifax, N. S., and formed the company of Grant, Pearson & Company, doing a general engineering business in New England. Mr. Pearson joined the West End Street Railway Company in 1889, and has had ever since complete charge of the designing and erection of the station, and the necessary outside structure. Mr. Pearson, though quite a young man, has undoubtedly made his mark as an electrical engineer, and his advice is eagerly sought in designing new electric plants.

Mr. Pearson is particularly fortunate in his two assistants, Mr. L. J. Hirt and Mr. L. S. Dumoulin, who have done magnificent work in their departments, Mr. Hirt assisting in the general mechanical department, and Mr. Dumoulin looking after the electrical department. Mr. Hirt was born in Paris, France, in 1854, and was educated at the École Professionel de Guebwiller, in Alsace, afterwards finishing as improver at Esher Weies & Company's marine shops, in Zurich. He afterwards entered the Northern Railroad shops of France, where he remained for one year, there after gaining a five years' general experience in England in various engineering capacities, after which he came to the U. S., where he has had a varied engineering experience for the past 10 years. Two years of this time was spent as traveling mechanical engineer for the Hill Clutch Works, of Cleveland, and he has assisted in designing and erecting many of the most important electric stations in the country. Mr. Hirt has now been with the West End Company about two years, and all the drawings of the station have been gotten out under his personal supervision; and he has proved himself a valuable man and well worthy of his position.

L. J. Hirt.

Mr. L. S. Dumoulin, who has attended to the electric work, both in the station and in the outside construction, was born in Liverpool, England, in 1845, and has been connected with the electrical business all his life, having started in the Eastern Telegraph service in its early days. He was then for a number of years connected with the submarine telegraph service in different parts of the world, entering the electric light business in London about 1875. Mr. Dumoulin came to the United States in 1879, and was at first connected with the Daft Electric Company during the early stages of electric light and power development. Later he became connected with the Electro Dynamic Company, of Philadelphia, and the Accumulator Company of New York, joining the West End in October, 1889. Mr. Dumoulin has thus brought to the West End Company a vast fund of electric experience, and well has he filled his position, working night and day to accomplish his object, until to-day he has succeeded in getting the vast system of electric cars working with perfect smoothness and reliability.

L. S. Dumoulin.

XXII.—CONCLUSION.

In the foregoing pages it has been my endeavor to describe in detail each feature of the central power station, including also, in a limited measure, the outside construction. In conclusion, a few words descriptive generally of the work accomplished by the West End Company in their electric system may be found interesting. The station itself has been finished in as complete a manner as modern science could suggest. The building is provided with a complete system of drainage, a complete system of fire hose and pipe connections in case of fire, and the whole building is absolutely fire proof throughout, being wholly composed of stone, brick, concrete and iron. In addition, fire proof windows and doors have been provided, and a complete system of electrical signalling between each department. At each engine will be erected a tastefully designed oak cabinet, on which will be mounted annunciator boards connecting with the generator-room floor and the switch or controlling room. As has been already mentioned, the growth of the business has been amply provided for, and in addition to the 26,000 horse-power which is being installed in the station described above, the West End Company are erecting another large station in East Cambridge, which will have a capacity of 9,000 horse-power when completed, and 6,000 horse-power is at present being installed. The old Allston station will also be kept in service, and this is equipped with 1,120 horse-power, the power being derived from Armington & Sims engines, with Thomson-Houston and Edison generators. It is worthy of note that the complete drawings and designs for the station have been made by the West End Company, who have employed an efficient corps of engineers and draughtsmen, and no outside companies have had contracts for construction, the whole of the work being supervised by the company's engineers. When the drawings of the transmission machinery were completed they were submitted to Professor Thurston, of Cornell University, who, after a thorough examination and recalculation of all the parts, together with a thorough investigation of all the strains to which such a station may be subjected from overload, etc., or when under heaviest duty, reported that everything was well proportioned for the work. Proof has already been had that the calculations were correct, as such parts of the station as are already finished have been put into daily service without the slightest hitch. As regards the economy of the station, it is interesting to note that it has been guaranteed by the engine builders that the Corliss engines will be run on 13 pounds of steam per horse-power in the cylinders, and from their actual experience in operation it has been estimated that the plant will produce an electrical horse-power at the switchboard on considerably less than two pounds of coal, while it is confidently believed that the entire system of cars can be run at a cost not exceeding seventeen cents per car mile, and probably considerably less. One great advantage in a station equipped with large engines and counter-shafting, as in the station just described, is the capability of loading each engine to its full capacity, where it necessarily works at its full economy; the belting also gives a great flexibility to the system, enabling the generators to overcome any great shock owing to sudden overload or short circuit. Experience will doubtless show many interesting new developments, and it is safe to assert that the working of the electrical system in Boston will be carefully watched by engineers in all countries. The West End Street Railway Company have succeeded in making Boston probably the most interesting city in the United States, from the present

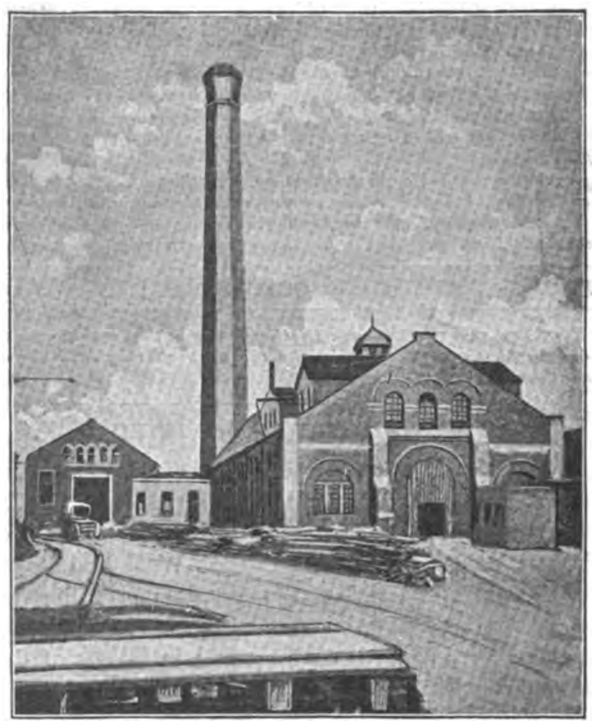

FIG. 31.—READY FOR THE WORK.

electrical point of view, and assisted materially in making it a centre, in America, of electrical science, as it has been for generations a centre of literature, culture and refinement.

A LEAD ALLOY FOR ACCUMULATOR PLATES.

The following lead alloy for accumulator plates is proposed by a M. Worms. It consists of 945 parts of lead, 22 of antimony, and 13 of mercury. The lead is melted first, and the antimony added, the mercury being introduced as the molten mass is run into the mould. The result is said to be an alloy of lead which can be easily split up into comparatively thin sheets.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XII. NEW YORK, OCTOBER 21, 1891. No. 181.

I have far more confidence in the one man who works mentally and bodily at a matter than in the six who merely talk about it. —Faraday.

ELECTRIC RAILWAY WORK IN BOSTON.

A LARGE part of the present issue of THE ELECTRICAL ENGINEER is devoted to a description by our New England editor, Mr. A. C. Shaw, of the work done in connection with the electric system of the West End Railway Co., of Boston. This article of 19 pages, copiously illustrated, is in fact the fullest account that has ever been published of an electric road, and is only equaled in fulness of detail by the article printed in our columns some months ago on the electric railway system of Buffalo.

The subject is evidently one of the utmost importance, and well deserving of the space and attention thus allotted to it. Mr. Shaw's article not only traces the history of the road, but touches upon many details of construction and operation. In some respects it recalls features in the series of New England electric light stations described recently in these pages, but electric railway work has many points of differentiation, and is therefore worthy of close study for its own sake.

We are free to confess that much as we admire the engineering skill and ability manifested in this great enterprise, our conviction has still to be formed that the best plan was adopted. There are various elements of doubt. One is as to whether the method of power transmission secures the best type of station and the highest efficiency in operation. Another is as to the best size of the units of engine and dynamo. The doubt arises in one's mind whether, if the plant had to be put in again, it would be put in upon the same plan and lines.

Yet we are very willing to accept the plant as a magnificent exemplification of the possibilities of electric railroading and of the future of the industry. This West End Road makes a memorable stage in the progress of the electric railway art, and the men who have been prominent in carrying out the work as set forth in our pages, may well be proud of their respective shares in its conception and execution.

THE CHICAGO ELECTRICAL CONGRESS OF 1893.

IT is encouraging to see that the good work begun two years ago in preparing for an electrical congress is already bearing fruit. The subject and the present situation were the theme of a very interesting address last Monday before the Chicago Electric Club by Dr. Elisha Gray, who, as was announced in our columns last week, has accepted the chairmanship of the Committee on Electrical Congress of the World's Fair authorities. With regard to the proposition, Dr. Gray said: "The movement as yet is in a formative stage, and much thought must be given to it before a detailed programme can be formulated. An advisory council must be appointed from the most eminent electricians from this and other countries. Some one, or more than one, must visit and confer with the noted men of the world, and no stone should be left unturned to make the Electrical Congress of 1893 the most important that the world has ever seen, not only in point of numbers, but in the eminent character of the men who attend, and the excellence and great importance of the work done."

This is well put, and the preliminary work cannot be undertaken too soon. Just what the Congress will be may be gathered from the following paragraph in Dr. Gray's address:

"The general outline of the Congress will probably be as follows. It should be divided into sections according to the various interests represented. First there should be a section devoted to the more purely scientific phases of the subject. This section should be composed of the most eminent scientific men in this and foreign countries. The standards that were adopted ten years ago will have had twelve years of trial by the time the Congress assembles. It may be that other units should be added to those already adopted, or that better definitions may be given to those already in use. Papers should be read by different individuals relating to the different theoretrical and scientific phases of the subject. Other sections should be organized, in the various interests of applied electricity; the number of which will be hereafter determined. In order to give all a chance to see and hear the great men of the world, all of the sections should meet together, on stated occasions, forming one grand general Congress, to listen to papers and discussions by the most eminent men of the world in electrical matters."

Dr. Gray offers the further suggestion that the various electrical bodies meet at Chicago in 1893. This will probably be done, although it is a matter to be determined whether their meetings should be held at the same time as those of the Congress. If they are, there will be apt to be too much of a good thing, but if they are not, it will be difficult to get electrical men together two or three times. The best way will probably be for the various societies to meet at the same time as the Congress, but provide very light programmes of their own. As a matter of fact, only two such bodies will really be affected, namely, the American Institute of Electrical Engineers and the National Electric Light Association; and the Congress will simply be doing the work of the former body on a larger and more comprehensive scale for the time being.

THE CENSUS OF THE ELECTRICAL INDUSTRIES.

WE have been favored with copies of the letters passing between the various departments at Washington as to the proposed census of the electrical industries. It is cheering to see that so many kind words are said in its behalf, but it is very apparent that little or nothing can be done unless the means are furnished to the Superintendent of the Census for prosecuting the scheme as laid out so carefully and ably by Mr. Allen R. Foote. All told, the electrical applications in America to-day rank probably among the first five industries, and yet we believe it is the only one for which the Government has not used its authority in order to secure definite data and information that would be of the utmost value and benefit. Every one knows that it is only the Government that can get this information, and therefore, unless the present effort is sustained and carried through, we shall have to wait another ten years, or until 1900, before anything can be done. The result will simply be serious loss, annoyance and trouble to everybody connected with electrical pursuits in America. Electrical engineers have the best reasons in the world for hoping that Congress will at least enable the Census Office to carry out this part of its programme.

LONDON'S UNDERGROUND ELECTRIC ROAD.

SOME of our New York papers have lately given up their columns to a discussion of the London electric underground road. The *Evening Post* has published several letters on the subject, the *Times* has had an admirable communication from a staff correspondent, and the New York *Sun* last Sunday devoted nearly a whole page to an illustrated description of the road and its operation. The appearance of the last-named article is the more refreshing, because the *Sun* has been systematic and even contemptuous in its method of opposition to rapid transit. The correspondent of the *Sun* is, however, compelled by the evidence of his eyes to confirm the favorable report made by the writer in the *Times*, who, if we mistake not, is the city editor, Mr. Lowenthal, that gentleman having recently returned from a trip abroad.

There is little that is new in any of these statements except the fact that they bring the inspection by keen and intelligent critics down to date. The *Sun* writer winds up by saying: "The City and South London Railway is an engineering success. Unfortunately it has not been a financial success." Yet, as he himself admits, the road was an experiment; it does not tap any of the great streams of traffic, and it was not supposed it would prove so effectual a demonstration of the possibilities. That such methods have abundant financial promise is seen in the fact that a new road, of which Mr. Lowenthal makes brief mention, is being actively pushed to traverse London directly from east to west, along a main artery of travel. That road, we predict, will be enormously successful, and it will embody many new ideas, and improvements going far to meet the few objections that have been raised.

Be that as it may, the practical success of electricity as a motive power has once more been shown. As a matter of fact, the electric power is the part of the question attracting the least attention; it "goes without saying." We have ourselves been in favor of the Greathead tunnel system not because it used electricity, but because it meets the other conditions of the problem. Even with such a near-surface system as the New York rapid transit experts have proposed, electricity will still be the motive power, but all the old difficulties of rights of way, existing franchises, etc., crop up again, and we cannot see that any advance towards the solution of the problem is secured. When we remember that only two or three months ago the objections to underground travel were made chiefly on the score of the inadequacy of electricity, and called forth a flat-footed challenge from Mr. Frank J. Sprague, one cannot but feel that in this shifting of the point of criticism, electricity has gained another victory. We are willing to stand by what Mr. Lowenthal says, and by the letter in the *Sun*, erewhile the bitter opponent of the whole thing.

THE NECESSITY OF STANDARD NOMENCLATURE.

IN the course of an able series of articles on the Frankfort Electrical Exhibition in *Industries*, Mr. James Swinburne writes as follows: "The indefiniteness of electrical nomenclature has led an important American contemporary (THE ELECTRICAL ENGINEER) to accuse us of writing about multiple currents without being acquainted with Mr. Tesla's work. We refer to the open and closed armature coupling as possibly being German modifications; in fact, we believe the interlinked coupling has been claimed as an important advance. We take it that our contemporary thinks that when referring to closed circuits we wrote of the ordinary short-circuited Tesla machine as a German modification. We need hardly assure our readers that we have studied the ordinary Tesla motor, and would scarcely venture to write on multiple currents without some acquaintance with both American and Continental practice, as well as information from experiments of our own."

In conclusion, Mr. Swinburne says: "We also fail to see that the triple-current is any real advance beyond the double-current machine, to whose development Mr. Tesla has devoted so much energy. Mr. Tesla in America and Messrs. Hutin and Leblanc in France are making progress in the direction of splitting a single into a double current by means of self-induction, capacity, and resistance suitably arranged. The solution of the problem of small motors may lie in this direction, but we do not think it lies in multiple-current motors, which do not fit the present systems of lighting.

"In mines, especially in dangerous mines, where it is most important that there should be no sparks, and where simplicity is demanded, the multiple current will probably come into general use; but at present it does not even promise a solution of the problem of alternating motors on supply circuits. What is asked for is a small motor to suit existing alternating circuits; what is offered is a motor which demands a new and complicated system of supply to operate it."

What Mr. Swinburne suggests as to the necessity of standard nomenclature is true. Not less true are his remarks relative to Mr. Tesla's priority in this field of work. Our recent narration of the facts in connection with this line of electrical application, showing Mr. Tesla's record in the matter, still stands; and the only inference can be that we ascribed to him no more than is fairly his.

ELECTRICAL WELDING AT THE PASSAIC WORKS OF THE INTERNATIONAL OKONITE CO.

The enormous advantages posessed by automatic welding machines over the old method of hand splicing are nowhere perhaps more clearly shown than at the works of the International Okonite Co. (Limited), at Passaic, N. J. Since the installment of the first Thomson welding plant in this factory the hand process has been entirely abandoned, and a visit to the works now shows an enlarged welding plant working continually, and giving the most complete satisfaction.

The generator is a self-exciting, constant potential alternator, of a capacity of 30,000 watts, belted direct to a Ball automatic engine, provided with extra heavy or "railroad" fly-wheels in order to maintain constant speed during the sudden demands on the generator. The welders used are what is known as type "1 A." for iron armoring or sheathing wires; two of type "2 A. A." for copper from No. 6 A. W. G. to No. 20 A. W. G.; two of type "10 A. A." for copper from half inch to No. 6 A. W. G.

In the accompanying illustrations, Fig. 1 shows two welders, one of large size, and one small bench machine, while Fig. 2 is a large welder in use in the armoring department.

After the wires are prepared for the weld, *i. e.* clamped and given the proper projection, the time of application of the current is but a small fraction of a second for all of the smaller sizes, such as telephone and telegraph wires, and the heat necessary to form a perfect union is all concentrated at the tip ends of the abutted pieces. Advantage is taken of this fact in welding wire, already insulated, into continous lengths, it being only necessary to remove the insulation far enough for the clamping process. The average daily output of copper, including all sizes, is about five tons, averaging about 200 welds.

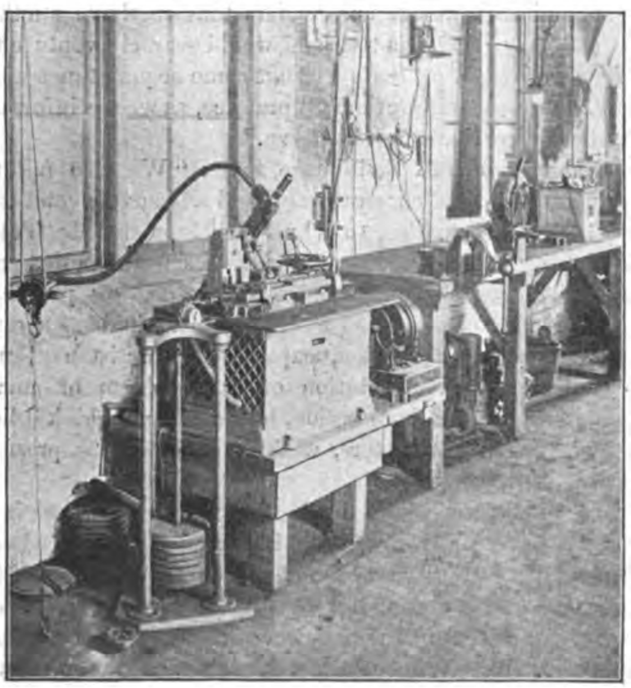

FIG. 1.—ELECTRIC WELDING AT THE OKONITE FACTORY.

The present plant is now running at almost full capacity, as the welders are situated in different parts of the factory, and welds are frequently made simultaneously on all welders, making very heavy and sudden demands upon the generator. The large 3,000 watt transformer in the testing department is continously operated by the small generator, taking 300 volts and ten amperes for the primary, and giving a maximum of 20,000 volts in the secondary.

If electric welding as done at the Okonite factory is to be taken as any criterion, it is a most assured success. At first glance it looks like the simple application of a current to obtain required results. Such is not the case, however, as different wires require different projections, of and pressures upon, abutted pieces, and different current strengths, and the current must be interrupted at the proper moment. To apply proper conditions to every wire in making a weld, however, requires no extra skill on the part of the manipulator. In the case of end pressure on the abutted pieces, he simply applies the number of weights given in a table which has been previously worked out, and varies the current strength for each wire by simply moving the shield on the reactive coil placed near the welder.

FIG. 2.—ELECTRIC WELDING AT THE OKONITE FACTORY.

THE NEW A. B. & B. RESISTANCE METAL.

The Aluminum Brass and Bronze Company, at Bridgeport, announce a new resistance metal in wire, sheet or castings, which seems to be a very important contribution to this class of material in electrical engineering. The wire samples we have seen resemble ordinary copper wire on the outside, and have a pinkish white tinge at the surface of fracture. The wire is very strong, without losing much ductility. The torsion test shows over eighty twists in six inches for an annealed wire, which still possesses 70,000 lbs. tensile strength to the square inch. The hard drawn wire runs to 100,000 lbs. tensile strength, with about forty twists in six inches. Combined with these admirable mechanical qualities, the wire has the remarkable resistance of thirty-five times that of copper with a temperature co-efficient of less than one-tenth of that of German silver; furthermore, the wire is cheap. We understand that, by having the resistance lower than in the samples described above, the tensile strength can be increased up to 140,000 lbs. per square inch. These particulars relate to wires .080 inch diameter and thereabouts.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

"I am here" is the Duke's motto; also the Advertiser's.

NEW SOMOFF INCANDESCENT LAMPS.

Fig. 1.

NEW applications of miniature electric lights spring up almost daily where they were the least expected to appear. As an example of this, Mr. J. L. Somoff, of No. 1 Ann street, who is now devoting his entire time to the manufacture of miniature incandescent electric lamps, mentions a number of city residences lit by "pea" lamps connected in multiple wires on a 110-volt circuit. The "peas" are enclosed in miniature colored Japanese lanterns, hung about a dozen in each room.

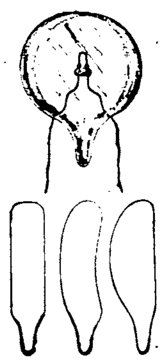

Fig. 2.

Some other residences use low candle-power lamps, having the appearance of the ordinary 16 c. p. lamps and connected as before mentioned.

Fig. 1 presents one of these low candle power lamps. The base is silver plated and fits either Edison or Westinghouse sockets. One side of the globe, if desired, is silver plated and acts as the most beautiful reflector.

Fig. 2 is a lamp much in favor with surgeons. As its name, "tongue-depressor lamp," implies, it is employed in connection with an instrument in common use with the medical profession.

The utility of such a lamp is obvious, since it can conveniently be mounted upon the upper side of the tongue depressor to supply the needful light.

The lower part of Fig. 2 presents three sectional views of the globe. It is flat, with sides either paralleled, plano-convex, or concavo-convex; and the curvature of the sides, one of which is silvered or platinized, serves the better to concentrate the light upon the required part of the mouth.

Fig 3.

Fig. 3 is a more substantial combination of a lamp with a tongue depressor, where the latter serves also as a switch to make and break the current. All metal parts of the instrument are plated with platinum to insure cleanliness and prevent corrosion.

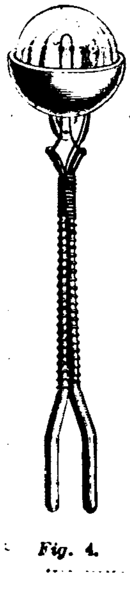

Fig. 4.

Fig. 4 is a "tulip" lamp without the "tip;" the air being exhausted from the lower end of the globe. The lower half of it is encased in a platinum reflector, and the ends of the two copper rods, upon which the lamp is mounted, are made to fit the handles of electro-cauterizing knives now in almost universal use.

THE D. M. STEWARD MANUFACTURING CO., of Chattanooga, Tenn., report that orders for lava insulators are greatly in excess of the business they have enjoyed at any time since they have been in business. Their request "write for samples" brings replies in almost every mail, and postage on samples has become quite an item.

LONG BRILL CARS FOR ELECTRIC ROADS.

A GROWING tendency to the use of longer cars, where the motor power is other than animal power, has developed the fact that but very little can be added to the length of a car of the ordinary type without considerable sacrifice of the time taken to load and unload passengers, and an increased difficulty in collecting fares on long cars having a platform at each end. The adoption of electricity and cable as motive powers, and the consequently quicker transit, has increased in a wonderful degree the number of passengers carried, and the railroad companies naturally seek to add to their carrying capacity in the most economical manner. To increase the seating capacity in a car without adding to the length on the street of the present horse car, and to attend to the passengers and to collect the fares by the employment of one man as conductors are the two directions by which this economy is reached. In a new car just completed for the Lindell Railway Co., of St. Lous, by J. G. Brill Co., the economical features above referred to are accomplished. This car is the invention of John A. Brill, vice-president of the J. G. Brill Co., and the novel features embraced in it are covered by three patents. The most evident novelty is that the car has no end platforms, but has a vestibule or platform enclosed on three sides near the centre of the car, which is open only on one side of the car and connects the two compartments by doorways. The front platform of an ordinary car has no use except for the motorman, carrying no passengers, and in this car the whole of one platform with its unnecessary length and weight is dispensed with.

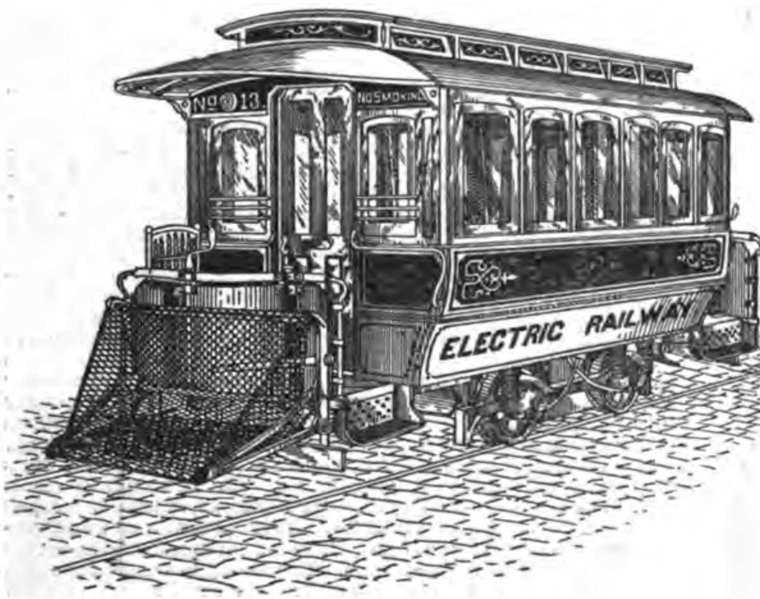
The car is divided into two compartments separate from each other; the forward compartment is for the usual mixed passengers, and the rear compartment is intended primarily for the use of smokers, the larger being 17½ ft. long, and the smaller 10½ ft. long. The seats in this car are placed transversely, with capacity for two persons on a seat, on each side of the aisle, and there is a seat on the closed side of the vestibule for three persons. At one end of the single step there is a convenient space guarded by a stout handrail of polished brass for the conductor to stand in, from which point he has complete control of the car, and can easily reach passengers who require his assistance in getting on or off the car. The seats in the car can be arranged if preferred in the usual manner of street cars, that is, longitudinally on the sides. The total seating capacity of the car is 46 persons. With this arrangement of the entrance near the middle of the car it is evident that the passengers will not require so long a time to get to or from their seats as they would in case where the entrance is placed at one end, and with the same reasoning the conductor can reach both ends of the car for collecting the fares with greater facility, and having the advantage, one man can collect all the fares and attend to all the passengers. An ordinary horse car is 23 ft. long, and with the horses attached occupies 35 feet in the street, seats 22 persons and requires one conductor. The new style of car is only 31 ft. 6 in. extreme length, seats 46 persons, and can be worked with equal ease by one conductor. As it carries as many passengers as two ordinary horse cars, there is a saving of one conductor for a given number of passengers. The saving in wages alone on a line using 100 cars is from $200 to $250 per diem, representing an annual saving of over $70,000, an amount sufficient alone to pay a dividend greatly in excess of the average dividend on street railroads. In cities with crowded streets, like New York, Philadelphia, Chicago, the saving of one-half the street space of cars is an item of enormous advantage. And this car is only 7½ ft. longer than the adopted size of motor cars with vestibuled ends, which seats only 22 persons. The motorman stands in a place four feet long and two and one-quarter feet wide, well sheltered, but with complete view of the track. This space is partitioned off with mahogany panels and plate glass sash, by which he is freed from all crowding and interference by passengers. Another important advantage which this long car has over a train of motor car and "trailer" is the superior control in stopping the car, which in the train cannot be made to act as promptly as desired unless by use of the automatic brake, which is effective, but costs $300.

The Lindell Railway Co. with its characterized generosity and desire to give its patrons the very best that can be had, has ordered this car to be finished in the most elegant manner, with solid mahogany, polished plate glass, embroidered linen shades, polished brass mountings, and seats where a passenger will not have to struggle for the 17 inches usually allowed to him. The successful working of this long car with electric motors is dependent, however, on the use of Brill's patented maximum traction trucks, on which more than 90 per cent. of the traction is upon the two pair of driving wheels of the trucks; and the peculiar form of the truck entering the bottom frame of the car body sets the car so low that it required only a single step of the usual height at the entrance. The use of this style of truck on the Newark Passenger Railway has made a great success of the operating of long cars at a time when the company was on the point of abandoning their use as being a failure, by reason of the deficient traction and excessive height of the car body, which caused two steps to be necessary.

THE APPLEYARD FENDER FOR ELECTRIC CARS.

EVER since the introduction of electric and cable cars there has been a growing feeling that there should be a guard on the front of the cars to protect people who happen to be in the way. There have been a number of accidents to life and limb, which, though unavoidable, would have been free from serious injury had there been some kind of protection on the front of the car. Acts have been passed to enforce the use of fenders and guards, and the board of railroad commissioners have at times required an arrangement of some kind which would render it impossible for a street car to pass over a body lying in the way of a car or knocked down by a car. We take pleasure, therefore, in illustrating in the accompanying engraving the Appleyard patent safety fender, which appears to fill all the requirements. The fender is at the front of the car and projects forward from the platform about four feet, with its lower edge about nine inches from the track, and is adapted to receive and hold the body of an individual or animal that may be caught upon the track and carry it along without injury.

To guard against the possibility of injury to a person falling into the receptacle by breakage of the rope net or by its sagging, a second or wire netting is attached to the lower portion of the frame. It will be seen that the front portion of the fender is located so near the road-bed or track that in striking a person it will inevitably cause the person to fall into the soft rope net and not suffer injury. As an additional means of safety a scoop is placed beneath the body of the car, so that, should a person fall in the act of crossing the tracks, he would pass under the first fender and on going under the car he would strike a lever, which would release a powerful spring and cause the scoop to come down and catch whatever obstacle might be in the way. The scoop is made to travel on the road-bed when down, so that it would be impossible for one to come in contact with the wheels.



APPLEYARD STREET CAR FENDER.

When not in use the fender can be folded up close to the dashboard, so that at the end of a route, when it is not required, it is not necessary to change the apparatus, but simply to fold up the one fender and let down the other ready for action.

This fender has already met with the approval of several street railroads and is being introduced by the Chester Manufacturing Company, whose address is 625 Exchange Building, Boston.

THE MINNEAPOLIS ELECTRIC RAILWAY.

THE article printed in our columns last week with reference to the results on the Minneapolis electric railway has naturally attracted considerable attention, showing as it does the remarkable superiority of electrical methods. It therefore deserves to be pointed out, by way of elucidation, that the road is in reality an Edison one, and not wholly run on the Thompson-Houston system, as might be inferred. The Minneapolis street railway has 128 motor cars, 60 miles of double track, and about 2,500 kilowatt station capacity. The St. Paul road has 80 motor cars, about 35 miles of double track, and 1,800 kilowatt station capacity. The cars take on an average about 6 c. h. p. per car. These roads were built from plans and specifications of the Edison General Electric Co., and the work of construction was done under the supervision of their experts.

HUNT ENGINEERING CO.

THE Hunt Engineering Co. have removed their offices from 238 Washington street, Brooklyn, N. Y., to 126 Liberty street, N. Y., where they will be pleased to see all their friends. This removal has been occasioned by the Brooklyn Bridge acquiring for terminal facilities the property occupied by them, necessitating an immediate removal on their part.

THE "ÆTNA" ARC LAMP INSULATOR.

The accompanying illustration shows a new form of insulator, designed and manufactured by Albert & J. M. Anderson, of Boston, for the purpose of suspending arc lamps so as to make a well-insulated support. It is called the Ætna arc lamp insulator, and a glance will at once explain its use.

The bell is a solid mass of Ætna insulating material, used largely for insulation in electric railroad work. The material is exceedingly strong and tough, does not crack or split under heavy blows, possesses superior qualities as an insulator, is impervious to moisture, and unaffected by atmospheric conditions or changes. The metal ring and spring clip are of brass, and will therefore not corrode, and no film of oxide forms over the insulating material to destroy its insulating properties in either dry or wet weather. The bell form offers maximum insulating surface, and is practically indestructible.

ÆTNA ARC LAMP INSULATOR.

This form of insulator has been found to be very effective. It is complete in itself, and all that has to be done is to press in the spring clip and hang up the lamp, the clip effecually preventing the lamp from being shaken out.

A NEW DOUBLE-DECK ELECTRIC CAR.

THE electric car recently designed by Mr. E. C. Sessions and Mr. C. L. Pullman resembles in general appearance the double-decked vehicles in common use in London and Paris. It is 32 feet long, 7 feet 4 inches wide, 14 feet 9¼ inches high, and will seat forty passengers on each deck. The car body is so arranged that passengers may enter at the centre of either side, where spiral stairs lead to the upper deck. Four stairways, combined with two at the bottom, separate toward the top, leading to either end of the car. The entrances at the centre occupy no more space than the end platforms on ordinary street cars. The lower car body consists of two compartments, each twelve feet long, with circular ends, seats being carried around the ends as well as at the sides. The upper deck is entirely covered with a canopy attached to the pilot house. The car is equipped with an electric chandelier and electric heaters in each compartment, and propelled by two Westinghouse motors of twenty-five horse-power each. The car rests on two trucks of special design, arranged with double-brake attachments, and a friction brake. The efficiency of the brakes was demonstrated by the stoppage of the car within its own length while traveling at a speed of twelve miles an hour in Chicago a few days ago. H. H. Sessions, manager of the Pullman Car Works, is the inventor of the brake attachment.

THE ELECTRIC MERCHANDISE COMPANY.

THE Electric Merchandise Co. will have their headquarters during the Street Railway Convention in Parlor 5, Monongahela Hotel, and from the position occupied by them in the electric street railway field, their headquarters will undoubtedly be a prominent feature of the convention. To no single company is the street railway manager as largely indebted as to this exclusive electric railway supply house. Owing to the well-recognized standing of the company and the success which has attended all their ventures, numerous offers have been made to them to handle other material, but it is their belief that the electric railway field is of enough importance to have at least one house devoted exclusively to that business.

Having a much larger experience than any other house in that particular line of business, and being altogether unbiased and anxious to furnish the best material possible, they give careful investigation to all devices offered to them or placed on the market by other companies. Their decision in matters relating to electric railway building and maintaineuce is recognized as authority by railway managers using all the different systems throughout the entire world. In addition to the very extensive printed matter furnished by the company, and which is certainly a great aid in deciding on the merits of different devices, the benefit of their wide experience is cheerfully given without charge to parties interested.

Samples of their complete line material will be on exhibition in their parlor during the convention, and careful examination is invited. The simplicity, combined with great strength and perfect insulation of their devices, are great points in their favor. The company has gone to great expense in perfecting a special composition bell insulator, as well as a simple but absolutely reliable clamp for holding the trolley wire. In many cases contracts with parent electric companies are made conditional on having the line devices of the Electric Merchandise Co. furnished.

Another matter which has been given great attention, and in the perfecting of which the company has spared neither time nor money, is the furnishing of an "ideal" rawhide pinion, one which under no possible circumstances will dry out or spread. They are now furnishing a pinion composed entirely of rawhide, with the necessary brass flange and free from glue or other objectionable foreign matter.

The position which the company has obtained received pleasant recognition some time since by the election of its manager, Mr. W. R. Mason, to the presidency of the Burton Electric Co. The result of this selection, and of the Electric Merchandise Co. as selling agents for the Burton electric heater, has been most encouraging to the company. The unique position occupied by the Electric Merchandise Co. has enabled them to place these heaters on a very large number of electric roads, and as the advantages of this method of heating are more generally understood they will unquestionably replace coal stoves, with their objectionable features of dirt, smoke, ashes and danger from fire.

In addition to a number of the representatives of the Electric Merchandise Co. who will be in attendance at the convention, they will have with them Dr. W. Leigh Burton, the inventor of the Burton electric heater.

E. G. BERNARD & CO.

MESSRS. E. G. BERNARD & Co., of Troy, N. Y., have recently placed an electric lighting plant of 100 lamps in A. J. Nuttall & Co.'s mill, Cohoes, N. Y. The firm's electrical display on the evening of the 15th, ult., in front of their warerooms, in honor of the unveiling of the monument, was exceedingly artistic, and attracted great attention from strangers and residents. A large corona of colored lamps, tastefully surrounded by the national colors in bunting, brilliantly illuminated the whole street, and was noticeable for a long distance. They have already received highly complimentary notices from the daily papers, and from prominent citizens, for the brilliant view afforded, and also as showing to how great an extent, and how easily, the electric light lends itself to the decorative art for balls, dinner parties and festive gatherings, as well as for store decorations and show windows.

THE NEW QUEEN CATALOGUE.

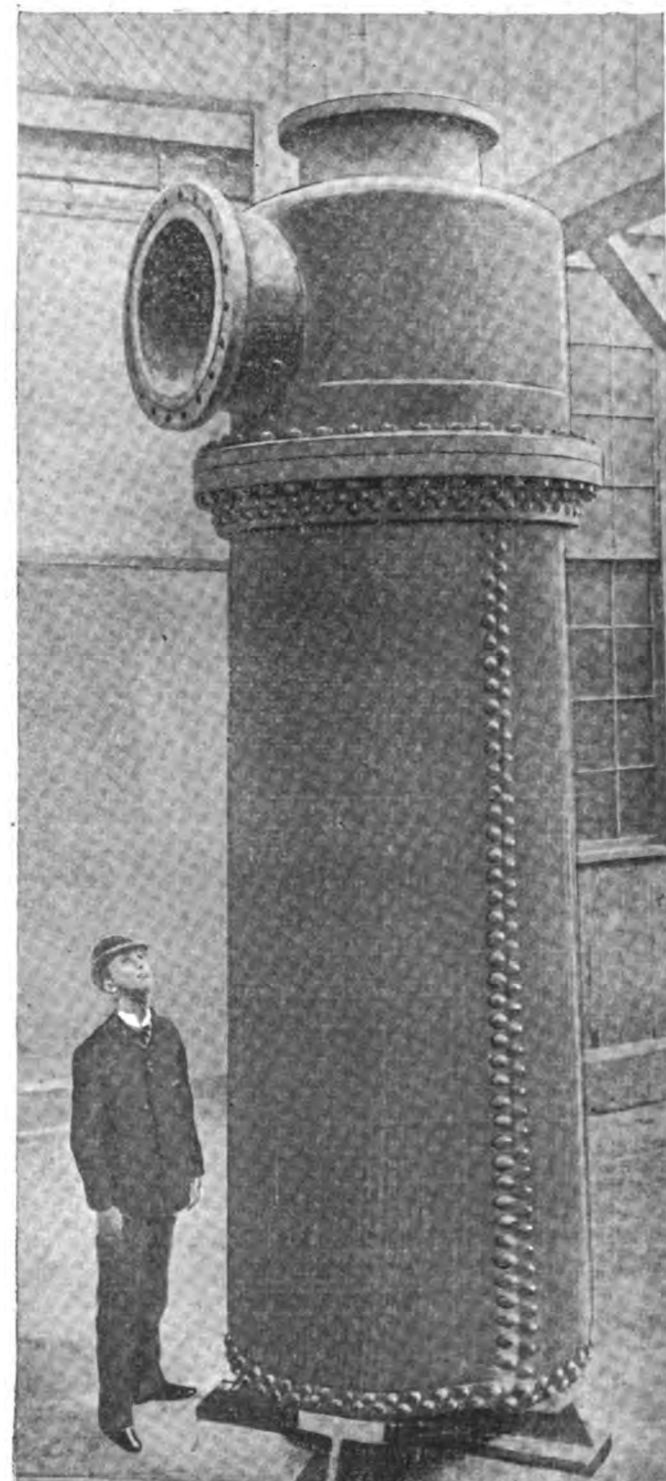
MESSRS. QUEEN & Co., of Philadelphia, have issued a new 124-page catalogue of their electrical testing apparatus and accessories, which in point of completeness excels anything of the kind previously issued by them. Among the apparatus described and illustrated may be mentioned their magnetic vane ammeters and voltmeters, hot wire voltmeters, electro-dynamometers, portable galvanometers, portable testing sets, electric light photometers, brackets, and cradle dynamometers.

MR. W. A. HATHAWAY, of the staff of the American Electrical Works, Providence, R. I., was married on October 15 at Edgewood, R. I., to Miss Louise H. Johnson.

AN IMMENSE STRATTON SEPARATOR.

Steam separators are now being recognized as a necessary adjunct of a perfect steam plant; the absolute certainty that none but dry steam will reach the engine being duly appreciated by every engineer.

The accompanying illustration shows what is believed to be the largest separator ever built for separating water from live steam. It was built by the Stratton Separator Co., of New York city, for



AN IMMENSE STRATTON SEPARATOR.

the Calumet & Hecla Mining Co., miners of copper ore on Lake Superior, Mich., and was constructed under the strictest requirements, and according to the specifications of Mr. E. D. Levitt, consulting engineer of the Calumet & Hecla Mining Co.

This immense separator is 3 feet 8 inches in diameter, 14 feet 5 inches in length over all, for a steam pipe of 21 inches diameter, and designed for a working pressure of 185 pounds. The shell is made from a single sheet of steel, and the top of cast iron gun metal.

The Stratton Separator Co. have furnished the Calumet & Hecla Mining Co. several separators for high pressure, that seen in our illustration being the most notable.

MESSRS M. R. MUCKLE, JR., & CO.

The above company are installing for Messrs. S. A. Crozer & Sons, of Chester, Pa., an incandescent light plant. The dynamo will be driven by a Westinghouse 10 inch and 18 x 10 inch compound engine.

About 380 lamps will be installed at present, placed on a large number of separate circuits, all separately controlled from the engine-room.

As a result of ten years' night and day use of the electric light and engine plant installed by Messrs. M. R. Muckle, Jr., & Co. in the Spreckels' refinery, Mr. Spreckels has ordered from them a 60 h. p. Westinghouse standard engine. This makes the sixty-third Westinghouse engine in use in this refinery.

Messrs. Chambers Bros. & Co., manufacturers of brick machinery have bought from Messrs. M. R. Muckle, Jr., & Co. a 35 h. p. Westinghouse engine to drive their electric light plant, which consists of a Thomson-Houston dynamo with a capacity of 350 lamps.

This purchase results directly from the investigation made by Cyrus Chambers, Jr., as president of the Bala & Marion Electric Light Co.

THE UNITED PRESS HEADQUARTERS, CHICAGO:

The offices of the United Press Association, in the new *Herald* Building in Chicago, are going to be the most complete and handsome offices of the kind in the country. The telegraph department will in itself comprise a large telegraph office, the instruments being of the most modern pattern, and highly finished, and beautiful specimens of the highest skilled labor. These instruments were purchased from the Central Electric Company, and are on exhibition in the salesroom of that progressive company.

AUTOMATIC SCALE COMPANY.

The Automatic Scale Company, a description of whose device appears in The Electrical Engineer of Sept. 30th, has just closed a contract with the United States Revenue Department for a large number of these scales. It is the intention of the Department to change the present method of gauging spirits and use these scales in the determination of the specific gravity of liquors, thereby arriving at the percentage of alcohol contained. The application of the automatic electric scale to this end is so obvious that its immediate adoption followed as a matter of course.

DAYTON FAN AND MOTOR CO.

The above company, of 10, 12, 14 and 16 South Canal street, Dayton, O., is in the field to supply fly and ventilating fans, electric and water motors, &c. Mr. W. B. Anderson is the president; J. A. Smith, vice-president; E. O. Waymire, secretary and treasurer; E. C. James, general manager, and W. F. Phelps, general superintendent.

U. S. ELECTRIC RAILWAYS CO.

We have been requested to state that the U. S. Electric Railways Co., of 10 Wall street, has no connection with the United States Railway Equipment Co. The former company says that it has had many inquiries as to the matter, and desires it to be understood that the concerns are entirely distinct and independent, and should not be confounded the one with the other.

THE BALL ENGINE CO.

The Ball Engine Co., of Erie, Pa., have received the following letter, which speaks for itself:

World's Columbian Exposition.

Ball Engine Co, Erie, Pa.

Gentlemen.—We started last night the 10x12 engine kindly loaned by you to us for our temporary power and lighting plant. I have to congratulate you herewith upon the start made, which I have no hesitation in saying was the prettiest I have known in my experience.

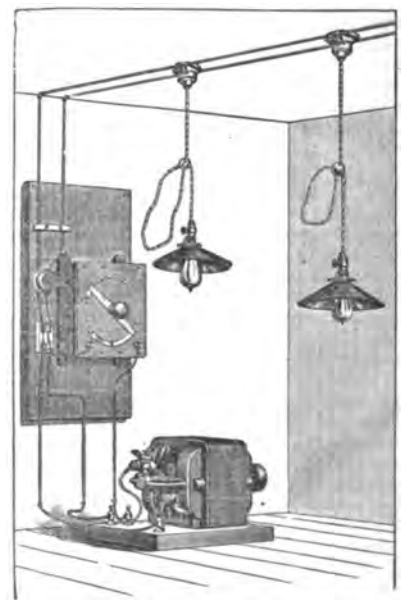
We started the engine under full load at six o'clock, and it ran until six o'clock this morning without the slightest trouble from heating or any other cause. I consider it a very valuable record.

Please accept my thanks for the promptness with which you filled our order, and for your liberality in furnishing us this engine.

Very respectfully yours,
J. C. Slocum, Mechanical Engineer.

A NEW BAIN ELECTRIC LIGHT PLANT.

A very compact electric light plant, simplified and relieved of all unnecessary features, is that recently designed by Mr. Forée Bain, of Chicago, and shown in the accompanying illustration. This apparatus is complete and ready for operation, and, it is claimed, will maintain without trouble its full load of 16 c. p.



Bain Electric Lighting Plant.

lamps. Various sizes of plants of this character are manufactured, ranging from 5 to 50 lights capacity. They are all carefully tested before leaving the factory, and any part of the entire plant can be furnished in duplicate.

ELECTRIC POWER IN INDIANAPOLIS.

A power-house is to be immediately erected by H. C. & M. P. Wright at the corner of Tennessee and Georgia streets. It will be four stories high, and will contain over sixty thousand feet of floor space, and will be equipped with heat, light, power, elevators, etc. The place is expected to prove a boon to small manufacturing interests, which cannot afford to buy their own plants. This is an enterprise for which both the Board of Trade and the Commercial Club have been working, and, while it is built by private capital, it will hold near relations to the Commercial Club, and will partake of the nature of a public institution. The plan embraces a scheme for greatly enlarging the capacity of the building when desired.

BERLIN IRON BRIDGE CO.

The Deleware Iron Company, owned and operated by Morris, Tasker & Co., of New Castle, Delaware, have decided to rebuild their plant which was lately destroyed by fire, and have placed the contract with the Berlin Iron Bridge Company, of East Berlin, Conn., for the entire plant, which will be constructed of iron from the designs of the Berlin Company. The work has to be completed by December 1st.

THE GERMANIA ELECTRIC CO.

Through its energetic treasurer, Mr. Otis K. Stuart, the Germania Electric Co. has secured the contract for building the entire plant of the Portland Electric Light Co., of Portland, Conn. The plant will start with 650 incandescent lights and 35 arc, and with engine and boiler capacity of 150 h. p.

RIES ELECTRIC SPECIALTY CO.

In the office of the Ries Electric Specialty Company, at Baltimore, hangs a magnificent set of resolutions elaborately framed, which was presented to their president, Mr. Elias E. Ries, and their vice-president, Mr. Lew. S. Greensfelder, by the board of directors, on Tuesday of last week. These resolutions were presented to the above-named gentlemen for their untiring efforts in behalf of the introduction of the new "Regulating Socket" for incandescent lamps, which was shown for the first time at the Exhibition of the National Electric Light Association, held at Montreal, Canada, September 7th, 1891. On each side of these resolutions hang photographs of the members of this Convention, taken in front of the Windsor Hotel. The display is neat, and the company look upon these as valuable souvenirs of this Convention, where their regulating socket received its introduction, and was pronounced "the feature of the Exhibition."

THE HARRISBURG IDE AND IDEAL ENGINES.

The firm of W. R. Fleming & Co., 174 Fulton street, New York City, selling agents for the Ide and Ideal engines, have been taking orders in such a persistent fashion, and in such quantities, that the factory they represent, the Harrisburg Foundry & Machine Works, have been unable to keep up with the increasing demand. Substantial additions have therefore been added to their extensive plant. All standard sizes of Ide and Ideal engines are now being built in quantity, and short deliveries will be the order. One of the most complete and finest engine-testing rooms in the country has just been completed and added to facilitate the large business now on hand.

A SEQUEL TO "KIND WORDS."

A few months ago the Fort Wayne Electric Co., through its energetic New York State agent, Mr. W. J. Morrison, published a most striking batch of testimonials under the title of "Kind Words." They have now issued a not less remarkable sequel. It consists of a batch of about 75 letters, from all parts of the country, to Mr. J. Findlay, of Ogdensburg, N. Y., by users of the Slattery alternating incandescent apparatus. The Fort Wayne Co. has been in the habit of making some pretty broad claims as to the merits of its apparatus. While it has such words of praise as these to support its assertions with, it can be no wonder that the system finds such rapid adoption everywhere.

OERLIKON MACHINE WORKS.

We are advised by the management of the famous Oerlikon Machine Works, of Oerlikon, Switzerland, that, owing to the rapid and continued growth of the Business, Mr. Emile Huber has become associated with the direction of the concern. Mr. C. E. L. Brown has resigned his position with the company as electrical engineer, it being his intention to devote himself to other special electrical work.

H. B. PRINDLE & CO.

Mr. H. B. Prindle, who for a long time past has had charge of the advertising and newspaper department of the Thomson-Houston Electric Co., with headquarters at Boston, Mass., has now established the above firm at Room 732 Exchange Building. He will not only continue in business of the same kind as that which has heretofore occupied his attention, but will have a special department for the preparation of catalogues and price lists.

BABCOCK & WILCOX BOILERS.

The Providence Steam Engine Co., Providence, is changing the drums of the boilers in the Narragansett Electric Light Co.'s station in that city to the Babcock & Wilcox system. The Babcock & Wilcox Co., of New York, has the contract for the alterations, which have been delayed until the job of putting in 1,120 horse power of its own boilers was completed.

DETROIT ELECTRICAL WORKS.

Mr. Chas. A. Benton, manager of the electric railway department of the Detroit Electrical Works, has recently visited Marion, Ind., and sold an 80,000 watt generator to the Queen City Electric Co., of that place.

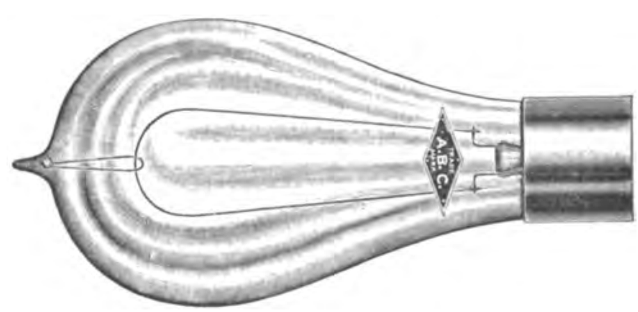
STREET RAILWAY STATISTICS.

Street railway statistics are given as follows by the *Street Railway Journal*: The total number of miles of street railways in the United States and Canada is 11,029, of which 5,442 are operated by animal power, 3,000 by electric power, 1,918 by steam power, and 660 by cable power. The total number of cars employed in the street railway traffic of the United States and Canada is 36,517, of which 25,424 are operated by animal power, 6,732 by electric power, 3,317 by cable power, and 1,044 by steam power. The total number of companies operating street railways in the United States and Canada is 1,003, of which 412 operate electric lines and 54 operate cable lines. The number of horses employed in street car service is 88,114, of mules, 12,002, and of steam motors, 200. It is interesting to note that since Nov., 1890, the number of horses employed on street railway lines has fallen from 116,795 to 88,114; that is, 28,681 in one year.

A NEW "A. B. C." RAILWAY LAMP.

The enterprising firm of Alexander, Barney & Chapin, of New York, have recently added to their line of "A. B. C." incandescent lamps one that is particularly intended for electric railroad usage. The high specific resistance of the "A. B. C." lamp filament produced by the peculiar methods of their manufacture enables the production of lamps with comparatively short and heavy filaments which, even unsupported, are well adapted for sustaining the vibration incidental to car use, and the strain produced by burning in an inclined position.

A supported filament must, however, necessarily offer advantages so long as the support is of such a nature as to produce no excessive abrasion at the point of support of the filament, and thereby shortening the life of the filament. The manufacturers of the "A. B. C." lamp have discarded the use of the platinum or metallic support, substituting in its place a carbon support.



New Railway Lamp.

As shown in the cut, a suitable length of carbon scarcely larger than the filament of the lamp itself, is bent with a sharp curve around the filament before the filament is introduced into the lamp globe, and its two ends are sealed close together by a drop of glass. This glass is subsequently sealed to the bulb at its tip during the operation of tubing the lamp for exhaustion. A support of this nature is practically invisible when a lamp is burning and has the advantage of being to a certain extent flexible. This relieves the filament from the injurious effects of moving sharply against an inflexible support with the consequent danger of loosening the filament connections and injury at its point of abrasion with the support. As such a carbon support will evidently withstand the heat given by a burning carbon filament, and as it itself is not traversed by current, there can be no danger of its wearing out during the life of the lamp.

Another possible advantage of the substitution of carbon with its low specific thermal conductivity for platinum is that the filament when brought against the support finds itself resisted in motion by a material similar in nature and to a considerable extent hotter than would be a metallic support, and thereby excessive and continuous localized changes in temperature are avoided.

BRUSH ELECTRIC CO.

Mr. Samuel M. Hamill, the secretary of the Brush Electric Company, of Cleveland, O., who has been in charge of the Eastern offices of the company, at No. 36 Union Square, for the past three years, has recently removed to Cleveland to assume the duties of general manager, under his present title of secretary, Charles S. Pease, the general manager of the company, having recently resigned.

The Eastern offices of the Brush Company, which have been for so many years located on Union Square, will be moved on October 1, to the Boreel Building, No. 115 Broadway, rooms 80-82. Mr. Hamill for the present will carry on the Eastern offices from Cleveland.

THE SHORT SYSTEM FOR EAST LIVERPOOL, O.

AFTER much competition the contract for electrical equipment to be used on the East Liverpool & Wellsville Railway has been awarded to the Short Electric Railway Company. The road will be about eight miles in length, connecting Ohio City, Wellsville and East Liverpool, with the power station in the last named place. Eighty-two pound Johnson girder rail will be used throughout the entire roadbed, grading for which has been pushed vigorously. A force of five hundred men has been at work for two weeks on the roadbed, which has been cut and filled according to the best practice for steam railways, and will, when completed, be practically level. Thirteen acres of ground have been purchased in East Liverpool, on part of which a handsome red brick power station is in process of erection. Power will be furnished by two one hundred and fifty horse-power Reynolds-Corliss engines with accompaniment of two three hundred horse-power boilers and a Worthington duplex pump. Two Short multipolar slow-speed dynamos of one hundred and fifty horse-power each and a handsome marbleized slate switchboard of the latest Short type fitted with all necessary appliances for the modern electric power station will complete the equipment of the power station.

Seven twenty-six foot car bodies have been purchased of the J. G. Brill Company, Philadelphia. These will be equipped with fourteen Short "Gearless" motors, having a capacity of twenty horse-power each. The line construction will be Short system throughout.

It is expected that the road will be put in operation on Thanksgiving Day, when the citizens of the two enterprising towns have arranged to decorate their streets and cars and to give a banquet in honor of the occasion. At this writing the usually quiet streets of both East Liverpool and Wellsville are filled with foreign workmen, several hundred men being employed at different points along the line. The greatest enthusiasm has been shown from the start by the people of the two towns, the cause of their hearty co-operation being immediate relief from the steam cars, which have been their only method of communication thus far.

REED & McKIBBIN.

IT appears to be now settled beyond any question of doubt that Olean, N. Y., will soon have an electric railway system, at least along the present street car line, and probably a considerable additional line, if no unforeseen obstacles are placed in the way of proposed extensions. President Forbes, on the part of the Olean Street Railway Company, has entered into a contract with Mr. Frederick H. Reed, of Reed & McKibbin, of New York, consulting electrical engineers and electrical railway contractors, to supervise putting in the electric plant and for the construction of the road. The trolley system will be used and the equipments will be of the best. While the contract with Reed & McKibbin is contingent upon certain provisions which have not yet been definitely settled, it gives the public the gratifying assurance that the Street Railway Company is actively at work toward the speedy consummation of the enterprise and that within reasonable time Olean will have a first-class electric street car line.

NEW PROCESS RAW-HIDE COMPANY.

THIS company have recently increased their facilities three-fold through additions to their factory, and they are now therefore in better condition than ever to promptly supply the trade. The demand for noiseless raw-hide gears has been, and is, steadily on the increase, hence the addition noted above. The New Process Raw-Hide Company will be represented at the Street Railway Convention at Pittsburgh by their president, Mr. T. W. Meacham, and their secretary, Mr. A. B. Vosburgh. They will have on exhibition samples of their raw-hide pinions for all electric railway purposes.

THE WIGHTMAN ELECTRIC MANUFACTURING CO.

THE Wightman Electric Manufacturing Co., of Scranton, expect to make a good display at the convention at Pittsburgh. One of their cars will run on the Second Avenue road, and one of their trucks fully equipped will be placed on board the exhibition boat. In addition, a line of insulators and other material will be shown.

ENCOMIUMS ON THE RIKER MOTOR.

THE RIKER ELECTRIC MOTOR Co., of Brooklyn, has just received a very complimentary testimonial from J. Y. Johnston & Co., of 23 Murray street, this city, on their motor, which has been in use some six months. The firm say that they "cannot praise it too highly;" that they have "absolutely not spent a penny for repairs," and that they "will be happy to recommend it to any one wanting a motor."

NEW ENGLAND NOTES.

THE PETTINGELL ANDREWS COMPANY, of Boston, have just got out their first catalogue, embracing a full list of all general electric light and power and railway supplies. The book is handsomely bound in black cloth, and has been carefully compiled under the immediate supervison of Mr. C. B. Price, one of the members of the company. Their new P. A. wire receives first attention in the catalogue and special attention is drawn to its peculiar virtues. The book is well illustrated, and comprises almost everything required in electrical construction, amongst which may be mentioned underwriter's wire, okonite wires and cables, tapes, connectors, terminals, George Cutter's specialties, insulators, tree insulators, P. and B. compounds, hard rubber, porcelains of all shapes, wood cleats, shade-holders, reflectors, shades, a complete line of K. W. cut-outs, rosettes and sockets, Economic incandescent lamps, tools, line material, batteries, bells, the P. A. Street fixtures, switches, motors, etc., etc. The catalogue also embraces a full electric railway supply department, which the Pettingell-Andrews Company are rapidly developing. The book is well got up and makes a handsome addition to any electrical engineer's manuals of useful information.

MR. F. DAY VOORHEES, of the Norwich Insulated Wire Company, of New York, was in Boston last week attending to the wants of his friends who use paper insulation. He reports that the company is all the time pushed with orders, and are at present extremely busy equipping the old Trinidad-Heimann factory at Harrison, N. J., with a complete set of machinery for the manufacture of paper insulated wires and cables. One of the specialties which they are now introducing is a flexible magnet wire, which is both fire-proof and waterproof. They are also busy preparing to supply the trade with the old favorite Trinidad line wire, which has not been manufactured to any extent for the past few years. Trinidad used to meet with a ready sale, and no doubt Mr. Voorhees will be able to work up a good business again in this line.

WESTERN NOTES.

ARMINGTON & SIMS ENGINES.—The Pond Engineering Company report an excellent demand from their various offices for Armington & Sims engines for driving dynamos. They are now furnishing engines for the State Insane Asylum, San Antonio, Texas; Pacific Branch National Soldiers' Home, Santa Monica, Cal.; Edison General Electric Company, Traverse City, Mich.; Waterloo, Ill., Electric Light Company; Provident Life Assurance Building, Waco, Texas.

MR. CHAS. G. ARMSTRONG the well-known consulting electrical engineer of Chicago, has just started up a plant very successfully at Monticello, Ill. The plant comprises a 750-light alternator Slattery system, and a 25-light Wood arc dynamo, both manufactured by the Fort Wayne Electric Co., of Fort Wayne, Ind.

WM. BARAGWANATH & SON, manufacturers of feed-water heaters, purifiers, boilers, etc., have booked among recent orders one 200 h. p. heater for the electric light company at Tuscarawas, Ohio, one 100 h. p. heater for Westinghouse, Church Kerr & Co. and one 600 h. p. for Cedar Rapids Electric Co.

THE CHICAGO INCANDESCENT LIGHT AND WIRING CO. have opened a handsome store at 155 Franklin street, where they are carrying wiring and construction supplies. They devote themselves to burglar, fire-alarm, call-bell and electric light work, and have a large number of contracts on hand.

NEW YORK NOTES.

THE CROCKER-WHEELER MOTOR COMPANY has recently added Mr. Thomas J. Fay to its already large electrical staff. This gentleman brings with him an extensive experience gained by a previous connection with the Edison, Thomson-Houston, and other prominent electrical companies, which will be of considerable value in his present work. Mr. Fay will have charge of the testing department, the force of which the company have lately increased.

MR. C. MCLAUGHLIN, of J. H. Bunnell & Co., has become actively identified with the Central Electric Railway Co., of Paterson, N. J., and has been elected one of the directors. The road will shortly adopt electricity as a motive power, and its prospects are very bright in every respect.

☞ ***Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Miscellaneous, etc., will be found in the advertising pages.***

THE
Electrical Engineer.

Vol. XII. OCTOBER 28, 1891. No. 182.

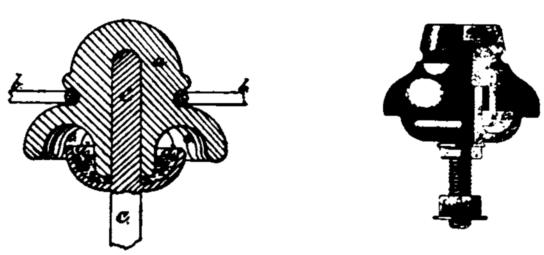
OIL INSULATION FOR HIGH-TENSION CURRENTS.

BY

Franklin Leonard Pope

THE utilization of electrical energy for the transmission of power to great distances, which in one form or another bids fair to take a position as one of the most striking achievements of modern science, can, in most cases, only be rendered commercially advantageous by the employment of very high electric potentials. The conduction of currents at high pressures in turn makes it necessary that the utmost attention should be paid to the problem of securing adequate insulation. Recently the use of liquid insulators, especially the hydrocarbon oils, has found much favor, and materials of this nature are now being used with much success, not only for subterranean and aerial electric conductors, but for transformers and other like accessory apparatus. This method of insulation has been used in the Lauffen-Frankfort transmission system, recently described in THE ELECTRICAL ENGINEER, in which a pressure as high as 18,000 volts has been dealt with, and apparently with the most satisfactory results.[1]

The discovery of the valuable properties of the hydrocarbons as non-conductors of electricity appears to have been made by the late David Brooks, of Philadelphia, who, as the result of a long series of experiments, took out a patent on Nov. 29, 1864, No. 45,221; reissue, 2,717, for a telegraphic line insulator, in which the effective non-conducting substance was paraffine, of a waxy consistency. Prior to the date of Mr. Brooks's investigations, the text books and treatises on electricity had contained no allusion to the matter, beyond classifying "oils" among conductors, accompanied in some cases with the observation that the heavier oils were the better conductors. The paraffine insulator of Mr. Brooks proved to be a very effective one, and during the next ten or fifteen years he devoted himself assiduously to the task of introducing it into practical use on the telegraph lines of America. In this he was in a considerable measure successful, although his characteristically aggressive and uncompromising advocacy of his views, and his caustic criticisms—albeit well founded—of the generally prevailing conditions of insulation upon American telegraph lines, created an inimical feeling in influential telegraphic circles, which had the effect of largely preventing the introduction of what was unquestionably an improvement of the highest practical merit. In the latter patterns of the Brooks insulator a semi-liquid form of paraffine, enclosed in an inverted blown-glass bottle, has been employed. In warm weather the hydrocarbon flows sufficiently to renew its surface, and thus for a considerable period the deleterious effect of dirt upon the insulating surfaces is avoided.



FIGS. 1 AND 2.

A subsequent inventor, Mr. W. E. Simonds, of Hartford, Conn., now United States Commissioner of Patents, obtained a patent June 29, 1869 (No. 92,111), for an insulator for aerial conductors, in which he sought to avoid the objection just mentioned. In this insulator, a section of which, reproduced from the drawings of his patent, is given in Fig. 1, the body *a* of the insulator is made of any of the ordinary non-conducting substances, such as glass or porcelain, to which the conductor *b* is secured in the usual manner. The supporting pin *c*, of malleable iron, is formed with the cup *d*, whose edge or lip projects up into a groove, *e*, formed in the under side of the insulator proper. This cup is filled with liquid paraffine or other non-conducting oil, as shown at *s*. In his specification Mr. Simonds says:

"The placing of the insulating substance in the cup, and around the extension of the insulator proper, so as to form an unbroken continuous surface from the insulator proper to the inside of the cup, over which the electricity must pass in order to escape, is a new thing, and is my invention."

We recognize here the fundamental principle of that generic type of insulator in which a liquid surface of non-conducting oil is maintained between the conductor and its support, which surface encircles the inner surface of the insulator proper, and is in a great measure protected from the influence of dust and dirt. For some reason Mr. Simonds's invention never went largely into practical use, but it may nevertheless be conjectured that, had he been an electrical engineer, a manufacturer of supplies, or an officer of a telegraph company, rather than an attorney-at-law in a provincial city, his invention would hardly have been relegated to obscurity.

Several years later the English telegraphic engineers, W. C. Johnson and S. E. Phillips, reinvented and patented an insulator substantially the same as that of Mr. Simonds, though differing in some of its details, which, having been put on the market in various forms by this enterprising and well-known firm, has met with extended acceptance. (See British patent 3,534, of Sept. 8, 1876).

In their specification the inventors say that the principle of the invention is the "introduction of a liquid insulator between the line and the earth," which may be effected in several ways. An ordinary cup-shaped insulator may be inverted, filled with the liquid, and provided with a cover to exclude the rain, or an erect bell-shaped insulator may have its lip turned up inwardly so as to contain the liquid, or, lastly, a bell-shaped insulator may have within it a cup-shaped vessel turned up outwards. The liquid to be used in all cases is by preference a hydrocarbon "which will

1. THE ELECTRICAL ENGINEER, Sept. 30, pp. 370, 371.

not support a film of moisture or dust on its surface." The accompanying illustration, Fig. 2, reproduced from *The Telegraphic Journal* of October 15, 1877, shows how nearly one of its forms resembles the one adopted by Simonds.

Most of the plants that have been established in Europe during the last few years for the transmission of electric power to considerable distances have found it necessary, or at least advantageous, to employ insulators embodying some one of the constructions pointed out in the Johnson and Phillips patent, as well as the general principle found in all these different forms suggested by them, for which principle we are indebted, in the first instance, to Mr. Simonds.

A still more recent improvement in the same line of invention, which seems likely to be of considerable importance, has just been patented by Robert J. Hewett, of St. Louis, Mo. Mr. Hewett has sought to provide for the constant and automatic renewal of a film of insulating oil, interposed between the electric conductor and the earth, so that its capacity to prevent the escape of the current cannot become impaired by exposure to dirt and moisture, even under the most unfavorable conditions, such, for example, as those affecting the conductor of an electric street railway when enclosed in an underground circuit. Mr. Hewett has ingeniously availed himself of a well-known, and often extremely troublesome property of the hydrocarbon oils, viz., their tendency to exude through minute capillary orifices in a containing vessel. One form of his

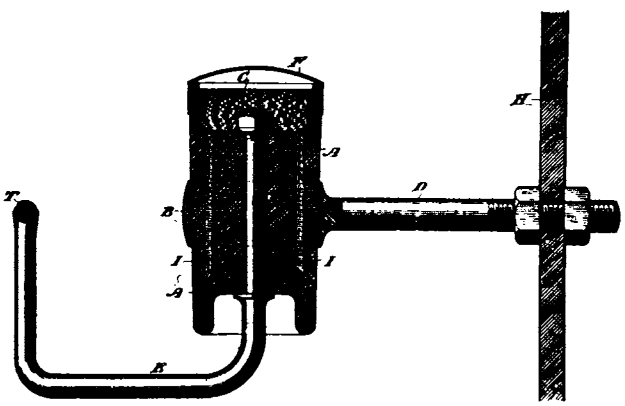


FIG. 3.

invention is shown in Fig. 3, in which the body of the insulator A is of unglazed or partially glazed porcelain or other like material, held and supported by a collar, B, having a shank, D, secured to a suitable support, H, which is shown in the figure as the wall of the conduit.

The upper portion of the insulator proper is formed into a receptacle, C, for containing a supply of liquid hydrocarbon, such as paraffine or rosin oil. The conductor T is attached to a stem or wire-holder, E, inserted in the body of the insulator.

The insulating surface is kept covered with a film of oil through the agency of ducts, I I, formed within the body of the insulator. These are kept filled from the receptacle C, and from them the oil slowly percolates through the porous material of the insulator, and flows in a thin stratum down along the external surface, dripping off at the lower edge. The non-conducting surface is thus constantly renewed with fresh oil, while any particles of dirt or conducting matter which may have lodged upon it are carried away. The receptacle C is covered with a cap, F, which may be removed when fresh oil is supplied.

Mr. Hewett's invention would seem to possess a peculiar value for underground conduit work, although it can hardly fail to find also extended application in the construction of lines of high insulation for long-distance power transmission.

In the Lauffen-Frankfort plant, the transformers have also been effectively insulated by the application of oil, in which the transformer is immersed.[1] The credit of this idea seems to be also due in the first instance to Mr. Brooks. Of course, a transformer is nothing more or less than a mammoth induction coil, and the difficulties which arise in the insulation of the transformer are of the same character as those which have always been met with in the insulation of the induction coil. Mr. Brooks obtained a patent on December 17, 1878, in which he claimed as his invention a method of insulating induction coils or bobbins of wire of other electrical instruments, which consists in immersing them in a liquid insulating substance, by preference paraffine oil. It was while experimenting in connection with this invention that Mr. Brooks made the singular discovery that paraffine oil offers even a higher resistance than dry air to the passage of the electric spark.

Space does not admit more than a mere mention of the application of liquid insulation to subterranean and submarine conductors, another conception of the fertile mind of Mr. Brooks, which has proved to be of importance and value. But the increasing attention which is now being paid to the utility of this method of insulation for many purposes has suggested that it is due to the memory of Mr. Brooks and other early workers in this field that their labors should receive due recognition.

ECONOMY IN ELECTRIC POWER DISTRIBUTION.

BY

J. Stanford Brown.

I REGRET that Mr. Leonard thinks the purpose of my note in THE ELECTRICAL ENGINEER (XII, No. 179, p. 397, of October 7, 1891) was an endeavor to show an error in his work.

His formulæ and deductions are certainly in a form to which many are unaccustomed, and by such have to be translated, so to speak, in order to get at their full purport.

Now the questions involved in the problem under consideration are certainly of vital importance, from an engineering point of view, and while Mr. Leonard has provided an elaborate paper, he has not, unfortunately, taken up the matter step by step and shown just how and where previous "authorities" went astray, and by figuring in K. Ws., instead of in H. P., has rendered comparison of his results with those of other writers more difficult.

That Mr. Leonard's formulæ referred to electric "power at the terminals of the translating device," instead of to "mechanical power at the pulley of the motor," as in Sprague's formula, was just the point requiring emphasis to show that these gentlemen did not argue from the same standpoint.

Mr. Leonard denies that the factor "1,000" has any relation to H. P., but does not explain its presence. It has been suggested that he has figured in "K. Ws. per 1,000 feet transmission," although such fact is nowhere apparent in the original article.

That Mr. Leonard did not make the motor efficiency a factor was evident; but supposing one wishes to get 100 h. p. out of a motor of 90 per cent. efficiency, should the wire be figured for minimum first cost CONSISTENT WITH maximum economy by the use of his formulæ and then 111 per cent. of the circular millage so arrived at be taken, or should the calculation be made to deliver 111 h. p. at the motor terminals? If the formulæ are not to be applied in either of the above ways, what is the proper mode of procedure?

Since Mr. Leonard's formulæ (E. E., XII, No. 180, p. 436, October 14, 1891) "were intentionally put in such shape

1. THE ELECTRICAL ENGINEER, Sept. 30, p. 370, Oct. 7, p. 399.

as to apply whether the energy be used for motors, incandescent lamps, etc., etc., " is it to be inferred that while the translating-device efficiency can be omitted in the case of motors, it must be taken into account in lighting, heating, etc., and if so, why can it be omitted in the former case? Any further comment upon the contents of Mr. Leonard's very interesting paper will, I trust, be taken by him and by "the electrical public" solely as an endeavor to evolve the true laws of economical distribution.

THE EFFECT OF ELECTRIC LIGHT ON PLANTS.

BY

Chas. Steinmetz.

With great interest I read in The Electrical Engineer of Oct. 14, the report on the experiments, undertaken at Cornell University, with regard to the determination of the influence of electric light on plant life. As I understand these experiments, there seem to be two distinct actions of the electric light upon living plants.

1. It increases their vitality. This is shown by the hastening of maturity, the early blooming before being in full leaf, and also the slender form.

2. It acts destructively upon leaves and flowers. The curling of leaves and the fading of flowers point to this influence, which might be, perhaps, a purely chemical action.

The first action will, in very many cases, be useful for agriculture; sometimes even of such great value as to be quite out of proportion to the cost of the light. For instance, if a wine crop, which otherwise would be a failure, could be made to ripen in time by the application of electric lights for a few weeks, this would sometimes save an immense amount of money. Hence I should consider it worth while to try whether these two actions of the light could not be separated, the latter one suppressed and only the former one retained.

Plants being especially acted upon by the long light waves at the red end of the spectrum, the increased vitality may be caused by these long waves of the electric light, while the fading of the colors, etc., seems to attribute the destructive action to the short actinic waves at the violet end of the spectrum, which are proportionally more intense in the electric arc than in the sunlight.

Hence I should suggest a repetition of these experiments, *blinding off* the *actinic rays* either partly or wholly to determine whether, in this way, the increase of vitality of plant life could not be got without the destructive action, while it would be interesting also to blind off only the long waves and leave the actinic rays, to determine by those plants which proved to stand the electric light best, whether an increase of vitality is still perceptible.

Incandescent light, which is rather poor in actinic rays, could be tried instead of the arc light, and should give only the first action, if this reasoning be true, and these different actions of the electric light are due to different parts of the spectrum. I should think it of great importance for agriculture to determine this, and well worth the while of an institution which has done so much already in solving electrical problems.

DISCOVERY OF MICA DEPOSITS.

A discovery of large quantities of mica is said to have been made at a point about twenty-five miles west of Muldiva, Australia. The plates, it is reported, are of fairly good quality, improving as the development proceeds, and are free from impurities. Four leases have been applied for, comprising an area of 100 acres.

WEIGHTS OF ELECTRIC CARS ON BRIDGES.

Several electrical engineers have had lately to deal with questions arising from the increased load that ordinary highway bridges have to carry on account of the passage over them of electric cars. The repair or strengthening of such bridges to withstand these loads is calling for a considerable amount of engineering work at the present time, but so far as we are aware nothing has appeared in print on the subject. Mr. Oscar T. Crosby has favored us with the following in reply to an inquiry addressed to us:

"The weights imposed upon bridges by electric cars may be considered in two ways,—first, as to the maximum weight per running foot, and second, as to the total weight irrespective of length.

"In regard to the first, the maximum may fairly be taken as the weight of a heavily loaded eighteen-foot car standing on a six-foot wheel base. The maximum total weight in such case may be taken at 25,000 lbs., of which 12,500 would then pass through each end of the wheel base, or 6,250 through each wheel. While this total weight of 25,000 lbs. is thus concentrated, or may be concentrated, within a distance of six feet measured along the distance of the bridge, yet of course the overhang of the car would make it impossible that any other weight should fall directly over the length covered by the car in question. Looking at it in this way it would therefore appear that 25,000 lbs. over a distance of about twenty feet would be about the maximum given by present practice. It may be that the use of separate locomotives would increase this as follows: A locomotive having, say, a six-foot wheel base will be followed immediately by a heavy car, either single truck or double truck. The worst case would appear to be when the locomotive is followed directly by a double-truck car.

"Let us suppose the total length of the locomotive does not exceed eight feet, which would be an overhang of one foot beyond each end of the six-foot wheel base. Further suppose, in order to get the limiting case, that the car has no front platform, but is coupled directly up to the engine, when the wheel base of this forward truck would fall within, say, a distance of ten feet measured to the rear from the end of the locomotive, or otherwise expressed; we should have distributed over a distance of seventeen feet, the total weight of the locomotive and half the weight of the car. The weight of the locomotive can only be approximately given now since there is no example of practical use before us. The uncertain factor in the case lies in this, that we do not know what weight of train will finally be attempted for street railway service. My own opinion is that a train of length equal to three sixteen-foot cars represents the limit which municipal governments will permit for the length of a single unbroken train. The weight of three such cars would be, say, 75,000 lbs. For such grades as would be attempted with such a train, the weight of the locomotive need not be greater than one-third of the weight to be hauled; this relation of course having to do with the required adhesion. We should then have 25,000 lbs. as the weight of the locomotive resting by supposition on a six-foot wheel base. The maximum weight resting on one truck of the double-truck car, say thirty feet in length, may be taken at 20,000 lbs., giving a total of 45,000 lbs. distributed over seventeen feet measured along the axis of the bridge. This we should consider about as far as we need figure for anything that may properly be called street railway pratice.

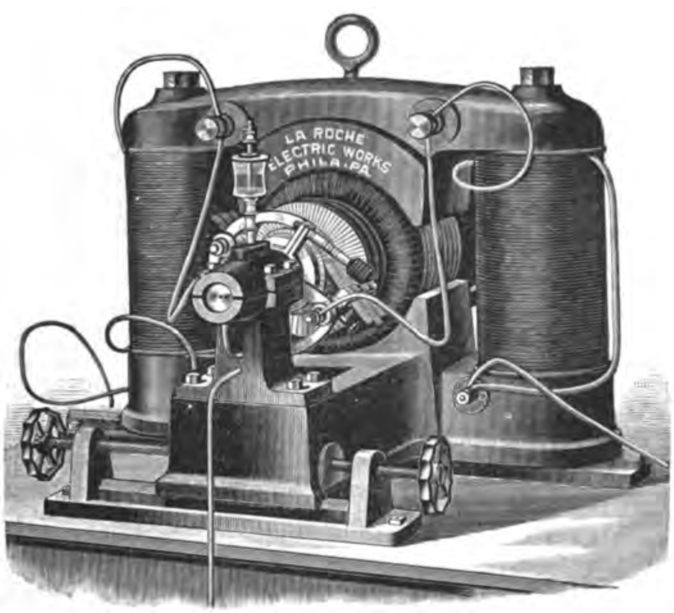
"As to the total weight that may go upon the bridge, it is probable that 100,000 lbs., made up as stated above by three sixteen-foot cars and one locomotive, will be the maximum for anything except elevated or underground service. In order that the bridge should receive the whole of this weight it must of course have a length equal to that of the cars plus the locomotive.

"If your correspondent has in mind the ultimate weights that electric locomotives will finally impose on bridges, that of course is another story. In the end we will be doing work of equal magnitude to that now performed by the largest steam locomotives. That character of work is not properly called street railway service."

THE LA ROCHE ARC LIGHTING DYNAMO.

We published recently an article on the La Roche system of electric lighting, with particular reference to the incandescent machine. We now illustrate Mr. La Roche's arc dynamo, which is built for 50 lights of full standard 2,000 c. p., at his works in Philadelphia. During the present year there has been an active demand for these machines, and one of them now running over three months with a load of 50 lights is pronounced a remarkable success. A test recently made with a machine carrying a circuit of nearly 40 lights showed that the number could be instantly cut down to even one light without an indication of variation of current in the lamp. Close regulation of this kind is a most desirable feature.

The armature is of simple construction, being built up of annealed iron wire as a core, and allowing of very free air circulation, so as to run perfectly cool. It has only 70



La Roche Arc Dynamo.

pounds of copper wire wound on it, and is run at a speed of 750 revolutions a minute. The running is extremely smooth, and gives no sign that the machine is doing work.

This dynamo, whose peculiarities of construction show very plainly in the illustration, has an insulating base, fitted with self-oiling bearings. It has also an excellent automatic adjustable brush holder. Carbon brushes are used, so that wear of the commutator is practically eliminated, and there is no sparking.

So well pleased is Mr. La Roche with this type, and so satisfactory has it proved, he is now building a 150-lighter to fill an order from Australia. This dynamo when finished will be one of the largest arc machines, if not the largest, in the world.

UTILIZING THE RHINE.

A syndicate of Swiss and English capitalists, it is stated, has been formed to utilize a part of the Rhine Falls at Lauffenburg for the generation of electric energy. The water will be led off to turbines by races of $\frac{3}{4}$ mile long, and will yield a total of 7,000 h. p.

THE LOCALIZATION AND REMEDY OF TROUBLES IN DYNAMOS OR MOTORS.—VI.

(Copyright.)

BY

Francis B. Crocker and S. S. Wheeler.

SPEED TOO HIGH OR LOW.

This kind of trouble in either dynamo or motor is a serious matter, and it is always desirable, and generally imperative, to shut off the current immediately and make a careful investigation of the trouble.

1. Cause.—*Overload.* (See Sparking, No. 1.)

Symptom.—Armature runs slower than usual. Bad sparking at commutator. Ammeter indicates excessive current. Armature or bearings heat. Belt very tight on tension side.

REMEDY.—Reduce the load on machine by taking off lamps in the case of a dynamo, or mechanical work in the case of a motor; decrease the diameter of driving pulley or increase the diameter of driven pulley.

2. Cause.—*Short circuit in armature.*

Symptom and remedy same as Heating of Armature, No. 2.

3. Cause.—*Armature runs slowly because it strikes pole-pieces.* Symptom and Remedy the same as Noise, No. 2.

4. Cause.—*Armature runs slowly because its shaft does not revolve freely in the bearings.*

Symptom.—Armature turns hard by hand; bearings and shaft heat when running.

REMEDY—Oil the bearings; clean and smooth, if necessary, the shaft and bearings; line up the bearings. See Heating of Bearings, all cases.

5. Cause.—*Field magnetism weak.*

This has the effect of making a motor run too fast or too slow, or in some cases even run backwards, but makes a dynamo fail to "build up" or excite its field and give the proper voltage.

Symptom and Remedy the same as Sparking, No. 7.

ATMOSPHERIC ELECTRICITY.

The most important recent experiment regarding atmospheric electricity in England, carried out by Mr. Alexander McAdie, seems to take one back to the very infancy of electrical science; for, though the conditions were somewhat different, the operation was substantially identical with Benjamin Franklin's historical experiment with the kite. What Mr. McAdie has demonstrated is that electricity can be drawn from a kite high in the air in a cloudless sky. The kite, Mr. McAdie states, discharged sparks from the lower end of an insulating wire reaching down to the earth, where an electrometer partly measured the increasing electric force. So nearly did the quantity of electricity in the upper air correspond to the height of the kite above the earth that the experimenter could usually determine whether the kite was rising or falling by simply looking at the needle of the electrometer.

THE DEPENDENT—OVERHEAD OR UNDERGROUND—SYSTEM OF ELECTRIC MOTIVE POWER.[1]

BY GEO. W. MANSFIELD.

FIRST, THE UNDERGROUND METHOD.

UNDER this heading I have classified all methods of conducting or transmitting electricity to the car by means of any conductors or devices placed underground. I might possibly divide into two classes: First, continuous bare conductors placed in an open slotted conduit; and second, all other devices of automatic character which enable the contact piece or device on the car to take its electric current from sectional bare conductor or from bare metallic points, automatically made alive. There have been in this country at least four practical experiments with the first-class, several hundred thousand dollars have been expended in testing it, and thousands additional in perfecting it, particular attention being given to the protection and insulation of the bare conductor. In spite, however, of all this refinement and study, practically nothing has been accomplished, and I have no hesitation in asserting that the continuous live conductor in an open slotted conduit is to-day a failure and that it cannot be made a success throughout our cities of to-day, its fatal weakness being our inability to prevent the conduit from becoming filled with water, mud, etc.

No large practical experiments have been made with this second class, but a large number of patents have been issued, and evidently there has been a great deal of careful thought and study bestowed upon it. I, however, have no hesitancy in asserting that this class also will never prove a success, nor can it be made to work successfully throughout any of our cities to-day. The reason for this is obvious. It is immaterial whether the automatic devices prevent the sections of contact points from being alive all of the time or not; if the conduit is filled with water or mud, and the points are made alive just as the car passes, there is bound to be a momentary grounding from these points. In other words, a point made alive in water with the other side of the circuit grounded is just about as dangerous and bad as if it remained alive. It is true that the grounding may not be as severe, but still it will occur, and with a large number of cars throughout the city moving at the same time, causing therefore a large number of points to be alive, if any number of points were grounded through water, it would cause a tremendous loss upon the central power station, and in all probability a complete grounding or short-circuiting of the entire system. Numerous ingenious schemes have been devised to overcome this fatal weakness. None, however, have ever been put to trial. I have seen many, yet to-day there is no hope in this direction.

SECOND, OR SURFACE METHOD.

The inventions covered by this method are somewhat similar to those employed in the conduit system, only in place of being in a conduit, they are placed upon the surface of the street. By far, however, the larger number of arrangements are based upon what might be called the "Interval" or "Point" system. Primarily, this arrangement consists of an underground insulated conductor connected by means of taps to contact points on the surface of the ground, held in place by means of iron boxes, and insulated therefrom by means of rubber, wood, fibre or other similar substance. Upon the car is swung a long contact plate, extending practically from one end to the other. This plate is carried close to the ground, and is arranged to touch the points as it passes along. It is plainly apparent that if these contact points are always alive, then every time the street is covered with water short circuits are inevitable. To overcome this, many automatic arrangements have been devised to cut these contact points into circuit by the car as it passes along. All these arrangements have the same fatal weakness—a liability to ground or short circuit. I do not consider any of them practically possible. There is one system, however which obviates many of the objections. The inventor has a slot between his rails, and boxes with a contact device within, placed at proper intervals. Upon his car is a plow which passes along through the slot, and also a long contact plate or arrangement extending its entire length. The operation of the invention is as follows: The plow as it passes through the slot strikes a lever placed in connection with each box, which lifts for a distance of six or eight inches above the ground a piston carrying the contact piece proper. This is made in the shape of a right-angle hook placed within a vertically moving piston, and thoroughly insulated from it. As this is raised up, the long contact plate under the car passes beneath the hook and holds its up. The current is taken into the car as the plate slides along under the live hook.

Naturally, as the car passes along, the hook slides off from the end of the contact bar and drops back into place. To protect this hook, or contact piece proper, it is covered by an extension of the cylinder, so that, as far as the street is concerned, the surface is perfectly smooth, and one sees nothing but a small round cover in the centre of each of these boxes. The contact hook is alive only when it is resting on the contact plate of the car. Certainly, in so far as getting rid of all the troubles due to the street being covered with water, this is successful. The fatal weakness whereby the contact points remain permanently on the street surface is obviated here by the contact point being practically lifted six or eight inches above the surface. In regard to the permanence and reliability of this system, I can say nothing, as no trials have been made. The inventor claims to have overcome every objection.

Summing up the general results of the underground and surface methods, it certainly looks as if we could not expect very much from them in the immediate future. Our rival is the cable. It certainly does look as if for the enormous sums they expend in making their system feasible we ought, for an equal sum, to make ours perfect. Mechanically it is an assured success, but electrically it has not so proved.

Is it not possible for some bright inventor to devise a scheme whereby the insulation of the live parts can be maintained? This is the sum of all the difficulties. A simple transposition of parts and the problem may be solved.

THIRD, OR OVERHEAD METHOD.

There are two general methods of operating the overhead system. One is by having a continuous trolley wire, and the second is to have this trolley wire divided into sections. For towns and for suburban traffic, the former is almost invariably adopted and carried out. Practice would seem to indicate that but little trouble is experienced, and that there is practically no advantage in dividing the trolley wire into sections. In fact, a disadvantage, since you lose its conductive capacity.

The sectional trolley wire surely must be used for all city work. It is, however, almost impossible to originally fix all of the divisions once for all. It is bound to be a gradual growth to a large extent.

Obviously the methods of feeding the trolley wire vary with the method of arranging the trolley wire. With the first method mentioned (using a continuous trolley wire) the feeders are either extended from the station the entire length of the line, tapping into the line at intervals, or else separate feeders are run out from the station to certain predetermined distances, and there tapped into the trolley wire. When more than one feeder wire is needed in either case a repetition of the scheme is carried out from feeder wire to feeder wire. There is little to choose between the two methods. Both are good.

With the second method (the divided trolley wire) there are two ways of accomplishing the feeding. First, to extend a feeder the entire length of the line and tap into the centre of each section of trolley wire; or second, to extend the feeder the entire length of the line and tap into both ends of each section. The advantages of the former are, that in time of trouble a man has to run to only one box to cut out a section, or the whole arrangement could be made automatic by putting a fuse or mechanical circuit breaker in the box. The disadvantage is that you lose the value of the trolley wire as a conducting medium, which in the case of hard drawn copper wire is considerable.

It is undeniably true that the question of feeder wires is one of great importance and a difficult one to always economically solve for all conditions. The point, however, which the railroad corporations should watch above all others is that they have enough. I have visited many roads where I found that the larger part of the trouble which they were complaining of lay in the fact that they did not have either sufficent trolley wire or track feeders.

I strongly recommend as many ground plates as it is possible to have, not only at the station, but also along the line. The plates can be made of sheet-copper or iron, preferably the latter, and should have a superficial area of several hundred square feet. The wire connecting them to the track should be of sufficient size and very solidly attached to the plate and the rails. The continuous supplementary wire should in all instances be employed, and the rails bonded at least once. In no instance do I think it necessary or wise to place the track feeders overhead. If this plan is adopted and carried out, and proper connections are made between the rails, I do not think the railroad companies will ever have any trouble with loss of power on their ground circuits.

Referring again to the overhead feeder system, I am strongly of the opinion that for large cities all feeders should be placed underground. The cities in which this underground work has been adopted are Buffalo, Minneapolis and St. Paul. I cry, all praise to the courage of these railway corporations.

I contend, however, that whenever anything can be done to advance the interests of the overhead system, it should be done. Now, will it not be materially assisting if you, when you go before your local municipal board and the public, petition for only the trolley wires, agreeing to place all other wires underground?

The construction work can be done simultaneously with the

1. Abstract of a paper read before the American Street Railway Association, at Pittsburgh, Oct. 21 1891.

track reconstruction, for it is my experience that whenever a large city railway adopts electric power it is almost absolutely necessary to rebuild its tracks. Under these circumstances I doubt if the cost of the conduits or ducts would be more than a few thousand dollars additional per mile.

In regard to the overhead devices and material used, I can only urge the advice that the most substantial and perfect apparatus that can be secured be used. Too much care and attention cannot be bestowed upon these devices. It is also well to consider the question of uniformity in the apparatus. The only part that is liable to deterioration is the insulating material. Make this, therefore, of a uniform pattern and arrange the various holders for its reception. With such a system nothing can fall, and the insulation can be maintained easily and perfectly. It would be like renewing a glass insulator on a telegraph pole.

I come now to the discussion of the answers to the forty questions I asked by circular letter.

Out of the 400 and odd circulars I sent out, some, however, being duplicates, I succeeded in getting answers from 137 roads, operating 1,546 miles of trolley wire and 1,657 motor cars. Of this number 71 were Thomson-Houston and 66 Edison or miscellaneous. For the sake of convenience I have divided the various questions into the following topics: 1. Trolley wire. 2. Span and guard wires. 3. Feed wires. 4. Loads carried and conditions. 5. Tests. 6. Accidents. 7. Miscellaneous.

First. The trolley wire: Of the 137 roads, 99 were using copper wire, 28 silicon bronze wire, 8 were using both, and 2 were using phosphor bronze.

Of those using copper, one used No. 000; 5 No. 00; 3 No. 1; 2 No. 2; one No. 5 hard drawn copper; one used No. 0 soft drawn copper, making 13 in all, and leaving 86 as the number using No. 0 hard drawn copper wire.

Of the 28 using silicon bronze, 16 used No. 4; 6 No. 2; one No. 3, and the five remaining roads had combinations of two or more sizes.

Of the 8 using both silicon bronze and hard drawn copper 6 prefer the latter.

Out of all these 99 using copper not one dissents, but of the 28 using silicon bronze 11 advise copper. The proof is conclusively in favor of hard drawn copper wire and of the larger sizes, No. 0 B. & S. seeming to be the standard.

In regard to the wearing, the universal testimony is that it is exceedingly slight. What wearing is observable is found to be at the switches or on the curves.

Serious mistakes have been made in the past by using iron flanged trolley wheels. These cut the trolley wire badly. Everything should be done to throw all the wear on to the trolley wheels.

It would seem that with the ordinary brass trolley wheel the wear was about .001 of an inch to the passage of 65,000 cars. This is at the rate of one in every six minutes, for eighteen hours per day, for one year. With only this wear the life of the wire would certainly be twenty years, unless through some process of crystallization it became more brittle. Undoubtedly, at curves and on switches the wear is somewhat greater.

The breaking of the trolley wire has been rare, the breaks occurring either at splices, or switches, or being due to some extraneous cause. In no instance was any casualty reported, excepting in one case where a mule was killed.

Forty-one roads have their trolley wires divided into sections, and consider it necessary and advisable. Analysis shows that these roads are in the largest cities or towns.

Second. Regarding span wires, 49 report as using galvanized iron wire, 55 as galvanized steel, 20 as using galvanized iron cable and one as using copper wire. The sizes range from No. 0 to No. 14. Comparatively few breaks and no casualties are reported.

My own experience has led me to adopt No. 4 B. & S. soft galvanized iron wire. Whenever a long span or a curve is to be constructed I have had two or more of these wires twisted together into a cable.

	Diam.	Breaking weight.	Breaking weight per square inch.	Elongation in six feet.	Twists in six feet.
No. 1 silicon bronze..	.200	2,550	81,800	.8 per cent.	37.4
Galvanized iron......	.205	1,720	52,000	7.8 per cent.	19

I have found that a cable made of small wires is hard to joint, and it rusts much more quickly. Avoid joints, and use a ball fastener in attaching span wire to eyebolt. On the whole, however, I have concluded that iron is not the proper material to use in any shape. It will rust, and then your structure is weak. Pursuing my investigations into this matter nearly a year ago, I found that a certain special quality of silicon bronze wire was the best. Tests of this wire in comparison with iron showed the results given in the preceding table.

I am aware that the price of this wire is five or six times as great as that of the iron wire, but as the total sum in either case per mile is small, I strongly recommend it. Some of this wire has been in service on the West End road, in Boston, for nearly a year. It certainly will never rust out. Guard wires are universally condemned, but are put up as a compulsory protection from existing evils.

Third. The descriptions of the various feeder systems are so vague I will not attempt to describe them. The average distance to which power is transmitted on these roads is about three miles. The greatest is 10.7 miles on the Tacoma & Steilacoom Railway, Tacoma, Wash. There are many, however, operating from eight to ten miles from the station.

Fourth. Loads and conditions: Under this heading I have included speeds, grades, number of tow cars hauled, passengers carried, etc. The average speed of all the roads is 8.7 miles per hour. The maximum is thirty. The average grade is 6.7 per cent., and but 12 roads report as having none, or very small ones. The maximum grade is 13¼ per cent., and this extends for 1,500 feet. The road suffering from such an infliction is in Amsterdam, N. Y. Thirteen roads report 10 per cent. or over. Nashville, Tenn., reports an 11¼ per cent. grade for 1,300 ft., and Burlington, Iowa, an 8¼ per cent. for 1,500 ft., while Wilmington, Del., reports a 7¼ per cent. for 3,000 feet.

The loads carried up these grades by two 15 h. p. motors are, to say the least, surprising. Amsterdam reports one motor car and fifty-two passengers. Nashville reports one motor car and seventy-seven grown passengers. Burlington, one motor car and seventy five passengers, and Wilmington, Del., reports one motor car towing a disabled motor. Several roads report as towing one car with both full of passengers up to eight and even nine per cent. grades, but for short distances. Auburn, N. Y., reports as having towed five cars all loaded with one motor car. The grades in this instance were slight. In all these instances unquestionably the motors were exerting power considerably beyond their rated capacity. Trains carrying 350 passengers have been moved by two 15 h. p. motors; 200 passengers is an every-day occurrence. Surely this is approaching steam railroad practice. Such information is certainly useful to the electric manufacturing companies.

Fifth. Tests: Out of the total number of 137 roads heard from, only 32 report as having made any tests of either engines, dynamo or motors, and 53 upon the overhead work. Surely this is lamentable. There is nothing more essential to an electric railroad than a first-class voltmeter, ammeter, galvanometer, and, if possible, a wattmeter. Electric light, telegraph and telephone, and all other electric companies are supplied with necessary testing instruments, and in most instances a most rigid system is maintained. Every railroad should be continually testing its circuits, station and cars for leaks or grounds. By this means, and this means only, can they avoid trouble and consequent damage. Furthermore, for the sake of economy these instruments should be used freely. Particularly is a wattmeter useful in power stations. I advise, urge and beseech every company to supply itself with these instruments, and to put them in the hands of a competent person, or if they can afford it, a thorough electrician.

Sixth. Accidents: I am happy to state that under this heading not one road reports as killed or even seriously injured an employee or passenger by the electric current, or falling trolley or span wire. Several report employees as receiving shocks, and one of a boy throwing a wire over the trolley wire and receiving the full potential of the current. None, however, were seriously injured. Several accidents are reported of collision and running over, but these cannot be entirely avoided, and are inherent in any system.

Miscellaneous: Under this heading I asked the opinion of the railroads as to the reliability, permanency, and safety of the electric system. All but one report most emphatically in its praise. I regret very much that this one prefers horses. Further evidence on this point is shown by the fact that 44 roads report as never having been stopped by any cause, 23 were forced to stop because of the steam plant, failure of water, floods or fire, and 26 from electrical troubles, the main cause of these troubles being lightning. I consider this a very fair showing, and feel confident that as the art advances, these tie-ups will grow less and less, and finally become of rare occurrence.

I have now briefly reviewed the Dependent System, or, as I should have preferred to call it, the Direct System. There are some grounds for hope in the direction of an underground or surface system. There is universal praise and encomium sounding on every side for the overhead system; 6,700 cars operated on 3,000 miles of track in the streets of fully 300 of our towns and cities, surely testify to its merits and value. Of this number of towns and cities fully one-third have absolutely no other means of transportation. What objections there are are purely sentimental grounds. Given a city with all wires underground, where would be the objection to iron poles and a single wire for each track? The rails themselves would be a thousand times more of a nuisance and dangerous. The benefits to come from its introduction are incalculable. In the words of Parnell, "Hold on, fight on. A magnificent future is before you" The wonderful and marvelous development of the past is not to stop, but inevitably must continue. Electric railroading, city, town, and suburban, is here for our upbuilding and natural prosperity as surely as steam railroading was fifty years ago. There are equally great opportunities for fame and fortune with this new agent as with the old. Let there be no uncertainty, no hesitancy.

ELECTRICITY THE MOST ECONOMICAL POWER FOR STREET RAILWAYS.[1]

BY J. S. BADGER.

THE elements which enter into a consideration of the questions at issue, are: First cost of road and equipment; operating expenses per passenger carried; ratio of operating expenses to receipt; and operating expenses per car mile.

Upon the first and the last must rest the decision as to what is the most economical power for street railways.

The element of first cost may or may not decide the question at once. If the capital available is limited to the amount necessary for the least expensive construction and equipment, this settles the question of choice of motive power. If the capital is limited only by the ability of the road to pay a reasonable return upon the investment, the question becomes more complex; and whether a cheap or expensive construction shall be adopted depends upon whether the interest charge added to cost of operation will be large or small when divided by the total number of units of comparison.

Cost per car mile, for cars of about equal carrying capacity, seems to be at present the only basis of comparison. This expense, within the limits of traffic for which the power plant and equipment are adapted, remains pretty constant regardless of variations in amount of traffic, but this is directly affected by change in value in any item of operating expense just to the extent that such variation is part of the whole expense.

A careful examination of the roads in question shows the incorrectness of the statement that those "which have the least expense per car mile have the greatest expense per passenger carried." There is no uniformity in this respect one way or the other, as between different roads. Theoretically, the expense per car mile would slightly increase with an increase in traffic. In a general way, and without attempting to produce any proof in support of this opinion, it may be said that, other conditions remaining the same, the expense per car mile would increase about as the cube foot of the number of passengers carried. In this way, and under conditions seldom realized in practice, the foregoing statement might be true.

While the manufacturing companies may have been guilty of sins of omission, the *operating* companies have been guilty of sins of omission and commission. Experience has been costly for both. Electrical apparatus must have intelligent care, or the repair bills soon assume large proportions, and this frequently causes railway companies, who do not understand the true cause of the trouble, to condemn electricity as an expensive motive power. What can be and is actually accomplished in practice is shown elsewhere in this paper; and it is not too much to say that there are few roads, operating under the Edison system, that cannot at least closely approach the average of the "Seven Representative Roads," referred to in the tables which are given herewith.

The item of first cost is the subject of considerable discussion. Direct information concerning cable roads has not been obtainable; but as the figures we cite are those given by the Census Department, and do not seem to have been questioned by any authority upon the subject, they may accepted as substantially correct. Our data concerning horse roads, being taken from sworn reports to the Massachusetts Board of Railroad Commissioners, can also be relied upon. The figures given concerning investment in electric roads have come from official sources, and are confirmed by private information. These are, however, excessive. Most of the roads mentioned were formerly horse roads, and to the original investment has been added the cost of change of motive power; and in almost every case the amount now charged to permanent investment is far in excess of what it would cost to renew the entire power plant, track and equipment.

An attempt has been made to show that electric roads cost nearly as much as cable roads for equal class of construction. As to how much a company might, for purposes of its own, or through mistaken ideas, see fit to invest, it is not necessary here to discuss; but as to how much is necessary for first-class construction, there is little question. One of the foremost roads, with an equipment first-class in every respect, has a permanent investment, including paving, almost exactly that given as the average in Table I.

Estimates upon track construction differ greatly, but the limit of profitable investment is not likely to exceed $10,000 per mile; while as fine and substantial a roadbed as electric car ever ran over was built at a cost, exclusive of paving, of about $5,000 per mile.

Seven Representative Roads, Operated Entirely by Electricity.

Road.	Length. Of all tracks.	Length. Of road.	Passengers carried annually per mile of road	Number of cars in daily operation.	Average daily mileage per car.	Average number of passengers daily per car.	Passengers carried per car mile.	Operating expenses per car mile.	Operating expenses per car per day.	Cost per passenger carried.
1	51.0	35.0	*162,857	50	100	318	3.13	12.29	12.29	3.93
2	40.0	19.5	487,582	140	91	188	2.06	7.80	7.10	3.79
3	16.0	10.0	199,000	16	125	348	2.75	8.43	10.54	3.07
4	8.5	5.0	*460,000	20	83	318	3.82	11.82	9.80	3.09
5	15.5	14.0	167,511	18	106	357	3.35	11.00	11.70	3.28
6	28.0	23.5	286,852	81	108	597	5.51	12 74	13.76	2.31
7	3.8	2.8	200,000	5	92	307	3.33	8.49	7.81	2.55
	162.8	109.8		280				9.83		3.28

*Estimated.

Total annual car mileage, 9,862,000. Total number of passengers carried annually, 29,144,000.

The overhead structure need not cost to exceed $2,500 to $3,000 per mile of single track for best wood poles, or $3,500 to $5,000 for iron poles. For double track, iron poles, it would vary from $4,500 to $6,500 per mile, centre pole construction being the cheaper and in many other respects preferable where it can be adopted.

$3,000 to $3,500 per car is a liberal estimate for 16-foot to 20-foot cars, fully equipped, and the average is about two cars per mile of road.

An allowance of 15 to 20 h. p. per car, at $80 to $100 per h. p., for station equipment, including steam plant, but not real estate or buildings, is very liberal.

Thus we have, as an extremely liberal estimate, $26,000 per mile, exclusive of real estate, buildings and paving, for a road suitable for the heaviest metropolitan traffic. And it is a fact that a good and satisfactory road can be built and equipped for $20,000 per mile.

Table I. shows that, taking street length as the unit of comparison, in the cases of the roads under consideration, the total permanent investment of the electric roads is only 15 per cent. more than that of the horse roads, while the cable roads cost more than nine times as much as the electric roads. The average speed of cable and of electric cars is about the same, consequently the cable roads ran about four times as many cars per mile of street length as the electric. This would be expected, as the cable roads generally occupy the routes of heaviest travel. The horse roads ran more cars than the electric, for an equal length of road, but the latter having an advantage in higher speed, greatly exceed in

1. Abstract of data prepared for the American Street Railway Convention, Oct. 21, 1891.

car miles run. The electric roads carried fewest passengers per car mile, but carried nearly as many per mile of street occupied as the horse roads. On account of their more favorable location, the cable roads exceed both the others in passengers per mile of route. The column showing passengers carried per mile run gives a general idea of the relative number of passengers on a car at any one time.

Table II. shows operating expenses per car mile, all taxes and fixed charges excluded, for each of the three systems; interest charge per car mile at 6 per cent. upon the total permanent investment; total of operating expenses and interest, per car mile; cost per passenger carried, interest charge excluded, and the same with interest charge included. Upon every point, save the one unimportant one of cost per passenger carried (interest excluded), the superiority of the electric road is plainly evident.

Comparison of Investment and Operating Expenses.

TABLE I.

	Total investment real estate road and equipment.		Car miles run per annum, per mile of street length.	Passengers carried annually per mile of street length.	Passengers carried per car mile run.
	Per mile of street length.	Per mile of track length.			
*22 Electric roads..	38,500	27,780	76,158	237,098	3.10

‡10 cable roads......	350,396	184,275	309,395	1,355,965	4.38

TABLE II.

	Operating expenses per car mile run. (Cents.)	Interest charge per car mile at 6% on total investment. (Cents.)	Total of operating expenses and interest, per car mile. (Cents.)	Cost per passenger carried, interest excluded. (Cents.)	Cost per passenger carried, interest included. (Cents.)
Electric roads.....	11.02	3 03	14.05	3.55	4.53
Horse roads.......	24.32	4.62	26.94	4.18	4.98
Cable roads........	14.12	6.97	20.91	3.22	4.77

TABLE III.

	Ratio of Investment, per mile of street length.	Ratio of car miles run annually per mile of street length.	Ratio of cost of operation per car mile, interest included.	Proportional traffic that must be done, per mile of street occupied, to pay operating expenses and 6 % on the investment.
Electric roads.	1.152	1.757	.485	.852
Horse roads.	1.000	1.000	1.000	1.000
Cable roads.	10 486	7.138	.722	5.154

* Car miles run per annum, 14,013.187; passengers carried per annum, 43,614,-973; street length, 184 miles; track length, 255 miles.

† All the roads in Massachusetts operated exclusively by horses for 1885–90. Average for six years.

‡ From Census Bulletin No. 55.

Table III. for greater convenience in comparison, shows the ratios of the three most important items, and the proportional traffic that must be done, per mile of street occupied, for each system, to pay operating expenses and 6 per cent. on the investment. Here, more than anywhere else, the superiority of the electric road is plainly evident, the last column showing that in but few cases can there be even a question as to which system offers the greatest inducement to the investor.

If the electric roads carried as many passengers per car mile run as the horse or cable roads, which they could easily do, and allowing for the increase in operating expenses due to increased traffic, the cost per passenger carried would be as follows:

	PER PASSENGER.
At 5.81 passengers per car mile (number carried by horse roads), the cost would be, interest charge excluded..........	2.38 cents.
At 5.81 passengers (as above), cost would be, interest charge included..	2.82 cents.
At 4.38 passengers per car mile (number carried by cable roads), the cost would be, interest charge excluded..........................	2.82 cents.
At 4.38 passengers (as above), cost would be, interest charge included..........................	3.51 cents.

This is not in any way an attempt to decry the cable system, as it is undeniable that it has a place of its own, where it is satisfactory to the public and profitable to the investors; but the claim is that, under all usual circumstances, the electric road can handle just as heavy traffic, as readily and satisfactorily to the public, with much greater economy in operation, and much less investment of capital.

OPERATING EXPENSES OF ELECTRIC ROADS.

Average of twenty-two trolley roads. Length varying from 3 to 51 miles; cars in daily operation, 3 to 140; daily mileage per car, 80 to 150; average daily mileage per car, 110.

	EXPENSES PER CAR MILE. (CENTS.)		
	Highest.	*Lowest.*	*Av'r.*
Maintenance of roadbed and track....	1.86	.10	.54
Maintenance of line....	.95	.01	.12
Maintenance of power plant, including repairs on engines, dynamos, buildings, etc......	.86	.05	.36
Cost of power, including fuel, wages of engineers, firemen, dynamo tenders, oil, waste, water and other supplies	4.95	.48	1.96
Repairs on cars and motors..................	5.24	.59	1.80
Transportation expenses, including wages of conductors, motormen, starters and switchmen, removal of snow and ice, accidents to persons and property, etc....	9 47	2.74	4.98
General expenses, including salaries of officers and clerks, office expenses, advertising, printing, legal expenses, insurance, etc...	2.95	.79	1.26
Total....	*22.99	*7.80	11.02

*Respectively the highest and lowest total for any one road.

Cost of coal varies from $1.00 per ton for slack, to $3.00 for R. O. M. (run of mine), and $3.80 for lump.

Wages of conductors and motormen vary from 10 cents to 20 cents per hour.

Consumption of coal varies from 4.3 pounds of slack per car mile to 12.2 pounds R. O. M. per car mile.

The station output varies from 3.7 E. H. P. (electrical horse power) to 8.4 E. H. P. per car in operation, for roads equipped with 16-foot cars and Edison motors. In the latter case the road had many heavy grades and sharp curves. One road, equipped with 30-foot double-truck cars (weight complete about 10 tons), 6 Edison and 14 Short double 15 h. p. equipments, traffic medium and grades moderate, required an average of 10.7 E. H. P. per car in operation.

The best station performance is 1 E. H. P. for every five pounds of slack or four pounds of nut consumed; and evaporation of 7½ pounds of water for every pound of slack consumed. Return tubular boilers, Murphy furnaces, Armington & Sims high-speed, single cylinder, non-condensing engines, and Edison generators are in use.

DETAILED DISTRIBUTION OF OPERATING EXPENSES.

For roads of ten or fifteen miles and upwards, operating twenty or more cars per day, averaging 105 to 110 miles each, grades moderate, a careful distribution of expenses, based upon the experience of the best roads, will *average* about as follows:

	EXPENSES PER CAR MILE. (CENTS)	
Maintenance of roadbed and track.......		.54
Maintenance of line........................		.12
Maintenance of power plant:		
Repairs on engines and boilers................	.180	
Repairs on dynamos.........................	.101	
Miscellaneous repairs...	.078	.36
Cost of power:		
Fuel......................................	.868	
Wages of engineers and firemen........	.653	
Wages of dynamo tenders, etc...............	.223

Miscellaneous	.091	1.26
Total		11.02

STANDARDS IN ELECTRIC STREET RAILWAY PRACTICE.[1]

BY O. T. CROSBY.

AFTER pointing out the necessity of some uniform standards of nomenclature, dimensions and method of keeping accounts, Mr. Crosby said:

While the adoption of a set of definitions by this Association would in no sense be binding, it would yet tend to make definite that which is now indefinite. As a basis upon which some further and better work in this direction should be done, I give herewith a table showing list of proposed terms, with various terms heretofore used as equivalents, and definitions properly limiting the proposed terms. In some cases when there has been satisfactory uniformity, no equivalents are given, but definitions are suggested. The list can, with benefit, be considerably extended.

NOMENCLATURE OF ELECTRIC RAILWAY TERMS.

Generator.—(Generator, dynamo) Machine in which the electric current is generated.

Motor.—(Motor.) Machine in which the electric current is transformed into mechanical power.

Frame.—(Frame.) Iron body of machine, including pole pieces and standards or side arms, if any, but not including base plates and bearings.

Standards.—(Standard bracket.) Supports of the bearings of generator.

Side Arms. (Side arms, check pieces, armature bracket.) Supports of bearings of railway motors.

Pole Pieces.—(Pole pieces.) That part of frame from whose surface lines of force may pass directly to the armature.

Field Coil.—(Field coil, spool.) Coils of wire wound on frame in such a way that a current passing through these coils makes magnets of the frame and pole pieces.

Brush Holder.—Device for holding the brushes in contact with the commutator, including the insulation used in its support.

Rocker Arm.—(Yoke, rocker arm.) Device for holding brush holders in position on commutator while attaching it directly or indirectly to the frame.

Fuse.—(Fuse, fusible plug.) A metal device for opening circuit when the current becomes abnormally large, the soft metal being melted by a current of fixed quantity.

Switch.—A device for closing or opening a circuit at one or more points.

Rheostat.—(Resistance box, rheostat.) Wire or other material suitably protected and conveniently arranged to be introduced in more or less proportion into a circuit.

Trolley.—(Trolley contact bar.) A device used to transmit the electric current from the overhead wire to the cars, consisting usually of a

Trolley Wheel.—A small metal wheel making rolling contact with the overhead wire.

Trolley Fork.—Mechanically connecting trolley wheel to

Trolley Pole.—Supporting the trolley fork and wheel and resting in a socket, which is part of the

Trolley Base Frame.

Trolley Wire.—Wire from which the trolley wheel directly receives current.

Trolley Frog.—(Frog, overhead switch, trolley switch.) A device used to fasten or hold together the trolley wires at a point where the trolley wire branches, and to guide, ordinarily automatically the trolley wheel along the wire over the track taken by the car.

Trolley Frog.—(Standard Frog.) A frog designed for use at a point where two branch lines make equal convergent angles with the main line.

Right Hand Trolley Frog.—A trolley frog designed for use at a point where a branch trolley wire leaves the main line to the right in the going direction.

Three Way Trolley Frog.—A trolley frog for use at a point where the line branches in three directions.

Draw Bridge Cross Over.—A device permitting the easy passage of a trolley wheel from one to the other of the two adjacent wires in a continuous direction.

1. Abstract of a paper read before the American Street Railway Association, at Pittsburgh, October 22, 1891.

Trolley Crossing.—(Crossing frog, cross over.) A device placed at the crossing of two trolley wires by which the trolley wheel running on one wire may cross the other; the device also holding the two trolley wires together.

Insulated Trolley Crossing.—A device placed at the crossing of two trolley wires, by which the two wires are insulated from each other, and by which the trolley wheel running on one line may cross the other.

Hanger.—(Line insulator, line suspension, trolley insulator.) A device for supporting and insulating the trolley wire.

Straight Line Hanger.—The hanger used on a straight line and supported from a span wire, the strain on same being essentially vertical.

Single curve hanger.—The hanger supported by a lateral strain in one direction and, ordinarily, on single track curves, except at ends, and the inside curve of double track.

Double Curve Hanger.—The hanger supported by lateral strain in opposite directions, used ordinarily at ends of both single and double curves and at intermediate points, and on double track curves.

Feeder Clamp.—Clamp with a device by which a feed wire may be coneected to the trolley wire.

Feeder.—A wire usually insulated, used for transmitting current from the power station to the mains or the trolley wire direct

Mains.—Wires usually insulated, serving for the distributing of current from the feeders to the trolley wire through tap wires.

Tap Wires.—Wires to convey current from feeders or mains at the pole to a near point of the trolley wire.

Trolley Section.—A length of one trolley wire with or without branches but continuous electrically.

Line Section.—A part of the overhead conducting system so insulated from other parts as to permit the supply of power to be separately controlled.

Section Box.—A box containing section switches and fuses used for control of a trolley section or line section.

Mr. Crosby then discussed standard methods of keeping accounts, exhibiting a number of blanks for the use of electric railway managers.

He said: In regard to standard methods of keeping accounts, I am permitted to present information prepared by Mr. W. E. Baker, of the Thomson-Houston Electric Co., long in charge of their work of maintaining of motors and lines for the West End Street Railway Co. Whether or not this Association should take any action, such as recommending one or another method of keeping accounts, I feel sure that Mr. Baker's suggestions will be of value to those who will consult them.

The first and most important matter in the expense accounts is the classification or division of expenses, and the second practical matter is how to separate into these divisions the expenses, without too much detail or clerical labor. For this purpose a manual should be carefully prepared.

In this manual there should appear four general divisions of expenses, namely: General expense, transportation expense, maintenance of way and buildings, and maintenance of equipment. Under these are subdivisions, and under each are clearly expressed the proper labor or material to be charged to them.

There has been considerable discussion of late in regard to a standard unit for the comparison of experses on electric roads. It may be doubtful if such standard unit can be satisfactorily agreed upon or will satisfactorily express the result; but, at any rate, it must be composed of some function of the results of operation.

The next matter is how to arrive at and keep these expenses sufficiently accurate and without too much clerical labor; and this brings us primarily to the Stock or Supply Account.

A careful record should be kept of all material received and all material used, on blanks bound in book form.

An invoice book with copies of all bills should be kept, and a monthly summary of both books will be made giving from the invoice book all the charges to stock, and from the material used all the credit to stock and all the charges of material to expense properly classified. If, in addition, a stock ledger is kept it will be found that all errors and mistakes in foremen's and in clerks' pricing, etc., will correct themselves, and it will easy at any time to check up the ledger with the material actually on hand in the stock room.

To summarize: If the superintendent, as is frequently the case, has an office distinct from the office of the company, he would be required to have the following books: Stock ledger, time books, pay rolls, material used and material received book; and copy books as follows will be a convenient arrangement: A letter book, a copy book for pay rolls, a requisition book, unless he buys his own supplies wholly, when this becomes an order book, a daily report of earnings' book or deposit book, a motor book for copying reports, and a statement and bill copying book for bills made against other parties; and the monthly reports to be made will be about as follows: Mileage report, material used report, balance stock ledger, receipts report, invoice summary. The daily reports would be of daily earnings and of condition of motor cars.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XII. NEW YORK, OCTOBER 28, 1891. No. 182.

Electric railroading, city, town and suburban, is here for our upbuilding and national prosperity, as surely as steam railroading was fifty years ago.—G. W. Mansfield.

THE AMERICAN ELECTRIC RAILWAY ASSOCIATION.

NO one who attended the great convention of street railway men at Pittsburgh could fail to see that it was to all intents and purposes an electrical meeting; and if the American Street Railway Association were forthwith renamed the American Electric Railway Association the new designation would hardly be inappropriate. Out of the 600 delegates and visitors a very small proportion had anything to do with horse or cable interests, and with the exception of one excellent but belated paper on cables, the whole work of the two active days lay in the discussion of electricity as a motive power for street railroads. When we remember that barely four years ago there were only a baker's dozen of electric roads, and that only two years ago a horse railway delegate wanted to put down all these new-fangled electrical ideas, one cannot but feel that success has been reached in a remarkably short time, and that after all the reward of persistent advocacy is seen in an industry that already embraces over 400 roads, or nearly half of all there are in the country to-day.

Just what the advance in this application of electricity is may be gathered from the figures presented by President Watson and quoted elsewhere in our columns. To these figures we are glad to be able to add those of the Census of 1890, now published for the first time, and furnished us kindly by Superintendent of Census, the Hon. Robert P. Porter, upon our application for them. These figures are the grand totals for the year ending June 30, 1890, since which time, it may be added, the electric roads have more than doubled; in fact, they have nearly trebled in some respects.

ITEMS.	All Motive Powers.	DISTRIBUTION.			
		Animal.	Electric.	Cable.	Steam.
Length of line	5,783.47	4,061.94	914.25	283.22	524.06
Length of all tracks	8,123.02	5,661.44	1,261.97	488.31	711.30
Number of cars	32,505	22,408	2,895	5,08[illegible]	2,113
Number of employees	70,764	44,314	6,619	11,673	8,158
Number of passengers	2,023,010,202	1,227,756,815	134,905,994	373,492,708	286,854,685
Total cost	$389,357,288.87	$195,121,682.50	$35,830,949.63	$76,346,618.28	$82,058,038.51

These figures are already changing. Thus, for example, since they were taken, the number of horses employed has, according to Mr. Watson, fallen off about 30,000; at which rate there will probably be none left by 1891. It will be observed again that the cable roads, 488 miles in length, cost $76,346,618, while 1,261 miles of electric, or nearly three times as much, cost only $35,830,-949. Another noticeable feature is that the horse cars, then numbering 22,408, required 44,314 employees. The electric cars then numbered 2,895, or only one-seventh as many, but with only 6,619 employees they carried nearly one-fifth as many passengers. It is matter of congratulation that, realizing the importance of street railway census statistics, the association passed a resolution asking that those of the electric roads be given with all the fullness possible, so that we may all have the information that is desirable and needful in marking the advance and amazing growth of this industry.

ELECTRICITY AND PLANT LIFE.

Mr. Steinmetz makes some very interesting suggestions in our columns this week relative to the effect of electricity on plant life. So far the work of investigation has been pursued along two lines, namely, the application of the current to the soil, and the use of the electric light; but we are not aware that there has been tried a combination of the two methods. Mr. Steinmetz, meantime, points out that some of the very evils that are attributed to an excess of the electric light may have been turned into benefits. If plant life and maturity may be stimulated by the light to such an extent as the Cornell experiments indicate, why should not crops of great value be cultivated far north of the line that now limits them? And why should it not be possible, as Mr. Steinmetz suggests, to euchre a frost that would otherwise destroy a whole grape crop and spoil the vintage? Even if the plants suffered to some extent from the stimulus, a partial crop would be better than none. In the case of flowers, the use of the light in intensifying color, etc., would not be less objectionable than is the use of coffee in the midnight hours by intellectual workers. It would be interesting, further, to try the effect of the light in the case of diseased plants or those whose leaves are infested by parasites. Altogether, it seems to us, and especially with the adoption of such suggestions as Mr. Steinmetz throws out, there is reason to believe that the electric light can be profitably used in the stimulation of plants without impairment of quantity or quality. It will be rather singular to see electricity taking the place of manure.

HOW TO OPERATE ELECTRIC ROADS.

There are many practical questions connected with electric railway work that might well be brought before the American Street Railway Association for discussion; but so far the papers listened to by that body have not been as helpful to managers and superintendents as might be expected. We are glad to note, therefore, that at Pittsburgh three excellent practical papers were read; and while these papers, by Messrs. Everett, Crosby and Mansfield, left a great many points untouched, they gave a wealth of information on some very vital subjects.

Mr. Everett's analysis of the features of a perfect street railway motor deserves commendation, but we do not quite follow him in his criticism of the price of equipment. If, as he says, the manufacturing companies could sell 40,000 cars instead of 4,000, were prices only lower, we may take it for granted either that the present manufacturers will cut prices or else that a dozen newcomers will compete with them for the business. Both contingencies may probably occur at once, but our opinion is that Mr. Everett exaggerates. When we see a new industry growing with giant leaps and bounds, it is pretty safe to assume that prices for apparatus cannot be very much out of the way. We do, however, expect to see the local street railway companies do all of their own repair and reconstruction work, and possibly some of them may build their own "spare" parts.

Mr. Mansfield's paper was worthy of his ability and of the experience that in spite of his youth he has gained as a pioneer engineer and inventor in this field. His remarks on trolley and guard wires were pithy to a degree, while his advice to bury all the feeders was as good as any given throughout the meeting. We do not quite share his pessimistic views touching conduit and storage systems. Our faith has been somewhat shaken by the failures of the past, and yet it seems to us that some of the conduit systems now known might be made to meet the situation fairly well. So, too, with storage battery cars. We do not entertain the belief that the arguments for them are, to use Mr. Mansfield's sharp words, "sophistries for the blind and unthinking." On the contrary, the work now being done deserves all possible encouragement, and we shall watch it with hopeful feelings and in a very kindly spirit. The reception given Mr. Neftel's little paper showed that his hearers were still willing to be convinced of the practicability of the storage battery system.

As usual, Mr. Crosby handled his subject of "standards" in a most masterly fashion, and it is devoutly to be hoped that the tendency towards standardization will make itself felt thus early, when the opposite tendency is naturally very strong. Steam railroading furnishes many a lesson and example in this particular respect. As with apparatus so with accounts. We have recently employed our pages in suggesting the best methods of finance and managment for central stations; and it is evident that the need of system is not less in electric railway work.

The above papers, with the very useful and exhaustive figures contributed by Mr. J. S. Badger, on electric railway construction, maintenance and profit, constitute a valuable résumé of the state of the art and of themselves made the Pittsburgh meeting as helpful as any of its predecessors.

Gearless Motors.

Many electrical engineers who visited Pittsburgh, last week, saw gearless electric railway motors for the first time. Opinions were, of course, varied, but, on the whole, the gearless may be said to have made a very favorable impression, and, under test, to have verified many of the claims made for it. Coming so quickly as it does upon the heels of the excellent single-reduction motors now in use, the public has scarcely been ready for it; but while to-day belongs to the single-reduction, it certainly looks as though to-morrow belongs to the gearless, unless something else equally meritorious arrives on the scene.

Oil as Insulation.

An interesting contribution to the history of oil as insulation is made in our pages this week by Mr. F. L. Pope, whose article deserves careful reading, especially in view of the recent work at Lauffen. With regard to that work, it would be valuable to know why the voltage was not carried up to 30,000 as originally proposed, but fell short at 18,000 or 20,000 volts. Our own impression is that the restriction to this lower voltage was due to heating up and the prevention of rapid radiation by the oil. This is open to remedy, and may not have been a serious trouble, but it is certainly one of the possibilities about which we would be glad to learn a little more.

A PERFECT ELECTRIC MOTOR.[1]

BY H. A. EVERETT.

In his report upon "A Perfect Electric Motor," Mr. Everett gave a brief history of the electric motor, its imperfections, and the steps taken to overcome them, and, after bringing the subject down to date and discussing the usages of various railways, summed up his idea of a perfect motor as follows:

Taking the trolley wheel, pole, and stand, I think it desirable to have a wheel that is capable of following the wire at any angle, with a trolley pole brittle enough to break should it become entangled in the wires, without pulling them down, and a trolley spring rigid enough to give good, steady pressure on trolley wire, and so constructed that when the car is in the car house or going under a low bridge, the pole could come very close to the roof of the car, also flexible enough to give good pressure when the trolley has to be 21 or 22 feet high at the railway crossings.

The car should have a lamp circuit, with plenty of lamps distributed properly.

The perfect motor ought to have, as hereinbefore suggested, a reliable fuse plug, that will invariably blow before injury is done to the machine.

Have on each car the best lighting arrester that can be secured in the market.

In coming to the motor proper, it is desirable to use a controlling switch that is easily operated and readily reversed, in case of accidents. The simpler the controlling device the better, and it should be constructed with a view to guard against any possible disarrangement of the parts, so that it will be reliable in all cases, both electrically and mechanically.

The rheostat should also be carefully looked after, and properly protected to keep it from injury, by reason of water, snow or dirt getting upon it. It should only be available in starting the car to avoid the lunge of a start, and should be so arranged as to be cut out as soon as the car is started, and give the entire efficiency of the motor proper.

The motor should be well protected in all its parts from any outside interference, so that in running along the street it will be impossible to pick up nails, wire, or anything that would short-circuit it, at the same time observing that a motor must be properly ventilated to keep it from heating while in use. The cover should be made so as to be easily removed.

I deem it very advisable to have an armature of a large diameter, making a small number of revolutions per minute, with the bearings made of extreme width with proper grease-cups, and in such a condition that they can be readily re-babbitted when slightly worn.

The diameter of the commutator should also be large, and to have the brushes easy of access is very desirable. The winding of the armature ought to be of the simplest kind, and the size of the wire and insulation of same should be carefully looked after. I think the insulation of wires in armatures is at present one of the weakest points in the motor.

The armature gears should have a wide face, and run in oil. The armature shaft ought to be of ample diameter, and there is nothing gained by having the keyway too small for the securing of the commutator to the shaft. The commutator should be carefully insulated, so that there will be no grounds between it and the case. The box in which this gear runs ought to be constructed of copper, or some light material that is somewhat flexible, so that if struck from the outside it will bend rather than break. The fields should also be wound with a wire of better insulation, and of ample size to take the current. Of course, in this particular, I do not intend that the wire of either the field or armature should be great enough to take more horse power than ought to be used by the machine. To my mind it is very desirable to have the armature in such a condition that it can be readily taken out from the machine and put in again.

One of the serious disadvantages to operators of electric roads is the expensive labor necessary in winding the armatures and fields, also in regard to high-priced mechanics who ought to be employed to attend to the machines. There is nothing gained in employing a cheap class of labor to handle an electric equipment either as electricians, armature or field men, or mechanics. This proposition is a self-evident truth, as can readily be observed in many roads now in in operation.

At present, I think the single-reduction motor is the nearest perfection of any on the market.

I think it very desirable that the electric companies should devote some time to the perfection of an electric brake to stop the car with the same power that runs it. This could be readily done, and would be a satisfactory improvement.

Electric heaters are now used in quite a number of places, and I think will prove quite satisfactory.

I have noticed electric signal bells on some of the cars, and they seem to work very well.

For a dasher gong on a motor car I am in favor of a foot tread, as in testing an electric gong we found that our men used it altogether too freely.

I am in favor of an oil head-light, one that can be removed easily, so that in the event of a trolley being broken or anything happening to the electric part of the car, or a light is desired underneath the car, the oil head-light can be used to better advantage than the electric. There ought also to be one oil light in every car for the same purpose. There is no reason why an electric fare register cannot be made to work successfully.

The durability of a motor is a question which requires very careful attention. The single reduction motor, when properly looked after, ought to last for many years. We have had one in operation for over 10 months, and it appears to be in as good condition as when it first went on the road. The car should be of moderate size, constructed with all modern convenience, but without fancy decorations or any unnecessary display.

The cars should be run on frequent headway, and at all hours of the day and night, at as high a rate of speed as the civic authorities will permit. The noise of the motors has been very largely done away with, and by careful attention the old countershaft machines can be used until worn out by simply covering the gearing with an oil box, and by not attempting to run them too many miles without inspection.

1. Abstract of a report presented to the American Street Railway Association, at Pittsburgh, Oct., 1891.

TENTH ANNUAL MEETING OF THE AMERICAN STREET RAILWAY ASSOCIATION, PITTSBURGH, OCTOBER 21-22, 1891.

The above meeting was begun at the headquarters of the association, the Monongahela House, at 10 a. m., on October 21. The convention was the largest ever held by the association, there being not fewer than 600 delegates and supply men in attendance during the week.

President Watson opened the proceedings with an excellent address, of which the following is an abstract:

THE PRESIDENT'S ADDRESS.

The president, after thanking the people of Pittsburgh for the warm reception tendered the association, said:

"The most important matters to be discussed in convention will be the problems which arise in the application of electricity to street railway traffic. It is a source of no little satisfaction to us to know that, in the development of the electric railway, America leads the world. Three years ago there were only 13 electrical roads in the United States; now there are over 400, and the advices from every part of the country indicate that before the close of the present year the number will be increased to 500. The capital now invested in American electric railways exceeds $75,000,000. 'Horse sense' counts for but little in this age of rapid transit. We old dogs have been obliged to learn new tricks, and without the usual privilege of serving an apprenticeship. Our stables are being converted into power-houses; the electrician has taken the place of the veterinary surgeon; our drivers are being educated as motor-men, and most of us have horse cars for sale.

"The following statistics have been compiled from returns made by street railway companies in the United States and Canada to the middle of September, and are believed to be as reliable as it is possible to make them:

Total number of miles	11,030
Number of miles operated by animal power	5,443
" " " " electricity	3,009
" " " " steam motors	1,918
" " " " cable	660
Total number cars employed in street railway traffic	36,517
Number of cars operated by animal power	25,424
" " " " electricity	6,732
" " " " cable	3,317
" " " " steam motors	1,044
The number of horses employed	88,114
" " " mules "	12,002
" " " steam motors	200
Number of companies operating street railway lines	1,003
Number of companies operating by animal power	537
" " " " electricity	412
" " " " cable	54
" " engaged in building new lines, about	75

"It is interesting to note that since November, 1890, the number of horses employed on street railway lines has fallen from 116,795 to 88,114; that is, 28,681 in one year. At this rate it will not take long to emancipate the horse from street railway business.

"According to the official figures taken from one of the street railway journals for the month of October, 1891, Philadelphia leads with 510 miles of single track; and after the Quaker City comes Chicago with 452 miles, New York with 289 miles, Brooklyn 285, Boston with 283, St. Louis 275, Baltimore 207, San Francisco 205, Cleveland 192, Cincinnati 180, Pittsburgh 168, Kansas City 141, New Orleans 139, Louisville 132, Buffalo 110, Minneapolis 101, Los Angeles 99, Detroit 94, Birmingham (Ala.) 92, St. Paul 90, Washington, 85.

"The official figures of the census just completed show that in December, 1889, 476 cities and towns possessed rapid transit facilities; and it is now difficult to find any town of 5,000 inhabitants without one or more street railways.

"While a large majority of us are interested in electric street railways, electricity will not be permitted to monopolize this convention. One of the features prepared for us will be the report of a special committee on 'A Year's Progress in Cable Motive Power.' This is well. We should not become so deeply interested in any one form of rapid transit as to lose sight of the good points of all others."

"Since the introduction of cable and electric transit," Mr. Watson continued, "some of the lines have been made U. S. mail routes. The plan is to place boxes for the collection of mail matter on all the cars. The mail is then sorted at some central point, and sent to the sub-stations without delay. In a city where all the cars come to a common centre, the plan seems feasible, and it is suggested that other companies consult the local postal authorities on the subject at an early day."

Mr. Watson closed by referring to the pleasure and benefit expected from the World's Fair in 1893, to the growth and strength of the association, and to the able work of the street railway press.

The report of the executive committee showed the association to consist of 187 companies, 22 having joined during the past year, and four having withdrawn. "Street Railway Law" has been enlarged by the addition of Vols. VII and VIII, consisting of the monthly reports of judicial decisions relating to street railway work. Attention was called to the fact that a hearty invitation had been tendered by the Rochester Railway Company to the association to hold its next convention in that city. The committee took occasion to express gratitude for the hospitality with which the visiting delegates had been received at Pittsburgh, and, in closing, called attention to the fact that, although the past year has been one of unusual mortality, no loss has occurred to the association by the death of any one of its representatives.

The convention then listened to a report by Mr. H. A. Everett, of Cleveland, on "A Perfect Electric Motor."[1]

A discussion arose on this paper as to the cost of electric operation.

MR. HENRY, of Pittsburgh, said: I have in my hand a copy of my last report. Our total cost, including conductors and motormen, all repairs, maintenance of way, general expenses and all other charges, amounted to 20.26 cents per mile. Separating this into strictly operating expenses, and fixed charges, we have operating expense of 12.74 cents per mile, and in comparing the same with the cost of operating the horse line, which was 10 cents per car mile, we must remember that we then paid but one man on a car. We paid four or 3 cents per mile against 6.60 cents now. This increased cost per mile for conductors and motormen is a necessary adjunct of rapid transit, and is not peculiar to the system. Allowing this, we have a difference of 1.04 cents per car mile in favor of electricity as against animal power.

MR. BICKFORD, of Salem—We have equipped our lines and run 12 cars. Formerly it took 18 cars to do the work 12 now do. One line where we ran twelve cars by horses, we run eight electric cars and carry more passengers.

MR. STEPHENSON, of Washington—That is the general information that I get. We have about 20 cars on our road, and I am satisfied that when we put on electricity 12 or 14 cars will carry the same number of people as the 20 now do. I am also satisfied that we shall have an increase in our travel of 25 or 50 per cent.

MR. PEARSON, of Boston—I think I can give some information on this subject. Our road has about 350 cars equipped with electric motors. The expense of operation with horses is about 25 cents per car mile, including everything connected with the operation, fixed charges and track repairs. In Boston the cost of operation is quite high as compared with some other cities. You will find in many cities the cost of operation of horse cars is below 25 cents, but we pay a good price for labor, on account of the running of our lines in the congested parts of the city, where we cannot get as much work out of a man as you can in other cities. This makes a greater cost of operation. The cost of operation with electric motors up to the present has been about 20 cents per car mile. The increased cost of operation in our city is also true to a great extent with electricity. We pay 25 cents a day more for motormen and electric car conductors than we do for horse conductors and drivers. That has been our experience up to this time. We save about 25 per cent. Our men are expected to work 10 hours a day, but we really get anywhere from 7½ to 9½ hours a day. The amount of power consumed is considerably more on account of the slow speed with which the motor cars have to operate in the downtown sections of the city. There the streets are crowded with teams and cars, and I suppose that the cars run at an average of perhaps one or two miles an hour for a distance of from one-half to one mile, which of course decreases the profits very materially. We expect to get the cost of operation down to 16 or 17 cents per car mile. Another item of expense to us is the high cost of power, we having been obliged to hire power from an electric light company and pay them a good price for it, of course much more than it would cost a street railway company if they had their own power house. As I said before, the saving of electric cars, as compared with the horse system, is about 25 per cent., being about 20 cents per car mile for the electric cars and 25 cents per car mile for horse cars.

MR. RICHARDSON, of Brooklyn—I would like to ask Mr. Pearson, before he takes his seat, what size cars his company has operated in its electrical propulsion and what size he thinks, from his experience, would be the best and most economically operated, all things considered.

MR. PEARSON—We began with a sixteen-foot motor car very similar to the old horse cars. We have changed from that to a long car, which is 26 or 28 feet long in the body and 35 feet over all; that is the car we have adopted as our standard. For our purpose we find a decided improvement in earnings and saving in operating expenses per passenger with the long car. I imagine that the conditions in Boston determine that for us, and in other cities it may be that the short car would be more profitable for operation. We find the long car earns a great deal more per car mile, and we need only the same number of men to operate it as with the short one. From our tests we find that the amount of power consumed on a level track is very little more for the long car than with the short one; in fact, the weight which we have in the car seems to have little to do with the current consumed, as long as the car is on a level track. From tests, we found that with a long car empty, weighing, perhaps, 18,000 pounds, using a certain average amount of current, the same car loaded with 15,000 pounds of weight used very little additional power until we come to a grade. We have experimented in this matter, and could hardly tell from the reading which was the empty and which was the loaded car. That being the case, it does not cost much more to operate long cars than short cars. Again, they carry nearly double the people, and do it with the same expense for conductors and drivers. Just how much more heavy cars will increase the track repairs of course we cannot tell at present.

MR. SAGE—Did you increase the headway?

MR. PEARSON—No, we are on the same headway.

MR. SAGE—Where do you get your additional passengers?

MR. PEARSON—They prefer to take our cars rather than the steam railroad. A great many people who formerly travelled on the steam road for short trips prefer to take our electric cars. The ride is pleasant, and in the suburbs we go very quickly.

MR. BALLARD, of San Antonio—I happen to know, from having seen the figures, a good many roads, and the profits they made were absorbed in paying bills for the new equipment. The shareholders, instead of making more advances of money, allow the profits to be used for that purpose. As to the advantages of these electric roads over a horse road, I do not think sufficient allowance is made for the natural increase of travel, and that people prefer to ride on an electric car. In the city of San Antonio the entire line has been equipped within the last year. The total gross revenue of the old horse line running regularly was about $6,500 a month. We are now running at an average gross income of $12,000 a month, with only an increase of the population of about 2,000. Our increased receipts are nearly 100 per cent.

MR SAGE—Have you increased your mileage?

MR. BALLARD—Very little. The increase in traffic is enormous.

MR. WM. RICHARDSON—Will the gentleman kindly state how much the cost of operation in the aggregate has been increased?

MR. BALLARD The increase is only twelve per cent. Our total outlay for operating expenses in earning a revenue of twelve thousand dollars a month, against sixty five hundred dollars a month, is only an increase of twelve per cent. I would also like the gentlemen to bear in mind that we have to pay five dollars and one-half for every ton of coal that we burn.

Adjourned.

EVENING SESSION, OCT. 21.

At the evening session a valuable paper was presented by Mr. G. W. Mansfield on "The Dependent—Overhead or Underground—System of Electric Motive Power."[1]

After the reading of this paper, some discussion arose as to the size and value of guard wires, Mr. Mansfield having suggested No. 14 as a good size for guard wire, Mr. Bickford said he preferred a No. 10 of steel.

MR. LITTELL, of Buffalo—I wish to ask Mr. Mansfield if he does not think it advisable to cut up his guard wire into sections of, say, one thousand or fifteen hundred feet, and put in circuit breakers, so that if any wire does fall, the current will not be sent a great distance.

MR. MANSFIELD—I would advise it, and it is done on many

1. See page 482.

1. See page 475.

roads; the West End road, of Boston, I believe, do it every five hundred feet.

MR. LITTELL—It is done in Buffalo.

MR. WATSON, of Cleveland—Mr. McKinstry, who is manager of the telephone lines in Cleveland, informed me that his telephone wires in the centre of the city did not last much over a year, sometimes a year and a half. In our span wires we used a galvanized steel wire, and at the end of a year and a half they were rusted to such an extent that we dare not tighten them up. We have a chemical works and an oil works in Cleveland, and we do not know whether or not it is due to the gases that come from these factories. I believe our road was the first one to use the soft drawn copper wire for span wires. The reason of using this in preference to hard drawn wire, or silicon bronze, was that silicon bronze was very brittle. We used a soft drawn number four, the same as for the ground work. That has been up now over a year, and there has been no perceptible elongation or stretching or sagging.

MR. RICHARDSON—I have had submitted to me a copper triangular tube, if I may so call it, intended to cover over the trolley wire and to guard it thoroughly from any interference with wires that might otherwise come in contact with it; I wish to ask the gentlemen's judgment of that device.

MR. MANSFIELD—I have looked into a great many methods of protecting the trolley wire outside of the stringing of additional wires, but I have not seen any which in my judgment would lead me to adopt it upon any road where my advice was asked. The trouble is that most of these devices will warp and twist, and unless they are made very large the trolley wire may swing to one side or the other. They entail heavy span wires and an additional strain upon the side poles for their support. In the winter time the top of these devices will be covered with a large accumulation of ice and snow, which throws a greater weight upon the span wires and strain upon the side of the poles, for their support. Then again they are difficult to put in place and maintain in place. That is the result of my observations, and I do not think there is anything as good as what is generally accepted and used to-day.

Adjourned.

THURSDAY MORNING SESSION.

At the opening of the morning session a paper was read by Mr. G. Hilton Scribner on "The Public and State Treatment of Corporations." It was an arraignment of both political parties as to their behavior respecting corporations, and a most eloquent plea for the work that such bodies can do in promotion of public welfare.

Next came a paper by Mr. Knight Neftel on "The Independent—Primary or Storage Battery—System of Electric Motive Power."[1]

MR. BAUMHOFF, of St. Louis—The Company which I represent have experimented with the storage battery, and I must say we have had no success. We had two cars, each equipped with one hundred and twenty cells on an average grade of two and one-half per cent., the steepest grade not over three and one-half per cent. We were unable to get a greater mileage than from eighteen to twenty-two miles out of each charge. The charging of the cars required from eight to twelve hours. We found also that aside from the leakage and the spilling of the liquid, the cells buckled and corroded, caused possibly by acids. We expended a large sum of money in these experiments, but finally gave them up as a hopeless undertaking. The storage battery is certainly not a commercial success.

MR. NEFTEL—I believe the experiments the gentleman refers to must have been made at least four years ago. In the past four years a great change has come over everything connected with the storage battery; and the storage battery of this day, as manufactured by the leading companies, is an entirely new thing. Great progress is going on in this direction, and we are not justified in throwing the thing aside as a failure. I remember five years ago receiving a letter from the Thomson-Houston Co., which I have preserved as a curiosity, asking me whether I thought electric traction would ever be successful, and whether it would pay an electric light company to manufacture motors for electric traction.

MR. BARR, of Newark, N. J.—On this question of storage battery I only wish to refer to the road in Philadelphia of which Mr. Sullivan is president. The Lehigh Avenue Passenger Railway was built to operate storage battery cars. In May, 1890, the road started with six storage-battery cars. In October, 1890, application was made to the city council of Philadelphia for the use of the overhead system, claiming that unless they could use it they would have to abandon the road. The council refused permission to the company to use the overhead wire, and on the 1st of Januars, 1891, the storage-battery cars were abandoned and the road has since been operated by horse power.

MR. VHAY, of Detroit—I represent a road which has, perhaps, experimented with the storage battery system more than any other road in this country. The Woodward storage battery put their car on our road for about a year and a half. The system worked very well. The cars ran at the rate of about twelve or fourteen miles an hour. The cost for coal was considerable, being ten dollars per day for one car. The trouble seems to be that it takes from seven to ten hours to charge these plates, and it is not possible to make over thirty-five miles a day; they make about four trips. Sometimes they can get into the house and sometimes they cannot. There were no grades, but some sharp curves. We thought that ten dollars a day for coal, two dollars and a half for the services of an engineer, and getting only thirty miles out of the battery was not much of a commercial success. We now have a road with cylinder underground filled with compressed air, and by cylinders connected with the car enough air pressure may be taken from the underground cylinder when the car stops for a passenger to propel it half a mile. The people say that it runs like a scared cat.

MR. NEFTEL—I think it is a mistake to expect batteries to make a long run. If we have a perfected storage battery system it will not be a system in which cars will run for one hundred or two hundred miles; but it will be a system in which each car will make one trip, and then newly charged batteries will be put in the car. The batteries can be changed easily, and there is no earthly object in dragging them along for thirty, forty or fifty miles; it is taking along an unnecessary weight in lead.

MR. E. A. SCOTT, of Philadelphia—I am the representative of the company that has put in two successful plants in Dubuque, Ia., and Washington, D. C. We are now operating them as a commercial success. The gentlemen connected with these roads, if they are here, can probably tell you better than I what the result has been. As Mr. Neftel stated, there is no more necessity to run a battery one hundred miles than there is of making a span of horses pull a car that distance. You can work a pair of horses until they drop in their tracks, and you can do the same with the battery until it becomes exhausted, but there is no necessity for it in either case. If you want to know whether any road can succeed, take the successful roads that are running at the present time. Go to Washington and examine the road there, and you will be delighted with the way the cars run. As to the length of time it takes to charge a storage battery, it has been correctly stated that it takes as long to charge it as to discharge it. We calculate to run about twenty or twenty-five miles before we make a change of the batteries; and if they are run in that way on a road where grades do not exist beyond five or six per cent. there is no trouble.

The question of how expensive the system is going to be is controlled by the question of how often you are going to renew the positive plates.

MR. CLEMINSHAW—How many cars on the line in Washington?

MR. SCOTT—Six; and nine in Dubuque.

MR. CLEMINSHAW—How long have they been running?

MR. SCOTT—Since early part of May in Dubuque, and about three months in Washington. On certain portions of the road in Washington they are making fifteen miles an hour. If the experience of everybody connected with the cars is to be believed, they run on their time as regularly as any other system, whether electric, cable, or horse. I noticed in the paper that was read this morning that the question of comparative economy in running is stated to be about that of horses. We believe from what we know that it is considerably less than horses, although we have no figures to show. We believe that in about a year it can be run in competition, so far as economy is concerned, with any overhead system.

MR. MONTAGUE, of Yonkers.—I have seen within three months a storage battery car, not the Edco, that will take eighty-five passengers on a sixteen-foot car and carry it up a grade of ten per cent, and do it easily and steadily. It takes an hour and thirty minutes to charge the batteries. They do not allow the batteries as a rule to run more than twenty or twenty-two miles; but on Decoration Day of this year three cars ran, respectively, forty-two, forty-six and forty-eight miles. When they came to the power house, the engineer had gone home, and they remained outside all night. In the morning there was sufficient power left in the batteries to take the cars into the house. It takes about thirty seconds to change the batteries. These cars run on the level ground at a speed faster than most city governments will permit, and in mounting grades they go quite fast. On one occasion a car was mounting a grade with thirty people in it. I got off and walked along side of the car, and it was not until it had reached the top that I could keep pace with it. The grade was about five per cent.

MR. RICHARDSON.—How many cars are run?

MR. MONTAGUE.—Six cars.

MR. RICHARDSON.—I want to state what seems to me to be a fair inference from what these gentlemen have told us and from my own investigations on the subject, and that is, the storage battery system seems only appropriate for roads running very few cars and on a headway of perhaps ten or fifteen minutes.

MR. HOLMES, of New York, entered into a calculation to show that the power required for the storage car as compared with the trolley car was in the proportion of 215 to 118, or nearly two to one. Mr. SCOTT figured that it took 1¼ h. p. per car mile for a storage car, and he doubted if the trolley cars could do much better.

1. See page 485.

A resolution was adopted calling for a report giving data on the best kind of engine for traction power plants.

MR. LITTELL, of Buffalo, then offered the following resolution:

Whereas, The American Street Railway Association having learned that the collection of the statistics of electrical railroads for the Eleventh United States Census has been transferred to the Division of Manufactures, and placed in charge of Mr. Allen R. Foote, special agent for the collection of statistics of the electrical industries; and

Whereas, The development of electric railroad construction and operation is of such recent date that nearly three times as many such roads are now in operation as in the census year; and

Whereas, Those interested in street railroads, in common with those in other branches of the electrical industries, regard a complete and accurate report by the United States Government of all electrical statistics, and especially those pertaining to electric railroads, as of vital and far-reaching public importance:

Be it resolved:

1. That this association approves of the action of the Superintendent of Census in placing the collection of the statistics of electric railroads in the Division of Manufactures, and in charge of Special Agent Allen R. Foote.

2. That it requests Superintendent Porter of the Census Bureau for the census year to collect and report the complete statistics for electrical railroads down to the date of publication, and thus give to them their highest degree of value.

3. That a committee on census composed of five members be appointed by this association to represent it in an effort to secure ample provision and authority for a complete census of the electrical industries, and this association pledges itself to support all reasonable measures to that end. Carried.

THURSDAY AFTERNOON SESSION.

A report was presented by Mr. Oscar T. Crosby on "Standards in Electric Street Railway Practice."[1]

At the conclusion of his report, Mr. Crosby made the following motion, namely, "That a committee on standardizing of ratings, nomenclature, dimensions and accounts for electric street railways be appointed by the association." Carried.

The committee on nominations reported in favor of the following officers for the year 1891-2:

For President, John G. Holmes, Pittsburgh, Pa.
First Vice-President, Thomas H. McLean, New York, N. Y.
Second Vice-President, James B. Speed, Louisville, Ky.
Third Vice-President, Albion E. Lang, Toledo, O.
Secretary and Treasurer, Wm. J. Richardson, Brooklyn, N. Y.

Executive Committee:

Henry M. Watson, Buffalo, N. Y.
Lewis Perrine, Jr., Trenton, N. J.
W. Worth Bean, St. Joseph, Mich.
Murray A. Verner, Pittsburgh, Pa.
Thomas C. Pennington, Chicago, Ill.

The committee also recommended Cleveland, O., as the place for the next meeting.

All these recommendations were duly adopted. The convention then adjourned.

THE INDEPENDENT—STORAGE OR PRIMARY BATTERY—SYSTEM OF ELECTRIC MOTIVE POWER.[1]

BY KNIGHT NEFTEL.

OWING to a variety of causes, the system which was assigned to me at the last convention to report on has made less material progress in a commercial way than its competitors.

PRIMARY BATTERIES.

So far, primary batteries have been applied only to the operation of the smallest stationary motors. Their application in the near future to traction may, I think, be entirely disregarded. Were it not a purely technical matter, it might be easily demonstrated with our knowledge of electro-chemistry that such an arrangement as an electric primary battery driving a car is an impossibility.

In view of the claims of certain inventors, I regret to be obliged to make so absolute a statement; but the results so far have produced nothing of value.

SECONDARY BATTERIES.

The application of secondary or storage batteries to electrical traction has been accomplished in a number of cities, with a varying amount of success. Roads equipped by batteries have now been sufficiently long in operation to allow us to draw some conclusions as to the practical results obtained and what is possible in the near future. The advantages which have been demonstrated on Madison avenue, in New York; Dubuque, Iowa; Washington, D. C., and elsewhere may be summarized as follows:

First. The independent feature of the system. The cars independent of each other, and free from drawbacks of broken trolley wires; temporary stoppages at the power station; the grounding of one motor affecting other motors, and sudden and severe strains upon the machinery at the power station, such as frequently occur in direct systems; the absence of all street structures and repairs to the same, and the loss by grounds and leakages, are also very considerable advantages both as to economy and satisfactory operation.

Second. The comparatively small space required for the power station. Each car being provided with two or more sets of batteries, the same can be charged at a uniform rate without undue strain on the machinery of the power station, and as it can be done more rapidly than the discharge required for the operation of the motors, a less amount of general machinery is necessary for a given amount of work.

Another and important advantage of the system is the low pressure of the current used to supply the motors, and the consequent increased durability of the motor, and practically absolute safety to life from electrical shock.

It has been demonstrated also that the cars can be easily handled in the street; run at any desired speed, and reversed with far more safety to the armature of the motor than in the direct system. The increased weight requires simply more brake leverage.

The modern battery, improved in many of its details during the last year, is still an unknown quantity as to durability. There is the same doubt concerning this as there was at the time incandescent lamps were first introduced. At that time some phenomenal records were made by lamps grouped with other lamps. Similarly, some plates appeared to be almost indestructible while others, made practically in the same manner, deteriorate within a very short time. It is, consequently, very difficult to exactly and fairly place a limit on the life of the positive plates as yet. Speaking simply from observation of a large number of plates of various kinds, I am inclined to put the limit of about eight months; though it is claimed by some of the more prominent manufacturers—and undoubtedly it is true in special cases—that entire elements have lasted 10 months, and even longer.

It must be remembered however, that the jolting and handling to which these batteries are subjected, in traction work, increases the tendency to disintegrate, buckle and short circuit, and that the record for durability for this application can never be the same as for stationary work. A serious inconvenience to the use of batteries in traction work is the necessary presence of the liquid in the jars. This causes the whole equipment to be somewhat cumbersome, and unless arranged with great care, and with a variety of devices lately designed, a source of considerable annoyance.

The connections between the plates, which formerly gave so much trouble by breaking off, have been perfected so as to prevent this difficulty, and the shape of the jars has been designed to prevent the spilling of the acid while the car is running. The car seats are now practically hermetically sealed, so that the escaping gases are not offensive to the passengers.

The handling of the batteries is an exceedingly important consideration. Many devices have been invented to render this easy and cheap. I have witnessed the changing of batteries in a car, one set being taken out and a charged set replaced by four men in the short space of three minutes. This is accomplished by electrical elevators, which move the batteries opposite the car, and upon the platforms of which the discharged elements are again charged.

The general conclusions which the year's experience and progress have afforded us an opportunity to make, may be summarized as follows:

Storage battery cars are as yet applicable only to those roads which are practically level; where the direct system cannot be used, and where cable traction cannot be used; and applicable to those roads only at about the same cost as horse traction.

I feel justified in making this statement in view of the guarantees which some of the more prominent manufacturers of batteries are willing to enter into, and which practically insure the customer against loss due to the deterioriation of plates; leaving the question of the responsibility of the company the only one for him to look into.

MR. DWIGHT B. DEAN and Miss Mary E. Sisson were married in Chicago on Oct. 7. The wedding took place at the house of the bride's parents, and after the ceremony the happy couple left for the East, where they will spend the honeymoon.

MR. GEORGE ELLSWORTH GALE, for many years connected with the Excelsior Electric Co., of this city, in a confidential capacity, was married Wednesday, Oct. 14, to Miss Edith Mary Clark, daughter of Mr. James T. Clark, of Brooklyn, at St. Mary's Protestant Episcopal Church, in that city.

1. See page 479.

1. Abstract of paper read before the American Street Railway Association, Oct. 23, 1891.

EXHIBITION NOTES.

THE ELECTRIC MERCHANDISE CO., of Chicago, had one of the most interesting exhibits at the convention in Parlor 5. The Burton electric heaters in operation were the rage, and their headquarters were crowded all the time. A fine line of railway material and specialties, comprising rawhide pinions, Chicago trolley clamps, "New Departure" bells, headlights and the new trolley pole and base, the invention of Mr. Elmer A. Sperry, and the new device for holding track brooms were exhibited. Mr. W. R. Mason, the manager of the company, assisted by W. L. Adams, E. H. Englund, F. A. Cicott and D. B. Dean, were kept everlastingly busy explaining the advantages of their railway material and especially the electric heaters. Mr. D. B. Dean in a moment of forgetfulness showed the delegates how to iron silk hats with the Burton heater and after that he had his hands full. He was presented with a trunk for his services in this line by an enthusiast, but when he started to remove it the bottom dropped out and he is still looking for it.

THE FOREST CITY ELECTRIC WORKS, represented by W. B. & G. W. Cleveland, together with the Lieb Machine Works, represented by Mr. Lieb and H. H. Harrison chartered a small "log cabin," facing the hotel on the river front, and made a striking exhibit. Their campaign ticket, "Harrison & Cleveland," attracted much attention. An automatic circuit breaker having many novel and advantageous features, fuse switch for feeder work and dynamo switch were shown by the Forest City Electric Works, and their new "Sandbagger" slow-movement car lighting switch, so called because the arc is smothered by means of fine sand instead of having any form of long-break, quick-movement device, called forth special comment. It was in operation on the 500-volt railway circuit. A non-flashing section switch for cutting out any portion of the line, made on the same principle was also exhibited.

THE SHORT ELECTRIC RAILWAY CO., of Cleveland, covered a large space in the centre of the boat with their exhibit, which comprised a 15 h. p. single-reduction motor, a 25 h. p. waterproof motor and the new gearless motor, which ran perfectly noiseless, and was a special object of attention. A large switchboard of polished oak was shown fitted with switches, circuit-breaker, instruments and the various adjuncts required in the station, and a neatly arranged exhibit of trolley-wire insulators, pull-off brackets, switches, cross-overs and special line tools. A large Short generator in operation, it being driven by a 15 h. p. railway motor, was quite a centre of attraction. The Short Co. also had headquarters in the hotel, in Parlor 11, where their fine catalogue of railway apparatus and the printing matter descriptive of their system was to be found. A beautifully finished car rheostat was on exhibition there.

ALEXANDER BARNEY & CHAPIN, of New York, had a most novel and attractive exhibit, situated directly in front of the ladies' parlor. The A. B. C. railway lamp received considerable attention from the delegates, and the visitors, especially the ladies and children, were infatuated with the "musical" coach and signal trumpet. This alluring siren was worked by the A. B. C. dry battery and manipulated by a 5-point switch. In addition to the above a complete line of railway supplies was shown, including station switches, A. B. C. tape-carbon brushes, fuse wire socket, Alexite cut-outs, and all necessary apparatus for the complete equipment of electric railways. Charles E. Chapin and Henry G. Issertel represented the company, the latter-named gentleman being the musical professor.

THE WESTINGHOUSE ELECTRIC AND MANUFACTURING CO., besides their very complete exhibit on the boat and at the hotel, extended an invitation to visit their shops and view their exhibit there. Practical torque tests of the double-reduction, single-reduction and gearless motors were to be seen and all the various parts of the machines and equipment apparatus. The principal and most attractive part, however, of this portion of their exhibit was a 300 h. p. railway generator in operation. The machine shows great beauty of design and absolute sparklessness at the commutator, even when the machine is heavily loaded and then the load suddenly removed by the operation of the automatic circuit breaker. Gearless motors were being turned out in large numbers, and the simplicity of these motors and the excellence of design and workmanship elicited the highest commendation.

THE SOLAR CARBON AND MANUFACTURING CO., of Pittsburgh, Pa., exhibited a very handsome line of carbon products. In addition to ordinary arc light carbons a number of specialties in this line were shown, among them a new carbon trolley wheel having metal flanges and carbon sheave or wheel. Their new soft-cored carbons specially adapted for arc lamps running on incandescent circuits are to be seen in practical operation in the Ward arc lamps. The mammoth carbons for aluminum smelting were also to be seen, and circular carbons for use in lightning arresters. A A pretty souvenir in the shape of a carbon medal was distributed by this company. Mr. Laughlin and Mr. Webb were on hand to show their products.

THE ELECTRICAL SUPPLY CO.'S exhibit, shown in Parlor 37, was complete in every detail, and of great interest to electric railway men on account of the many new devices, improvements on old ones, shown. Some of the new articles might be briefly described as follows: Trolley wire hangers so formed that it is impossible for them to drop the trolley wire.

A reliable pole ratchet that can be sold at a low price.

A trolley catcher that pulls down the trolley pole as soon as the wheel jumps the trolley wire, and holds it out of harm's way till adjusted.

Improvements in anchor plates.

A strain insulator, guaranteed to insulate and to stand a strain of 6,000 pounds.

The Wirt volt and ampere indicators.

Sunbeam railway lamps.

The Reed oil feeder for trolley wheels.

Ward's connector for lighting trailer cars.

Ward's duplex fuse box.

In addition to numerous other specialties, the Electrical Supply Co. placed on exhibit some very handsome reels of Habirshaw wire, Shield brand wire and magnet wire.

THE EDISON GENERAL ELECTRIC CO. occupied a large parlor on the ground floor of the hotel, and had a comprehensive and beautifully arranged exhibit. The lighting effects by means of various colored miniature incandescent lamps were excessively striking in appearance. Over the entrance to their parlor was a monogram formed of these lamps and inside the words, "Edison General Electric Company." A No. 13 Brill truck equipped with two 15 h. p. single reduction-motors was in operation, run from the hotel lighting plant. A handsome controlling stand, of colored marble fitted with special new switches, and measuring instruments, etc., was placed on one side of the room. Artistic lighting fixtures were displayed, showing the beauty and finish which has been attained in this line.

THE THOMSON-HOUSTON ELECTRIC CO., in addition to their exhibit on the "J. M. Gusky," had a handsome suite of parlors in the hotel, where they entertained their many friends, and also had an attractive exhibit in the shape of a large board containing samples of their appliances for overhead railway construction situated in the hall on the second floor of the hotel, and also had an imposing array of catalogues and printed matter descriptive of their system, which rapidly vanished, so interested were the delegates in their products. The company also distributed copies of THE ELECTRICAL ENGINEER of Oct. 21, containing Mr. A. C. Shaw's article on the West End road.

THE WESTINGHOUSE ELECTRIC AND MANUFACTURING CO. made a striking display of their motor equipments, etc., on the barge. An ordinary standard single-reduction motor immersed in a tank of water and run from the street railway circuit attracted a great deal of attention. They also had a Hubbard truck equipped with two single-reduction 20 h. p. motors and a Gilbert truck fitted with two of their new "Gearless" motors, a sample switchboard furnished with circuit breaker, ammeters and voltmeter, lightning arrester, switches and resistance box, and a full line of detail parts of their system, showing the working of the various parts and making a highly interesting exhibit,

THE WIGHTMAN ELECTRIC MANUFACTURING CO., of Scranton, Pa., showed a truck equipped with two 20 h. p. single-reduction Wightman motors, and their special controlling switch. On a sample board they also had a complete outfit of line material. Their new trolley and base were also shown. The truck was manufactured by Dorner & Dalton, of Cleveland, O., and is known as the Du Pont truck. H. Bergohltz, M. Wightman and P. D. Nicholl were in attendance, and the exhibit was in charge of D. F. Kennedy.

THE THOMSON-HOUSTON ELECTRIC CO., of Boston, showed a fine line of their standard electrical equipments, occupying the lower end of the boat. Amongst the apparatus exhibited was a 15 h. p. double-reduction a 15 h. p. single-reduction, and a 15 h. p. double-reduction, adapted for use on narrow-guage railroads. A handsome polished slate switchboard was equipped with the various switches, automatic circuit breakers, instruments, etc. The trolley and rheostats of this system were also shown.

THE CHAS. MUNSON BELTING CO. made a handsome display with a 48 inch belt 110 feet long for main driving belt, and two generator belts each 22 inches wide and 50 feet long. These belts were manufactured for the Birmingham Traction Co. This company have also furnished belting for the Pleasant Valley road and the Duquesne Traction Co., there being in use on each road two 48-inch belts 135 feet long. Col. J. H. Shay, a noted figure at street railway conventions, and N. H. Byam, looked after the company's interests.

THE ELECTRIC CONSTRUCTION AND SUPPLY CO., of New York, made a very practical display of the widely known Ward arc lamps, 10 of these being run in series on the exhibition boat from the street railway current. They burn with a clear, steady arc, and at night made a most attractive sight. R. B. Corey and J. C. Knight were in attendance.

THE REVERE RUBBER CO., of Boston, Mass., exhibited their new flexible conducting "Flexite" for use in place of hard rubber, and especially for conduit service in buildings and cars; also their trolley insulator compound belts which are unbreakable under ordinary use. A fine sample board set off their parlor to advantage; friction tape, rubber belting, packing, and steel wire wrapped hose formed a pleasing combination. The glass paper weight souvenir and calendar presented by the Messrs. Ellicott & Chaney, of the company, were eagerly sought after.

THE CARPENTER ELECTRIC HEATING MANUFACTURING CO., of St. Paul, Minn., showed their electrical heating apparatus, which comprised their new car heaters, sad irons, etc. The electric car heater exhibited by this company consists of a plate of cast iron, to one side of which the resistance wires are attached, being insulated and embeded in a coating of emanel. Mr. Carpenter was in attendance explaining his heating apparatus.

THE WESTERN ELECTRIC CO. had headquarters in Parlor 34, where they exhibited a very complete line of supply material for all kind of uses electrical, manufactured by the company. Among their specialties was shown a new trolley wire clamp. Some fine samples of trolley and feeder wire switches, and railroad lamps were exhibited. The company was ably represented by E. W. Bennett, M. B. Austin and S. A. Chase.

THE CALORIFIC VENTILATING HEATER CO. showed a number of their heating services in Parlor 3. It formed an exhibit of great interest. Three different styles of heaters were shown. The "Calorific" is fed with coal from the inside and the ashes removed from the outside, and maintains a uniform temperature in all parts of the car without overheating in the vicinity of the stove.

THE MITCHELL BRANT COPPER CO., of Erie, Pa., showed a line of tempered copper commutator strips in Parlor 5. Mr. Daniels was kept busy explaining the advantages of their product, and the samples he exhibited were perfect and fitted together just as they are cast, like fine clockwork. This copper is exceptionally pure and of the very highest electrical conductivity.

THE J. G. BRILL CO., of Philadelphia, made a very fine exhibit in Parlor 11, of models of their several styles of trucks, and also had one of their latest trucks, forming a part of the Edison exhibit. They also had a 25-foot double-truck car on exhibition on Water street, and an 18-foot car equipped with Short gearless motor running on the streets.

THE LIEB MACHINE WORKS had a complete outfit of overhead equipment material, including their new trolley hangers with mechanical clip and molded asbestos, bell insulators, trolleys with bearing in the fork instead of the wheel, as in most forms, strain insulators, etc. A small Lieb fan motor, of which a large number have been sold during the last summer, was shown.

PIERCE BROS. & CO., of Leominster, Mass., made a fine display of overhead appliances for electric railway construction, comprising single and double pull overs, bracket-arms, cross-overs, insulated crossings, span holders etc. They also exhibited a portable railroad machine to take the place of a ratchet drill and having an emery drill grinding device.

THE GOULD & WATSON CO., of Boston, showed their mouled mica insulators in all kinds of shapes and sizes. This material has been very widely used in electric street railway work, and the exhibit in the hall leading to the meeting room was so much studied as to be an innocent cause of blockade all the time.

PARTRIDGE CARBON CO., of Sandusky, O., made a large display of their carbon brushes in Parlor 5. They have acquired quite a reputation for these goods, especially due to the fine lubricating qualities of their carbon and the excellent shape in which they maintain the commutator.

THE LEWIS & FOWLER GIRDER RAIL CO., of Brooklyn, made a fine display of girder rails on the second floor of the hotel, and also exhibited their fare registers, which are so widely used. As usual they ran a special train to bring their many friends to the convention.

THE ENGINEERING EQUIPMENT CO., of New York and Boston, showed a very complete line of street railway equipment, notable among their specialties being the Anderson Ætna insulators and the Boston trolley. They had their exhibit on the steamer "Mayflower," which was moored just below the boat "J. M. Gusky."

BENEDICT & BURNHAM MANUFACTURING CO., of Waterbury, Conn., were represented by E. H. OSWALD, who exhibited some neat reels of hard drawn copper trolley wire, insulated feed wire and magnet wires. Some handsome leather wire cards were given away as souvenirs by Mr. Oswald.

THE JOHNSON CO., of Johnstown, Pa., had an exhibit of their various types of girder rails on board the "Mayflower," including slot rails and sections showing method of making crossings. Samples of Johnson girder rails were also placed on the sidewalk in front of the hotel.

THE UNITED STATES GRAPHITE CO., of Saginaw, Mich., were represented by Mr. W. G. Wilmot, who exhibited their Sonora graphite specialties. This lubricant is especially adapted for motors, gearings, and other bearings for street railways.

POST & CO., of Cincinnati, had a very attractive exhibit of street railway specialties and fixtures in the hall on the 2d floor of the hotel, and Mr. I. Kensey was kept busy explaining the merits of his many valuable devices.

THE NEW YORK CAR WHEEL WORKS had an artistically arranged space, with floral decoration around their comprehensive exhibit of machined street car wheels, manufactured from the very best charcoal iron.

THE TRIPP MANUFACTURING CO., of Boston, exhibited their roller bearings for car axles, which are in extended use, and a trolley equipped with similar bearings. A special piston packing also formed a part of their exhibit.

THE ROCHESTER CAR WHEEL WORKS, of Rochester, N. Y., exhibited a number of street car wheels of various sizes. A Barr contracting chill employed in the manufacture of these wheels composed a part of this exhibit.

THE STANDARD UNDERGROUND CABLE CO. exhibited lead-covered cable for use underground, and their well-known wires for overhead and feeder work. They made a neat and handsome display of their products.

THE R. B. NUTTALL CO. made a splendid show with their raw-hide pinions, gear wheels, steel pinions, and other electric railway specialties. Mr. Nuttall, Mr. Mayer and Mr. Manning were in attendance.

THE ROBINSON MACHINE CO., of Bellwood, Pa., had a Robinson Electric motor truck on exhibition entirely made of steel, with 30-inch wheels, combining great strength and durability with simplicity.

THE BALTIMORE CAR WHEEL CO., of Baltimore, Md., had a new pattern truck on exhibition. It is fitted with a special form of brake and oil and dust proof bearings and fitted with 36-inch wheels.

THE PECKHAM MOTOR TRUCK & WHEEL CO. had a single side frame of the cantilever pattern on exhibition, and Mr. Peckham was in attendance. They also showed a radial geared cantilever truck.

THE H. M. LOUD & SONS LUMBER CO., of Oscoda, Mich, exhibited their octagonal poles for railway and electric light work, and were represented by G. H. Keating, of Bay City, Mich.

THE EDISON GENERAL ELECTRIC CO. had headquarters for their intelligence department in Parlor 160, where Mr. M. J. Suilivan, the representative of this department, was to be found.

JOHN WHITE, of Allegheny, showed a full line of his famous "baked wood" insulators for trolley and feed wires, etc., and also many novelties for use in electric railway construction.

JOHN H. GRAHAM & CO., of N. Y., exhibited a number of the New Departure platform alarm bells. These bells were also shown by the Electric Merchandise Co., in Parlor 5.

THE MORTON SAFETY HEATER CO. made an attractive exhibit on board the "Mayflower" of their system of heating street cars, by storing heat in earthenware tubes.

THE WALKER MANUFACTURING CO., of Cleveland, O., made a prominent display of photographs and a working model of the Walker differential cable drum.

THE HILL CLUTCH WORKS had a plentiful supply of photographs and literature regarding the famous Hill clutches and devices for power transmissions.

THE BODIFIELD BELTING CO., of Cleveland, O., showed a 25-inch double belt, a 48-inch and an 8-inch dynamo belt and a 24-inch heavy double belt.

THE BROWNELL CAR CO., of St. Louis, exhibited outside the hotel their new accelerator car, which possesses many novel points in construction.

BRYANT & BARBEY, of Boston, made a display consisting of a portable rail saw for cutting rails without removal from the ties.

THE EASTERN ELECTRICAL SUPPLY CO., of Boston, showed a fine line of overhead railway appliances and other specialties.

THE RELIANCE GAUGE CO, of Cleveland, had a good display of their popular safety water columns and other steam fittings.

A. WHITNEY & SONS made an exhibit of chilled car wheels, both in the rough and bored, and mounted.

THE PENNSYLVANIA STEEL CO. exhibited frogs and fastenings and several styles of girder and tee rails.

THE HALE & KILBURN MANUFACTURING CO., of Philadelphia, made an attractive display of car seats.

J. H. BUNNELL & Co., of New York, did not make any exhibit, but they were, as usual, keenly alive to the situation as shown by the presence of Mr. C. McLaughlin and Mr. J. J. Ghegan, who took in everything in a very quiet, but expert and critical fashion. Mr. McLaughlin, who is an old steam railroad man, is now actively interested in one of the larger electric roads in New Jersey.

WESTINGHOUSE, CHURCH, KERR & Co. were represented by Mr. A. C. Kerr, whose recent Franklin Institute talk on the steam loop is one of the most valuable of recent contributions to steam literature. It is now obtainable in pamphlet form. The concern had also some other pamphlets for distribution, of great utility.

JOHN A. ROEBLING'S SONS CO., had a good exhibit, and were well represented by Messrs. Shippy, Bailey and others. They have the peculiar advantage of being on both sides of the fence at once. If a man decides to put in a cable plant, they sell him the wire rope; if electric, they sell him the wire.

THE STREET RAILWAY JOURNAL, in spite of great difficulties caused by the local printers' strike, managed to issue a most creditable daily bulletin of no less than 20 pages. It was represented by Messrs. McGraw, Fairchild, Blake, Stump, and others of its staff.

THE NATIONAL CONDUIT MAFUFACTURING CO., of New York, were represented by Mr. J. P. McQuaid, who had with him some very interesting photos showing curves of very short radius in some new underground work, using their cement-lined iron pipe.

THE AMERICAN ELECTRICAL WORKS issued several additions to its Comic Library, and all were eagerly sought after. Perhaps the pack of playing cards was the most successful of these amusing publications. Mr. P. C. Ackerman acted as colporteur.

THE UNIVERSAL ELECTRIC CONSTRUCTION CO., of Philadelphia, made an exhibit of their "friction clutch," the object of which is protect street car armatures. They have also brought out a new form of armature, for which many merits are claimed.

THE DUPLEX STREET RAILWAY TRACK CO., of 51 Wall street, New York, made an exhibit of their ingenious rail by which continuity of the ground return is maintained, obviating the necessity of rail bonds. It has been desribed in these columns.

MR. H. W. SMITH, of the Smith Electric Conduit Co., distributed modest brochures relative to his solution of the conduit problem. His plan is an ingenious one and he is quite sanguine as to its ultimate adoption and success.

THE ENGINEERING EQUIPMENT CO. were early on the ground and stayed late, Mr. W. F. D. Crane being their representative. They had a great many specialties, such as Kellogg poles, Underwood cotton belting, etc.

THE SIMPLEX ELECTRICAL CO., of Boston, were present to advocate and demonstrate the merits of their wire for railway work. Mr. W. H. Gordon was also present to speak for this specialty.

THE FORT WAYNE ELECTRIC CO. has not yet cut much figure in the electric railway world, but it is already in line, and was represented at the convention by Mr. W. R. Kimball.

THE INTERNATIONAL OKONITE CO. was well represented, not only by its various selling agencies, but by Capt. W. L. Candee and Mr. T. McCoubray.

MR. VAN NUIS, of Ajax switch fame, carried his new "Fulmen" lightning arrester as a watch-charm. Every one who saw it pronounced it a "corker."

THE BENEDICT & BURNHAM CO., of New York and Waterbury, made a good display of their electric wires, etc., through Mr. D. L. Hungerford.

THE JEWELL BELTING CO., of Hartford, Conn., showed a 48-inch double belt manufactured for the Toledo Electric Street Railway Co.

THE PULLMAN PALACE CAR CO., which is now putting so many electric car bodies into active work, was represented by Mr. W. S. Loutitt.

THE FIELD ENGINEERING CO. was present in the person of Mr. C. J. Field, who has done so much in electric railway construction work.

HOLMES, BOOTH & HAYDENS, of New York, were represented by Mr. Lafayette Cole, who spoke for their specialties in insulated wire, etc.

THE BROOKLYN RAILWAY CO., of New York, exhibited a "Walk-away" snow plough of the road scraper pattern for two or more horses.

THE MCCONWAY & TORLEY CO., of Pittsburgh, showed a line of rail joints.

THE ELECTRICAL SUPPLY CO'S SOUVENIR BADGE proved extremely popular, and as much disappointment was expressed by railway men who were not fortunate enough to procure one before the supply was exhausted, the Electrical Supply Company has promised to have some more made and forwarded to all electric railway men who write for them.

MR. F. MANSFIELD exhibited his new electric city tramway system, which consists of a new form of underground working by means of a guide slot construction, the circuit being made above ground and without the use of a conduit proper, a shallow box-lid arrangement being used instead and containing the contact-making mechanism.

JOHN R FLETCHER'S Dayton arc light cut-out was exhibited by the Electrical Supply Co. The advantages gained by using this invention are too apparent to practical men to need any extended notice. Full particulars can be obtained by addressing the Electrical Supply Co., Chicago, or John R. Fletcher, Dayton, Ohio.

THE DETROIT ELECTRICAL WORKS showed a very beautiful model of their railway system, and were represented by Mr. Louis Warfield, Mr. C. A. Benton and Mr. Frank Rae. Cars equipped with their motors were running on the streets, and they consider this the best kind of an exhibit.

THE INTERIOR CONDUIT AND INSULATION CO., of New York, exhibited a section of their underground conduit. This conduit is used for drawing-in bare conductors, and has won notable success in the street railway lines of Minneapolis and St. Paul.

THE EQUITABLE ENGINEERING & CONSTRUCTION CO., of Philadelphia, showed a line of centre curve insulators, trolley wire joints, line insulators, pole ratchets, and all necessary appliances for overhead electric railway construction.

WM. H. WESTON, of Philadelphia, made a handsome display. Among the specialties shown was a quick-break railroad switch of 800 amperes capacity, and several knife switches. Mr. E. Plowman was in attendance.

THE PITTSBURGH STEEL HOLLOW WARE CO., made a good display of their rolled steel bells and gongs, which are made by an entirely new process and are remarkable for tone and durability.

THE JOHNSTON SAFE AUTOMATIC ELECTRIC DISCONNETOR CO. showed their new automatic disconnector in operation. It is an excellent device and will no doubt be widely used.

CHAS. A. SCHIEREN & CO., of New York, made a comprehensive exhibit of perforated and link belting. Mr. E. P. Atkinson and Mr. G. H. Fisher represented the company.

WALLACE & SONS, of New York, represented by Mr. James Goldmark, made an attractive display of hard drawn copper trolley wire.

THE WASHBURN & MOEN CO., Worcester, showed a fine lot of samples of trolley wires, steel railway cables and bare copper wires.

THE SCHNEIDER COMBINATION CAR CO., of Chicago, had some very handsome models of combination summer and winter cars.

WM. GARDAM & SON, the well-known electrical model makers of New York, were represented by Mr. J. Gardam.

THE BALL ENGINE CO., of Erie, Pa., showed photographs and wood cuts illustrative of their well-known engines.

THE P. & B. INSULATING PAINT CO., of New York, made a fine show of their various P. & B. specialties.

THE PITTSBURGH TROLLEY CO., a new and pushing concern, were represented by Mr. J. S. McCormick.

THE ALUMINUM BRASS AND BRONZE CO., of Bridgeport, Conn., were represented by Mr. J. H. Conkling.

THE P. WALL MANUFACTURING SUPPLY CO., of Allegheny City, showed their forged steel car gongs.

THE GISHOLT MACHINE CO., of Madison, Wis., showed their "Renewable Rim" motor gears.

MR. JARVIS B. EDSON exhibited at the Duquesne Hotel one of his recording registers for steam.

THE GENETT AIR BRAKE CO. exhibited the Genett air brake.

THE MEAKER MANUFACTURING CO., Chicago, had a very complete exhibit of fare registers.

THE AMERICAN TUBE & IRON CO., of Pittsburgh, exhibited their electric railway trolley pole.

THE BRIDGEPORT BRASS AND COPPER CO. had a pleasing exhibit of feeder and trolley wires.

THE ELECTRICAL ENGINEER made its headquarters in parlor 5 and was represented by Messrs. T. C. Martin and W. F. Collins. So many applications were received for its issue containing the West End article that a large edition was completely exhausted by Thursday forenoon.

NOT A FEW notable electricians and manufacturers of the earlier day were to be noted in the crowd. Among them may be mentioned Mr. H. Ward Leonard, Prof. W. A. Anthony, Prof. D. C. Jackson, Mr. J. B. Wallace, and Mr. W. Baxter. The last named is working hard again at electric railway problems.

"ELECTRICITY."

It is announced that Messrs. Dickerson and Washington have resigned their respective positions on the new Chicago journal *Electricity*. Mr. Dickerson has a great many friends in the electrical field, to whom the news of his recent severe illness has been a shock, but they will be glad to learn that he is on the high road to complete recovery, and will soon be among them again. He has been succeeded in his editorial duties by Mr. H. L. Webb, who is well known by his various contributions to the electrical journals, and probably best by his recent articles in our columns on the testing of wires and cables, now about to issue in book form.

Society and Club Notes.

THE ELECTRIC CLUB.

The Electric Club will have a most enjoyable time on Thursday evening, when it will celebrate a Warzburger Nacht. The Entertainment Committee have kept very quiet about the details of this, and hence have piqued curiosity. It is confidently expected to be one of *the* nights of the year.

MR. F. V. HENSHAW BEFORE THE BROOKLYN INSTITUTE ON ELECTRIC MOTORS.

The first meeting of the season of the Electrical Section of the Brooklyn Institute was held in the hall of the Y. M. C. A. of that city at 8 P. M. Oct 16. President James Hamblet made a few remarks upon the very interesting meeting held in conjunction with the American Institute of Electrical Engineers at Columbia College, where they listened to Mr. Nikola Tesla on the subject of incandescent lighting by his new induction system of high frequencies. Mr. Hamblet then introduced the lecturer of the evening, Mr. F. V. Henshaw, electrician of the C. & C. Motor Company.

Mr. Henshaw began by comparing the magnetic circuit of the motor, its properties and analogies, to that of the electric circuit, illustrating his remarks by diagrams on the blackboard, showing the different forms of fields, beginning with the two-pole Edison type. He illustrated successively the double-circuit curved-magnet type of the well-known C. & C. motors, the Manchester dynamo, the ironclad, and various others. It was then explained how the entire action of the motor depended upon the relationship between the strengths of the two magnets constituted by the fields and the armature. Attention was called to the differences between ring and drum types of armatures, and to the superior copper economy of the drum, and to the fact that the air-gap with that type could be made much less than with the other, owing to the fact that after being built up the armature could be turned off in a lathe; while the chief advantage claimed for the ring was slow speed and better insulation. Mr. Henshaw then took up the question of design, prefacing his explanation with the remark that many who understood quite thoroughly the various questions involved were often at a loss where to make a starting point in planning a motor for any given set of conditions. Where the motor is to be operated on a constant-current circuit it was shown that the horse-power at once determined the E. M. F., while, if for use with constant potential, the power to be developed at once gave the amount of current. It was also pointed out that a constant-current motor could not be "wound" for automatic regulation, but required a mechanical governor to control the counter E. M. F., which would otherwise tend to rise until it equaled that of the generator, were the mechanical strength of the motor sufficient to allow so great a speed to be attained without flying to pieces. The general current equation was given as $C = \frac{\text{H. P. } 746}{\text{E}}$. Shunt, series and compound windings were explained and their special adaptability for particular applications. For instance, the shunt type, where constancy of speed was desired, or the series, where the load was constant, as in operating a ventilating fan, or where torque was of importance, as in the case of street railway motors. When considering the efficiency of a motor it was shown that the efficiency would be 100 per cent. when the counter E. M. F. was equal to that of the current supplied the motor, in which case its current would be zero, and showed therefore that the aim, so far as efficiency was concerned, was to get the equality between these two electromotive forces as near as possible. The number of turns on the armature was to be made as great as possible in order to produce a maximum of E. M. F.; while on the other hand this introduced resistance, and these two conflicting conditions ought to be equalized according to other factors. The question of heating in the armature coils, as is true also of fields, was shown to depend not so much on the surface of the wire, but on the amount of exterior surface of the armature or coil as a whole. As a general rule, with coils in depth from 1 to 1¼ inches; 2 square inches per watt was a fair figure for temperature of 60° C. The purpose of making the resistance of a shunt motor as high as possible was shown to be merely that of cutting down the amount of current for producing the same amount of field strength. With regard to operating machines where the heating was very great, it was pointed out that the increase of temperature above that of the surrounding air was the question to be looked at rather than the absolute amount of heat being generated in the coils. For instance, a motor and dynamo creating an absolute amount of heat might become very much hotter without danger were it situated in an engine-room where the temperature was 120° than one where the air was very much cooler. A temperature from 40° to 60° above that of the surrounding atmosphere was not to be exceeded under ordinary circumstances, although such difference might be reached for a short time without absolute danger to the insulation. With regard to the question of sparking, diagrams were drawn to show the greater twisting of the force lines out of their normal paths from pole to pole when the load on the armature was large, and how these lines' shrunk back again into place as the armature current fell. The question of air space was considered with regard to the difference in its effect in large and small motors, the limits between which it would be reduced being very small in the latter case. With regard to the term, magnetic resistance, it was shown that the magnetic resistance of a circuit varied, while that of the electric circuit was a constant quantity. With regard to the proper velocity of inductors (armature wires) it was shown that the best results were found in actual practice when such speed was from 40 to 50 feet per second, The speed and work being given determined the armature diameter. The efficiency gave at once the amount of waste energy to be divided between the losses in the field and armature, which, in motors ranging between one and 100 H. P, would be in the field from 10 to 2 per cent., and in the armature 12 to 4 per cent. approximately. The diameter of the armature and the amount of heat would at once limit its length, which, for a drum armature, should be such as to provide so much surface as to allow of not more than one watt per square inch. The air gap then gave the attainable field strength; from the field strength and the speed the armature turns would be had, and the size of armature being given, therefore its resistance, and from that the size of wire was found. The magnetic resistance was dependent upon the loss allowed in the field. The cross-section of the magnets depended on their material, whether wrought or cast iron, and also on the particular qualities of the special iron used. For wrought iron from 10,000 to 15,000 lines per square centimetre were allowable; for cast, only 4,000 to 7,000. The formulæ for the magnetic resistance was given as follows:

$$\text{Iron Mg. R.} = \frac{L}{\eta A}$$

or length divided by the area into a constant, best determined by actual test of the particular iron to be used; and it was shown that one difficulty in treating the magnetic circuit was due to the fact that it usually contained not only air, but iron of two different kinds. The area of the pole pieces, with regard to the armature, was considered in some detail, showing the danger from leakage in the way of short circuiting of the magnetic lines, where the arc of the pole was made too great. This was illustrated with diagrams of various types of motors, and the general principle was stated that not over 80 per cent. of the circumference of the armature should be embraced by the pole pieces; that for two-pole machines the arc was usually made about 135°, and that it was found, where they approach nearer than this, sparking would be produced at the brushes. The relative advantages of multipolar motors were considered, and, time being short, the lecture closed with the operation of a two-horse power C. & C. standard motor, together with the exhibition of different parts, such as brushes, commutators, segments, etc. It had been Mr. Henshaw's intention to illustrate the lecture with some induction experiments, but, unfortunately, through some mistake, the apparatus was not taken over to the hall.

Mr. J. Stanford Brown remarked that, probably, no one present could fully appreciate the value of the lecture to which they had just listened, who had not been called upon to attempt the design of a commercial machine, and he also claimed that the slur could no longer be made upon American electricians that they were designing machinery by the old "rule of thumb methods, so prevalent up to the last year or so.

Mr. Charles D. Emery, president of the engineering section of the Institute, then rose, and, after complimenting Mr. Henshaw on his avoidance of intricate technicalities, and his having interwoven with his outline facts of great practical value, moved a vote of thanks, after the adoption of which the meeting adjourned.

Mr. F. H. Sparling, late of W. H. Gordon & Co., has been appointed New York State agent for John A. Roebling's Sons Co., for electrical work.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED OCTOBER 13, 1891.

Alarms and Signals:—

Circuit Connector for Electric Signaling Apparatus, W. L. Gates, 461,075. Filed July 19, 1889.

Electric Signaling Apparatus, E. G. Mettler, 461,104. Filed Oct. 15, 1890.
Adapted to give notice of the breaking of wires arising from over-heating or burning-out.

Non-Interfering Fire-Alarm Box, F. F. Loomis, 461,169. Filed May 1, 1891.

Electric Boiler-Alarm, M. Beckers, 461,178. Filed Dec. 24, 1889.
For signaling the level of water in a boiler.

Signaling Switch and Circuit, J. W. Stover, 461,194. Filed May 29, 1891.
Adapted for police and fire-alarm systems.

Fire-Alarm Apparatus, W. C. Shaffer, 461,371. Filed Dec. 14, 1888.

Clocks:—

Combined Electric Clock and Thermoscope System, H. J. Haight, 460,963. Filed Mar. 7, 1887.
Patented in Great Britain Mar. 10, 1887, No. 4,135 A.

Conductors, Conduits and Insulators:—

Device for Stretching Heavy Wires on Poles, H. P. Ball, 461,109. Filed Mar. 21, 1891.

Connection for Electric Conductors, J. Dillon, 461,195 Filed May 13, 1891.

Electric Conductor, F. A. Perret, 461,272. Filed May 21, 1889.
Employs as an insulating compound collodion and glycerine or a solution of a natural gum and glycerine in collodion; the solution is used in connection with a fibrous covering.

Distribution:—

Electric Inductional Transformer, W. Stanley, Jr., 461,135. Filed Jan. 16, 1891.
Claim 1 follows:
A sectional transformer-core composed of detached plates or groups of plates held loosely in their supports, so as to be capable of mutually independent self-adjustment in planes substantially parallel with their respective surfaces.

System of Distributing Electric Energy, R. Kennedy, 461,139. Filed Sept. 24, 1890.
Claim 1 follows:
In a system of electrical distribution, two armature-windings which alternately traverse the same or similar magnetic fields, whereby alternating electrical pulsations of unlike phases are induced in the respective windings, in combination with independent pairs of main conductors, independent commutators whereby the alternating pulsations induced in the respective windings are rectified before traversing the respective pairs of main conductors; a conductor directly uniting one positive brush of one with one negative brush of the other of said commutators, and translating devices connected between the conductor connected with the other positive brush of one pair and the conductor connected with the other negative brush of the other pair of said mains, substantially as set forth.

Dynamos and Motors:—

Rheostat, O. A. Kessner, 460,972. Filed March 18, 1891.
A rheostatic switch for regulating shunt wound dynamos.

Electro-Magnetic Brake, A. J. Shaw, 461,052. Filed July 2, 1891.
Adapted to bring a motor, or machinery driven by it, to a stand-still immediately upon the interruption of the working current.

Commutator-Oiler, F. L. McGahan, 461,105. Filed Nov. 7, 1890.

Dynamo-Electric Machine for Alternating Currents, R. Kennedy, 461,140. Filed Oct. 30, 1890.
Claim 1 follows:
In a dynamo-electric machine or motor, the combination of a field-magnet having multiple poles disposed in two groups of opposite polarities, each of said groups being composed of a plurality of radial polar extensions, two annular laminated armatures having a radial thickness not less than the breadth of the faces of the radial poles, and a cylindrical iron shell inclosing and supporting said armatures and serving to concentrate the magnetic lines.

Dynamo-Electric Machine, E. T. Gilliland, 461,240. Filed Jan. 31, 1891.
A design and construction of frame and pole-pieces intended for facility of manufacture and assembling.

Armature for Electric Motors, C. J. Van Depoele, 461,296. Filed April 7, 1891.
Claim 1 follows:
In an electro-dynamic motor, an armature the sections of which are spaced by separating blocks or strips and which is enveloped by an exterior winding or covering also of magnetic metal.

Actuating Device for Moving Commutator-Brushes, C. J. Van Depoele, 461,297. Filed May 20, 1891.
Employs frictional connections between the commutator and contact devices, a detent holding the contact carrier, and means for periodically retracting the detent.

Galvanic and Thermo-Electric Batteries:—

Electric Battery, D. M. Lamb, 461,023. Filed Dec. 7, 1889.
Employs granular active material having each granule enveloped in a water-repellent substance.

Composition for Electric Batteries, D. M. Lamb, 461,024. Filed April. 10, 1890.
Employs pulverized clay and calcined gypsum in combination with the active material.

Electric Battery, D. M. Lamb, 461,025. Filed July 23, 1890.

Compound for Electric Batteries and Method of Preparing the Same, D. M. Lamb, 461,026. Filed May 26, 1891.
Prepares active material by coating each separate granule with water-repellent material and then mixing the coated material with other ingredients.

Electric Battery, D. M. Lamb, 461,027. Filed May 26, 1891.

Galvanic Battery, P. Hieronymus, 461,262. Filed Feb. 12, 1891.
Uses a partition held a short distance above the bottom of the jar; elements rest on the partition; employs a wick for conducting water from the lower part of the jar to the elements.

Lamps and Appurtenances:—

Fuse-Box for Electric Lamps, A. B. Holmes and G. F. Gale, 460,968. Filed April 15, 1890.

Incandescent Electric Lamp, A. L. Reinmann, 460,991. Filed Feb. 11, 1891.
Relates to sealing-in conducting wires and is designed to save in the cost of platinum.

Electric Arc Lamp, E. Thomson, 461,144. Filed June 14, 1890.
Claim 1 follows:
The combination, in an electric arc lamp, of a positive feed-gear, such as a worm and screw, a pivoted frame sustaining one member of the gear and the carbon carrier connected with said member, an electromagnet for actuating said frame to bring the two members of the gear into engagement and form the arc, and a derived circuit actuating magnet for operating the other member of the gear to cause a feed of the carbon.

Measurement:—

Electric Meter, G. R. Baldwin, 461,229. Filed Nov. 20, 1890.
Claim 1 follows:
In an electric meter, the combination of a lever, an adjustable fulcrum for said lever, a current-indicating device which controls said fulcrum, a rigid backing-piece by which said adjustable fulcrum is supported when the lever is forced down upon it, a registering device, and a clockwork, each connected to said lever.

Metallurgical:—

Electro-Magnetic Separator, G. M. Gouyard, 460,962. Filed Jan. 6, 1891.

Miscellaneous:—

Electric Soldering Iron, W. Mitchell, 460,978. Filed Jan. 9, 1891.

Electric Soda Fountain, W. Mitchell, 460,979. Filed Feb. 9, 1891.

Electric Heating Core for Smoothing Irons, W. Mitchell, 460,980. Filed March 24, 1891.

Electric Parlor Game, W. L. Gates, 461,076. Filed July 19, 1889.

Electrical Automatic Fire-Extinguisher for Buildings, W. H. Soley, 461,087. Filed Jan. 17, 1889.
Electro-magnetic valve-opening devices.

Fire-Extinguisher, J. Wolstencroft and W. H. Soley, 461,089. Filed Feb. 1, 1889.
Thermostat and electro-magnetic controlling devices.

Electric Door-Operating Device, R. F. Troy, 461,122. Filed Sept. 18, 1890.

Switch Box, H. A. Foster, 461,239. Filed Oct. 24, 1890.
Designed to secure the exclusion of moisture and thorough insulation while furnishing facilities for the ready operation of the switch and access to the interior of the box.

Watchman's Electric Time Recorder, F. W. Schiefer, 461,279. Filed April 15, 1891.

Automatic Electric Pump, C. J. Van Depoele, 461,294. Filed Feb. 26, 1891.
Application of a reciprocating electric motor.

Electrically-Actuated Pump, C. J. Van Depoele, 461,295. Filed March 27, 1891.
Employs a reciprocating motor.

Electric Switch, S. P. Van Nort, 461,298. Filed Nov. 21, 1890.
A continuity-preserving switch.

Railways and Appliances:—

Trolley-Catcher for Electric Cars, W. L. Browne, 460,942. Filed June 26, 1891.

Electric Signal for Railway Trains, L. Dunn, 460,958. Filed Feb. 18, 1891.
For signaling from one part of a train to another. Designed to supersede bell-ropes.

Track Rail for Electric Street Railways, J. T. Hill & B. Meiring, 460,967. Filed Dec. 29, 1890.

Electric Railway, B. R. Shover & W. C. Dickson, 461,057. Filed Feb. 25, 1891.
An induction system, precluding the necessity of contact with the supply conductor.

Electric Car Motor, G. Willett, 461,228. Filed Dec. 22, 1890.
Armature shaft arranged longitudinally of the car; employs worm gearing.

Motor Truck, C. J. Van Depoele, 461,293. Filed Sept. 25, 1889.
Claim 1 follows:
The combination of a spring-supported truck-frame adapted to sustain the car-body, a secondary frame depending therefrom, one or more motors sustained at one end upon the truck axle or axles independent of the springs, and yielding connections between the free ends of the motor or motors and the secondary frame.

Telegraphs:—

Telautograph, M. Soblik, 461,152. Filed March 23, 1891.
Operates by means of variations in the resistance of the main circuit.

Letters to the Editor.

Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents.
Anonymous communications cannot be noticed.
The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.
In order to facilitate reference, correspondents, when referring to any letter previously inserted, will oblige by mentioning the page on which it appears.
Sketches and drawings for illustrations should be on separate pieces of paper.
All communications should be addressed EDITOR OF THE ELECTRICAL ENGINEER, *150 Broadway, New York city.*

THE ROBERTS CHROME ARC LIGHT PENCIL.

IN my article in THE ELECTRICAL ENGINEER of Oct. 14, on Chrome Arc Light Pencils, a mistake was made in saying that "some changes must be made in this pencil before it can be used." It should have read, "Some changes must be made in the lamps now in use before this pencil can be properly used."

These changes are only slight, and when made will enable this pencil to be used in connection with any sytem.

NEW YORK, Oct. 20th, 1891. ISAIAH L. ROBERTS.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

Modern advertising is the creation of successful business men.

THE NOWOTNY IMPERIAL BATTERY.

In developing the Imperial battery, it has been the aim of the manufacturers to produce a battery that is superior to anything heretofore put upon the market, regardless of cost.

The Imperial is an improved form of the multiple. Its combined strength, durability, recuperative qualities and long life with an enormous working power are even beyond the expectations of the makers.

In this battery there is by actual measurement 196¼ square inches of available carbon surface below the fluid line exposed to chemical action. This surface is placed in such a manner that the internal resistance of the cell is cut down to the lowest possible point.

Nowotny Imperial Battery.

The entire outer cell is made of carbon, taking the place of the glass jar, and serving the double purpose of a negative-exciting element and a retaining vessel.

There are eight inwardly projecting ribs of carbon extending over the inner surface of the cell pointing towards the centre, and surrounding the zincs on all sides. The inside of the cell is also corrugated for the purpose of increasing the surface.

This Imperial battery is manufactured by the Nowotny Electric Co., 30 E. 5th street, Cincinnati, O.

THE BALL & WOOD CO.

The Ball & Wood Company were represented at the National Street Railway Convention at Pittsburgh, by Mr. F. H. Hayward, formerly connected with the Straight Line Engine Co., of Syracuse.

A. M. Morse & Co., mechanical and contracting engineers, have located at St. Louis, Mo., as the selling agents for the company. Mr. Morse is an experienced engineer, and a very successful salesman, formerly of the firm of English, Morse & Co., of Kansas City.

The firm of Mead & Stringham has been formed with offices in the Hammond Building, Detroit, Mich., where they will conduct a general engineering and contracting business, and will act as special agents for the Ball & Wood Company. Both members of the firm are mechanical engineers with wide experience in steam construction, and well known to the trade throughout Michigan.

The Ball & Wood Company have found it necessary to run the Elizabethport shops all night that they may keep up with orders, that have been coming in very rapidly.

THE ELECTRICAL ENGINEERING AND SUPPLY CO.

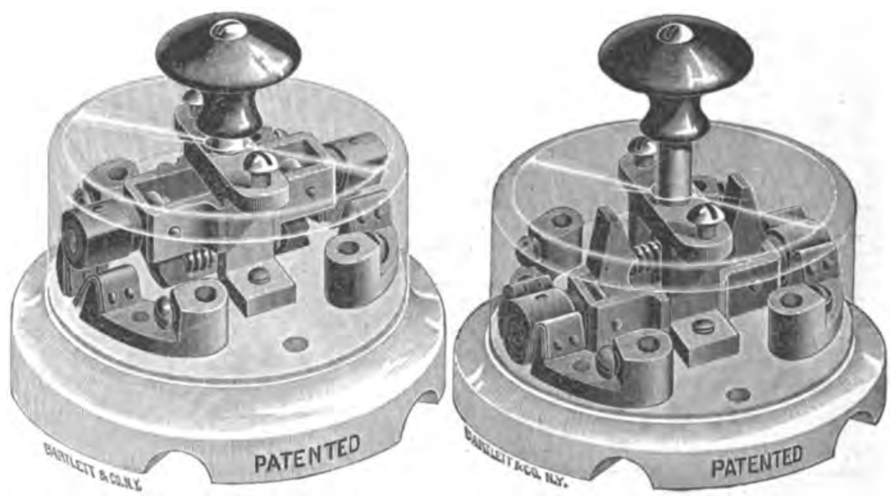
The above company, of 134 East Sixth street, St. Paul, Minn., have found, in moving into their new quarters, that business is again growing upon them. They have now been going just a year, and their supply trade has proved most encouraging right along. Mr. Morgan Brooks, the treasurer, writes us: "We have recently completed the installation of an incandescent plant at Audubon, Ia., and having received check in full for same last week, it makes us feel as if our efforts were successful. That was a plant of the National system. With the enormous crops harvested this fall, we feel that business will continue to boom for many months to come. Our greatest difficulty at present is that we cannot get supplies shipped to us promptly enough to fill orders."

THE PERRET ELECTRIC MOTOR.

The Elektron Manufacturing Co., of Springfield, Mass., have issued a very well printed and illustrated pamphlet, descriptive of the Perret motors manufactured and sold by them. The body of the work is taken up by a detailed description of the motors and their advantages, while the last two pages are devoted to testimonials of a flattering character recently received by the company. The New York office of the Elektron Manufacturing Co. is at 89 Liberty street.

A NEW "UNION" SWITCH.

The accompanying illustrations, Figs. 1 and 2, show the new switch designed and brought out by the Union Electric Mfg. Co.,



Figs. 1 and 2.—New "Union" Switch.

of Bridgeport, Conn. As will be seen, the switch is shown open in Fig. 1 and closed in Fig. 2. The mechanism is so plainly shown that nothing remains to be said in regard to the switch, except that no expense has been spared to make it perfect in every respect.

UNDERWOOD COTTON LEATHER BELTS.

The Underwood Manufacturing Co., sole makers of the well-known cotton leather belting, have shipped to Pittsburgh, for exhibition at the Street Railway Convention, a big cotton leather belt which is to go to the Chicago City Railway Co. as one of two belts for that company. The length is 200 feet, width 62 inches, and the belt speed is to be over a mile a minute. The same company have in use two 48-inch Underwood C. L. belts, each 172 feet in length, which have been in use over four years. The belts are run about twenty-two hours per day.

The Engineering Equipment Company, of 143 Liberty street, New York, selling agents of the Underwood Manufacturing Co., arranged to exhibit this big belt at Pittsburgh, and Mr. Crane, who represents their railway department, was in attendance at the convention.

Mr. F. P. Mack represents the Underwood belting interests in Chicago, at 65 South Canal street.

Mosher Arc Lamp Co.—The above company, of 125 Ontario street, Chicago, J. M. Fisher, manager, write us that orders for lamps are exceeding their most sanguine expectations. It is all they can do to supply the demand. Customers are delighted with the appearance of the lamp and the steadiness of the light, as well as with the simplicity of the system.

SOUTHERN ELECTRIC CO.

MR. J. F. MORRISON, the president of the Southern Electric Co., Hoen Building, Baltimore, Md., has issued the following important notice: "Having associated with me several well-known business men, we have incorporated under the laws of Maryland the Southern Electric Company, and will carry on the electric supply and construction business, heretofore conducted as an individual enterprise. This incorporation broadens our field of operation and affords us much greater facilities for handling with dispatch all business entrusted to us. We are in position to give estimates, at reasonable notice, on all work pertaining to our lines, and with a full corps of experienced workmen, are prepared to fill contracts and execute orders promptly. By faithful attention to business, with good and honest service to our patrons, I hope to merit, if possible, a higher degree of confidence for our company than has been so kindly extended to me personally."

Associated with Mr. Morrison as directors of the company are Aubrey Pearre, of Pearre Bros. & Co.; F. W. Schultz, of the Schultz Gas Fixture and Art Metal Co.; John Waters, builder, and J. S. Boyd, who is secretary and treasurer.

C. & C. ELECTRIC MOTOR CO.

THE C. & C. Electric Motor Company, New York, are very busy. They have recently installed a 75 light dynamo for the Show Steam Pump Co., Buffalo, N. Y.; one 175 light for the Cogdon Brake Shoe Co., 59th street, Chicago, Ill.; one 500 light in the Mitchell Flats, Cincinnati, O.; two 250 light in the St. Nicholas Hotel, Cincinnati, O.; one 125 light for Mock, Berman & Co., 119 West 3d street, Cincinnati, O.; one 150 light for W. J. Morgan & Co., Cleveland, O.; one 100 light for the Bethel Association, Cleveland, O.; one 60 light for the Northern Ohio Asylum for the Insane, Cleveland, O.; one 100 light for the Steamer "Royal," Evansville, Ind.; one 40 light for the Upton Glue Co., Gardiner, Me.; one 40 light for the Boston Paper Co., Hallowell, Mass.; one 200 light for the iron foundry of T. Shriver & Co., 333 East 56th street, New York.; one 150 light for Messrs Weser Bros., piano manufacturers, 524 West 23d street, New York; one 40 light for the Upton Glue Co., Peabody, Mass.; one 150 light for Jordan & Goodrich Shoe Co., Ravenna, O.; one 500 light for lighting the offices of the Brush Electric Light Co., Rochester, N. Y.; one 40 light for the Upton Felting Mills, Salem, Mass.

ELECTRICAL WORK AT POTTSVILLE, PA.

THE new court-house of Schuylkill Co., situated at Pottsville, Pa., was opened on the 3d inst. The building is of a very handsome design, built of Ohio sandstone, and wired throughout for electric lighting. The building is divided into four circuits, supplying current for 500 20 c. p. lamps. No expense has been spared, and the whole work has been installed in a very thorough and careful manner. The wire in use is manufactured by the well-known Safety Insulated Co., of 234 W. 29th street, New York, and in order to ensure more perfect insulation each wire is enclosed in "interior conduits," about 6,500 feet of which have been used. When all lamps were burning the whole installation showed only a drop in potential of 2 per cent., a result which shows the general excellence of the work. The fixtures were furnished by the Mitchell-Vance Co., and the large ones in the court-rooms, having from 20 to 24 lights, deserve special mention, being of exquisite workmanship and beauty in design.

The installation was under the supervision of Mr. G. H. Barker, general manager of the Edison Electric Illuminating Co., of Pottsville, who received many flattering congratulations from the court officials.

The Electric Co. have at present nearly 3,500 lamps in use, and a number of new orders in hand.

F. P. LITTTLE & CO.

THE above active concern, of 141 East Seneca street, Buffalo, N. Y., have just closed a contract with the Broezel House, of that city, which calls for wiring for 800 lights, including two arcs. The plant will consist of two Thomson-Houston dynamos of 300 and 500 lights respectively, driven by a 30 h. p. and a 50 h. p. Rice automatic engine. The contract includes the construction of the plant complete.

THE STEWARD LAVA INSULATORS.

THE D. M. Steward Manufacturing Co. of Chattanooga, Tenn., write us: "August was a good month in lava insulators, but September is a long way ahead of it. It seems that when electricians get an unusually trying place for an insulator, and everything else fails, they fall back on the old reliable "Lava."

POND ENGINEERING CO.

THE Waterloo, Ill., Electric Light & Power Company are making good progress with the installation of their plant, and expect to be ready for operation by November 1. The work is in the hands of the Interstate Complete Electric Construction Company, of St. Louis, and the steam plant will be furnished and erected by the Pond Engineering Company of the same city. The latter contract covers Armington & Sims engine, steel boiler, Lowe heater, Blake boiler feed pump, and Universal injector. The Heisler system of long-distance incandescent lighting is to be used, and the plant is to be a model one in every respect.

ANOTHER GOLD MEDAL FOR OTTO GAS ENGINES.

THE German correspondents of Schleicher, Schumm & Co., Philadelphia, inform them that at the Strasburg Industrial Exposition, where an unusually large number of gas engines of all makes and description were exhibited, they alone were awarded for their "Otto Gas, Gasoline and Petroleum Engines" the highest diploma and gold medal for superior design and workmanship. Second prizes were given to Adam, Benz, Buss-Sombart & Co., Hille, the Kobers Iron Works, Escher-Wyss & Co. Third prizes to Grob & Co. (Capitaine Petroleum Motor), Korting and Bitschweiller (Petroleum Motor).

THE IMPERIAL SOCKET.

THE accompanying illustration shows a new socket manufactured by the Imperial Electric Company, of 1218 and 1220 Filbert

THE IMPERIAL SOCKET.

street, Philadelphia. The insulation of the socket is made entirely of porcelain, and is, therefore, unaffected by heat or moisture. The principal feature claimed for this socket is, however, that, by reason of its construction, it is very easily wired, and is, therefore, especially adapted to chandelier and fixture work. The design is simple and neat, and the appearance symmetrical and sightly.

ORDERS FOR SCHIEREN BELTS.

CHAS. A. SCHIEREN & Co., of 47 Ferry street, this city, have received an order from the Diamond Electric Co., Seventeenth and Clearfield streets, Philadelphia, for two 30-inch double belts; one 16-inch double; one 15, two 12, and four 11, for their new power plant. This is the entire belt equipment. The firm report a steady increase in the demand for their patent "Perforated" belting, especially for electric railway work, where it is desirable, because, it is said, it can be run slacker than an unperforated belt; without slipping. No charge is made for the perforations; they are given gratis.

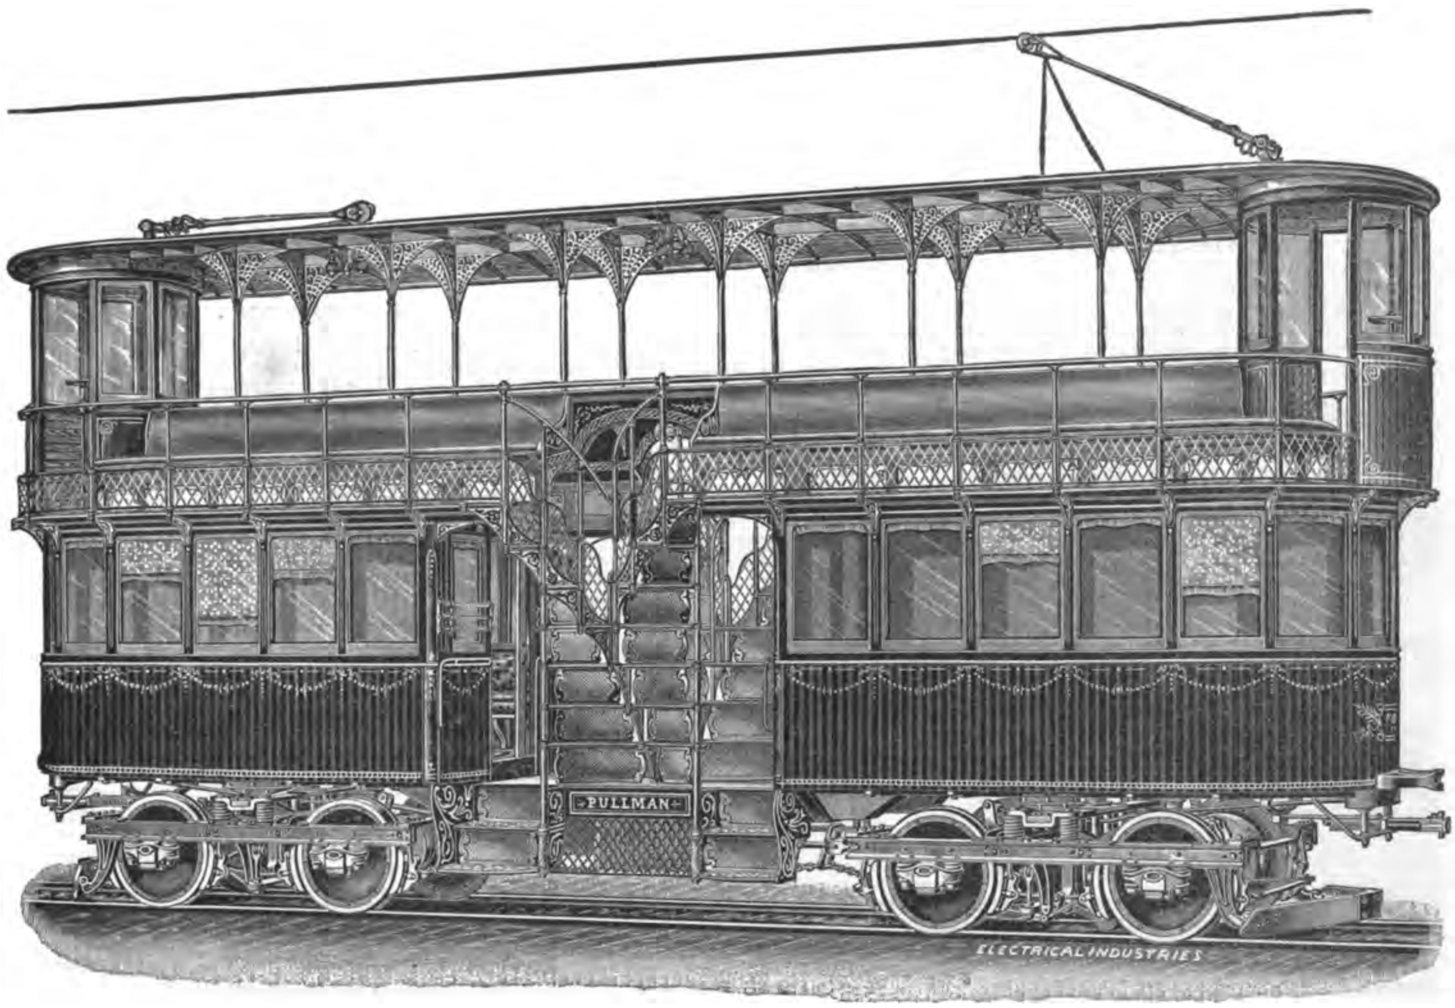
THE MERRIMACK ROAD, LAWRENCE, MASS.

THE local *Telegram* says: "The advent of electric cars in Lawrence is followed by greater prosperity to the Merrimack Railway Co. than ever before known." The road is equipped with eleven motor cars, and four more are at once to go into service. On a recent Tuesday and Wednesday 35,000 people paid fares. The motors of the Detroit Electrical Works are used. Mr. J. E. Lockwood was in charge of fitting up the cars, assisted by Messrs E. P. Ashton and L. H. Temme.

THE PULLMAN CENTRE-VESTIBULE DOUBLE-DECK ELECTRIC CAR.

THE accompanying illustration shows the new double-deck electric car recently built by the Pullman Palace Car Co., and described in our columns last week.

The car is sheathed outside with narrow strips, the same as the ordinary passenger coach; the inside finish is mahogany, with decorated quartered-oak ceiling. The glass in the windows is crystal sheet, while that in the doors is French plate, embossed. Mirrors are placed on the upper deck and on each side of the doors, and the car is provided with spring seats and backs, covered with tapestry. The car is provided with two gates, each gate equipped with a seat. The wheels are Allen 30 inch, with steel tires. The motive power is furnished by two Westinghouse single-reduction motors of 25 h. p. each, one motor on each truck. The whole electrical equipment is due to the judgment of Mr. C. L. Pullman, the contracting agent of the Pullman Company.



PULLMAN CENTRE-VESTIBULE DOUBLE-DECK ELECTRIC CAR.

It is interesting to add that the West End Electric Railway Co., of Boston, have already ordered four of these cars.

FITCHBURG STEAM ENGINE CO.

THE Fitchburg Steam Engine Co., Fitchburg, Mass., report business as being exceedingly good just now, and that they have a large amount of work on hand, but expect to remove their plant to their new works very soon. They are just shipping a 600 h. p. cross-compound condensing engine to the Powelton Electric Light Co., Philadelphia, this being the third engine of the sort they have shipped them; also two 60 h. p. engines to the Norman Paper Co., Holyoke; and expect to soon ship two large engines for the W. C. T. U. Temple, in Chicago, Ill.

They have recently received the following orders: Two large engines for the American Sugar Refining Co., to go in at the Havemeyer Co.'s works, in Brooklyn; 175 h. p. engine, Sayre & Fisher, Sayreville, N. J.; 150 h. p. engine, including boilers, etc., for Geo. W. Sharer, Little Washington, N. J.; two large tandem compound high-speed engines for L. W. MacCormack, Chicago, Ill.; 125 h. p. engine for the Revere Rubber Co., Boston; 75 h. p. engine for Keasbey & Mattison, Ambler, Pa., this being the fourth engine they have shipped them; 50 h. p. engines for the Meriden Curtain Fixture Co., Meriden, Conn.: Wilcox, Crittenden & Co., Middletown, Conn.; L. Sartelle & Son, Pepperell, Mass.; also, orders for smaller engines for the Rockland Building Association, Rockland, Me.: J. D. Bergen & Co., Meriden, Conn.; C. T. Sampson Mfg. Co., North Adams, Mass.; John Bower, Philadelphia; Hollingsworth & Whitney, Boston, and the Northampton Emery Wheel Co., Leeds, Mass. They have also recently started large compound engines for Gallup & Houghton, North Adams, Mass., besides many large engines in Philadelphia and the immediate vicinity.

"A PAINT WHICH COMBINES THE MOST GOOD QUALITIES."

THE Roessler & Hasslacher Chemical Company, 73 Pine street, New York, are prepared to prove that their protecting and insulating "Isolatine Paint" combines more good qualities than any other paint now in the market, and to judge from the array of evidence which they produce, managers, superintendents and contractors will find it to their interest to investigate these claims. This evidence will be published shortly.

It is not supposed, of course, that the statements of the manufacturers will be taken without additional trials, as naturally new combinations of circumstances create a vast number of variations, so that the material must show its capacity for each individual case before being accepted.

However, the tests made by the above firm with "Isolatine Paint" may be taken as proving conclusively what they assert, and just that much labor is saved.

A paint which remains always pliable will prove valuable in many a place. If to that is added permanent adhering and waterproof qualities, it at once embraces practically the entire protective and anti-rust field. And supplement this with good penetration for both metal and wood; a fine glossy, black, finish; the highest resistance to electrical currents, as well as to solutions of acids, alkalies and salts, and you have "Isolatine Paint."

DETROIT ELECTRICAL WORKS.

THE above progressive and energetic concern have issued for distribution at Pittsburgh a very interesting and pithy pamphlet which discusses the various questions connected with electric railway work and touches on each so as to bring out the distinctive merits of their system. Great emphasis is skillfully laid upon the various good features of the single motor, with its one armature, one set of field coils, one commutator, one set of armature bearings, and one set of brushes; yet driving upon both axles, so as to obtain the full measure of possible tractive effect.

THE WILLIAMS RADIAL TRUCK.

THE Williams radial truck designed by Mr. H. B. Williams, of 157 State street, Rochester, N.Y., consists of a pair of wheels placed under a bolster and fifth wheel and attached thereto with spiral springs. A king-bolt fastens the body of the car to the bolster. Attached to the axle by a journal are two arms that act as supports for an axle on which are a pair of pilot wheels. These arms also extend backward and support a similar pair of pilot wheels. The arms extend 24 inches either way, so that when the car is started in an opposite direction the back pair is forced down to the track, and in turn become pilots or guides. The reversing is done by hand at the beginning of a trip, and the pilots are held down to their place by a bolt slipping through a hole in a hanger attached to the bolster. The pilot wheels are mounted on ball bearings and run without noise. Their duty is to feel curves before the big wheels reach them, and by their leverage swing or turn the bolster radially with the track and prevent the flanges of the carrying wheels from grinding, or much more than touching, the rails. An arm reaching forward and backward from the bolster, and attached to the centre of the pilot axle, is really the lever by which the bolster is turned. Each pair of carrying wheels is similarly mounted, and acts entirely independently of the other, so that while the forward pair of wheels may be turning, the back pair may be running straight until they reach the curve or switch.

The bolster turns on a fifth wheel, and attached to it are a pair of small roller wheels which travel on the fifth wheel, and allow the bolster to be very easily turned. Leading backward and forward on the fifth wheel is an incline of a few inches, at the bottom of which the roller wheels rest while the car is running straight, effectually locking the truck by the weight of the car. Whatever the length of the car, the carrying wheels are only placed 24 inches from the extreme end. Thus a 24-foot car would have a wheel base of 20 feet. This great base does away with the annoying vertical motion.

The car will turn in a 10½-foot radius with but little more draft than on a straight track, owing to the absence of grind on the rail by the load-carrying wheels. A 24-foot car can be easily turned in less than its length. A balloon at the end of the track can be made very small, in fact, in a narrow street, so that a car can be turned without shifting the trolley. Owing to the trucks becoming radial, the ends of the car remain nearly over the centre of the line of curvature. There is plenty of room to hang a motor under the bolsters, and the economy of power in curving is another important feature.

H. WARD LEONARD & CO.

H. WARD LEONARD & COMPANY now have on exhibition at their offices, in the Electrical Exchange Building, 136 Liberty street, a Crocker-Wheeler motor operating under Mr. Leonard's new principle for controlling the speed, torque and direction of motors. The motor is made to perform various work in such a manner as to show clearly the principle used and the facility with which either the speed or torque is controlled. The exhibition is extremely interesting.

The first elevator to be operated upon the new principle invented by Mr. H. Ward Leonard was tested on Thursday, the 6th inst., and the result was an unqualified success in every particular. The elevator is that in the Central Station of the Edison Electric Illuminating Co., of Brooklyn. The operation of the elevator is controlled entirely by the movement of a handle in the elevator car, and the operation of the elevator is under the most perfect control. The smoothness of the motion of the elevator, both in increasing and decreasing the speed and in reversing the direction of motion, is extremely surprising to those who have been used to the peculiar sinking sensation experienced in the modern high-speed elevator. Supt. Barstow is much pleased with it.

The company report that their subscriptions for "Electrical Intelligence" are coming in in an extremely satisfactory manner. Owners of central stations and isolated plants seem to quickly appreciate the great advantages to be derived by securing information from a concern such as this at such moderate rates. Quite a large number of supply houses and even electrical manufacturing companies are among the subscribers. For special information, such as is called for by concerns of the latter description, special rates are quoted.

"THE TRAMWAY AND RAILWAY WORLD."

UNDER the above appropriately selected title, a new monthly illustrated review, devoted to the interest of steam, electric, cable and other traction, is to be published in London, England, at an early date. Its special province will be to promote European and also American traction interests abroad, and it will afford a valuable medium for advertisers on both sides of the water. As is well known, improved methods of street railway traction have received enormously wider practical adoption in this country than in any other part of the world, and to advocate and promote the use of these modern means as employed here will be a special feature of the new journal.

The present time appears especially opportune for the establishment of such a paper, in view of the fact that several concessions have recently been granted for the construction of electrically equipped lines by means of the overhead trolley system in various parts of Europe. Further, it is an interesting fact that all the Continental Europe, South American and Indian tramway and railway companies are owned and have their offices in London, and there being no similar publication, the paper will fill a field peculiarly its own.

Prominent and influential men associated in traction industries abroad recognizing the need of such a journal, have already accorded to the promoters their official support, and its prospects are of the most encouraging nature.

Mr. Frank X. Cicott, of Chicago, will leave shortly for London, to assist in launching the new venture, and on his return will represent its interests in this country. The staff will comprise editorial and business talent, both English and American, and the gentlemen composing it have had wide experience in the several branches of tramway and railway interests.

A LARGE SHIPMENT TO BRAZIL.

THE Berlin Iron Bridge Co., of East Berlin, Conn., have just sent 23 carloads of iron building material at one shipment by a special train over the N. Y., N. H. & H. R. R. for the Companhia Nacional de Fojas e Estaleiros, Rio de Janeiro, Brazil, S. A. This is one of the largest single shipments that ever passed through New England, the combined weight of the 23 cars being nearly 1,000,000 pounds. The shipment goes to the Harlem River station, New York, and is there lightered aboard a Brazilian steamer and shipped direct to Rio de Janeiro.

This building is for a car works for the Companhia Nacional de Fojas e Estaleiros. Not only the building is to be furnished in this country, but also all the tools and machinery for the entire equipment.

THE "IDEAL" ENGINE.

THE hotel "Marlborough" Co., cor. 36th St. and Broadway, are about to install a 100 h. p. "Ideal" engine. This makes the third of these celebrated self-oiling automatic engines that they have ordered. These engines are built by the Harrisburg Foundry and Machine Works, Harrisburg, Pa., whose factory is busy with the many orders they have received. They have recently made large improvements in their equipment in the way of new machinery, which enables them to fill their orders promptly. A great many of the orders they now have are from the New York representatives, W. R. Fleming & Co., 174 Fulton street.

BALL ENGINE CO.

THE Ball Engine Co., Erie, Pa., has shipped the World's Fair one 60 h. p. engine for operating the incandescent electric light plant on the grounds.

The Wesleyan University, Middletown, Conn., are installing a 25 h. p., built for them by the Ball Engine Co., Erie, Pa.

The Johnson Co., Johnstown, Pa., have recently ordered from the Ball Engine Co., Erie, Pa., a 60 h. p. engine, being the twenty-second engine built by them for the Johnson Company, aggregating over 3,000 h. p.

MR. J. STANFORD BROWN.

THE above-named electrical engineer is now well established at 611–612 Electrical Exchange, Liberty street, this city, and is actively engaged in consulting and constructing, his assistance being sought in connection with a great variety of important work. Mr. Brown has had special experience in motor construction and electric railway work, and his services are found of value in that still new department of applied electricity.

THE TORONTO CONSTRUCTION AND ELECTRICAL SUPPLY CO., Toronto, Can., have been appointed agents for the Dominion for the New York Insulated Wire Co., to handle Grimshaw "White Core," B. D. wires, tapes and compounds, and the "Vulca" ducts and interior wiring appliances.

CHICAGO INSULATED WIRE CO.

THE town of Sycamore, Ill., has secured the Chicago Insulated Wire Co., which is expected to give employment to 125 hands. Sycamore gives the company a bonus of $12,000 and four acres of valuable land adjacent to two railroads.

AMERICAN ENGINEERING CO.

THE American Engineering Co., of Jersey City, N. J., has been formed with a capital stock of $1,000,000 to construct steam and electric power plants, manufacture machinery, etc.

NEW YORK NOTES.

THE "C. & C." ELECTRIC MOTOR CO., New York, are installing a 100 lt. dynamo for Mrs. Mary Jacobshagen, Union Sugar Plantation, La.; one 100 lt. for John T. Moore, Shriver, La.; two 600 lt. and one 300 lt. in the Erie County Savings Bank Building, Buffalo, N. Y.; one 200 lt. for John D. Muller, corner 5th avenue and Union street, Brooklyn, N. Y.; one 100 lt. for the Crescent Farm Planting Association, La.; one 125 lt. for Shaffer Bros., Ardoyne Sugar Plantation, La.; one 125 lt. for Messrs. Walbridge & Co., Buffalo, New York, and one 100 lt. for the Magnolia Plantation, La.

THE CROCKER-WHEELER MOTOR COMPANY, of New York, has placed Mr. D. Herbert Jeffery, of Jersey City, N. J., in charge of its offices, handling its large correspondence, management of records, etc. This step has been found necessary to relieve the other officers of the company of these duties in order to enable them to meet the exacting requirements of their several branches of the business, electrical, technical, installation, etc., each of which receives the personal attention of an officer.

THE ENGINEERING EQUIPMENT COMPANY have leased for a term of years the handsome store premises next the main entrance in the Central Building, 143 Liberty street, where they are now located on the second floor. By this move they secure stock room for Underwood cotton leather and other belting specialties, etc., which have been kept at 73 Cortlandt street. The Boston offices and salesrooms of the company are at 126 Pearl street, where Mr. F. A. Magee, who is in charge, is kept busy on Eastern trade.

MESSRS. DICK & CHURCH, whose New York office is at 16 Dey street, are selling a great many of their automatic cut-off engines. These engines are built at the Phœnix Iron Works, Meadville, Pa., and are made simple, tandem compound, cross-compound, and triple-expansion. They also manufacture boilers, heaters, etc., and furnish estimates on electric light and railway power plants. One of their latest engines was described in THE ELECTRICAL ENGINEER of September 30th.

MESSRS. J. JONES & SON, of 602 and 604 W. 22d St., have a very complete assortment of electrical apparatus and supplies, including lamps, push-buttons, annunciators, bells, batteries, and electric gas lighters. The Berlin watch demagnetizer, one of their specialties, was described in THE ELECTRICAL ENGINEER of March 18th.

THE NEW YORK AND OHIO CO., recognizing the demand for a one ampere 50 volt lamp for use in central stations where the cost of power is excessive, are now ready to supply them. This lamp absorbs about 3 watts per candle, and notwithstanding the high efficiency has a long life, and like all the other Packard lamps, is entirely free from discoloration.

MR. J. HOLMES, of 74 Cortlandt street, has commenced a business in second-hand electrical materials, including arc and incandescent dynamos, motors, lamps, and general supplies. He also deals in engines, boilers, pumps, etc., and complete steam plants.

PHILADELPHIA NOTES.

MR. L. ATWOOD a mechanical expert, was called to Richmond, Va., last week, by the city engineer to confer with him and the committee on streets for the purpose of considering the methods of relief from the unnecessary noise made by the motors on both the Union and City Passenger Railway Co's. roads. After a consultation they have decided to try the Atwood patent motor gear, which has been in use on the Richmond & Manchester Railway for the past year, giving perfect satisfaction to the citizens and owners of the road. These gears are being manufactured in large quantities by Mr. Atwood at Bridgeport, Conn. It is said that by the use of his gears the noise is eliminated, while the gears require no lubrication and are stronger than steel or iron. Chilled pinions can be used with these gears, which reduces the cost of pinions to about $2.

THE ARNOLD ELECTRIC CO., of Chester, Pa., has just installed a 500 light plant at the Thackara Mfg. Co.'s store and factory.

THE LAROCHE ELECTRIC WORKS are compelled to run a portion of their works night and day owing to the large demand for their improved dynamos. They report the following recent installations: Col. Henry A. du Pont, Wilmington, Del., 150 arc; J. E. Frick & Co., Langhorne, Pa., 75 incandescent; American Hosiery Mills, Royersford, Pa., 75 incandescent; A. P. Hill, Darby Road, Pa., 100 incandescent; T. J. Oliver, 19th and Reade streets, 35 incandescent; Gerson's Millinery, 8th street, 15 arc; Quaker City Watch Case Co., 6th and Chestnut streets, 5 h. p. motor; J. P. Weimer, 705 Sansom street, 2 h. p. motor; J. P. Mathews & Co., Phila., 100 light dynamo; Wm. J. Callaghan, 22 North 5th street, 2 h. p. motor; Oliver R. Reed, 1323 Arch street, two ½ h. p. motors; Geo. H. Earle, Devon, Pa., 1 h. p. motor.

DR. W. A. DRYSDALE, the consulting electrical engineer, has removed his office from 1531 Arch street and now occupies handsomely furnished offices in the Hale Building, Juniper and Chestnut streets. Dr. Drysdale has just completed the installation of the work at the Empire Theatre and is now busy with the plants at Messrs. Bailey, Banks & Biddle, the Philadelphia jewelers; Messrs. Boothby & Kugler's restaurant; a large storage battery plant for Wm. Simpson's Sons & Co.; the New Century Club, and a number of other smaller equipments.

MESSRS. THOS. H. DALLETT & CO., of Philadelphia, intend making a specialty of the Billberg generator, which they manufacture, coupled direct to the Triumph valveless compound engine on one base. This will do away with friction clutches and details of a similar nature. This company is the sole Eastern agent for the above engine. Mr. Newton L. Schloss, the manager of the New York office, has had wide experience in this direction with the Edison General Electric Company, and is especially fitted for this class of work.

MESSRS. WRIGHT & STARR, electrical engineers, have removed their office from 37 South 3d street to Room 501 Girard Building. Their car "Direct," which has been equipped with the Waddell-Entz system of storage batteries, has been out on the road several times recently, and is expected to be in service this week on the 2d street road at Chester. The Union Car Co., as well as Messrs. Wright & Starr, are very much satisfied with the working of the battery up to date.

MR. J. COOPER CLOUD, representing the Thomson-Houston Electric Light Co., has secured the contract from the Bala & Merion Electric Co. to install their entire plant consisting of two 650 light alternating dynamos; two 65 h. p. Westinghouse compound engines and two 70 h. p. horizontal tubular boilers, made by the Coatesville Boiler Works. The competition for this plant was exceedingly sharp by parties representing the standard makes of machines, and much credit is due Mr. Cloud for capturing this plum.

THE MILLVILLE, (N. J.) ELECTRIC LIGHT & POWER CO. has contracted with the Fort Wayne Electric Co., through their Philadelphia agent, Mr. G. A. Wilbur, for three 50 Wood arc light dynamos. Messrs. Clay, Pepper & Register have been awarded the contract for the construction work, which will necessitate the use of over fifteen miles of "Simplex" wire.

MR. H. T. PAISTE is moving his factory and office from 12th and Market streets to the Fuller Building at 10 South 18th street, where he will occupy the entire third floor. New machinery will be put in, which, with the commodious quarters, will enable Mr. Paiste to keep pace with the increasing demand which he is receiving for his electrical specialties.

NEW ENGLAND NOTES.

THE WHITNEY ELECTRICAL INSTRUMENT COMPANY, formerly of Manchester, N. H., have decided to build a three-story factory 100 feet long and 50 feet wide at Penacook, N. H. The site secured is an admirable one, with ample room for enlargement, and with a large and powerful water power. Two 54 inch wheels will be put in at present, and power leased to neighboring shops. The Whitney Company will manufacture instruments, the inventions of E. R. Whitney and Dr. A. H. Hoyt, and the stock of the company is chiefly held by members of the Gould and Watson Company, of 35 Hartford street, Boston, where the management of the company have their office at present.

THE BERLIN IRON BRIDGE CO., of East Berlin, Conn., have received the contract for the new blacksmith-shop building for the Dixon Mfg. Co., of Scranton, Pa. Owing to the peculiar formation of the ground the building will be in the form of a letter L, and will be 60 feet wide by 235 feet long, constructed entirely of iron.

MR. ALBERT SCHEIBLE, representing Mr. George Cutter, of Chicago, was in Boston a few days last week getting acquainted with his numerous customers and patrons. Mr. Scheible is well known as having been largely instrumental in the designing of Mr. Cutter's many clever advertisements.

THE TESTING DEPARTMENT of the Massachusetts Electrical Engineering Company, of Boston, has just issued a pamphlet calling attention to certain points concerning the use and reliability of fuse wire. They show the necessity, not only of using a properly tested wire, but also for the exercise of care and judgment in the selection of the size to be used when the surrounding conditions are unlike those of testing. For example, a wire which fuses at 50 amperes in a fuse-link five inches long would require over 100 amperes if the link had but one inch of wire. This company have designed especially for each system of cut-outs, fuse-links made of their tested fuse wire attached to copper terminals.

THE WAINWRIGHT MANUFACTURING COMPANY of Boston, have recently sold the following heaters: Frackville and Gilberton Electric Light, Heat and Power Company, of Frackville, Pa., 100 h. p.; the Wilmington City Railway Company, Wilmington, Del., 300 h. p.; Liberty Electric Light Co., Liberty, Miss., 50 h. p.; Suburban Electric Light Company, Philadelphia (third order) 200 h. p.; Sternes, Roger & Company, Denver, Col., one 200 and one 300 h. p.; A. M. Holter Hardware Company, Helena, Mont., 150 h. p.; and Russell & Company, Massillon, O., 400 h. p.

CLAFLIN & KIMBALL, of Boston, report the fact that the special railway lamp which they have introduced during the past season has met with a very large sale and has been very successful in practical use. The lamp is specially constructed to stand the variations in potential, and the severe jarring consequent from service on electric cars. The lamps are so made that they can be placed in any position; will resist vibrations and stand shocks better, they claim, than any other lamp hitherto constructed for that purpose.

MR. ALBERT H. MILLS, of the Steele and Johnson Manufacturing Company, of Waterbury, was in Boston last week looking up his numerous friends, and reports business as being extremely brisk in the Naugatuck Valley. The Steele and Johnson Company have made quite a reputation for themselves on their well-known shade-holder, and have obtained a large business in the general manufacture of light brass goods for general electrical purposes.

THE SAMSON CORDAGE WORKS, of Boston, note a largely increased demand this fall for their solid braided trolley cord, the most common orders being for white cotton No. 8, waterproof. The linen cord is somewhat stronger, but the manufacturers consider that cotton is more economical and amply strong for the purpose. Samples, catalogue and discounts are gladly sent on application.

ALBERT & J. M. ANDERSON have, up to the present, equipped every car on the West End Street Railway, of Boston, with their patent tapered steel trolley pole, with the exception of a very few still using the old wooden pole. Their trolley base is also in large demand, and they have recently received several orders from Europe.

THE NEW HAVEN INSULATED WIRE COMPANY, of New Haven, Conn., in order to meet the increasing demand for their insulated wires, have opened an office at room 308, 18 Cortlandt street, New York, in charge of Mr. H. G. Madden, as sales agent.

MR. C. E. BIBBER, of the Consolidated Electric Manufacturing Company, of Boston, is at present in the West, and will return by way of Pittsburgh.

WESTERN NOTES.

THE WRITING TELEGRAPH.—A highly successful trial of the writing telegraph was made Sunday, Oct. 4th, between St. Paul and Chicago. The instruments of the Writing Telegraph Co. have now been so perfected that the sending between very long distances is eminently satisfactory and reliable. Mr. W. E. Gump, the general manager of the company took the St. Paul end of the line, andMr. H. Etheridge, the Chicago one at the office of the North American Telegraph Co. The writing was exceptionally good, maintaining exactly the characteristics of the handwriting of the sender.

THE ELECTRICAL SUPPLY COMPANY, of Chicago, report an increasing demand for their Ajax dry battery. A recent shipment of 1,200 to one Western firm would confirm the idea that dry batteries are a fixture.

MR. F. H. LEONARD, JR., vice-president of the Electric Engineering and Supply Co., of Syracuse, New York, was a recent welcome visitor to Chicago. Mr. Leonard is making an extended Western trip in the interest of his company, and reports business as excellent.

GEORGE CUTTER has received another large shipment of "Cutter's Elastic Tape," which he is selling steadily in connection with Simplex rubber wire. It is made from a pure rubber stock and is said to give a fine joint even when no heat is applied to it.

THE ELECTRIC MERCHANDISE CO. report for the last week sales of Burton electric heaters to the following roads: Spokane Electric Railway, Spokane, Wash.; Danville Electric Railway, Danville, Ill.; Stillwater Electric Railway, Stillwater, Minn.; Terre Haute Street Railway Company, Terre Haute, Ind.: Burlington Electric Railway, Burlington, Iowa; Reading and Southwestern Railway, Reading, Pa.; Eau Claire Street Railway, Eau Claire, Wis.: People's Street Railway, Springfield, Ill.; Salt Lake Rapid Transit Company, Salt Lake City, Utah; Electrical Supply and Construction Company, Pittsburgh, Pa; Minneapolis Street Railway Company, Minneapolis, Minn.; Pullman Palace Car Company, Pullman, Ill.; Windsor and Sandwich Railway, Windsor, Canada.
Electric heating by the Burton Company's process is a fully demonstrated success, and the great advantages of this method of heating are realized by managers of electric roads.

MR. WILLIAM HOOD, 239 La Salle street, Chicago, is still filling orders for the favorite "Jewel" incandescent lamps, which are now to be found in use in a large number of central stations and isolated plants, where they are giving excellent satisfaction and proving to fill the requirement for a reliable, long-lived lamp, using small current and maintaing full candle-power. Mr. Hood will also place on the market shortly a new dry battery having exceptional properties and remarkable constancy, and which he is preparing to manufacture on a large scale. These dry batteries have received exhaustive tests. One small cell will ring an ordinary bell for seventy-eight days of twenty-four hours each absolutely continuously.

MR. C. M. BARCLAY and Mr. W. Sharpe, both gentlemen well known in the electrical business, have opened an office at No. 549 "The Rookery," Chicago, under the firm name of Barclay & Sharpe. They have secured the agency of the Woodbury automatic engine, and the water tube and steam boilers manufactured by the Stearns Manufacturing Co., of Erie, Pa., and also of the Padway heater. Both gentlemen are wide-awake business men, with a large acquaintance, and will undoubtedly do a prosperous business.

PROF. ELISHA GRAY, of Highland Park, laid some Okonite wire under ground ,without any protection whatever, over three years ago, on which his telautographic experiments have since been conducted. The wire is still in perfect condition, showing an infinite insulation resistance. The Central Electric Company report that they never have any comments on this superior grade of insulation, except such as are favorable, and of which the above is a sample.

OKONITE TUBING seems to be fast replacing the soft-rubber tubing for special insulating purposes. This is composed of a tough and almost indestructible compound and has all the high insulating qualities that the Okonite wires possess. It has a decided advantage over the ordinary soft-rubber tubing in that it is not in any way affected by exposure or by the action of the elements.

MR. H. M. UNDERWOOD, widely known in electrical circles and until recently general agent of the Interior Conduit & Insulation Co., of New York, has associated himself with the Knapp Electrical Works, of Chicago, as general salesman. Mr. Underwood will devote special attention to pushing "Safety" wire.

MR. L. W. COLLINS, who for some time has represented *The Electrical Review* of New York in the West, has resigned his position and accepted one as general representative of *Electricity*. Mr. Collins is a pushing, wide-awake advertising agent, and well known and popular among the electrical fraternity.

THE CENTRAL ELECTRIC COMPANY feel happy over the fact that their sales of Packard high-grade incandescent lamps are constantly increasing, and report that there is a great tendency towards using better material in electric light construction. These lamps satisfy the most exacting demands.

MR. J. GODFREY, general manager of the New York Insulated Wire Co., made a short stay in Chicago last week. Mr. Godfrey is on his way to the Pacific Coast, and he keeps catching orders for Grimshaw wherever he goes.

MR. GEORGE E. C. JOHNSON'S eldest daughter was married last week to the Rev. J. H. Henry, of Chicago. Mr. Johnson is well known in electrical circles as president of the Lafayette Street Railway Co., of Lafayette, Ind.

FRANK B. RAE, the well-known electrical engineer, of Detroit, was a recent visitor to Chicago.

☞ ***Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Miscellaneous, etc., will be found in the advertising pages.***

THE

Electrical Engineer.

VOL. XII. NOVEMBER 4, 1891. No. 183.

THE ACCUMULATORS AT THE FRANKFORT ELECTRICAL EXHIBITION.—II.

BY

Dr Paul Schoop

THE Correns plate avoids this drawback, as the bars of the lead grid are of the form shown in Fig. 5.

This grid seems to be cast by means of metallic moulds, using the trick of placing the milling of the lower part of the mould upwards and that of the upper part downwards. Fig. 4 gives an idea of the process, and Fig. 3 shows a grid with some of the active material in place.

The positive and negative electrodes seem to be exactly alike; the mode of connection of the plates to a section is

FIG. 3.

similar to that observed in the old style E. P. S. cell. The plates are perhaps one-quarter of an inch thick, longer than they are high, and are provided at the upper part with two projections for the purpose of suspension. It is now almost universal not to have the sections or plates standing on a frame at the bottom of the containing vessel, but to hang the electrodes, using two wooden boards or two glass plates as supports.

We may here mention, also, the plates of the "Accumu-

FIG. 4.

lator-Actien-Gesellschaft." This concern manufactures the system of secondary-batteries, formerly known as the "Tudor" accumulator. Indeed, this company claim all the advantages for their products that have been claimed during the last year for the Tudor cell, notwithstanding the fact that the manufacture seems to be quite different. This cell was intended to stand at least six years without getting out of regular working order, and to be practically indestructible. Even at the Frankfort Exhibition a positive plate may be seen (carefully enclosed in an elegant box with a glass cover) with the notice in gold letters: "Plate after six years' use", or something similar. Do the promoters of such schemes really believe that people are fully satisfied with such assertions? Would it not be worth mentioning whether this plate, or battery, was used

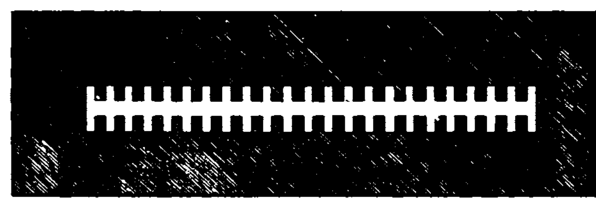


FIG. 6.

daily, and what the daily work was, calculated for the unit of weight and cost? And should it not be necessary, even if such most desirable information could be given, that it be testified to by disinterested people? It seems to the writer that such ways of making a noise (for it is nothing else) are most adapted to make those interested unbelieving and suspicious.

The old style Tudor plate was obtained by pressing lead by hydraulic pressure through a die. Fig. 6 shows a sketch of die, and Fig. 7 a section of the old style of plate. The plate being about one-half inch thick, and the corrugation only about one thirty-second inch deep, it will be obvious that the positive lead plate

FIGS. 7 AND 8.

must last longer than a grid with bars of only one-sixteenth inch diameter. The capacity of such plates was, per unit of weight, only about one-fourth that of E. P. S. plates for instance. Of course, this small capacity had to be enlarged, and in pursuing this purpose the good old plate has been so remodeled that there remains hardly any resemblance to the Tudor. It is very expensive and difficult to form plates of commercial size, say two or three feet broad, by hydraulic pressure, since very large presses would be necessary. It is easier to cast large plates, and this is done by the successors of Messrs. Tudor. The question whether or not pressed and cast lead will behave about the same, seems to be usually considered immaterial, though not by the writer. Instead of corrugations of one thirty-second inch, channels of a little more than one-fourth of an inch are found more practical, in order to augment the capacity per unit of weight, and the so-called Tudor plate of to-day is as shown by Figs. 8, and a six-year-old plate of this pattern after full daily work will probably also be put in an elegant showcase!

The samples of goods exhibited by Mr. J. Hagen, Köln, are most interesting. There are lead castings of such fine workmanship, and of such complicated designs, as to be simply astonishing. Probably these castings were not obtained by means of metalic moulds, but were cast like iron or brass.

Fig. 9 represents a grid for positive or negative plates. Of this pattern there is exhibited a battery of about sixty cells. No doubt the greatest mechanical strength with the

FIGS. 5, 9 AND 10.

least weight of lead is here combined; plugs of active material cannot fall out of such a grid. The castings are without any failures or weak points. It is to be hoped that the cost of making such grids is not too high for general practical use.

Fig. 10 is a grid for both positive and negative electrodes for higher rates of charge and discharge for unit weight of cell.

Fig. 11 seems good for small-sized plates, and for the highest possible rates of current. It seems especially adapted to train lighting, electric launches and power purposes.

Fig. 12 shows a piece of grid for large-sized plates, in-

FIGS. 11, 12 AND 13.

tended for use in batteries for lighting, and Fig. 13 is a piece of grid for largest size electrodes; this sample is a marvel of lead casting. It seems to consist of three separate grids, connected with each other by numerous cylindrical bolts, but the whole is made in one cast.

THE LOCALIZATION AND REMEDY OF TROUBLES IN DYNAMOS OR MOTORS.—VII.

(*Copyright.*)

BY

Francis B. Crocker and S. S. Wheeler.

MOTOR STOPS OR FAILS TO START.

This trouble is, of course, an extreme case of the previous class (Speed too High or Low), but it is made a separate class because it is so perfectly definite and requires somewhat different treatment. This heading does not, of course, apply to dynamos since they are usually driven positively by an engine and do not like a motor, depend on their own operation for their motion.

1. Cause.—*Great Overload.* (See Sparking, No. 1.) A slight overload causes motor to run slowly, but an extreme overload will, of course, stop it entirely or "stall" it.

Symptom.—On a constant current circuit no harm results, and motor starts properly when load is reduced or taken off.

On a constant potential circuit the current is very excessive, and safety fuse melts, or, in the absence or failure of the latter to act, armature would be burnt out.

Remedy.—Turn off switch instantly, reduce or take off the load, replace the fuse or cut-out if necessary, and turn on current again, just long enough to see if trouble still exists.

---

2. Cause.—*Very excessive friction due to shaft, bearings or other parts being jammed, or armature touching pole pieces.*

Symptom.—Similar to previous case, but is distinguished from it by the fact that armature is hard to turn by hand, even when load is taken off. Examination shows that shaft is too large, bent or rough, or bearing too tight, armature touches pole pieces or other impediment to free rotation.

Remedy.—Turn current off instantly, ascertain and remove cause of friction, turn on current again just long enough to see if trouble still exists.

---

3. Cause.—*Circuit open* due to (*a*) safety fuse melted, (*b*) wire in motor broken or slipped out of connections, (*c*) brushes not in contact with commutator, (*d*) switch open, (*e*) circuit supplying motor open, (*f*) failure at generating station.

Symptom.—Distinguished from Nos. 1 and 2 by the fact that if load is taken off motor still refuses to start, and yet armature turns freely by hand.

On a constant current circuit the switch arcs badly when turned on if motor circuit is open; but there is no current, motion or other effect in motor. On a constant potential circuit, field circuit alone of a shunt motor may be open, in which case pole pieces are not strongly magnetic when tested with a piece of iron; if armature circuit is at fault there is no spark when brushes are lifted, and if both are without current there is no spark when switch is opened.

Remedy.—Turn current off instantly. Examine safety fuse, wires, brushes, switch and circuit generally for break or fault. If none can be found turn on switch again for a moment, as the trouble may have been due to a temporary stoppage of the current at the station or on the line. If motor still seems dead, test separately armature, field coils and other parts of circuit for continuity with a magneto or cell of battery and electric bell. (See Instructions for Testing.)

---

4. Cause.—*Wrong connection, or complete short circuit of field, armature or switch.*

Symptom.—Distinguished from Nos. 1 and 2 in the same way as No. 3, and differs from No. 3 in the evidence of strong current in motor.

On a constant potential circuit, if current is very great, it indicates a short circuit. If the field is at fault it will not be strongly magnetic.

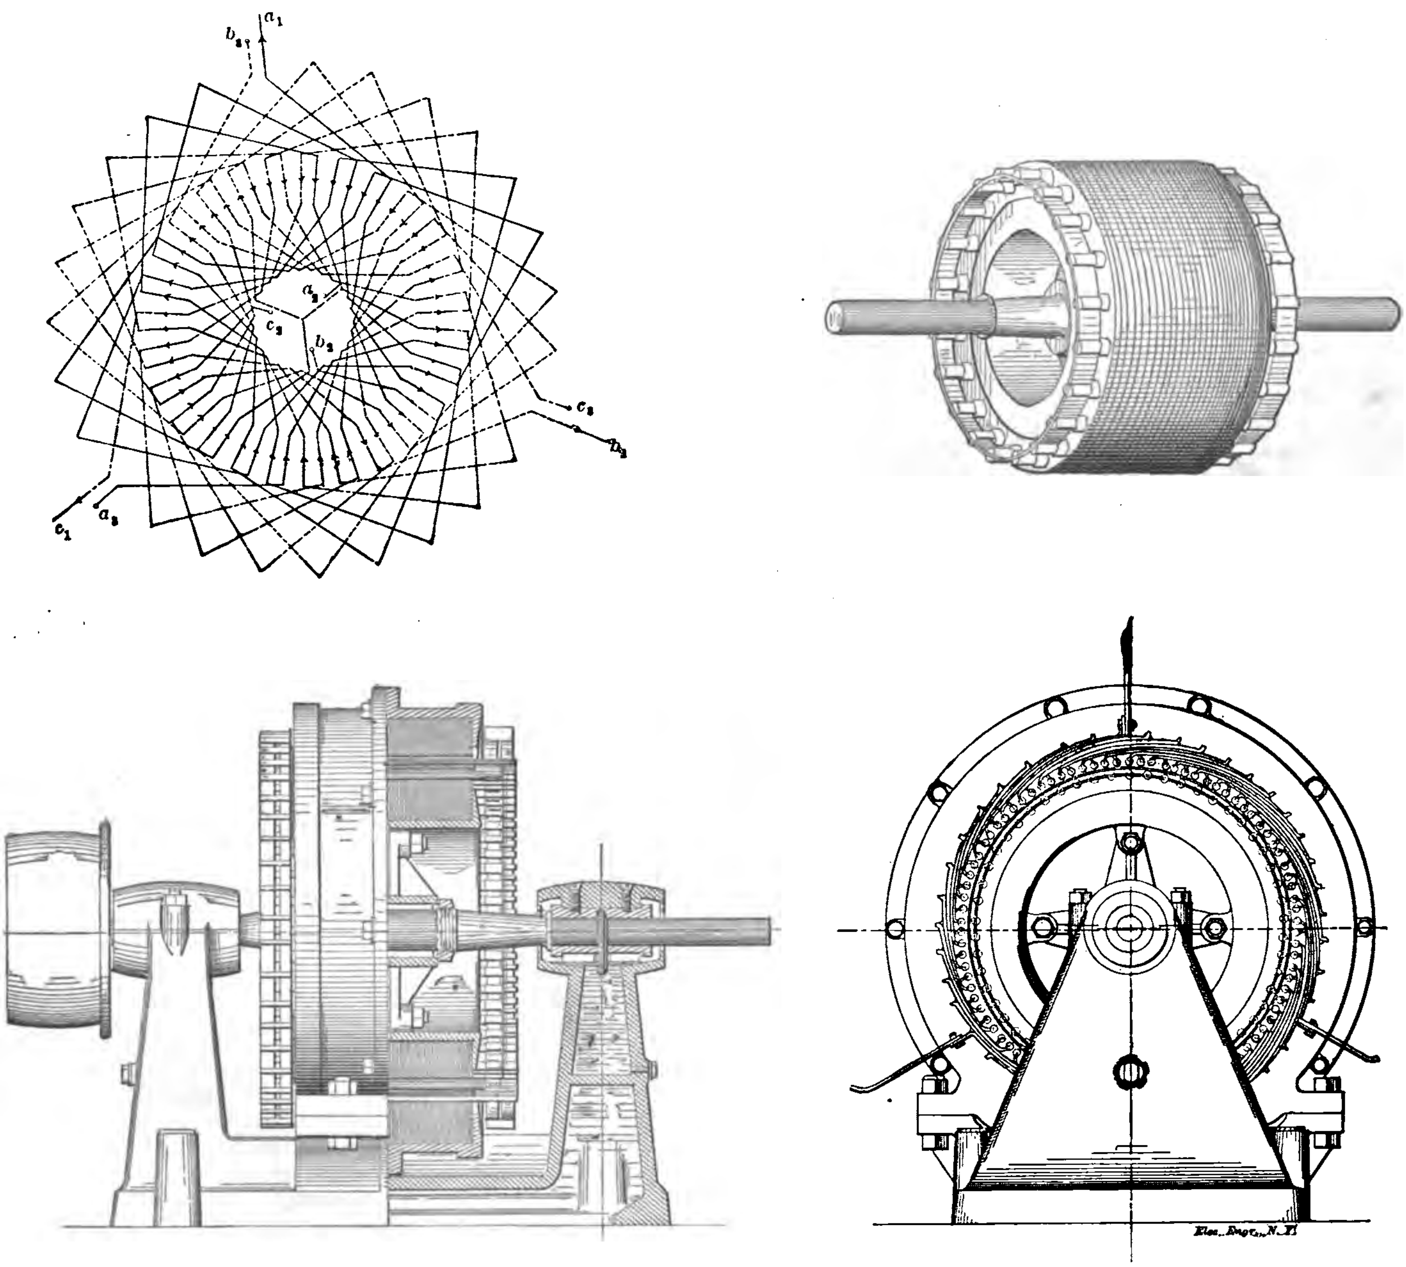
The possible complications of wrong connections are so great that no exact rules can be given. Carefully examine and make sure of the correctness of all connections (see Diagrams of Connections). This trouble is usually inexcusable, since only a competent person should ever set up or change the connections of a motor.

C. E. L. BROWN'S 20 H. P. THREE-PHASE ALTERNATE-CURRENT MOTOR

About the middle of last year Mr. C. E. L. Brown gave his attention to the use of multiphase currents, since the absence of sliding contacts in multiphase machinery is sometimes a considerable convenience, and may in the future be of great importance in the industrial use of electric motors. The Allgemeine Electricitäts Gesellschaft in Berlin were working in this direction, and the Oerlikon is not generally known, suggested the Frankfort-Lauffen experiment; one of these machines being, in fact, employed at Lauffen. The perforated armature in this application offers, among other advantages, the possibility of reducing the magnetizing current to a minimum.

In the accompanying illustrations, Fig. 1 is a diagram of the armature circuits, and Fig. 2, the armature. Fig. 3 is a side elevation and half section of the machine and Fig. 4, an end elevation.

The three armature circuits are connected as in a



Figs. 1, 2, 3 and 4.—Brown's 20 H. P. Three Phase Motor.

Company eventually joined with them to develop this system. In August, 1890, the first multiphase motor on a commercial scale was built after Mr. Brown's design. This machine developed 2 h. p., and had a perforated or "hole armature;" that is to say, an armature in which solid bars of copper are completely embedded in holes in the iron core, the connections being made as in the Gramme ring. In the same month Mr. Brown applied this perforated armature in connection with drum-winding to the 300 h. p. generator and motor designed for the electric transmission of power between Bülach and Oerlikon, which, though it Thomson-Houston armature, and the winding is so arranged that four rotating poles are produced. With 40 cycles the motor makes about 1,200 revolutions per minute. The motor takes 50 volts normally; a reduction to 30, or an increase to over 100, will not make any practical difference in the speed. Of course, in the first case, the heating of the armature wire is greater, and in the second the heating of the iron is increased. The magnetic field rotates, and is produced by the armature reaction, thus avoiding all sliding contacts. The field magnet is composed of a laminated ring with holes, in which are placed insulated copper bars. The free ends on both sides are connected by copper rings. It is not easy to imagine a more simple construction. Before giving results of the trials, however, some general data of the motor may be of interest.

The armature has 90 conductors of about 40 sq. mm. section. The weight of copper is 20 kg., the iron about 100 kg. The breadth of the armature is 20 mm., the outer diameter about 500. The rotating magnet carries 54 copper bars, with a section of 100 sq. mm. The weight of the copper is 15 kg., that of the iron is 70. Recent trials in Oerlikon with this motor showed that it can easily supply 20 h. p. No part of the motor showed with a continuous run a higher temperature than 20° C. to 25° C. above the temperature of the test-room. It may be of interest to mention that the rotating part shows practically no heating. The difference of speed between no load and full load is only about 3 per cent. The torque of the motor at starting is considerable. It easily ran a separately excited dynamo, which was working on a resistance absorbing 20 h. p. Over 200 kg. torque could be obtained on the 20 cm. pulley. The motor can carry also a considerable overload, and runs without the least noise. The starting of the motor is similar to that of a continuous-current motor controlled by a resistance in series with the armature circuit. Regarding the commercial efficiency, no accurate tests have been carried out. The losses in armature copper amount to about 4 per cent. in the magnet copper and iron, inclusive of friction, to 4 per cent. From this there would be efficiency of 92 per cent. A commercial efficiency of 90 per cent. may be relied upon. That the losses are very small is further clearly shown by the very moderate heating, in spite of the small size of the motor and the absence of ventilation. A further advantage is that the commercial efficiency remains high, even if it works on a light load. The weight of the motor is 420 kg., say a trifle over 20 kg. per horse-power. For locomotive purposes it might without difficulty be reduced to 300 kg., the result of which would be only 15 kg. per horse-power. This result must be looked at as a very good one, especially considering the low-current density with which the motor is worked. The bearings are automatically oiled, and contain large oil reservoirs, so that this motor should run without any attention for months.

THE ECONOMIC LIMIT OF LARGE POWER UNITS.

BY "CARLETON."

THIS subject has always been one of deep interest to all persons interested in electrical development, and many electrical engineers have in no way changed their views from the first, concerning the size and style of engine for electrical requirements. No well-organized and regulated gas company would put all of its gas into one holder if such a thing were possible, as an accident in their works would prevent production for a short time, even if the reserve in the gas holders would continue to supply the demand. Let the gas holder be ruined or disabled for an indefinite time, then production and revenue not only cease, but business reputation suffers, a loss of confidence possesses the community and a feeling of uncertainty exists.

The vital question to be considered by electrical promoters is not what a steam horse power costs at its station, obtained from an improved and complicated engine designed to show at its official trial a unit, for a pound, and fraction of a pound, of coal, but what does it cost to produce light commercially at the permanent location of the lamp.

Take, for example, the long-stroke, slow-speed, direct-acting, compound or triple expansion engine, with its multiplicity of valves and intricate connections.

Floor area in places where real estate is of great value becomes the first consideration. Then multiplicity of parts increases the liability of disaster, while variation of load produces internal condensation of steam in the cylinders, caused by constantly changing temperatures, resulting in direct loss, showing a consumption of coal per horse-power per hour in the majority of direct-acting engines to be over five pounds.

Electric railway work is proving to be the most severe problem the steam engine builder ever contended with. Rolling and saw mills were thought to be very exacting in their requirements, but now the yielding of steel and iron billets in their semi-fluid state when entering a train of rolls, as well as the entering of the circular or band saw into the log, passes out of mind when the engine builder knows and realizes that many times during the day the majority of street cars on an electrical railway start and stop simultaneously. These conditions produce a blow on the piston of the engine, which is communicated to the cross-head pin, crank pin, main bearing, and then to the dynamo through the belt. As long-stroke, slow-speed engines, with an independent cut-off for the valves, run with but little if any compression in the cylinders, there is nothing to relieve this sudden blow which occurs twice during each revolution, and the result is quickly seen in the bearings of reciprocating parts, as well as the disintegration and unreliability of belts. The lining metal of the various boxes, which is comparatively soft, yields to the violent and sudden stress put upon it, necessitating frequent driving of keys and adjustment of quarter boxes, accompanied by heat from excessive friction, not only resulting in loss of power, but in increasing the cause of expense and chances of disaster.

It is, without doubt, reliably estimated that the steam horse powers of the world have doubled in the past seven years. This wonderful increase of power has been demanded and required by electrical development, and the shareholder now asks if a permanent and reliable investment can be offered to him, as he realizes that the days of borrowing an engine, boiler and dynamo, together with a few lamps, placing them in some old and almost worthless building, at the same time calling the combination a "Central Station," is a thing of the past. It is to be regretted that numerous electrical engineers are for the sake of personal advancement constantly bringing forward, at the expense of the shareholder, new and untried experiments in special engines. The compound non-condensing engine has had quite a run, much to the disgust of the shareholder who finds with variable load and pressure the direct-acting, non-condensing engine is more economical. As the electrical engineer is without financial responsibilities, the burden of loss is not with him. A recent number of London *Engineering*, the leading and most reliable mechanical paper of the world, says, "Nothing is to be gained by running a non-condensing compound engine, unless it be specially designed, having constant load and pressure." In addition to this authority, it is well known that the Corliss Steam Engine Co., and the Armington & Sims Engine Co., Providence, R. I., builders of long-stroke, slow-speed, and short-stroke high-speed engines, respectively, refused to build non-condensing compound engines. Comment is unnecessary, unless it be to say that these well-known builders are more friendly to the electrical shareholder than his electrical adviser.

The various triple expansion engines which are now attracting considerable attention, have not yet been long enough in operation to judge of their fitness for central station work. They possess many of the objections before mentioned, and their greatest claim for superiority is based on their economical running. The measure of economy of the steam engine is determined on the consumption of steam per horse power per hour. The builder cannot always guarantee the amount of coal to be used in developing a certain amount of horse power, as more boilers evaporate seven pounds than nine pounds of water to a pound of coal, while some of the builders of safety water-tube boilers claim an evaporation of ten and even eleven pounds of water to a pound of coal. Recently, an official test of a triple-expansion engine was made in a well-appointed central station in this country. The published result was a horse power obtained for about 12½ pounds of water. This result was certainly remarkable and unexpected, showing rapid advancement had been made. The publication of the official test showed that an allowance of a certain percentage had been made for saturation of steam by water. What this means and how the result was obtained, the report does not say, and but very few mechanical engineers claim to understand it. Without this allowance for saturation, whatever it may have been, the amount of water actually consumed was about 14 pounds per horse power per hour, and as this amount was paid for, together with the coal used to convert it into steam, the practical central station manager would base his cost of electrical production on the results of 14 pounds, rather than on the theoretical 12½ pounds, which in reality means nothing commercially.

If the required favorable conditions can be given to the properly proportioned and constructed triple-expansion engine, viz., constant pressure, load and speed, then its economical performance cannot be surpassed; but vary the conditions, as in electrical railway work, and the results must be anticipated by the practical manager, without mechanical knowledge. Many of the modern fast ocean steamships claim to produce a horse power with their triple-expansion engines for from 1½ to 1¼ pounds of coal, but as a round trip of these steamers cost $75,000, and the consumption of coal is 300 tons per day, it is of course impossible to obtain reliable data, and the result given is arrived at by estimating. From the Navy Department *Intelligence Series* we find it is customary to estimate the amount of coal consumed on the new cruisers. How can it be otherwise, as facilities for weighing cannot be had? There is, however, the published result of one steamship trial worth repeating. The builders claimed a horse power for their engines of one and one-half pounds of coal. Permission was asked by a professor of a technical college to ascertain if possible the truth of the statement. It was freely given, possibly because it was thought impossible. The ship and engines were reported to be in first-class order and condition. The professor and about twenty assistants carried on their experiments, and after a continuous run of eighteen hours, actual results showed a horse power for two and one-fourth pounds of coal. A claim was then made that the ship and engines were not at their best, but would soon be made so, and an invitation to repeat the experiments was given and accepted. Nearly three years have passed since the first trial, yet the professor has never been asked to continue his investigations, and he never will be although he obtained and gave as reliable data commercial results. They were not wanted. In case of warm bearings, or breakings of parts of the steamship engines, it is an easy matter to slow down, and if necessary to stop for an hour or two, but not so with the triple, expansion street railway engine, with more than double the number of valve-gear parts. *It must not stop.*

Electrical engineers from abroad say we are three years behind them in electrical development, and claim that our large unit system of engines, with belt transmission, is also three years behind modern progress, although these large engines in some parts of the country have not yet started. Let us hope for their success, and that their comparison to the single gas-holder practice may be an unfulfilled prophecy.

To say that the high-speed, high-pressure engine meets all requirements would be absurd, yet it must not be denied that this class of engine has made rapid advancement when it is known that the builders of the first successful high-speed engine in this country were compelled about ten years ago to lay aside for two years their inventions and improvements, owing to intense and not well-founded opposition. It is this class of engine that has more than contributed to doubling the horse power of the world, at the same time compelling the builders of every known kind of engine to run it faster, improve its design and workmanship. It has compelled boiler-makers to use better materials and improve their workmanship, as higher pressures are demanded. It has not only been the means of improving the standing of mechanics, materials and engineers, but it was the pioneer engine that gave commercial electricity its first start, enabling it to get a foothold.

The credit of bringing the high-speed engine into electrical prominence, although a matter of necessity, belongs to Mr. Thomas A. Edison, and an enthusiastic mechanical admirer says: "As was the inspiration of James Watt to steam, so is the knowledge of Thomas A. Edison to electricity." THE ELECTRICAL ENGINEER, April 23d, 1890, is quite clear on this subject, and says: "This is but a return to the original plan of Mr. Edison with his first 'Jumbo' dynamo and the Armington & Sims engine that was sent to the Paris Electrical Exhibition, in July, 1881. This combination is still doing good daily service. It should some day be brought back to this country and placed in the National Museum, at Washington, as it was the first successful combination ever constructed, and should be preserved." The combination should, however, first be placed in the World's Columbian Exposition, to be held in Chicago, 1893, and deserves a prominent place in the Department of Electricity among the first inventions.

Seven of the "Jumbo" combinations are still running in a central station in Milan, Italy, and although antiquated, give proof of the wisdom of the first thoughts of Mr. Edison, that should have been enlarged on by his less able and erratic followers and assistants.

Another pleasing and successful illustration is the Thomson-Houston multipolar dynamo directly connected to the double upright high-speed engine for ship lighting on the Government cruisers and merchant steamers. A large number have been built, and the combination grows in favor on its merits.

Why not continue and proceed on this line of advancement, arriving at the extreme power unit of the future for large central stations, which is to be a compound condensing engine of 500 horse power, with a speed of not less than 200 revolutions per minute, and piston speed of 600 or 750 feet? Stroke should be 18 or 20 inches, which will permit of direct-acting, positive valves, without complication. Armatures should be part of the engine shaft, of as great a diameter as practicable to compensate for the absence of driving pulleys or balance wheel, a most essential requisite. Simplicity reduces to a minimum the liability of disaster. Suppose a central station required 5,000 horse power, then ten 500 horse power engines should be put in, and in case one, or even two of them, or the dynamos are disabled, the remainder would have enough of reserve force to supply all demands unknown to the electrical consumer or customer or until former conditions are restored.

Two of these extreme units would not be suitable for a station of 1,000 horse power, as a number of these combinations of various powers should be placed in each station, and if water for condensers cannot easily be obtained at small expense, then use the direct-acting engine, as about 25 times the amount of water pumped into the boilers for a certain load is required for the condensers. As the engine and dynamo duty increases, add to the present requirements another unit, and when decreasing, take from it permanently, at the same time stopping all expense of that particular unit without destroying its efficiency as a reserve factor.

The managers of small stations should not be carried away with the one gas-holder theory, but build wisely and well for their patrons and shareholders.

MR. J. M. STEPHENS has been appointed superintendent of the Western Union fourth district, succeeding the late Mr. Meriwether.

ELEMENTARY GEOMETRICAL THEORY OF THE ALTERNATE-CURRENT TRANSFORMER.—XVII.

BY

Chas. Steinmetz.

THE mean value of all the alternate E. M. F.'s of our machines and apparatus, so long as no mechanical commutation is used, equals zero ; that is, $\int e\,d\,t = 0$ and there is no hope whatever of deriving *continuous currents without commutation* except by *electro-dynamic induction* from alternating waves. Every line of magnetic force, which, during a complete magnetic cycle, is cut one way by the electric conductor, must be cut again during the same magnetic cycle, the other way, thereby inducing an E. M. F. of equal but opposite integral value ; and therefore, to get continuous currents from alternate circuits, we have to rely either upon mechanical commutation, or look out for something else still unknown. Electro-dynamic induction can *not* give it.

The E. M. F.'s of the spark-inductors have the same property, but the mean values of pulsating currents are other than zero. Hence, while true alternating currents are unable to produce continuous magnetism without commutation, pulsating currents do so.

The most important non-sinusoidal currents, however, are the *interrupted current* and the *pulsating current.* The *pulsating current* can be considered as a superposition of a continuous current upon a true alternating current, and will, for graphical treatment, best be broken up into these two components, the alternating part of it giving the induction-affects, and the continuous part of influence only so far as it changes the apparent magnetic susceptibility of the circuit, the magnetism fluctuating around a positive average value.

A more complete explanation of the phenomena of pulsating currents, and of the interrupted or intermitting current, we must leave to another occasion, and give only the result here. "*The curve of* E. M. F.'s, *induced by intermitting or interrupted currents, is represented in the polar-diagram by the loxodromic curve,*

$$e = A\,\varepsilon^{-\frac{2\pi t}{T}\cot\Theta}$$

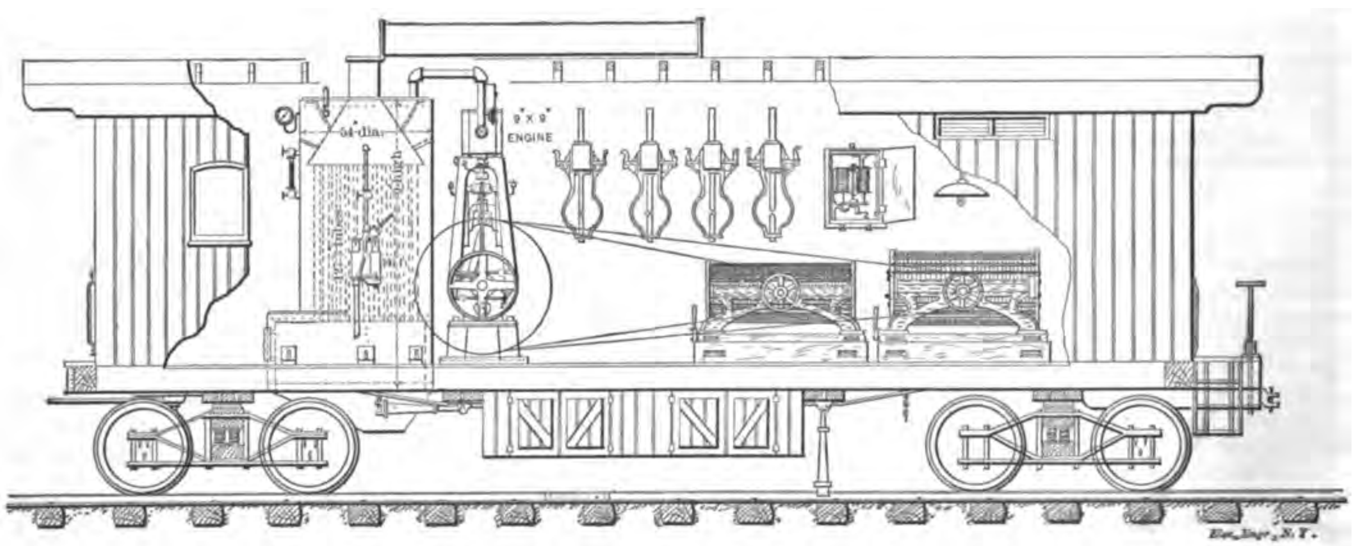
that is, that curve, which intersects all the radii vectores under the same angle Θ, this angle Θ being determined only by number of turns, electric and magnetic resistance, and frequency."

This loxodromic curve shares with the sine-wave the feature, that all the currents, E. M. F.'s, *etc, produced or induced by loxodromic curves are loxodromic curves again,* the original intermitting E. M. F. being represented by the characteristic angle $\Theta = 0$.

But, while the *sine-wave* is the curve of *stationary conditions,* the *loxodromic* is the curve of *disturbed equilibrium.* Hence it appears always, where sudden changes occur.

For instance, when current is thrown on or shut off, a transformer, or when the secondary resistance is changed, the instantaneous values of the electric and magnetic quantities of the transformer travel on loxodromic curves from the diagram representing the former conditions to the diagram representing the altered conditions.

For the loxodromic curve the ratio between primary impressed, and secondary induced E. M. F. is not proportional to the ratio of turns, but entirely independent of it. Therefore the occurrence of sudden loxodromic changes in an alternate-current apparatus may introduce the danger of destruction by excessively high induced E. M. F.'s.



THE CUMBERLAND VALLEY PORTABLE LIGHTING PLANT.

THE CUMBERLAND VALLEY PORTABLE LIGHTING PLANT.

BY

C. H. Hull

HAVING recently read of portable electric lighting as being a new scheme, I send you prints of a portable electric light plant designed and built by me for the C. V. R. R. Co., at the Chambersburg, Pa., shops, in 1883, and which has been in constant use up to date. The accompanying illustration explains the construction. We use this plant for lighting at wrecks, and rent it for pic-nics, camp-meetings and often for public lighting. The capacity of the plant is forty 2,000 c. p. and two 65 c. p. incandescent series lamps.

This plant consists of a fifteen 2,000 c. p. lamp dynamo, built by the Thomson-Houston Electric Company, 1880, purchased by our company in 1882 ; a twenty-five 2,000 c. p. lamp dynamo, spherical type, purchased in 1886, operated by a 35 h. p. vertical automatic engine and a 40 h. p. vertical submerged flue boiler, built by the Taylor Mfg. Co., Chambersburg, Pa. The plant has given entire satisfaction.

A USEFUL HORSE POWER DIAGRAM.

BY

Franklin Sheble

THIS diagram gives a quick means of determining the horse power required to haul a given weight at a certain speed, either on a level or on a given grade. It is within the range of ordinary street-car practice, but can easily be extended by other plots, or by finding the power required for a fraction of the speed or weight and multiplying this by the whole number.

The scheme is applicable to determine the resultant of any number of factors, and is that used by Mr. Hering to determine the sizes of wire.

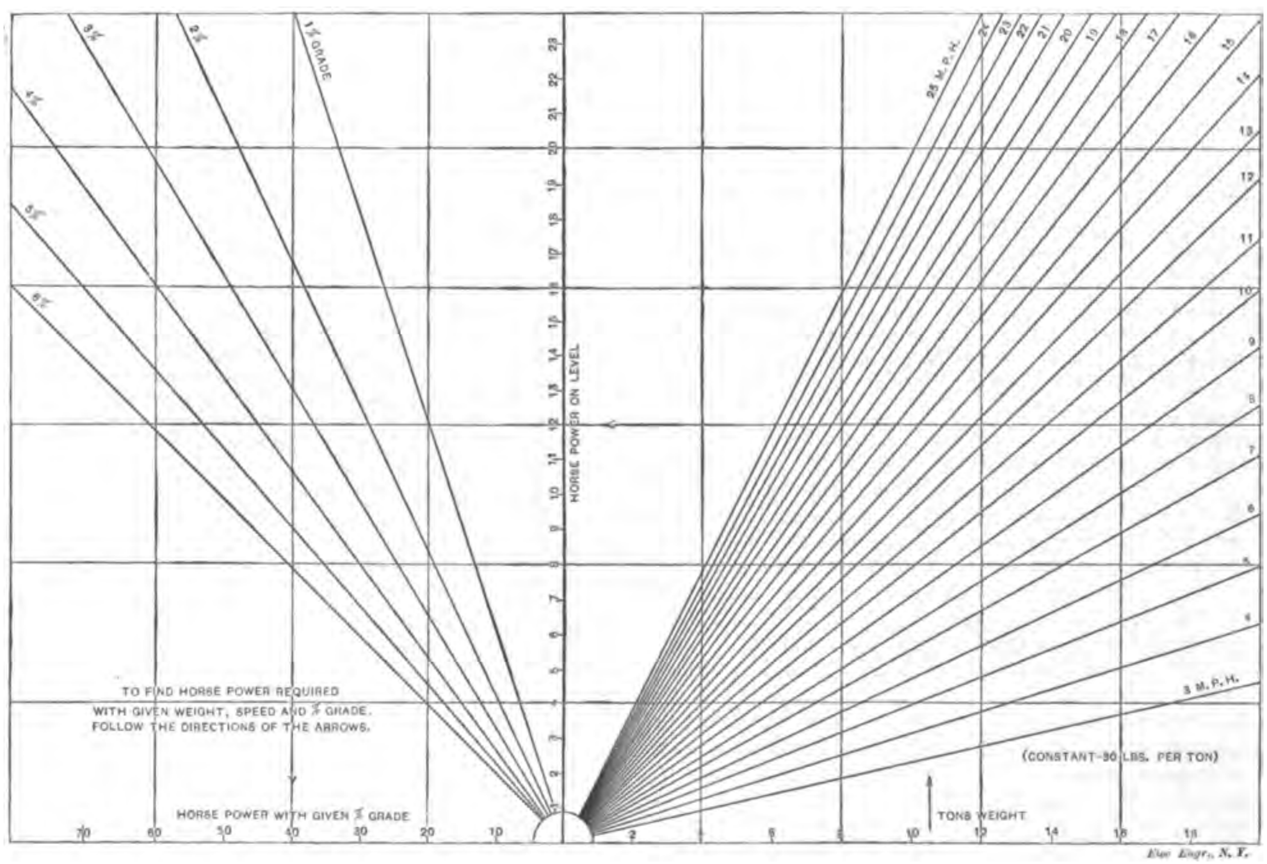
In this case the variables are weight, speed and per cent. grade. The horse-power varies directly as the weight and speed, while the power on a given grade depends on the power required on a level, plus that due to the grade. The formula for horse-power is too well known to need further consideration. The constant for traction here used is 30 pounds per ton.

The following examples clearly show the use of the chart:

1. Suppose the total weight of the car is 20,000 pounds, or 10 tons—following this ordinate to the 15 mile per hour line, and then across, we find that it will take 12 h. p. to draw this car at the given speed; viz., 15 M. P. H. on a level. If it is necessary to ascend a 2 per cent. grade at this speed, we find, by continuing across to the 2 per cent. line and down to the horizontal line, that it will require 28 h. p.

2. Suppose that the car complete weighs 15 tons, equipped with two motors which are capable of delivering 20 h. p. each. Passing upwards on these ordinates we see that on a 6 per cent. grade, 40 h. p. will draw the car at 6.6 M. P. H., on a 5 per cent. grade 7.6 M. P. H., on a 2 per cent. grade 14.2 M. P. H., etc.

3. A motor may be capable of delivering 15 h. p. at 15 M. P. H. This will draw a total weight of 24,500 pounds If it is necessary to climb a 2 per cent. grade the same horse-power will draw this car at 6.3 M. P. H. Two of these motors on the car will, of course, draw 49,000 pounds at 6.3 M. P. H. or 24,500 pounds at 12.6 M. P. H. up a 2 per cent. grade.



THE SHEBLE HORSE POWER DIAGRAM.

HOW IRON MAY BE SEPARATED FROM NICKEL AND COBALT BY ELECTROLYSIS.

So closely allied in many of their properties are the metals iron, nickel and cobalt, that great difficulty is experienced in separating them when they happen to occur together. This difficulty is, says the London *Electrical Review*, dealt with in a new method of separation recently proposed by G. A. Le Roy. The solution containing these metals and also manganese is mixed with a large excess of concentrated and strongly ammoniacal solution of ammonium sulphate after the addition of sufficient citric or other acid to prevent precipitation of the metals. The solution is then electrolyzed with the current from two Bunsen cells (or their equivalent); manganese separates at the anode, and iron, cobalt and nickel at the cathode. The cathode is washed, and is then put into a concentrated solution of ammonium sulphate saturated with ammonia. It now serves as the anode, a weighed platinum plate being the cathode; and when the circuit is closed, the nickel and cobalt are transferred to the new cathode, while ferric hydroxide partly remains on the anode and partly floats in the liquid, but it is free from any appreciable traces of nickel or cobalt.

ECONOMY IN ELECTRIC POWER DISTRIBUTION. REED vs. LEONARD AND THE FACTOR "2 D."

BY

J. Stanford Brown.

ELECTRICAL ENGINEER, XII., No. 177, page 344, Sept. 23, '91, Mr. Chas. J. Reed writes: "In equation (2), for instance, [of Mr. Leonard's paper "Minimum First Cost," etc., ELECTRICAL ENGINEER, XII., No. 174, page 249, Sept. 2, '91], is a numerical error which follows through all the other equations. The numerical factor in the denominator should be 15 instead of 7.5, and the equation becomes $T = \frac{D^2 \times K. W.}{V(E - V) \times 15}$."

ELECTRICAL ENGINEER, XII., No. 177, page 344, Sept. 23, '91, Mr. Leonard replies: "I find that Mr. Reed has fallen into the error of forgetting that we are dealing with a complete metallic circuit, and that we must provide for a conductor both ways. The formula which Mr. Reed gives would give the correct weight of the copper conductor for the distance D, but, of course, for any distance of transmission D we must provide a conductor whose total length would be $2\,D$, so that the equation (2) as given in my article is entirely correct."

ELECTRICAL ENGINEER, XII., No. 178, page 383, Sept. 30, '91, Mr. Reed rejoins: "He (Mr. Leonard) starts out with an arithmetical error and in his reply adheres to the error, insisting that it is correct. I will call his attention to it specifically. In his expression for the weight of the conductor he uses M, the area of $2\ D$ as a factor, and then introduces the factor "2," again, giving the weight of a conductor $4\ D$ in length."

ELECTRICAL ENGINEER, XII., No. 179, page 410, Oct. 7, '91, Mr. Leonard explains: "Formula (1) determines the cross-section of the conductor in circular mils. In order to get this cross-section it became necessary to consider the resistance of the total length ($2\ D$) of the conductor both outgoing and returning; this introduces the factor $2\ D$ for the first time. Having now obtained the cross-section M of the conductor, we next get its weight per foot, and then to get the weight of the total length of conductor both ways we must again multiply by $2\ D$. This introduces $2\ D$ for the second time."

Mr. Leonard's equation referred to, so far as the point in question is concerned, is entirely correct. A different way of explaining the matter may however make it clearer to those who have failed to comprehend it.

If the resist. of 1 ft. of wire of 1 mil area $= R = 10.7$ ohms (H. W. L.).

Therefore " $2\ D$ ft. of wire of 1 mil area $= 2\ D.\ R$

" " $2\ D$ " " (M) " $= M. 2\ D.\ R$

" " 1 ft. " " (M) " $= \frac{M. 2\ D.\ R}{2\ D}$

or the resistance *per foot* of (M) area $= M.\ R.$

Again:

If the weight of 1 ft. of wire of 1 mil area $= F = .000,003,027$ lbs.

Therefore " $2\ D$ ft. of wire of 1 mil area $= 2\ D.\ F.$

" " $2\ D$ " " (M) " $= M.\ 2\ D.\ F.$

" " 1 " " (M) " $= \frac{M.\ 2\ D.\ F.}{2\ D}$

or the weight *per foot* of (M) area $= M.\ F.$

In fact it should be evident that resistance *per foot* is independent of the total number ($2\ D$) of feet even though in getting resistance of (M) one had to consider the length $2\ D$ in order to have the same volt loss in a foot of (M) area as in a foot of 1 mil area.

The $2\ D$, then, taken in by Mr. Leonard in getting the value of M, really canceled out again, so that *taking it in for the second time, only left it in once.*

STREET RAILWAY WORK IN PORTLAND, OREGON.

BY

Arthur C. Robbins

SINCE November, 1889, electricity as the motive power has been adopted by three of the street railway companies of Portland. An aggregate of 32¼ miles of track is now operated in this manner, and an additional 32 miles is being converted into electric roads, or is under proposition to that end.

The City and Suburban Railway have been using electric motor cars since November, 1889, and are now operating 15 miles of road in this manner. They still have 15 miles of steam road on the east side, which is to be changed to electricity as soon as possible; and on the west side the Third street line, consisting of 17 miles of horse line, is already under transformation to an electric service. Thomson-Houston, Sprague and Westinghouse motors are used by this line. They have 18 cars in present use. The heaviest gradients of this road are 200 feet of 11 per cent., with another 200 feet of 9 per cent., from which no trouble is experienced. The generators used are two Edison and two Thomson-Houston, operated by one 16 x 16 Ball, and two 16 x 24 Russell engines. Power for the Third street line will be furnished by the Union Power Company.

The Metropolitan Electric Railway Co. have been in operation since January, 1890. Their route consists of 2¾ miles double track on Second, First and Front streets, with an extension of three miles single track southward to the cemeteries outside the city limits. Their funeral train service seems to be very satisfactory, and they have recently ordered two additional funeral cars from the Columbia Car Works.

This road has 200 feet of 8 per cent., and 400 feet of 7 per cent. consecutive gradients. They are at present operating 18 motor cars, one of which is used across Madison street bridge in connection with the Mount Tabor steam road, for which electric motive power is under consideration. Westinghouse and Sprague motors are in use on this road. The current is supplied by four 70 h. p. Edison generators at 500 volts. The engines used are single non-condensers, one 16 x 16 Ball and one 16 x 18 Beck being required. The double-track cars are making 120, and the single-track 60 miles daily, under a six-minute headway.

The Multnomah Street Railway has been in operation since March 26th, 1890, and now has something over nine miles of double and single track road on Washington street and branches. Their heaviest gradient is 400 feet of 7 per cent. They have 17 motor cars equipped with the Edison system, and 10 interchangeable summer cars. One hundred and eight miles is a day's run on this road. Power is supplied from a 175 kilowatt dynamo at the Union Power Company's plant. They also have in reserve the power plant formerly used, consisting of two 100 h. p. Taylor boilers; two 80 h. p. Beck engines, and two No. 20 Edison generators, which are kept ready for immediate use in case of emergency. The company are justly proud of their record which shows only one interruption since they have been in operation—caused by the breaking of the driving rope.

The Union Power Company have recently entered the field for supplying current for power purposes, and it is said that they have the most perfect steam plant equipment on the Pacific coast. It consists of 10 boilers, one 1,000 h. p. compound-condensing Corliss, and one 500 h. p. Buckeye engines, to which generators are being attached as required. Their fuel supply is derived from a large saw-mill, and is handled from the saw to ash pans entirely by mechanism.

The Columbia Car Works was organized less than a year ago, and has recently removed to the old exposition building, occupying nearly an entire block, two stories in height, where they have room for 48 cars. The capacity of the Works is limited, and I am informed that they have recently been obliged to decline an order for 26 cars from want of facilities for manufacturing promptly. Their force now consists of 25 men, which will be doubled as soon as machinery ordered can be put in operation. They now have nine motor cars in process of building, including two funeral cars for the Metropolitan Company. The funeral cars will be 34 feet long over all, double-truck and single-reduction motors, with a seating capacity of 44 passengers. Six of their cars are now running on the West Portland and two on the Metropolitan roads. They have orders from the Point Defiance Electric Railway, of Tacoma, Wash., and for one car for Boise City, Idaho. The cars complete, including trucks, are made by this company.

"THE MOST CONCISE REPORT."

A LEADING electrical engineer and contractor in Canada writes us: "Let me congratulate you on the appearance of your Convention number, which contains the most concise report of the proceedings in full, in the handiest possible form."

REPORT ON UNDERGROUND WIRES FOR THE DISTRICT OF COLUMBIA.

THE report of the board, composed of Mr. Andrew Rosewater, Mr. Henry A. Rowland and First Lieut. Francis R. Shunk, Engineer Corps, appointed by the President under due authority of the District appropriation act approved August 6, 1890, to consider the location, arrangement and operation of electric wires in the District of Columbia, has been placed in the hands of the President.

The report itself is a long and able document and it is accompanied by a voluminous mass of charts, tables, diagrams and exhibits of various kinds. The report sketches first in a general way the investigations made by the board and the general results of the correspondence of the board with the telegraph companies and others interested. It then goes into an interesting discussion of the manner in which the underground problem has been dealt with in various cities and then proceeds to treat of the situation in Washington. It starts out with the broad and definite proposition that "all future conduits shall be built, owned and controlled by the District," and to that end has prepared plans, in which practical approval is given to the Lake and Lynch system of vitrified clay conduits, recently described exclusively in THE ELECTRICAL ENGINEER. The report says :—

"These plans provide conduits with a minimum capacity of four ducts to a maximum of sixteen ducts. For purposes of uniformity and economy we recommend the location of signaling and alarm stations, as far as practicable, at the southeast corner of the intersections, within reasonable distances apart. These stations can and should be combined with an electric light pole of approved artistic pattern, so as both to economize space and avoid useless expenditure. The plans and estimates are based upon the rectangular vitrified glazed clay conduit, which has been heretofore referred to, and has been found from sufficient trial in the District to meet all the requirements. It is not as cheap as the creosoted conduit systems in use in Philadelphia or Brooklyn, but if encased, as provided, in concrete, its construction will be of a permanent character without liability to partial combustion by electric leakage in accidental cases of injury to the cable. On the other hand, its cost will be less than iron or other material and its relative capacity of ducts greater.

"The details of construction have been only outlined for general estimates, as they will vary with every block and relative position to the gas, water and special electric service pipes and conduits.

"The important features in the construction of this system are: First, a permanent and uniform base of concrete (6 inches is a fair thickness); second, the careful laying and alignment of the sections so as to insure true lines and continuous ducts; third, the proper bedding and encasing of each tier of sections in a uniform layer of small stone or gravel concrete; fourth, the proper construction of the manholes with a good coating of cement mortar or concrete from the base up to the top, to render them impermeable both to moisture and gas as far as practicable; fifth, the efficient ventilation of the manholes through lamp connections; sixth, provisions for tight, close-fitting covers and plug or valve sewer connections to manholes in the lower section of the city liable to overflow or subject to back water, and ventilated covers with open trapped sewer connections for manholes in the upper section of the city.

ESTIMATE AND COST.

The following is an approximate estimate of the length and cost of the conduits and manholes comprising the system:

219,800 lineal feet or 41.54 miles duct conduit....	$241,230
50,100 lineal feet or 9.49 miles 8 duct conduit.....	105,210
17,600 lineal feet or 3.33 miles 12 duct conduit....	52,800
11,600 lineal feet or 2.20 miles 16 duct conduit....	46,400
	$445,640
298,600 lineal feet or 56.56 miles, allowing 10 per cent. for contingencies and supervision........	44,564
	$490,204

Total length of ducts, $317\frac{68}{100}$ miles. Cost per mile, $1,543.

"Considering that after construction it will take several years to fill all the ducts and the cost of maintenance and supervision, we regard that 7 cents per lineal foot per year for each duct used as a reasonable rental for the first few years.

"The estimates contemplate manholes on an average of 300 feet apart. Local conditions will make this a variable factor.

"The cost of manholes also varies with the size of conduits, ranging from $40 to $140 each. The figures given will in the aggregate be found sufficiently accurate for purposes of legislative determination.

"Accurate and exact details will necessarily have to be prepared under the supervision of the electrical department after a general plan shall have been determined upon, with special regard to all the governing local conditions of each section of the city.

"In determining the sizes of the respective lines of conduits we have taken into consideration the service already provided for by the telephone and electric lighting companies. The five miles of conduits laid by each of these companies during the year 1891 have been subject to stipulations in the permits hereto appended. We do not regard it unreasonable to require from each of them the free use of one duct in each line of conduit for the public service."

The report concludes with the recommendation that a permanent electrical bureau be created to supervise all electrical work in the District, to consist of a skilled electrician as chief, with a corps of competent experts. It is suggested that a fair salary for the chief of the bureau would be $4,000 per annum, with $2,000 for his principal assistant.

THE WORLD'S FAIR ELECTRICITY DEPARTMENT.

THE Department of Electricity of the World's Columbian Exposition is making every effort to secure among the exhibits in the electrical line a complete collection of historical apparatus. Chief Barrett's assistant, Mr. E. E. Keller, has the matter in hand, and has opened correspondence with parties supposed to have in their possession various apparatus of this kind. The intention is to secure apparatus used by the old scholars in their researches and to combine this in an exhibit showing the progress of the science, from as early a date as possible. There is doubtless considerable apparatus of this nature in existence in Europe and in America, and the problem is to get possessors of such apparatus to place it at the disposal of the Department of Electricity. Mr. Keller is fully aware that this is no easy task to accomplish, and he is anxious to have all persons having a knowledge of the existence of anything in the line of electrical apparatus communicate with him and aid him in the location of apparatus of interest.

The Construction Department is now perfecting plans for the location of restaurants, lavatories, cloak rooms and offices in the Electricity Building for the consideration of Chief Barrett and his assistant.

The location of these conveniences have not yet been definitely settled upon, but the matter will probably be settled in a few days. The classification of the Electrical Department has been completed and is in the hands of the printer.

A recent letter from Mr. Hornsby to Prof. Barrett, written in Frankfort, states that he left there for Nuremburg on the 7th ult. to visit Schuckert & Co. From there he goes to Berlin, Cologne, Breslau, Dresden, Vienna, Buda Pesth, Paris and London, to visit the works of the most prominent manufacturers met at the exposition. He has been sufficiently encouraged there to visit these places. He is already assured of extensive and complete exhibits. Hartman & Braun, of Bockenheim, assure him that they will make a magnificent display of their justly celebrated electrical instruments, etc. Dr. Hoepfner, the well-known electro-chemist of Giessen, was visited, and promised a complete exhibit of his method of electrolytic extraction and purification of copper and other metals. Dr. Werner Siemens has expressed a willingness to make a fine exhibit.

Prof. Ferraris, of Turin, Italy, wishes to visit the Fair, and the Electrical Congress especially. He says that he hopes the date for the Congress will be fixed for August, 1893, as all of the professors of Europe have their vacation during that month, and a better attendance could be had.

Mr. F. A. Haselwander, so prominently connected with the Lauffen transmission scheme, promises to exhibit a street railway conduit, and has made, in connection with Michael Von Dolivo-Dobrowolsky of the same enterprise, an assertion that they are ready to transmit 1,000 to 5,000 h. p. from Niagara to the World's Fair at a pressure 50,000 volts over a bare wire. The Ganz people, of Vienna, talk of running an electric road from the Exposition grounds to St. Louis, making the run every half hour.

A number of letters, telling the location of interesting historical apparatus and relics to be gathered in the historical section, have been received.

SOMETHING NEW IN CAMPAIGN BANNERS.

DURING the recent political demonstration in Harlem the Stuyvesant Democratic Club had a 20-ton truck equipped with a dynamo, engine and boiler, and a large upright sheet of galvanized iron, supported in such a way as to turn in any desired direction. This iron sheet formed the background of a banner, and was pierced with holes through which incandescent lamps protruded and spelled the inscription: "Flower, Sheehan, 1891, Stuyvesant Democratic Club, Harlem, N. Y." The truck also carried a search light and was drawn by eight horses, each horse having lamps attached to the harness. The display was exceedingly conspicuous, and excited much comment.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XII. NEW YORK, NOVEMBER 4, 1891. No. 183.

Magnetic flux in fact is not to be enchannelled, because there is no known magnetic insulator, and this fetters by complication the quantitative grasp of the subject.—A. E. Kennelly.

UNDERGROUND WIRES IN WASHINGTON.

FOR some time past, a special commission, composed of Mr. Andrew Rosewater, C. E., Prof. H. A. Rowland and Lieut. F. R. Shunk, has been at work on the preparation of a report to Congress with respect to the placing of wires underground in the District of Columbia. The commission, as we have had opportunities of knowing, has devoted itself to the investigation with unusual diligence, and the report now made bears evidence of a desire to ascertain all the facts bearing upon this very important matter. It is, we believe, the first systematic effort made in this country to gather for the specific purpose all the information obtainable; and while it thus necessarily includes much that is old and familiar, its results and conclusions cannot fail to interest every electrical engineer.

As will be gathered from the abstract which we give of the report on another page, the commission, after a careful examination of the various conduits, has recommended the adoption of the Lynch-Lake rectangular vitrified, glazed clay conduit, of which a very full, illustrated description was recently given exclusively in THE ELECTRICAL ENGINEER. This conduit is bedded in cement. The plans presented provide for conduits with a minimum capacity of four ducts to a maximum of sixteen ducts. It is stated that these conduits, of whose permanence no doubt whatever can be entertained, are not quite as cheap as the conduits of creosoted wood, but cost less than those of iron, such as are in use in New York. For 56 miles of conduit, furnishing 317 miles of duct, the estimated expense is $490,204, or $1,543 per mile—a very moderate figure—although there seems to be an extra allowance for manholes 300 feet apart, at a cost ranging from $40 to $140 each, making, say, another $1,000 per mile. It is not quite clear, however, that this is an additional item in the estimates.

A notable feature of this subway scheme for Washington is the proposition that the District of Columbia shall own them outright and shall make a charge of seven cents per lineal foot of duct per year. In New York we have tried the other experiment of letting the subways be built and owned by a private corporation, which has simply carried out, or has been supposed to do so, the wishes of the Board of Electrical Control. It is early yet to say that the plan is not a success, or that the particulars in which it may have failed are not due to the very peculiar conditions under which the whole subway work was devised and carried out. Possibly this public ownership may work well in Washington, where paternalism finds its practical apotheosis in the absorption by the National Government of all civic functions, but there seem reasons to prefer ordinary methods in such a city as New York. It is, perhaps, the fact that all Washingtonians are wards of Congress that impels the commission to recommend as it does municipal street railway ownership for the District. One is tempted to say that it is none of the commission's business, but if the Congress of the United States determines, on the basis of this report, to go into street railway enterprises and put up its roads to lease for ten-year periods, Mr. Rosewater will certainly have secured for Mr. Victor Rosewater, his promising nephew, who has so tried the souls of electric light managers struggling to earn dividends, a vindication and justification for his social and economic theories which could hardly have been expected by that young Bellamyite. Congress will then, of course, feel equally under an obligation to exemplify its approval of the municipal ownership idea by securing the local electric lighting plants, and all the stage lines, as well as the hackney coaches and hansoms that perambulate the asphalt of the National Capital.

But while we look askance at any plan which would thus divert improperly the proceeds of taxation, we are heartily in favor of the electrical bureau that the report suggests. Public control is infinitely better than public ownership, and there can be no objection to the exercise of a vigilant and comprehensive supervision of all electrical work in every city. One of the best signs of the times has been the appointment all over the country of city electricians or the establishment of electrical boards. The step shows that the importance ef electricity in the community is duly appreciated, while the work of these authorities, if fairly and honestly done, will go far to protect electrical investment and ensure a high standard of electrical equipment. In Washington it is proposed, moreover, that the District Electrical Bureau shall have charge of the fire-alarm and police signal service, to which, as we have already said, it would be unreasonable to object under the circumstances.

MR. EDISON'S RAILWAY INVENTIONS.

Our columns contain this week the bitter protest of a correspondent against the various reports that have appeared in the newspapers with regard to some new work of Mr. Edison in electric railways. It is a matter of fact that, as there stated, the effect of these newspaper articles has been to put a check upon immediate investment in existing methods of electric railway work, and for that reason they are to be deplored. But it is hardly fair to hold Mr. Edison responsible for the exaggerations and bulls crowded into these reports. Some day the newspapers will perhaps employ skilled men on their technical work as they now do on that which relates to music and the drama; but in the meantime we must be thankful things are no worse. If this talk arrests development, the Edison General Co. will suffer with the rest, and even his worst enemies will credit Mr. Edison with shrewdness enough to see that palpable and obvious fact. There is, however, offset to the harm done. It is a great thing to have the whole country talking and thinking about electric railroads, for in due course misinformation will be corrected and the truth shine clear. Having tried ourselves for ten years past to engage public attention on electric railroad work, we are glad to see that the subject is now ripe for a nation's thought. If Mr. Edison, too, can add to existing methods one by which low voltage may be used, it is cause for general congratulation, even though to many of us lowering voltage looks like a decided step backwards. We are all gainers by every extension of the field, and in the long run not a cent less will be spent in railway investment. Moreover, there is no evidence that existing methods or apparatus will be wiped out, even by the most revolutionary invention. Each new invention simply restricts other ways of reaching results to their strictly legitimate sphere of greatest profit and benefit; and as far as electrical plant is concerned, the depreciation is generally so slight that, even in spite of the great advances made, apparatus is still running with satisfaction that belongs to the very early stages of the art. In a word, we do not see the slightest reason why any single railway project entered upon or even broached should not be carried to a conclusion. When Mr. Edison puts his plan on the market it will be time enough to discuss its actual effect.

IMPROVING THE SIGNAL SERVICE.

Brig-Gen. W. A. Greely, Chief Signal Officer, in sending his annual report to the Secretary of War, has made an appeal for means to improve the military field telegraph system. The fact is that this country has fallen very much behind in this respect. The armies of England and the Continent are to-day expert in the use of the telegraph, the telephone and the electric light for purposes of warfare; and the unsettled state of affairs on the other side of the Atlantic acts unceasingly as a stimulus to the evolution of new ideas and methods of conveying intelligence. But it is within bounds to say that in this country no advance has been made upon the achievements of the Civil War; and while the Signal Corps may be expert in the use of the telegraph, we believe that it has had virtually no experience at all with the telephone and the electric light when utilized for operations in war. Pointing to the prompt adoption of these new aids abroad, Gen. Greely says: "The results of such inventions are quickly applied in foreign armies to the solution of professional questions arising in connection with military duties, and if the professional standing of the American army is to be maintained, similar application must be made in this country, otherwise a few years would leave the entire army unskilled in the most important of modern appliances." So little do the authorities at army and navy headquarters appreciate this truth, that, as we complained recently, such men as Sprague, Fiske and Murdock are sent off on old ships to the far ends of the earth, while others, such as Duncan, Greene, Crosby and Shallenberger, quit their profession to seek an avenue for merit and aptitude in various electrical vocations that were not contemplated in their training at West Point or Annapolis.

THE ECONOMIC LIMIT OF POWER UNITS.

It is the fate of all good things to run to extremes, the inevitable result of which is that a reaction sets in sooner or later, which in its turn goes to the other end of the scale, and this sort of oscillation continues until a rational medium is reached. Even the medium is a function of more or less variable circumstances.

Nowhere has this tendency been more marked than in the case of power units. It having been proven that a large steam engine could be run with greater economy than several small ones under certain conditions, there has been for the last few years a movement in favor of larger and larger units until of late the economic limit appears to have been exceeded, and a return to the old practice seems imminent.

In view of these facts the paper by "Carleton" on another page is especially timely, and cannot fail to be highly interesting to every central station manager, and, for that matter, every stockholder of an electric light or power company. An intelligent consideration of existing conditions is of the very first importance, and "Carleton's" simple and masterly handling of his subject is well calculated to impress many who might otherwise be led away by popular opinion. Our contributor, who is admittedly one of the foremost men in the steam engineering profession, whether in this country or in Europe, has put his points very strongly and we do not expect that all our readers will agree with him. But what he argues was worth saying and is opportunely said.

The Electrical Congress of 1893.

It is encouraging to see that the proposed Electrical Congress at Chicago in 1893 is already arousing much interest. That Congress must be an honor to the electrical profession in America, and too much time and thought cannot be bestowed upon its plan and details. Not only has work begun in Chicago, but the American Institute of Electrical Engineers, as the national technical body, is already following up its action of the past two years by organizing for an active campaign, and has appointed Messrs. Anthony, Hering and Kennelly to formulate a programme that it may suggest as the basis of the proceedings of the Congress.

MAGNETIC RELUCTANCE.[1]

BY A. E. KENNELLY.

THE science of magnetism was a collection of facts concerning magnets until Coulomb first brought to light a quantitative relation between a few of its phenomena, and thus entitled it to appear among the exact sciences. He determined by measurement that the forces of attraction or repulsion between the poles of long, thin bar magnets were proportional to the strengths of those poles and inversely to the square of their intervening distance.

In one respect, it has since been shown that the discovery was unfortunate, for it served to depress rather than to stimulate further inquiry into the laws of quantitative magnetic relationships. The application of Coulomb's law soon brought into use a conception of magnetism, suggested perhaps by the analogy the law bears to that of gravitation force. This was the hypothesis of a layer of fluid or imponderable matter resident on the surfaces of magnetic bodies and endowed with attractive and repellent forces on all portions of such fluid, in exact similarity to the two-fluid theory of electricity. Each element of surface magnetism would exert according to Coulomb's law a definite force upon every other element of its own, or of other magnet surfaces, and when the distribution of the magnetic matter or fictive layer was known, the total forces active between the magnets forming the system could be determined by the summation of all the elementary actions. This was the polar conception and mathematical theory of magnetism. It was not only artificial; it was also misleading. It assumed that definite action could be exerted at a distance, ignoring the action of the intervening medium. Nevertheless, a slight modification of the polar theory rendered it capable of expressing a mathematical theory of magnetism with apparent success, and exhibits in this respect, like the theories of gravitation, the remarkable construction of purely artificial frameworks of thought, void of all attempt at reality, yet capable of affording useful applications and exact quantitative results, while beneath their foundations the real and natural active forces still lie in undiscovered concealment.

It was soon apparent that magnetism considered as a fluid could not be confined to the surface of bodies, since it was only necessary to break a bar magnet asunder in order that new poles and new magnetic fluid should be exhibited. The amendment to the original theory was then framed that a condition of molecular magnetization extended, veinlike, throughout the substance of the magnet. The termination of each vein at the surface exposed a definite quantity of polarized magnetic matter, while within the veins the polarity was neutralized by the successive layers of opposite molecular poles. This was a great stride beyond the original theory, for it ascribed magnetism not alone to a fictive superficial layer, but to the combined effects of all the molecules in the magnetized body, whose substance, no longer a mere frame for supporting the layer, became invested throughout with a definite condition.

The amendment in time became classical, and subverted the original conception, for the polar theory only recognized superficial magnetism, while the vein theory did not make any such reservation. It was only necessary to assume that the veins varied in richness at different parts of the magnet, or that they might be subjected to faults and partial discontinuities, to introduce unneutralized polarity within the mass which might be capable of exerting external influence, a condition neither the simplest nor most usual, but which the experiment of superposed magnetizations in steel has rendered familiar. This irregularity of vein structure would add a volume distribution of magnetic fluid through the interior of the magnet to the surface distribution on the outside.

On the vein theory, the intensity of magnetization at any point of the magnet would be defined as the amount of magnetic matter cut through in the veins per unit area by a plane section perpendicular to their direction, at the point in question.

A unit magnetic pole, situated in free space, at the end of a very long thin bar magnet would by definition repel with unit force a similar pole one centimetre distant—that is, resident on the surface of the sphere one centimetre radius, of which it occupied the centre. The surface area of this sphere would be 12.57 (4π) sq. cms., and over all this surface the pole would thus establish a magnetic field of unit strength and exert a magnetic stress equal to unity. Each square centimetre of the surface bounds an area of stress which emanates from the pole, and consequently the latter must emit 4π units of stress flux. In the language used by Faraday, it would throw off 4π lines of force. This stress flux has somewhat unfortunately received from Maxwell the name of induction, and the induction through the surface surrounding the pole would be 4π units.

The interest connected with the nature of this stress demands a moment's pause at this point. While its real character is still as great an enigma as the real character of magnetism itself, some of its laws are well understood. There exists along the direction of the stress a tension accompanied by a general pressure at right angles, just as in the case of stimulated muscular fibre, which tends to shorten and expand laterally, or, as it is generally expressed, the lines of force tend to contract while repelling one another. Since the time of discovery that the plane of undulation in polarized light waves twists in passing through certain magnetized substances it has been supposed that the stress might be of a rotatory character. Like an incompressible fluid, it can neither accumulate nor vanish locally, and as much stress flux must leave any region as enters it, if no magnetic pole exist within the confines. Its intensity is very remarkable for it is far in excess of any stress that we can exert without the aid of cohesion in matter. This may be judged by comparing the quantities of energy that can be stored in a given volume of space—say air space. It is, of course, easy even without the assistance of iron to magnetize a cubic centimetre of air to a flux density of 5,019 C. G. S. lines when it will possess an energy stored up in magnetic stress of one megalerg (1,000,000 ergs or 0,0737 foot-pound) while if this magnetization be alternated 227 times per second the average rate of absorption and discharge would be 45.5 watts, and one cubic inch of this air would stow and release energy with the average activity of one standard British horse. Under electrostatic stress, air not in the immediate neighborhood of a conductor appears to break down when the E. M. F. per linear centimetre exceeds 32,000 volts or 110 A. E. S. U., so that the maximum electrostatic energy that one cubic centimetre will hold without rupture is about 500 ergs or two thousand times less than that resident in air stressed magnetically to 5,000 lines, while a cubic centimetre of air near the earth's surface illumined by bright sunlight does not hold more radiant energy than about fifty microergs.

An alternating current transformer is a device in which the secondary coil absorbs the energy out of air and iron, pervaded by the stress flux from the excited primary coil. Unfortunately while magnetically stressed air yields, so far as we know, all its stress energy back into either the primary or secondary circuit, stressed iron fails to do so entirely, and absorbs energy at every cycle, a process known as absorption by hysteresis. The iron directly converts the magnetic stress energy into heat energy, just as a spring absorbs some of the energy imparted to it during every cycle of compression and recoil.

These 4π units of stress flux are not confined to a spherical surface of one centimetre radius, but would be found by summation over any enveloping surface containing a single unit pole, just as the delivery of material liquid must be the same in a steady stream at any section of its course independent of the channel area there existing; for at ten times the distance, the spherical area would be 100 times greater and the stress by Coulomb's law 100 times less, leaving the total area of total stress unchanged, and it follows in fact that the stress flux over any boundary is always 4π times the strength of pole enclosed, no matter whether that pole be alone in space, or be the sum of any number of magnetic systems, in molecules or in masses.

On the vein theory, however, the strength of a pole is the quantity of magnetic matter on its surface, assuming that the veins meet it perpendicularly, or it is the aggregate surface intensity of magnetization, so that the stress flux through each unit of polar surface is 4π times the intensity of magnetization. This is true not only for the polar surface, but also for the interior of the magnet, and every unit vein of magnetic polarized matter carries associated with it a stress flux of 4π.

The magnet may itself be situated in a field of force so that its substance may be pervaded by a stress flux independent of that in its veins. It may and generally does happen that part of this separate stress flux issued from its own poles, in which case it will enter in the opposite direction to the vein or internal flux and will tend to reverse the molecular polarity of the vein structure, but whenever such additional flux is present, the resultant total flux at each point will be the geometrical resultant of that in the veins compounded with the external flux by the parallelogram of forces. In the important case of a long bar of homogeneous soft iron submitted to the influence of a uniform magnetic field acting in the direction of its length there will be a uniform induced molecular polarization or magnetization set up along the bar. Suppose for instance a bar of iron five square centimetres in uniform cross-section pointed in the direction of the dipping needle near Paris. The earth's field there being 0.46 unit, or its stress flux 0.46 units over each normal square centimetre, that stress would be active in setting up polarity in the molecules of the iron along the bar. The degree of magnetization would be also influenced by its own resulting polar stress unless this effect could be rendered insensible by sufficiently extending the length and thus carrying the poles out of the field. With a very long bar magnet the magnetization would be everywhere about 40 times this strength of field, or numerically 18.4 units, and on the vein theory there would therefore be 18.4 units of magnetic matter exposed on the surface of each square centimetre in a slice made across the bar at any point or 92 units over the whole section. The polar surfaces would also be covered by 92 units of positive and negative matter respectively. Associated with each unit vein of polarity, however, would be 4π units of stress flux

1. Read before the American Institute of Electrical Engineers, Oct. 27, 1891.

giving a total flux of 1156 units in the bar which would emerge from the polar surfaces and unite in surrounding space. The whole induced system would, however, be immersed in the earth's field that evoked it and which would be superposed upon it throughout. There would thus be 1156 + 2.3 or 1158.3 units of flux in ordinary phaseology 1158.3 lines of induction through the bar, a density of 231.6 C. G. S. units per square centimetre. The law that the whole flux is the field flux compounded with the induced flux of 4π times the magnetization, which holds uniformly at all points throughout the bar in this simple case is true at any individual point in the most complex case, however variable the field or magnetization may be.

The fact that the stress flux has the same total value over any envelope surrounding a magnetic pole, however widely the stress may be diffused and rarefied, that it follows curves in space whose existence can be rendered evident by iron filings and curves that form closed loops through the substance of the magnet itself, gradually suggested the notion of a magnetic circuit in which the circulation was neither a fluid nor an energy-exchanging condition like a current but a stress.

This conception once firmly established proved of great advantage. Not only has the dynamo been greatly aided in development by the applications of this theory, but the inter-relationship between magnetism and electricity has been brought into clearer recognition in consequence. From this point of view the ideas and analogies of the galvanic circuit became paramount and eclipsed the original notions of magnetic matter and magnetization. All that was essential on this hypothesis was a magneto-motive force in a circuit having conductivity, and a flux or magnetic current resulted. The magneto-motive force in permanent magnets was the result of a definite molecular condition in the iron, while in the neighborhood of an electric current it was always active. According to Ampere's theory that magnets had molecules in which electric currents ever circulated, the two sources of magneto-motive force were united.

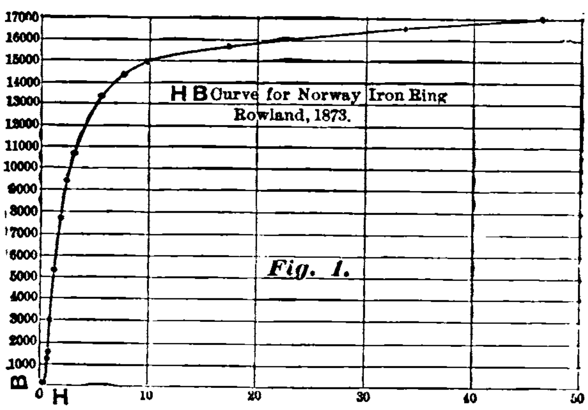

Fig. 1.

Some contention took place between the claims of the vein theory and the circuit theory for the interpretation of magnetic phenomena, and the question as to their relative merits is yet often raised. It seems, however, early to decide upon the acceptance of any theory while the ultimate origin and nature of magnetism remains unexplained, and it is better to regard both theories as working hypotheses to account for the effects of magnetic laws, equally capable of yielding correct results and therefore closely associated, while the preference between them will depend upon the nature of the problem to be attacked. The circuit theory is the simpler for general purposes of theory and particularly for dealing with the phenomena of electro-magnetism. The vein theory, on the other hand, while very artificial, is often more convenient in dealing with the magnetic behavior of the three metals iron, cobalt and nickel, and it is the natural accompaniment of Ewing's modern theory of magnetization which at present appears to best represent the facts.

On the circuit theory the magnetic-conductivity of all substances is very nearly the same as that of an air-pump vacuum, and constant, notably excepting the three magnetic metals whose conductivity is enormously greater, but variable with the conditions of the circuit.

The existence of magnetic conductivity known as "permeability" necessarily involved the inverse quality of magnetic resistance.[1] Some debate has taken place as to the validity of this term or its application for the reason that the resistance which usually enters into practical magnetic circuits is generally far more variable than that found in the metallic circuit of electricity. It is now generally admitted, however, that the term magnetic resistance is fairly applicable in virtue of analogy if not of exactitude. The term magnetic reluctance then suggested by Heaviside, has however the advantage that "reluctance" as one word is less cumbrous than "magnetic resistance," and for that reason only it is advantageous to retain it. Similarly the reluctance per unit volume or the magnetic resistance of one cubic centimetre has been called "reluctivity" and is perfectly definite if not quite euphonious under that title. It is this quantity which will occupy our further attention.

1. Bosanquet. *Phil. Mag.* Vol. xxv, 1888, p. 419.

This magnetic circuit differs from the galvanic in one important particular. In the latter we most frequently meet with a conductor carrying the flux or current through an insulating medium such as air in which no current—certainly no measurable current—passes. In the magnetic circuit this condition of things while approximated to and often for practical purposes assumed in dynamos or electromagnets is only realized in one actual instance—that of a closed Faraday ring uniformly wrapped with wire carrying a current. In every other real case the flux is diffused more or less through the surrounding substances and does not follow a simple passage. Magnetic flux in fact is not to be enchanneled because there is no known magnetic insulator, and this fetters by complication the quantitative grasp of the subject.

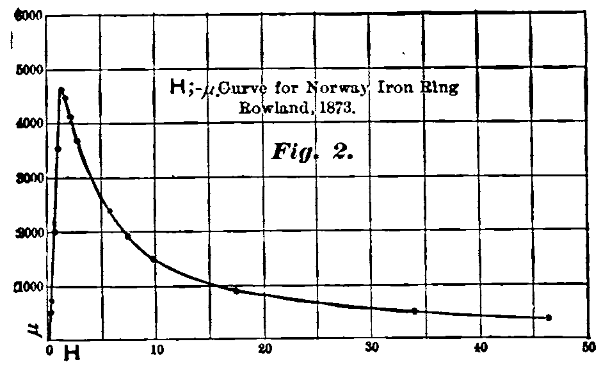

Fig. 2.

The law of the magnetic circuit is like Ohm's law that the flux is equal to the magneto-motive force divided by the reluctance. That is regarding the circuit as a whole. For any one point of the circuit the law is that the flux density is equal to the drop in magneto-motive force per centimetre, there existing, divided by the reluctivity—corresponding exactly to the case of Ohm's law at any point in an electric circuit. This "drop" is called the magnetizing force, denoted by H, and is the strength of the magnetizing field at the point. Owing, however, to the great variation that exists in the reluctivity of iron which enters into nearly every practical magnetic circuit, the law is of much less service than Ohm's electric law. The reluctivity depends not only on the magnetizing force, but also on the degree of purity of the iron, and iron possessing 12 per cent. of manganese is almost non-magnetic.[1]

A number of attempts have been made by different observers to establish a definite relationship between the flux density and the magnetizing force or the permeability in order to so amend the magnetic Ohm's law as to give serviceable results for even pure iron. The results obtained, excepting the formulæ of Frölich and Lamont, have generally been regarded as unsatisfactory. They have usually been expressed graphically as curves in one of three types:

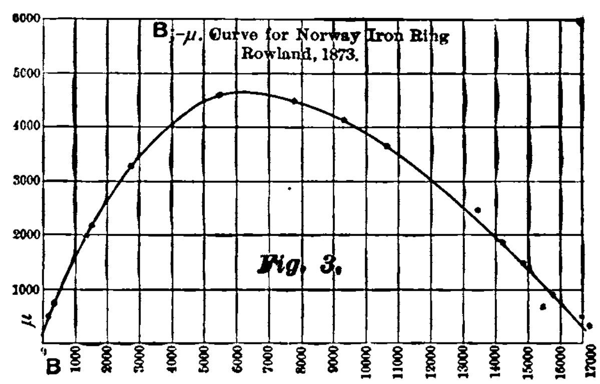

Fig. 3.

1. H—B or curves of magnetizing force and flux density.
2. H—μ or curves connecting permeability and magnetizing force.
3. B—μ or curves connecting flux density and permeability.

It is the object of this paper to show that there is a fourth relation that has not received the attention it seems to deserve—

1. Hopkinson. *Phil. Trans.* 1885, part ii, p. 462.
2. Rowland. *Phil. Mag.* 1873, p. 153, table v.

namely, the curves connecting the reluctance with the magnetizing force.

As an example of the comparative forms of these well-known curves, types 1, 2 and 3 are represented in Figs. 1, 2 and 3 for a sample of Norway iron whose results are among the first on record, being published in 1873.[2] The curve connecting the reluctivity with magnetizing force is shown in Fig. 4 and exhibits a greater degree of simplicity than any of the others. Curve 4 consists in fact of two lines that are very nearly straight, united

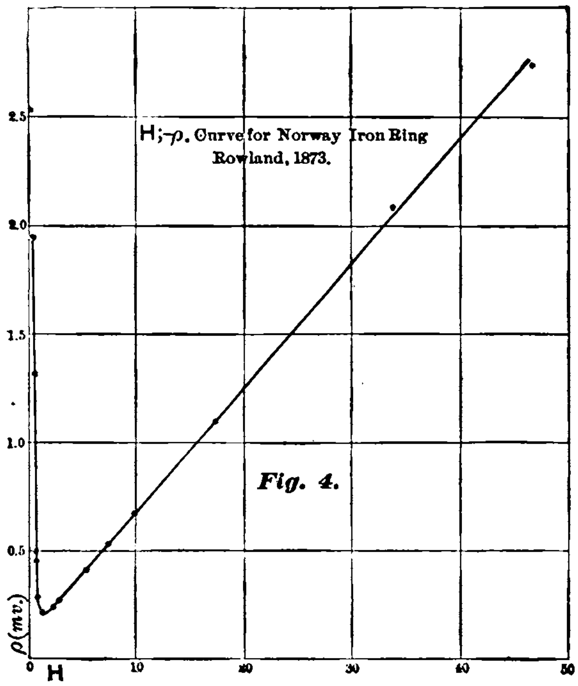

Fig. 4.

by a rounded elbow; and these outlines express the fact that the reluctance of this sample of iron was very nearly a linear function of the magnetizing stress brought to bear upon it. The ordinates for this curve are given in thousandths of an absolute reluctance unit, a quantity we may call provisionally a milli-unit abbreviated *MU.* The reluctance of 1,000 *M U.* in series would be that of one cubic centimetre of air. Reluctivity curves plotted from various sources all of which are duly given in the Appendix appear in Fig. 6 for various samples of iron and steel. The general type consists of two lines nearly straight, connected by an elbow which is sharper and more defined as the iron is softer and more nearly pure. With hard steel the change from the descending to the ascending line is very gradual. The reluctivity of iron appears from these curves to commence at a certain definite and moderately large value which we may denominate its initial reluctivity, descends very rapidly and nearly on a straight line to what may be called the critical reluctivity at the critical magnetizing force, turns abruptly, and then advances along a nearly straight line. Before the turning point in Fig. 4 the reluctivity may be expressed approximately by the equation $\rho = 2.9 - 3.5\,H$ while beyond the bend the equation becomes $\rho = 0.1 + 0.058\,H$. The flux density existing in this sample of Norway iron can be calculated by the Ohm's law formula for any value of H when the corresponding value of the reluctivity is taken from one or other of these two equations and the resulting curve of $B - H$ will practically coincide with that in Fig. 1 except in the immediate neighborhood of the critical value of H. This relation also exhibits the foundation that exists for the Frölich formula which has long been known to be practically valuable and even very accurate in application to dynamo-magnetic circuits, although both the method by which it was arrived at and the light in which it has since been regarded appear to have been empirical rather than fundamental.[1]

Fig. 5 shows that the minimum reluctivity for soft iron is about 0.15 *MU.* while its initial reluctivity is about 3.0 *MU.* The critical value of H is also in the neighborhood of 2. If any critical H can be said to exist for glass hard pianoforte wire it would be in the neighborhood of 35 units, and every description of hard or impure iron met with in practice not containing much manganese appears to have its critical H between these limits. These reluctivity curves also illustrate perhaps more clearly than any others the leading features of Ewing's theory of magnetization. There is first the initial stage of diminishing reluctivity during which the imaginary molecular magnets are being deflected from their original configurations, then a short critical range of magnetizing force in which nearly all the original groupings are disrupted at the point of lowest reluctance, and finally a steady increase of reluctance as the molecules are gradually forced by increasing magnetic stress into parallelism.

This bilinear characteristic curve of reluctivity is not confined only to iron. Fig. 6 shows the same general outlines in the case of nickel, taken from the observations of Rowland and Ewing. Here the initial reluctivities are higher, and the descent to the critical points much sharper than in iron, while the ascending lines are also steep but nearly straight.

Taking the equation $\rho = a + bH$ in the ascending curve, the first term a only disappears in one known instance—that of nickel under a mechanical stress of 19.8 kilograms per square millimetre or 28,160 lbs. per square inch—as seen in Fig. 7 taken from Ewing's results. The lowest ascending curve prolonged downwards almost meets the origin. Consequently the flux equation for such nickel would be

$$B = \frac{H}{bH} = \frac{1}{b} = \frac{1}{0.000177} = 5650$$

and this flux is practically constant for any magnetizing force within further considerable limits, representing early saturation. The influence of compression in diminishing the reluctance of nickel is clearly shown in Fig. 7. The critical reluctance is gradually diminished by the stress applied from 14.5 *MU.* at *H.* 30 to 2.6 *MU.* at *H* 12.

Fig. 8 gives the corresponding curves for cobalt. The same features are again observable. Only in one case, that of cast cobalt at 230° C., is there any considerable deviation from a straight line in either rise or descent from the critical segment of the curve, and this represents a series observed by Rowland under some experimental difficulties and alluded to as somewhat doubtful.

We have now examined the reluctance of the three magnetic metals collected from all the best-known experimental observations. In addition to these it appears that every reliable series of tabulated results for iron, pure, impure, cast or forged, exhibits the same types of bilinear reluctance referred to H between zero and 150, although in very hard or impure specimens there is no clear indication of a critical point. This assumes, however, that the observations are not vitiated by residual magnetism. For example, the curve obtained by plotting the reluctivities of cast iron as quoted by Silvanus Thompson from Hopkinson's observations[1] differ considerably from this type, but the difference appears to be accounted for by taking the mean between ascending and descending values. The ballistic method of measurement with anchor rings, in which the progress of the magnetizing force takes place by extending reversals, gives reluctances that appear to be as nearly linear as those which are obtained by a single increasing

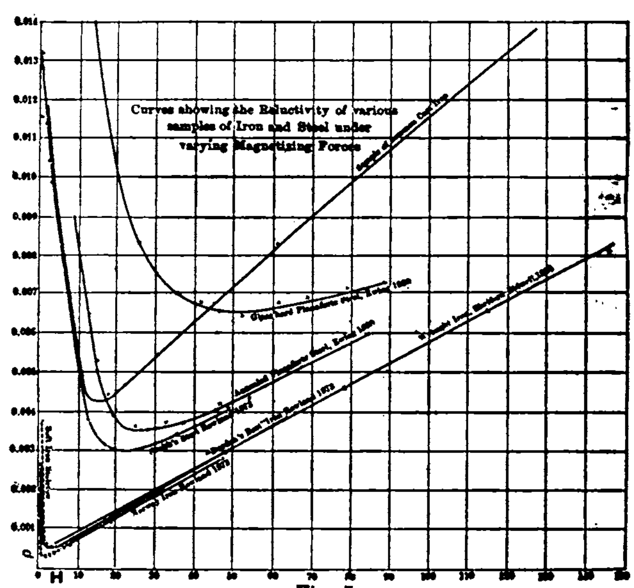

Fig. 5.

amplitude of magnetization, the influence of hysteresis being apparently nearly uniform in ratio.

An examination of reluctivity curves naturally suggests the question as to whether there is really a strict linear relationship between H and ρ. In other words, whether the divergences of the observation curves from geometrical straight lines can be fairly ascribed to errors of observation, allowing for the influences of residual magnetism.

1. Silvanus Thompson. "Dynamo Electric Machinery," p. 302.

First confining the inquiry to the ascending reluctivity line—that which is geometrically consequent upon Frölich's formula and also under special interpretation with Lamont's formula—the agreement of the plotted observations with a straight line between the neighborhood of the critical H and $H = 150$ is often so good as to intimate the existence of a definite linear relationship. It is generally to be found, however, that beyond 150 C. G. S. units of H, the line bends downward until all hope of rectilinearity is lost. That is on the simple circuit theory of reluctance. If, however, we introduce an amendment into the definition of reluctance borrowed from the vein or polar theory, the rectilinearity appears to be nearly sustained for a much greater distance. lines prolonged downwards nearly strike the origin. It is to be observed that at the limiting observation for wrought iron its reluctivity is nearly 20 per cent. greater than that of air or of the air-pump vacuum.

According to the simple circuit theory, the reluctance is of course the ratio of the magneto-motive force to the flux and the reluctivity this quantity locally reduced to the unit of volume. On the vein theory, however, which as we have seen distinguishes the vein flux from the magnetizing flux superposed thereon, the conductivity of a mass of iron is the conductivity of the iron itself added to that of the space it occupies, and consequently applying the vein theory to the magnetic circuit we have the

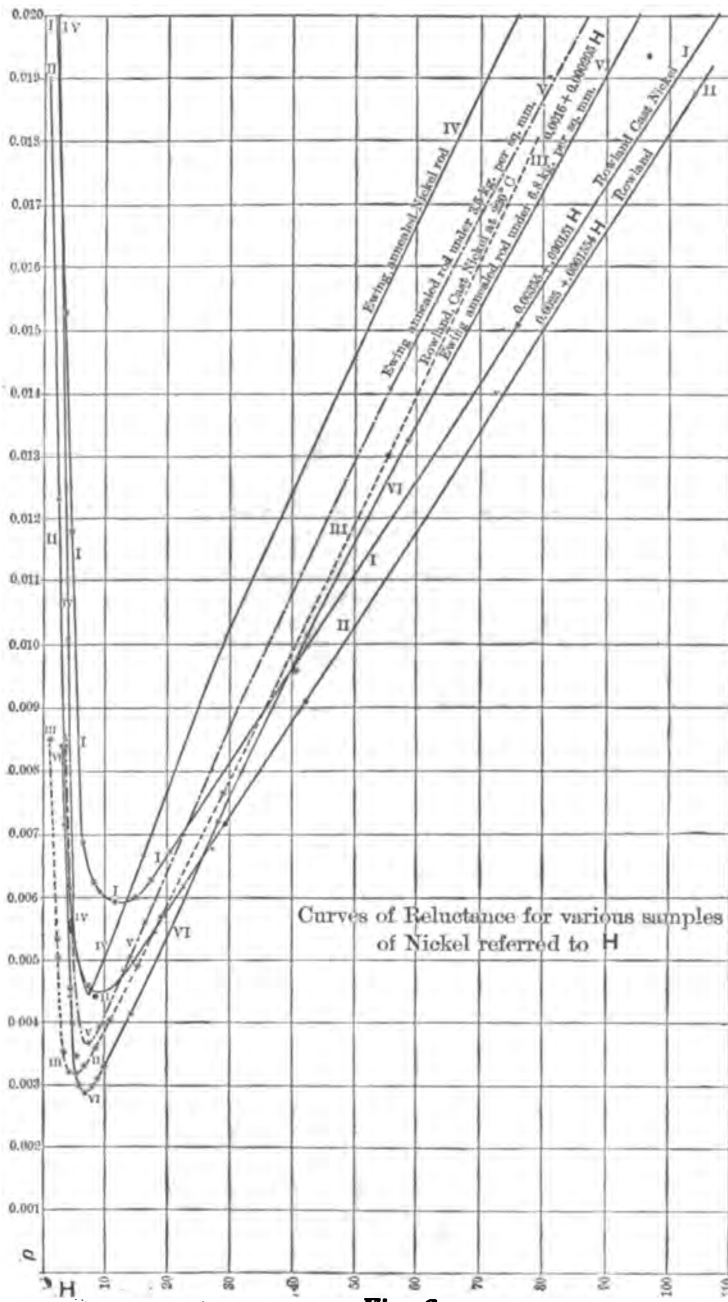

Fig. 6.

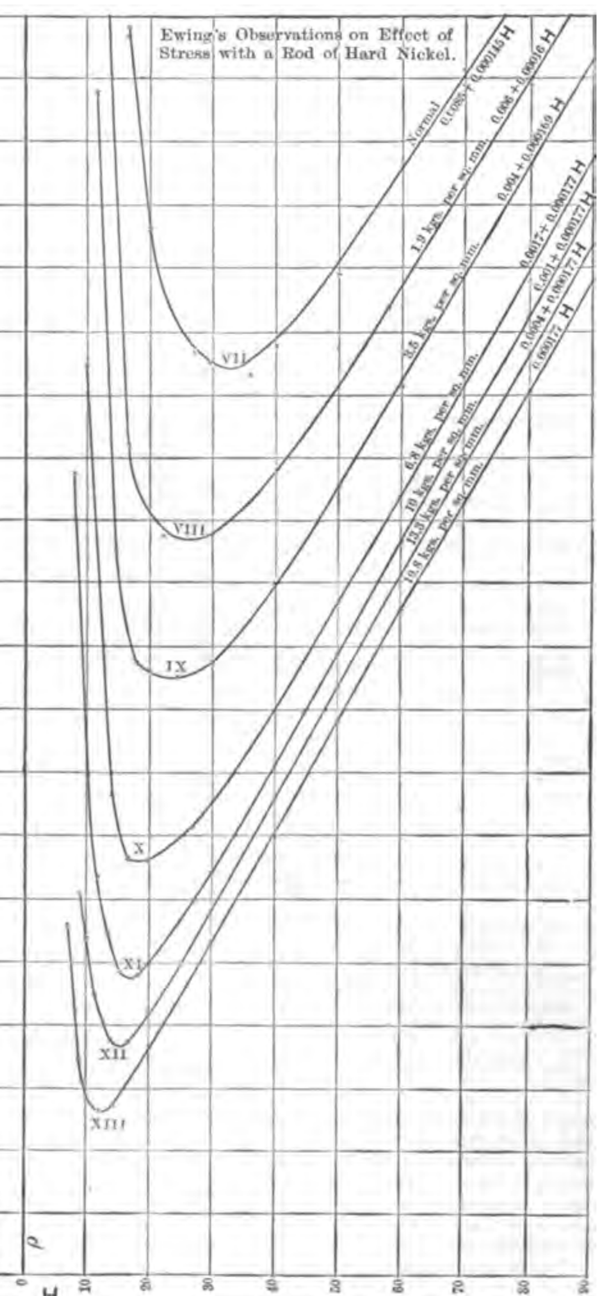

Fig. 7.

Experimental observations of the reluctances in circuits of the magnetic metals under powerful magneto-motive forces are yet very scanty, but judging from the results of Ewing and Low[1] the reluctivity of wrought and cast iron on the amended definition appears to be a linear or at least nearly linear function of the force as far as H 25,000 and H 11,000 respectively, the limits of the quoted measurements.

The graphs of these measurements are given in Fig. 10. The observations run from H 3.630 to 11,200 for wrought iron with an isolated observation at H 24,500 in a separate instance, the similar series for cast iron running from 3,900 to 10,610 units of H. The linear relationship is very fairly maintained and the apparent reluctance of the iron mass as the joint reluctance of two paths in multiple arc, one through the iron itself and what might be called its metallic reluctance, the other through the reluctance of the space occupied by the iron, and the removal of the iron would leave this latter unaltered. The difference between the apparent and metallic reluctance is inappreciable while the latter remains small, that is generally speaking when H is below 150, a limit rarely exceeded, and consequently the question does not present itself under practical conditions, but for large values of H, the difference is considerable and the metallic reluctance approaches the linear relationship with H while the apparent reluctance deviates considerably from it.

These assumptions from the vein theory while they may be

1. "*The Electrician*," London, 1890, July 25 and Aug. 1.

convenient are somewhat artificial for they postulate that the space reluctance of a given volume of air is not altered when the volume is occupied by iron. This may not be impossible but it is difficult to imagine any reluctance mechanism of ether that would remain undisturbed by the introduction of a massive substance. On the other hand while the vein theory imposes this principle not touched upon by the circuital hypothesis, it explains very satisfactorily the fact now apparently beyond dispute, that while iron can be saturated there is no limit yet attained to the flux density that can be made to pass through it. Ewing's results give no limit at the observed flux density of 45,350 C. G. S. nearly three times the flux density at which iron is commonly worked in practice, while at the same time they indicate a limiting value of magnetization long before that density is reached. Following the vein theory, the polarization of the iron is then complete and the intensity of magnetization or magnetic matter per unit cross-section of veins finds its maximum so that while the total flux can go on increasing indefinitely, it can only do so by adding to the permeating field flux, the vein flux having reached its full limit. It is not impossible to represent the observed condition of affairs by the simple circuit theory but the mental picture is not so clear. It would be possible for instance to imagine that the molecules of all substances transmitted the stress flux with the same or almost the same facility as the ether surrounding them, but that in the magnetic metals they exalted the stress in transmission. Maxwell supposed that the iron molecules were so constructed that they could take part in the ether spin that might constitute the stress, and if so by adding to it their momentum of revolution, they could augment its value. There would be then perhaps at a certain stress, a

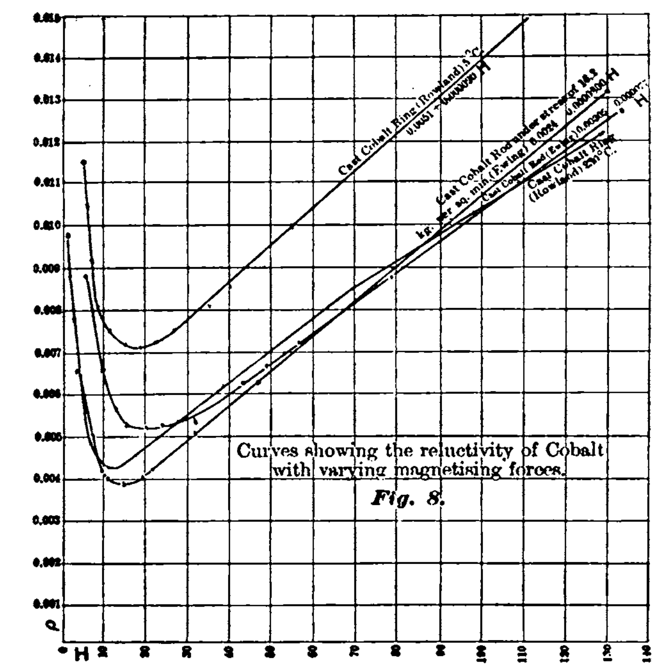

Fig. 8.

speed of revolution which the iron molecules would not exceed and their reinforcement would be at a maximum, while for stresses enormously greater than this the molecular augmentation would be lost in comparison with the strength of field and the iron molecules would in the aggregate behave almost like the motionless transmitters of other substances. The consequences of this conception seem more complex even if more nearly true.

Turning now to the descending curve of reluctivity between the initial and critical values, closer examination will show that here at least the linear relation is only an apparent one. The descent is so steep that on the scale of projection it appears nearly straight, but when magnified it has a distant curvature. Rayleigh[2] and others have shown that for small degrees of *H* the permeability commences with a definite steady value and this being the case it would be impossible for the reluctivity—the reciprocal of that permeability—to be linear towards *H*. Series of observations covering with sufficient detail the range of *H* from zero to unity are apparently few, and Fig. 9 gives the plotted values of the reluctivity on an enlarged scale observed by the writer for a sample ring of Norway iron. The descending line has a marked curvature approximately logarithmic, that would be almost inappreciable, however, on the scale of the other reluctivity diagrams.

Even, however, if we admit that there exists a linear relationship between H and ρ beyond the critical point, that is to say if the experimental results justify the belief that Frölich's formula is not merely an empirical one, we are scarcely entitled to attribute to this relationship an intrinsic physical signification. It may enable us to grasp the salient features of the magnetic circuit by the re-establishment of Ohm's law, but the relationship is more likely to be the consequence of a more remote fundamental

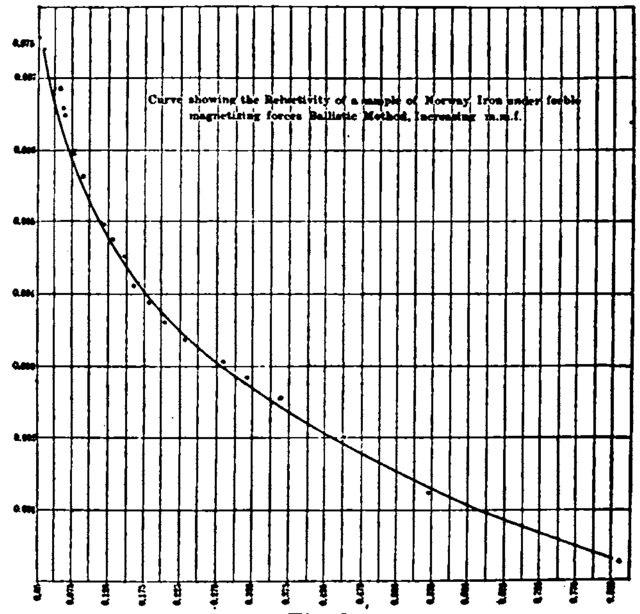

Fig. 9.

agency than to be significant of any physical condition resident in metallic reluctivity itself. This is for the reason that the increase of flux under M. M. F. in a magnetic circuit due to the presence of iron is more probably owing to an assisting M. M. F. set up in that iron under stress than to any change in the latter's reluctance, and the removal of the initial source of M. M F. from the circuit still leaves some M. M. F. active as residual magnetism.

The case is similar to that of an electric circuit containing a polarizing electrolyte. It might be more simple to ignore the counter E. M. F. of polarization and to regard the resulting diminution of current as the result of an extra resistance whose value might be tabulated or possibly even reduced to simple laws. So again in alternate current circuits it is often more convenient to speak of a resistance coil with inductance as possessing an impedance greater than its ohmic resistance and to determine the flow of current on the basis of impedance calculated to the original E. M. F. whereas the direct and fundamental method would be to keep the resistance at its true value and determine the current by allowing for the counter E. M. F. of inductance in quantity and in time.

Retaining then the latter analogy, we may say that flow in an electric circuit is subject to Ohm's law simply when the E. M. F. is constant, but when the effective E. M. F. varies periodically, the resistance has to be increased by a definite amount depending on the inductance and the manner of fluctuation in order to obtain the correct effective current under those conditions. Similarly

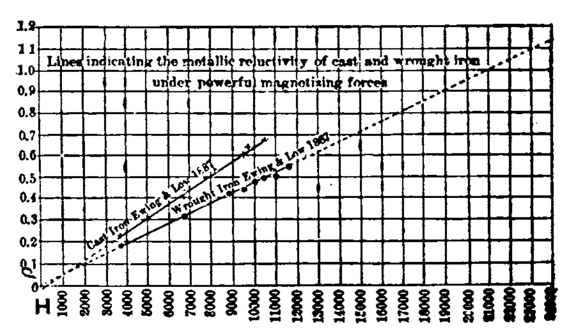

Fig. 10.

that the flux in a simple magnetic circuit of air or vacuum is subject to Ohm's law, but that if the circuit includes a magnetic metal, the reluctance in the formula has to be changed in a definite way depending on the quality of the metal and on the magnetizing force in order to obtain the corresponding true flux density. The change in reluctance is the ideal

2. *Phil. Mag.*, March, 1887.

connection of a shunt metallic circuit in parallel with the air circuit, and the reluctivity through the metal is nearly $a^1 - b^1\ H$ for values of H below the critical and $a + b\ H$ for values beyond, with a litttle uncertainty in the vicinity of the critical point itself.

ARTIFICIAL RAIN-MAKING AND ELECTRICITY.

In a lecture recently delivered before the Electrical Section of the Franklin Institute, Prof. Edwin J. Houston, after discussing the efficacy of various methods, and the causes tending to bring about the desired result, concluded as follows:

Since success in artificial rain-making is probably dependent on the meteorological conditions, both of the lower and upper layers of the atmosphere, efforts should be made to enlarge our present very limited knowledge of such conditions.

Captive balloons, containing registering electrometers, telethermometers, tele-hygrometers, tele-anemometers, etc., might be connected by wires with recording apparatus placed on the earth's surface. The cost of maintaining such aerial stations of observation would be but insignificant when compared with the benefit that would accrue not only toward the solution of the problem as to the probable success in rain-making, but the general operations of the United States Weather Bureau in particular, or of meteorology in general.

During the general prevalence of moist, warm air, when but a slight cooling is necessary to cause a general down-pour, effective rain-making might be obtained by the sudden breaking or opening of cylinders of liquefied gases, whose expansion would cause an intense chilling of the surrounding air; such cylinders could be readily opened by means of earth-controlled electromagnets.

The following general conclusions may, in view of the present state of meteorological science, be properly drawn concerning the artificial production of rain:

(1) That rain can never be made to fall at will by mid-air explosions on any part of the earth's surface, irrespective of the climatic conditions there existing.

(2) That during certain meteorological conditions mid-air explosions may result in rainfall over extended areas.

(3) That the liberation of energy necessary for such rainfalls is not due, except initially, to the mid-air explosions, but to the energy stored up in the moist air from which the rain is derived.

(4) That the meteorological conditions which must exist for the successful action of mid-air explosions would probably, in most, though not in all cases, themselves result in a natural production of rain.

(5) That a comparatively high difference of electric potential between different parts of the air or between the air and the earth, is possibly favorable when taken in connection with other meteorological conditions for artificial rain-making.

(6) That an undirected mid-air explosion is not as likely to produce rain as an explosion in which the main tendency of the energy liberated is to cause a general up-rush of the air.

A TECHNICAL REPORT ON "TANITE."

We give below a most striking report just made on tanite by Dr. Coleman Sellers, Prof. J. E. Denton, and A. R. Wolff. This report is entitled "The Comparative Value of Fifteen Varieties of Solid Emery Wheels," the investigation being made at the invitation of the Tanite Co., of Stroudsburg, Pa. The report is of a very interesting nature and runs as follows:

"At the suggestion of the Tanite Co. we associated ourselves in an inquiry as to the comparative value of the solid emery wheels. Our first object was to settle the question as to what constitutes a good, solid emery wheel; second, to establish test conditions of such scientific accuracy as to prevent any doubt of the results; third, to give thorough trial, under uniform test conditions, to the various wheels, and to secure a mass of exact data.

"Having determined on the qualities which constitute a good, solid emery wheel, we established our own conditions of test, and submitted to such conditions wheels of our own selection. The wheels of fifteen different mannfacturers were selected. These were: Celluloid, Crystal, Detroit, Grant, Hampden, Lehigh, Norton, Northampton, Norwich, Sterling, Tanite, Union Stone, Vitrified, Vulcanite, Waltham. Among these fifteen varieties only one compared favorably with the tanite wheel, the latter having easily beaten all competitors save one. The comparative values of the tanite and its one rival will have to be ascertained by further trials.

"It was unanimously agreed that hand testing must be done away with and the personal factor eliminated, in order that the results might be unimpeachable. The defect of existing test machines was speedily recognized, and it became necessary to invent a new testing machine. After much study and many trials your board, with the valuable assistance of Prof. Webb, of Stevens Institute of Technology, at Hoboken, constructed a machine which met the approval of all concerned. This machine was so constructed that the wheel and work were brought in contact by definite and measurable pressure without any obstacle being interposed to the free wear of either metal or wheel. The results approximated closely to those obtained by hand pressure, and yet were independent of all influence from the operators of the machine. The power consumed was measured by a dynamometer attached to the driving shaft, and the speed recorded by a tachometer. The resistance between wheel and metal was indicated continually by a standard scale.

"To constitute a good, solid emery wheel the following qualities should be combined: Safety under the widest conditions of use and misuse; rapidity of cut; freedom of cut at moderate pressure; reasonable amounts of wheel loss and power consumption; evenness of wear; general staying quality, and reliability under the widest range of circumstances. Our board had the test machine erected in the machine shop of the Stevens Institute of Technology, at Hoboken—and had the various wheels (bought directly by themselves) delivered at Stevens Institute. The grinding was done on cast-iron bars supplied directly to us by one founder. Special care being taken as to quality of metal and size of bar. The trials reported on were made at the Stevens Institute during 1889 and 1890, the tabulations being too voluminous to admit of detail here. During the latter part of this investigation the assistance of Prof. Jacobus (assistant professor of experimental mechanics at Stevens Institute) was secured.

"Our report is based on a long series of trials at three different pressures—42 lbs., 60 lbs. and 100 lbs. These separate trials numbered several thousand, during each of which exact data were recorded as to speed, power, resistance between the wheel and metal, amount of metal ground off, amount of wheel material consumed, and observations made as to the cleanness of cut, amount of heat generated, amount of glazing or clogging up of wheel with metal, and as to cracks, breaks and defects of wheels.

"Of the fifteen varieties six were found too unsafe to warrant their general use, 57 per cent. of the wheels bursting under the same conditions which other wheels passed through uninjured. Eleven varieties (among which are included the six unsafe varieties) were found to be such slow cutters that the average metal removal of ten of them was less than the general average of all the wheels. Of the fifteen varieties only four were found to be rapid cutters. Of these one wore so rapidly that the cost of its rapid cut was unreasonable. This left three safe, effective and satisfactory wheels, one of which, however, was demonstrated to work at a greater cost than the tanite. The rivalry was thus narrowed to two wheels, and, in the judgment of our board, further trials are necessary before the relative value of these two can be determined.

"One striking feature characterized these two. That is, that in every series of trials these wheels increased in productive capacity, the average of the last cuts of all the series being greater than the average of all the first cuts. The 13 other varieties of all decreased in productive capacity, the average of the last cuts being less than the average of the first. Some of these which made a brilliant show at the start, cut scarcely anything at the close.

"As nearly all the preliminary and collateral trials were made with tanite wheels, more than three times as many of these were used as of any other make. In all this use, under every degree of measured automatic pressure and under the heavy pressure of long bars used by hand (a test applied to no other wheel), and also at a speed nearly double that of any wheel save one, *not a single wheel burst.*"

The committee have in their possession an accumulation of data bearing on these tests.

Letters to the Editor.

THE EFFECT OF "NEWSPAPER INVENTIONS."

In the present depressed condition of the electrical trade, with investors hesitating about venturing in enterprises of any kind, it seems, to put it mildly, a little hard on the trade that the columns of the daily papers are being used to prematurely advertise alleged inventions, not yet invented, with a view of influencing the stock market for certain stocks, to the detriment of legitimate trade. The writer knows of several instances of street railways deferring change of motive power to electricity because these much-heralded inventions (?) are likely to revolutionize and cheapen the application of electric power. If such use of the daily papers is not intended for stock-jobbing purposes, it would seem a wiser and better course to wait until the details are completely worked out and then spring them on an admiring public. To any one at all familiar with the amount of business being done by the leading "parent companies," this particular use of the daily press savors of both stock-jobbing and dog-in-the-manger spirit.

TROLLEY.

NEW YORK CITY.

Reports of Companies.

ANNUAL REPORT OF THE W. U. TEL. CO.

THE annual meeting of the Western Union Company was held last month, and the old board was re-elected. The report for the year ended June 30 makes the following showing compared with the previous year:

Year, June 30,	1890-91.	1889-1990.	Decrease.
Gross rev............	$23,034,326	$22,387,028	*$ 647,296
Expenses............	16,428,741	15,074,303	*1'354,438
Net.	$6,695,584	$7,312,725	$707,151
Int. and s. f..........	931,219	915,135	*16,084
Balance..............	$5,674,365	$6,397,590	$723,225
Dividend............	4,309,607	4,956,008	646,401
Surplus......... ...	$1,364,758	$1,441,582	$76,824
Total surplus........	11,417,741	10,002,983	*1,364,728
Miles poles..........	187,981	183,917	*4,064
Miles wires..........	715,591	678,997	*36,594
Messages sent ......,	59,148,343	55,878,762	*3,269,581

*Increase.

The Western Union's report shows that the capital stock is unchanged, and the net bonded debt is $14,801,864, against $14,779,528 a year ago. The company charged to operating expenses $2,500,627 for maintenance and reconstruction of lines. The gross revenue from messages was $20,704,270, an increase of $1,240,622. The loss in revenue was from the falling off in commercial news service, rental of private wires, dividends from other companies and the rental of buildings. The increase in expenses was largely due to repairs after storms, repairs of both Atlantic and one Gulf cable, and the fire in the main building. The average tolls per message were 32.5 cents, against 32.4 last year. The average expense was 23.2 cents, against 22.7 last year. For the first time under the Gould management a balance sheet is printed. It shows a gross floating debt of $2,815,152, offset by $857,422 cash, and $2,129,852 accounts receivable. The cost of repairs, etc., on the Dey street building is, so far, $358,062; real estate is valued at $2,908,918, supplies $320,231, securities of leased telegraph companies $8,182,300, stocks of other companies $7,599,812. The plant, etc., is valued at $96,745,391. The total surplus has been expended upon the plant. The new miles of poles and cables added in the year were 3,964 miles, wire 36,594, and new offices 716. The uncapitalized surplus put into the property is $13,015,925. There is no important change in the securities of other companies in the treasury.

THE GREAT WESTERN ELECTRIC SUPPLY CO.

THE regular dividend, two per cent. in cash, amounting to $7,500, was paid October 10th on the $375,000 of the preferred stock of the Great Western Electric Supply Co. A dividend is also to be paid on the common stock of the company, if the business continues to prosper for the next two or three months as it has for the past three.

Society and Club Notes.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

AT the meeting of the council on Oct. 27, the following gentlemen were admitted to associate membership:

De Khotinsky, Capt. Achilles, electrician Germania Electric Co., Boston, Mass.
Dunston, Robert Edward, president the Connecticut Motor Co., Plantsville, Conn.
Middleton, Edward T., instructor in electricity and physics, Rutgers College, New Brunswick, N. J.
Monell, Joseph T., with F. B. Crocker, New York City.
Smith, T. Carpenter, partner in firm of M. R. Muckle, Jr., & Co., Philadelphia, Pa.
Strong, Frederick G., electrician Midland Electric Co., Denver, Col.

The following were transferred from associate to full membership:

Eustis, Herbert H., president and electrician Eastern Cable Co., Boston, Mass.
Paine, F. B. H., consulting electrical engineer Chas. Paine & Sons., New York City.
Curtiss, George F., electrician Thomson-Houston Electric Co., Lynn, Mass.
Boynton, Edward C., Elektron Manufacturing Co., Springfield, Mass.
Weller, H. W., R. R. inspector Edison General Electric Co., New York City.
Delany, P. B., inventor, South Orange, N. J.

A meeting of the Institute Committee on the International Electrical Congress of 1893 was held in the office of the secretary, 12 West Thirty-first street, New York City, October 27th. The committee is composed of the following members: Edward Weston, Dr. S. S. Wheeler, Geo. A. Hamilton, Prof. Henry Morton, Prof. Chas. R. Cross, C. H. Haskins, R. W. Pope, Prof. W. A. Anthony F. L. Pope, Prof. E. J. Houston, T. C. Martin, T. D. Lockwood, G. M. Phelps, C. O. Mailloux and Carl Hering. The committee organized permanently, and elected T. C. Martin, chairman, and R. W. Pope, secretary. It was voted that the members of the existing Committee on Units and Standards be added to the Congress Committee, also the following members: Prof. Elihu Thomson, Prof. Alexander Graham Bell, Dr. E. L. Nichols, Mr. Nikola Tesla and Mr. Ludwig Gutmann. A subcommittee of three was appointed by the Chair, composed of Messrs. Carl Hering, W. A. Anthony and A. E. Kennelly, to formulate a provisional programme for the work of the Congress. The chairman is a member ex-officio of this committee. It was recommended that the Council appoint a committee to be sent to Chicago as soon as possible, to represent the claims of the Institute to a leading part in the Congress and to arrange for its co-operation with the authorities there upon a proper basis. The Council subsequently appointed Prof. Elihu Thomson, Mr. C. H. Haskins and Mr. F. L. Pope as such committee.

A "WURZBURGER NACHT" AT THE ELECTRIC CLUB.

UNDER the title of a "Wurzburger Nacht," an entertainment was given at the New York Electric Club last Thursday that proved an immense success, not only in point of attendance, but in the real enjoyment derived by everybody from the affair. The name was a suggestion from Mr. P. H. Alexander, the chairman of the House Committee, and the execution was due to Secretary S. L. Coles. The parlors of the club were laid out in smoking concert style; a German flag was festooned around the mirrors, and to make it feel at home a keg of Wurzburger bier and a white-aproned Gambrinus were installed opposite to it at the other end of the room. The proceedings were veiled under a mist created by 150 yards of clay pipe, but when the clouds of smoke had rolled by it was seen that nothing had happened that could bring a blush even to the sensitive maiden cheek of the *Mail and Express*. During the evening a number of pieces were sung by the Gilbert Quartette, composed of C. D. Mead, first tenor; A. C. Plant, second tenor; E. Hammann, first base, and Eugene A. Demonet, second base. Mr. Caldwell, a guest of the club, and a member of the Miss Helyett Co., favored the club with several fine songs, and Mr. Prine, the well-known New York tenor, also contributed. Piano selections were given by Dr. Wangemann, Messrs. Guy, Maguire and Colvin, and recitations by Messrs. H. M. Peckham, Issertel and Muldaur. The evening went off so well that the Entertainment Committee has already been asked by several members to arrange for another "relaxation under a pseudonym," and proposes to do so on either the last night of 1891 or the first night of 1892, when the club silver punch-bowl is brought out.

NEW YORK ELECTRICAL SOCIETY.

THE New York Electrical Society inaugurated the series of lectures, which it has arranged for the season of 1891-2, on the evening of the 22d inst., when Dr. Schuyler S. Wheeler gave some valuable data on the "Management of the Electric Motor." The lecture was fully illustrated by drawings and experiments, and the audience were able to see in actual operation many of the distinctive characteristics of various kinds of motors. Such lectures as these are calculated to do an immense amount of good, combining as they do the enunciations of principles and their practical exemplification. The society is to be congratulated on its new departure, and the excellence of Dr. Wheeler's lecture augurs well for the rest of the series.

WIREMEN AND LINEMEN'S UNION.

A SPECIAL dispatch from St. Louis says: Henry Miller, formerly President of the Wiremen and Linemen's Union, of St. Louis, has returned from an extended trip, during which time he organized unions in Louisville, Ky.; Omaha, Neb.; Minneapolis, St. Paul, Duluth, Milwaukee, Chicago, Toledo, Cincinnati and Indianapolis. These unions will send delegates to attend a national convention in St. Louis, Nov. 21. The electric wiremen are now affilated as locals with the American Federation of Labor. Unions with a membership of 25 will be entitled to one delegate, unions having 50 members to two delegates, unions having 100 members to three delegates, and each additional 100 members or fraction thereof not below 50 one more delegate. The organizing committee of the Electric Wiremen and Linemen's Union, of St. Louis, will hold a special meeting for the purpose of making arrangements for the convention. About 28 unions are now organized in the United States.

NATIONAL ELECTRIC LIGHT ASSOCIATION.

AT the last meeting of the Executive Committee of the National Electric Light Association a very complimentary and deserved resolution was unanimously passed, thanking Mr. John Carroll, of the Eugene F. Phillips Electrical Works, of Montreal, Canada, for his untiring and eminently successful labors in connection with the reception of the Association during its Convention at Montreal. These resolutions were ordered engrossed and presented to the above-mentioned gentleman. Every visitor to Montreal at the Convention will add his endorsement to this resolution. Mr. Carroll was simply indefatigable, and much of the great success of the occasion was due to him.

ELECTRICAL SECTION OF THE FRANKLIN INSTITUTE

AT the stated meeting held Tuesday Sept. 8, 1891, Prof. Edwin J. Houston read a paper on "The Artificial Production of Rain." There was much discussion on this subject, and also on the queries from the question box regarding the comparative intensity of the magnetic north and south poles of the earth, and the results obtainable in using Edelmann's electrometer as described in Ayrton's *Practical Electricity*.

Legal Notes.

INTERFERENCE: STANLEY AND EDISON—HAIR FILAMENTS.

A PATENT was issued on December 12, 1882, to William Stanley, Jr., for an incandescent lamp burner of carbonized hair, and a process of making the same. Thomas A. Edison filed an application for a patent, with broader claims, including, however, the subject-matter of Stanley's claims, on January 4, 1884. An interference was in due course declared by the Patent Office. Counsel for Edison then moved for a dissolution of the interference, on the ground that no interference in fact existed, in view of the prior state of the art as set forth in certain British patents. Commissioner Simonds decided on October 3, that in a case where an applicant has claimed a genus, and a patentee a species, clearly coming within such genus, and when the interfering applicant has recited the same species as being within the genus, there must be an interference in fact, and that therefore the interference could not be dissolved.

WESTINGHOUSE CO. vs. EDISON CO.—ENCLOSING STREET RAILWAY CAR GEARS.

THE Westinghouse Electric & Manufacturing Co. has commenced a suit against the Pittsburgh & Birmingham Traction Co., operating under the Edison system, alleging infringment of letters patent No. 442,459, of December 9, 1890, granted to the Westinghouse Co. as assignee of Albert Schmid, for an enclosing case for enclosing the gears of a street-car motor to suppress noise, and at the same time provide for automatic lubrication.

Patent Notes.

A DECISION AGAINST THE DRAWBAUGH TELEPHONE CLAIMS.

THE Drawbaugh telephone case, which has been dragging through the Patent Office for the last eleven years, was decided on October 28 by Commissioner Simonds's affirmation of the decision of the Board of Examiners-in-Chief, denying the patentability of the subject-matter of an application for patent for telephones, filed by Daniel Drawbaugh on April 3, 1884, in continuance of his original application filed July 26, 1880. The decision is on the ground that the invention was put to public use by Thomas A. Edison and others for more than two years prior to the date last mentioned, the evidence being presented that Edison had made the complete invention as early as July 30, 1877, as disclosed in the shape of his British patent of that date, etc.

College Notes.

KANSAS STATE UNIVERSITY.

AT the last meeting of the Topeka, Kan., local committee on university extension education, final arrangements were made for the lectures on electricity and magnetism by Prof. Blake, of the Kansas State University, to be delivered with suitable experiments conducted with the help of a skilled assistant and all necessary apparatus, in the high school rooms, Topeka, on Friday, the 23d of October, between the hours of 8 and 10 P. M., and every fourteen days thereafter, at the same time and place.

Personal.

MR. A. F. MADDEN.

MR. A. F. MADDEN, the well-known electrical engineer and inventor, appeared in New York last week for the first time in four weeks. A month ago he had about one chance in a thousand of retaining his sight, and when it is said that to-day both of his eyes are as sound as they ever were, it is unnecessary to add that he is happy and also full of gratitude to Dr. Charles I. Kipp, to whose skill he is indebted for his escape from blindness. A month ago he was superintending some work in the shop of Lloyd & Paxton when a chisel in the hand of a workman broke, and a fragment of the steel struck Mr. Madden in the right eye. It was an inch long, one-quarter of an inch wide and one-eighth of an inch thick, with jagged edges. It partly embedded itself in the eyeball, splitting it from the iris to the muscle in the corner of the eye. It was so firmly fixed that Mr. Madden had to exert considerable strength to remove it.

He jumped into a cab and was soon in Dr. Kipp's office. The latter introduced cocaine into the eye, thus stopping all pain, and then sewed up the ugly seam which the steel had made. Thereafter a professional nurse attended Mr. Madden at his home in a dark room, and applied compresses of ice every two minutes to keep down the inflammation, which, had it prevailed, would probably have involved both eyes and destroyed them. Fortunately the steel was a fresh piece, which had not oxidized and had no poison on it. Nevertheless, Mr. Madden rightly regards his recovery as remarkable, and gives praise to Dr. Kipp for performing with success a wonderful operation. Dr. Kipp's own opinion of the case may be inferred from the fact that at the outset he gave Mr. Madden very little hope of saving his sight.

For some little time Mr. Madden will wear smoked glasses. The injured eye betrays little sign of the great peril and severe ordeal it has been through.

MR. LAURENCE J. WEBSTER, of the Massachusetts Electrical Engineering Company, sailed on the S. S. "Umbria" recently on a business trip of several months in England and Germany.

Appointments, Etc.

MR. L. A. SHERMAN, manager of the Port Huron, Mich., telephone exchange, will shortly relinquish his position.

MR. J. P. GRIFFIN has become associated with the Eastern District of the Edison General Electric Co.

PLOUGHING WITH DYNAMITE.

SUB-SOIL ploughing with dynamite fired electrically is one of the new methods in the South, and it is said to be equal to the process of trenching used by market gardners to loosen the earth to a depth of two or three feet, and allow the absorption of a good deal of water for sustaining vegetation during a drought. The inventor drills holes two or three feet deep and five feet apart, making 1,600 to the acre. In each he puts an explosive, and, after tramping, discharges it, the whole nmber being connected with a wire leading to a battery. In a recent experiment the explosive used was one-fourth of a small-sized dynamite cartridge, with about an ounce of Judson powder. The surface of the ground appeared to be lifted two or three feet, a few small clods being thrown up to the height of a house. It was broken to the depth of 30 inches at the points of the explosion and sidewise for a part of the distance between the holes.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

Advertising is a common sense way of getting business.

THE HALL SAFETY ELECTRIC CUT-OFF.

THE safety electric cut-off, shown in the accompanying illustrations, Figs. 1 and 2, consists of an electromagnet, conveying the current from a dynamo into two contact levers, through which a working current passes, and is so arranged that when the current fails the united levers fall apart, breaking the line in two places instantly. It frequently happens that the current, although not totally failing, is partially interrupted, producing flashing of the lights, or unevenness of current employed for motors. While this cut-off is very sensitive in movement, it is so constructed that it prevents the opening of the line unnecessarily in such instances. It will be seen that the cross bar which connects the levers near their free ends is also connected by a link to a piston rod of a dash-pot, the upper end of the link being pivoted to a bracket secured on a cross-bar, and the lower end of the link being pivoted between ears. The lower end of the piston rod is fitted with a plunger working in a dash-pot, partly filled with glycerine, which slightly retards the movement of the falling lever when the circuit is broken. The use of the dash-pot allows the current to circulate about one second, which enables the electromagnet to restore the lever to its proper position if the current be immediately re-established in full force.

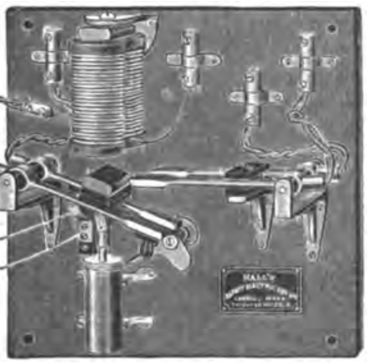

Fig. 1.

The object of this cut-off is to guard against accidents from broken wires.

An alarm device consisting of a small buzzer or bell is arranged in a short line containing a battery and a spring switch. The terminals are normally held apart by their own elasticity, and are brought in contact by an arm connected with the lever of the main switch over the dash-pot, which falls downward when the main line becomes broken.

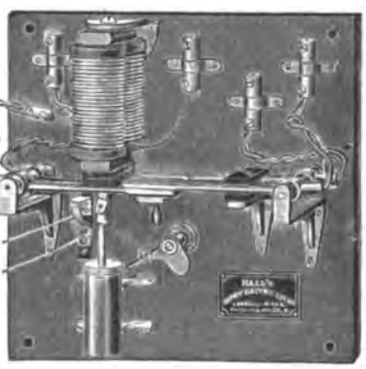

Fig. 2.

This invention is said to work perfectly under all conditions. It was invented by Mr. George L. Hall, an electrician of Lowell, Mass., and is patented in the United States and foreign countries. A company is being formed to manufacture and introduce this cut-off, and it is now in the hands of the Patent Electric Cut-Off Co., Box 599, Lowell, Mass.

THE RAE CAR IN PITTSBURGH.

DURING the recent convention in Pittsburgh an inspection trip was made over the lines of the Duquesne Traction Co. by the car just put on the road by the Detroit Electrical Works. Everything worked very nicely, and the only disappointment was due to the fact that full speed could not be made owing to the presence of a car of another make on the same track, just ahead. The Rae car beat the record, however, by climbing the steepest grade in 2 min. 40 sec. as against 3 min., the previous best time. This was done with 28 people on the car. In view of the assertion sometimes made that the Detroit Works cars do not take kindly to sharp curves, it was worthy of note that with a 6 ft. 6 in. wheel base truck, this car went around a 27 ft. radius curve with as little apparent effort as if it had been a 40 ft. curve.

PERRET MOTORS FOR CHURCH ORGANS.

THE following letter bears eloquent witness to the successful use of electric motors for organ blowing:

READING, PA., Oct. 24th, '91.

THE ELEKTRON MFG. CO.,

GENTLEMEN: Find enclosed check in payment for motor furnished us. The motor is giving perfect satisfaction to ourselves, the church and the organ builders—such satisfaction that the organ builders have resolved to use the Perret motor exclusively for blowing organs wherever possible to do so.

Respectfully,

PRINTZ & HILL.

SHORT ELECTRIC RAILWAY CO.

THE Short Co. have taken a contract for the equipment of the Trenton, N. J., Passenger Railway Co.'s road. The first delivery of apparatus will comprise 15 motor cars and three generators, to be followed by five motors and an additional generator. The first part of the plant will be put in early next spring, and a very large portion of the line will probably be equipped by next fall. The motors will be single reduction of the latest type, and the generators will be of the new design.

THE MICHAELIS COAL MINING MACHINE.

Electric coal mining machines have now been introduced in the Monongahela coal fields for nearly two years, and since then their adoption has rapidly increased. One of the latest mines to be operated by these machines is the O'Niel & Peterson mine, at Bunola, on the Pittsburgh and Belle Vernon Railroad, on the Monongahela river. The contract for equipping the Bunola mine was made with the Michaelis Electric Coal Mining Machine Company, of Pittsburgh. The plant consists of one 50 h. p. steam engine, one 30 h. p. Westinghouse alternating current generator and eight mining machines with the Tesla motor of the Westinghouse Electric and Manufacturing Co. attached to each machine.

The Michaelis coal mining machine has long passed the experimental stage; it has in fact been in practical successful operation for 15 months. The capacity of each machine per day is 65 tons of coal, or about one square foot of undercut per minute for ten hours each day. The machine requires very little attention, only one man being necessary to attend to it.

W. H. GORDON & CO.

W. H. GORDON & Co, 115 Broadway, New York, have taken the selling agency for Bryant's sockets, switches, cut-outs and specialties, Sunbeam incandescent lamps, Fletcher's specialties, as well as electric railway line material. They desire to call the attention of central stations and isolated plants to the fact that they are "headquarters" for all these goods, and that they are now carrying quantities in stock, so that orders can be filled promptly and satisfactorily. The reputation of this house for prompt shipments has become proverbial, while, as Mr. Gordon expresses it, "We are keeping in step with the decline in prices, and believe, considering the quality of goods we recommend, they are the cheapest in the market. We want to win the reputation of selling the best goods at reasonable prices, so that a company wanting something good and reliable will naturally think of coming to us for it." This would appear to be the right policy for a firm who are in the trade to stay.

ELECTRIC HOISTS.

THE Pleasant Valley Coal Company, of Salt Lake City, Utah, have for the past year at the Castle Gate Mine, in Utah, used a hoist or haulage drum operated by electricity. The drum was made by the Lidgerwood Manufacturing Company, of New York, and the electric motor and the electrical equipment furnished by the Thomson-Van Depoele Electric Mining Co., of 620 Atlantic avenue, Boston, Mass., together with all the electrical apparatus for the power station.

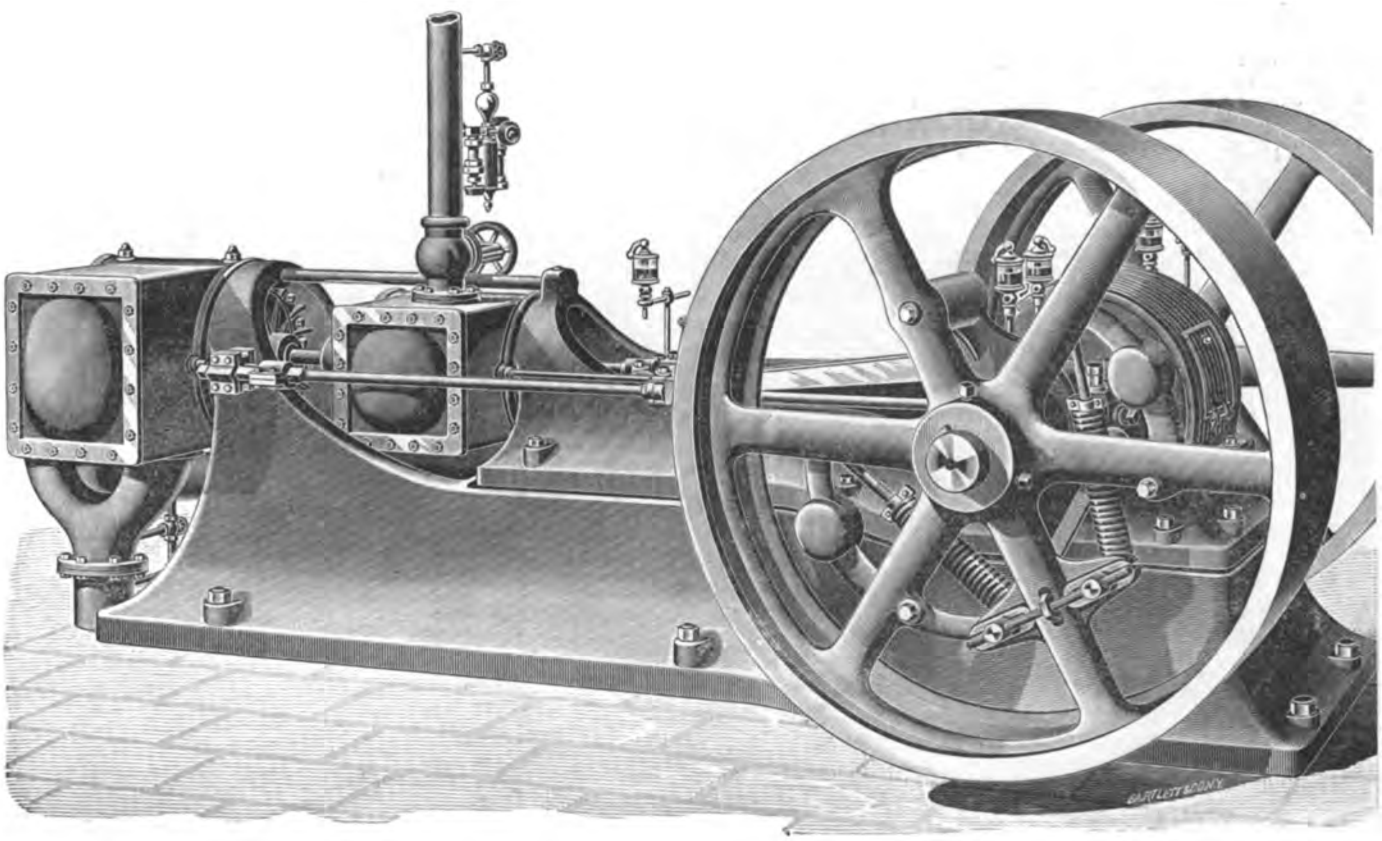
Trains of sixteen large pit cars run out of the mine by gravity, dragging the tail rope after them. The empty trains are hauled back into the mine by the haulage drum, located nearly 2,000 feet from the chute in the interior of the mine. The operation of this apparatus has proved so satisfactory and so economical that the company have ordered two more electric hoists of more powerful type.

In every way the electrical apparatus has been satisfactory to the company—so much so that for the Winter Quarters Mine, operated by the same company, they have ordered an electric locomotive and the equipment of nearly two miles of underground railway with the Thomson-Van Depoele system.

THE WESTON COMPOUND ENGINE.

THE accompanying illustration shows the Weston compound engine, built by the Weston Engine Co., Painted Post, N. Y., and handled in New York City by Julian Scholl & Co., 40 Cortlandt street.

As will be seen, the sub-base is made a part of the engine proper by extending it and projecting a neck in front of the high-pressure cylinder for the attachment of the large or low-pressure cylinder. This arrangement has several advantages, principal among which is the accessibility of the low-pressure cylinder for inspection. As leakage from this cylinder represents the most serious loss, it is obvious that the usual practice in tandem compounding of making the low-pressure cylinder practically inaccessible is a mistake, as, if no opportunity is given for examination of the piston, the loss from this item may be enormous. Another advantage of this form is the total elimination of cylinder vibration, securing great rigidity and permanent alignment. These engines have a balanced four-admission valve on each cylinder, and both valves are attached in a direct manner without rocker arms to an automatic governor, thus keeping the load about evenly divided between the two cylinders. This is claimed to have decided advantages over the usual arrangement of having a low-pressure eccentric fixed to the shaft or adjustable by hand. As the actual load is frequently considerably below the maximum in practice, the vital feature of compounding is destroyed; whereas, with the automatic attachment to each valve, the engine is always in condition to take care of any load within the range of its capacity and without disturbing any of the essential elements of compounding. This feature of two automatic valves will doubtless be well received, and where strict economy of fuel is necessary its advantages are obvious.



WESTON COMPOUND ENGINE.

THE GREAT WESTERN ELECTRIC SUPPLY CO. are having splendid success with their Sun arc lamp, which is manufactured by the Sun Arc Lamp Co., of Chicago. They have installed a number of Series sets in various railroads throughout the West, and in every case the lamps are giving most excellent satisfaction. They operate either 5, 6 or 7 in series, on a 500 volt railroad circuit. These give a beautiful white light, without flickering, and are made in from 1,200 to 2,000 candle power each. For lighting car barns and power houses, as well as street crossings and areas through which railroads pass, they cannot be excelled. The Great Western Co. have just completed the delivery of the steel poles for the Citizens' Street Railway Co., Indianapolis, Ind., the contract for which they were awarded a few months ago. The Citizens' Street Railway Co. express great satisfaction with their poles, and consider them an ornament to the streets through which the lines pass.

POOR ELECTRIC LIGHTING AT COHOES, N. Y.

A TRUSTWORTHY correspondent writes us: "The electric lighting system in Cohoes, N. Y., is a cause of widespread dissatisfaction to many of the heaviest taxpayers. The cost to the city per lamp or candle power could not be ascertained at the time of a recent visit, and data promised has not come to hand, but your correspondent was shown several street lamps which appeared as though formerly used for gasoline and which had not been cleaned for some months. Inside the square lantern a single incandescent lamp had been placed, and when lighted, the glimmer of the lamp through the dust and cobwebs of an age unknown hardly gave a favorable comparison with the kerosene street lamp of years past. The arc lights at the intersections of the main streets were but fair, and the area of light was quite circumscribed in extent. It would appear that the management of the electric light station in this city would bear a lively overhauling, and that unless it is done at once, and a daily supervision of each and every light inaugurated, an investigation will be set on foot to either know why the service cannot be improved, or else compel a return to the ancient order of lighting.

"The gas furnished in the stores and factories is of good quality and illumination, and although several of the factories have recently placed private plants for electric lights in their workrooms, yet the public streets are not as fully illuminated as they should be with the power expended; neither has the electric lighting company been very successful in displacing gas in the stores."

THE JOSEPH DIXON CRUCIBLE CO.

THIS company have for a number of years been preparing, at their factory at Jersey City, N. J., graphite mixtures for lubrication, which have found great favor with machinists and steamfitters throughout the country. Their graphite pipe-joint mixture is claimed to be infinitely superior to anything else for the same purpose, while their graphited oil is used for lubricating bearings.

The *Moniteur Industrielle* recommends the use of a mixture of oil and graphite on all screws in machinery. It says it will effectually prevent them from becoming fixed, and protects them for years from rust while at the same time the mixture facilitates tightening up.

THE ALUMINIUM CARBON CO.

MR. FRED V. DOTY, the general manager of the Aluminium Carbon Co., of Buffalo, N. Y., writes us that, although the capacity of their factory is 60,000 a day, they are now running night and day to keep up with orders. "Our carbons have proved all that we have claimed for them. That is, they are more than 25 per cent. longer lived, and are of lower-resistance than any others on the market."

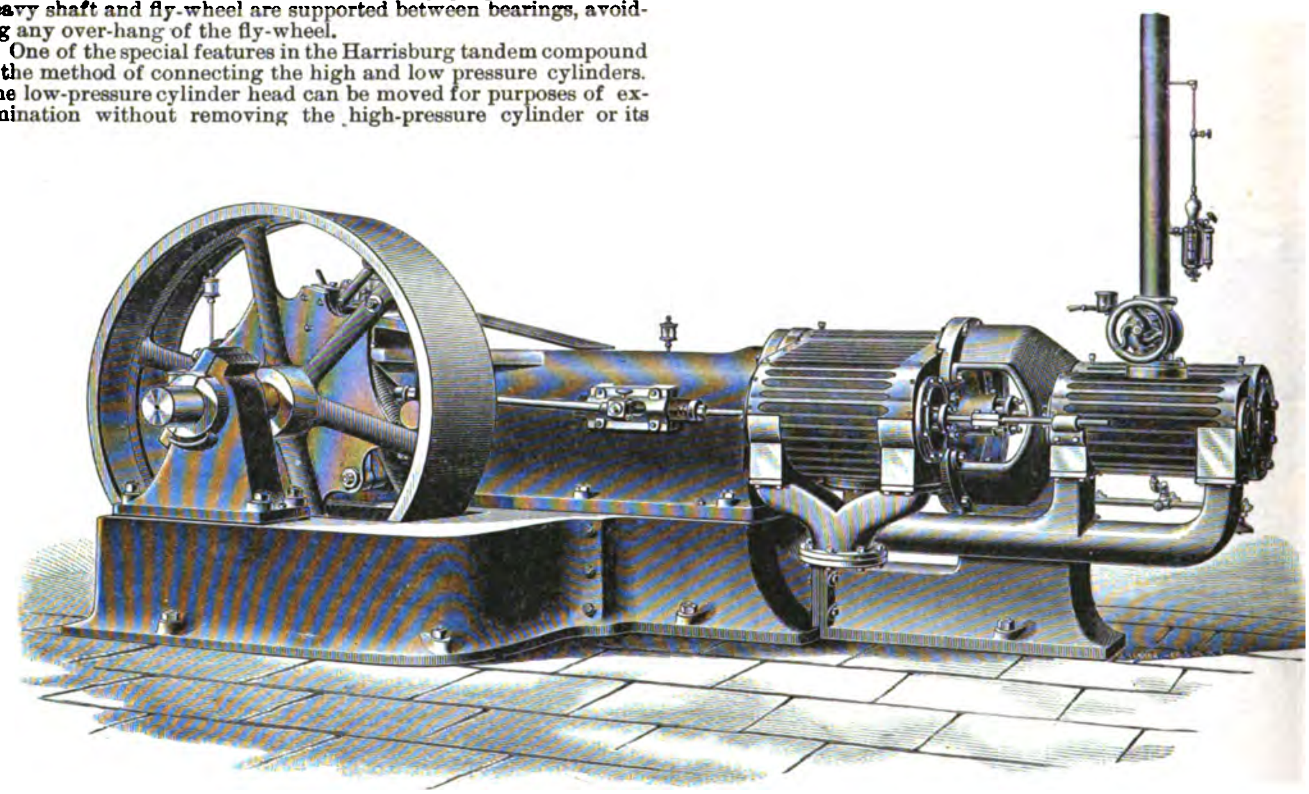
THE HARRISBURG TANDEM COMPOUND ENGINE.

THE Ide tandem compound engine, as manufactured by the Harrisburg Foundry and Machine Works, and represented in the accompanying illustration, is substantial and compact in design, neat and attractive in appearance, and is made exceptionally large in all bearings and journals, with a view of comfortably transmitting the maximum power, when run condensing.

It is well adapted for the transmission of power for electric railway lighting or factory use, being designed for working at high relative speed for direct belting if desired, with the extraordinarily close regulation for which the simple Ide engine is remarkable. When used for electric railway purposes the extra heavy shaft and fly-wheel are supported between bearings, avoiding any over-hang of the fly-wheel.

One of the special features in the Harrisburg tandem compound is the method of connecting the high and low pressure cylinders. The low-pressure cylinder head can be moved for purposes of examination without removing the high-pressure cylinder or its steam and exhaust connections. The inablity to do this has been one of the greatest objections to the tandem compound engines as usually built. The manner of supporting the high-pressure cylinder is very substantial, avoiding the vibration of cylinders when working under full load. The advantages obtained in making this connection between cylinders has been regarded so important that a patent has been applied for.

The Harrisburg Foundry and Machine Works are represented in New York, Boston and Philadelphia, and other cities through their regular agencies.



HARRISBURG TANDEM COMPOUND ENGINE.

THE RIES ETECTRIC SPECIALTY COMPANY.

THE Ries Electric Specialty Company, of Baltimore, are meeting with an unprecedented demand for their regulating sockets which they exhibited at the Montreal Convention. A combination of skillful advertising, hustle and general merit is bringing in orders for these sockets beyond even their most sanguine expectation. The last addition to their circular matter is a handsome four page folder, showing a cut of their socket and giving eight common sense points regarding the desirability of its use under different conditions. Those unfamiliar with the device should apply for a copy of this circular at once.

RESTAURANTS IN THE ELECTRICITY BUILDING, WORLD'S FAIR.

ALL of the restaurants in the Mines and Mining and Electricity Buildings will be in the galleries. This was determined in order to leave the ground floor free as far as may be for intending exhibitors. It is thought also that restaurants on the second floors of the buildings would prove an attractive feature. It was also decided that the restaurants in the Electricity Building be located in the two bays at the north end of the hall. In each bay there is to be one large dining-room, surrounded by several smaller rooms twenty-three feet square. The balcony connecting the two is to be fitted up for serving temperance drinks and ices. In the great Manufacturers Building about 40,000 square feet have been set apart for restaurants.

A CONVENIENT SOLDERING FLUX.

No one who has had the care of a central station can fail to recall the numerous "faults" which developed on account of bad joints. It is not always possible to use continuous lengths of wire, but no splice should be left unsoldered. Soldering with acid being a disagreeable and slow task, we are glad to call attention to a convenient article in the form of a soldering salt put up in bottles by the Electrical Supply Co., of Chicago. This only needs the addition of water to make it ready for use. It is claimed that there are no unhealthy fumes, and that it will not corrode the wire.

TRIUMPH COMPOUND ENGINE CO.

THE new machines for setting type, lately introduced by the Commercial Gazette Company, are operated by one of the engines built by the Triumph Compound Engine Company, of 211-217 West Second street, Cincinnati. Situated in the fifth floor of this building, the engine is a marvel—noiseless, producing no tremor, and doing its work perfectly. It is especially desirable for driving high-speed machinery, where close regulation is necessary, and economy of space important.

THE GLOBE CARBON CO.

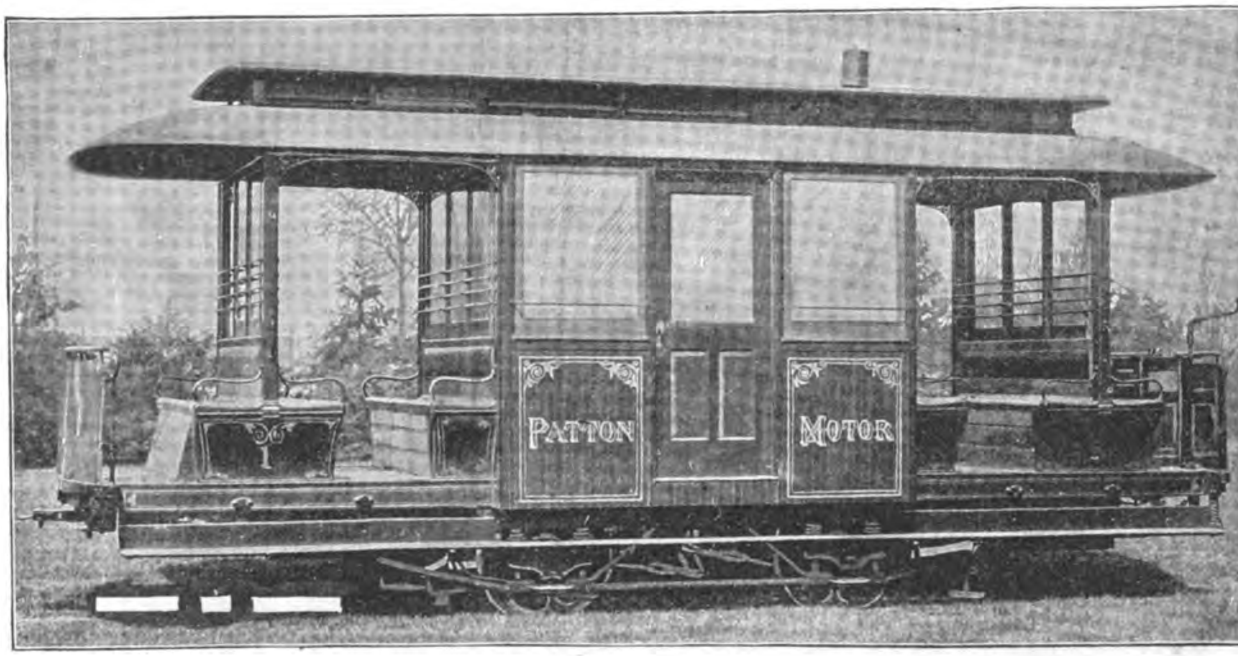
THE above company have recently removed their works to Ravenna, Ohio, where they will have a capacity of 100,000 finished carbons per day, and the most approved appliances for the manufacture of a superior article.

THE PATTON MOTOR CAR.

AMONG the latest developments of self-propelling street cars is that designed by Mr. William H. Patton, who has been giving attention to the question for several years, and which can now be seen in daily operation at Pullman, Ill.

At first sight the combination, which comprises a gasoline engine, dynamo, motor, and set of storage batteries, the latter being employed to render the generating apparatus as compact as possible and to enhance the reliability of the car, appears complicated, but the fact is the apparatus is exceedingly simple in operation. The weight of car complete is 14,600 to 16,000 lbs.

The motor car is shown in the accompanying illustration. In the centre of the car is a covered cab, in which the motive power is contained. The gas engine, which develops 10 h. p., is geared directly to the dynamo by means of an Evans friction pulley. The dynamo is wired directly to the motor, which is geared to the axle in the usual manner. The storage batteries are inserted in a branch circuit, and become charged by the portion of the current from the dynamo not used by the motor, which, when the load is light, is a large percentage of that generated.



PATTON MOTOR CAR.

When in ascending a grade or in starting, a large amount of power is called for, the electromotive force of the dynamo tends to drop, and the storage batteries furnish all the extra current required by the motor, until the load becomes normal. The dynamo is then capable of furnishing the required amount of current to the motor, and supplying a small surplus to the batteries, thus maintaining them always charged.

Each car carries 100 accumulator cells, two volts to the cell, supplying current of 300 amperes, developing eighty h. p. when needed.

The engine is placed in position on the trucks, entirely independent of the car body, and is geared direct to the dynamo by means of a friction pulley, no belts whatever being used. It is controlled automatically, and requires no attention. The electric motor is geared directly to the axle, and derives its energy from the dynamo current, this being supplemented when required by the reserve power from the accumulators; this additional current being automatically governed. In descending a grade, running on a level track, carrying a light load, or when car is not in motion, there exists a constant generating power, producing a surplus electric force. It is here that the accumulators play an important part, they being arranged to take care of the surplus that would otherwise be wasted. They are charged in series but discharged in multiple with the dynamo. Therefore, when any contingency arises where an extra amount of power is required, the accumulators, fully charged, are prepared to supply the required current.

The engine and dynamo occupy a space six feet square, completely housed, and with the accumulator cells conveniently stored away, the entire mechanism of the car is out of public sight. The car is operated by one man stationed upon either platform. Any desired degree of speed can be attained.

It is a well-known fact that a gasoline engine ordinarily has to be started by hand, but in this case the batteries are employed to perform this work by utilizing the dynamo as a temporary motor. The motor car is of sufficient power to haul one or more trail cars, as required.

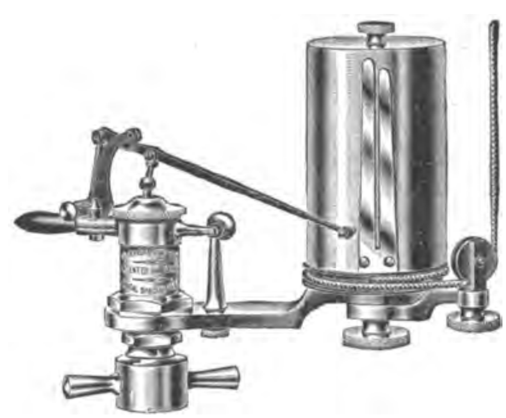
The cost of operation, it is stated, is 17 to 20 cents per hour, inclusive of wear of machinery. The officers of the company are: A. B. Pullman, president; H. H. Latham, vice-president; W. H. Dyrenforth, secretary; H. G. Bird, treasurer; Thos. Saunders, general manager; W. H. Patton, superintendent. The office is at 45 Lakeside Building, Chicago.

The successful tests at Pullman are said to have shown the practicability of the system, and the company are now prepared to furnish equipments and all details and particulars.

THE HINE & ROBERTSON INDICATOR.

THE accompanying illustration shows a straight line steam-engine indicator manufactured by Messrs. Hine & Robertson, 45 Cortlandt street, the peculiarities of which are the simplicity of the parallel motion, and the auxiliary spring by which it is held up to one working surface and the appearance of backlash prevented.

The guiding mechanism for the parallel motion is placed as near the fulcrum as possible, where the momentum will be the least. For a card of average height, a side movement of not more than one-eighth of an inch is necessary to allow the pencil to move in a straight line, and for so slight a movement very little mechanism should be sufficient. In this indicator this is accomplished by two rocking surfaces, one attached to an upright, and the other permanently fixed on the pencil arm. The one on the upright is circular, and the other of such form that when the lever rises and falls, the two roll together for a very



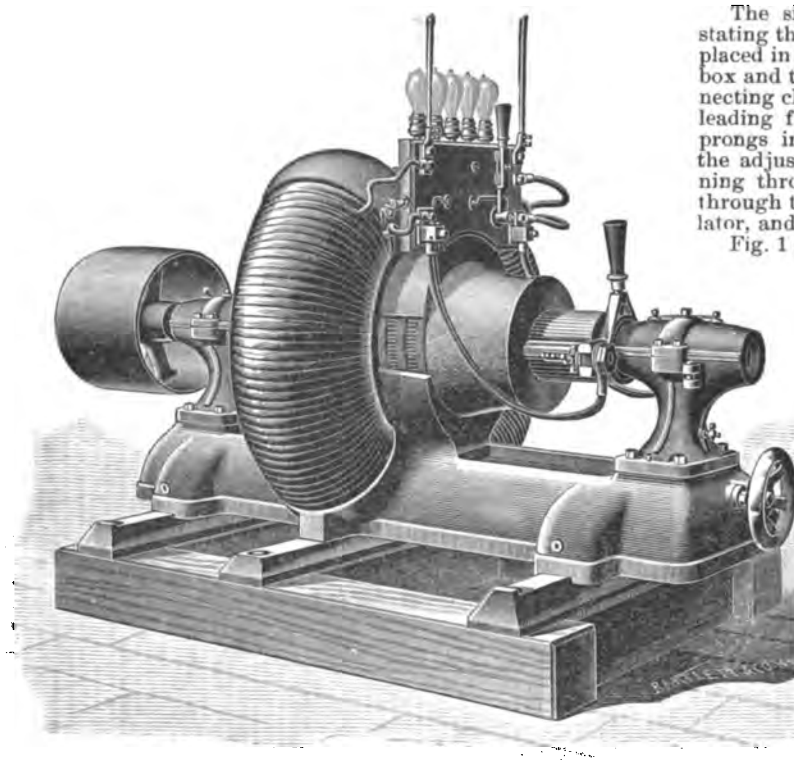
HINE & ROBERTSON STRAIGHT LINE INDICATOR.

slight distance and cause the pencil to move in a perfectly straight line throughout its full range. All that is required of the auxiliary spring is to keep these guiding surfaces in contact while the instrument is running. This spring is intended to take up all play that may ever appear in the joints and oblige the pencil to always follow in the same path. The first of these indicators made was subjected to the test of being run continuously nine hours a day on a high-speed engine for over a month, and showed no appreciable wear, what there may have been being taken up by the auxiliary spring, and the instrument being improved if anything by this hard usage.

The effect of the auxiliary spring on the main spring is to weaken it. This is allowed for in numbering the spring, and the scale is therefore the net resistance of the two springs. The moving parts of the instrument are very light and the weight is disposed so near the fulcrum that its little movement makes the momentum very slight and specially adapts it for the highest speeds.

A NEW TYPE "C. & C." DYNAMO.

The accompanying illustration is taken from a photograph of a 50 h. p. "C. & C." dynamo, placed on the market by the "C. & C." Electric Motor Co., 402 & 404 Greenwich street, during the past summer. The design is similar to that of the well-known circular field and consequent pole motor already so familiar to the public. It is said that there is not an electric light company in the country operating an incandescent circuit of any size that has not one or more of these motors in operation. The machine



New 50 H. P. "C. & C." Dynamo.

represented is wound for 500 volts and specially designed for power circuits. For a long transmission of power this machine can be specially wound to give perfectly automatic regulation under the very greatest possible variation in load. A substantial terminal-board is bolted to the upper pole-piece, and is provided with a heavy knife-switch for opening the main circuit. This board also carries the field and armature connections, all of which are of solid metal and in plain view. The commutator is of the most substantial construction, being built up of heavy copper bars insulated with the best mica. With proper care it will last for years. The mechanical construction is of the best throughout, skilled mechanics and the most improved machine tools being employed. The armature is wound to carry a much greater volume of current than the nominal capacity of the machine requires, thus making it practically impossible to burn them out by overheating. The circular shape of the magnets gives them the greatest possible development of power for least weight.

The 100 h. p. dynamo made by this company is of exactly the same form as the dynamo here illustrated, and is especially for street railway circuits, its high efficiency and mechanical excellence making it a favorite with station superintendents.

These dynamos are wound in standard sizes from 1 to 100 h. p. for electric lighting as well as for power transmission, and especially for isolated plants and for use in mills, office buildings, banks, etc,

Although the "C. & C." Electric Motor Company has but recently entered upon this field, the long list of companies now using their dynamos for lighting purposes is the best possible indication of the success with which they are meeting.

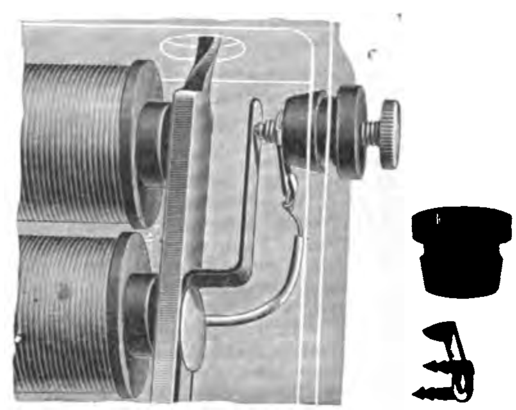
THE VARLEY COMBINATION ADJUSTING BELL SCREW.

Looking at the ordinary electric bell now so universally used, one would hardly think there is room for improvement. Perhaps not, so far as the user is concerned, but the manufacturer is ever on the alert for methods that will tend to better the bell without adding to its cost.

An exceedingly clever and valuable improvement in bell manufacture has recently been patented by Richard Varley, Jr., of Passaic, N. J., whose late inventions have attracted considerable notice. This device is called "A New Method of Assembling Bells." It consists of but three parts, which take the place of the somewhat complex method now in vogue for the adjusting attachment. These parts are the rubber stopple, Fig. 2, which affords an insulator for the adjusting screw and serves as a lock nut by compression of the rubber; the adjusting screws itself and a connecting clamp, Fig. 3. The office of this clamp is to connect the wire from the coils to the adjusting screw, it being held in position by the two prongs that fit into the small holes shown in rubber stopple.

The simplicity of this device may be briefly explained by stating the method of adjusting it to the bell. The stopple is first placed in position by forcing it through the hole in the side of the box and through the upright in the skeleton bell. Next the connecting clamp, which has previously been connected to the wires leading from the magnets, is placed in position by forcing the prongs into the stopple. This brings the hole through which the adjusting screw passes diametrically opposite the hole running through the stopple, Lastly the adjusting screw is pushed through the rubber stopple which forms at once a perfect insulator, and a lock nut for keeping it in position.

Fig. 1 shows the device complete attached to an iron box bell



Figs. 1, 2 and 3—Varley Bell Screw.

In skeleton bells a lug is cast on the frame in place of the regular binding post now in use. Through this lug is drilled a hole which admits the rubber stopple, as in the box bell described.

Aside from cheapening the materials necessary to make a bell, it greatly economizes the labor necessary for assembling the parts. It also adds to the bell's efficiency to the extent of preventing it getting out of adjustment by loosening of the screw, as the latter cannot turn in the soft rubber bed. In places where there is considerable jarring, such as in cars, factories, etc , the question of loose screws is an important one to be considered.

This valuable device has been placed on the market by Jones & Son, 602 West 22d street., New York.

THE

Electrical Engineer.

VOL. XII. NOVEMBER 11, 1891. No. 184.

COUNTING A NATION BY ELECTRICITY.

BY

T. C. Martin

I.

CENSUS-TAKING is a modern art. Ancient records are full of statistical information as to the number of people in certain nations at a given time, but it is to be deplored that the work was entrusted chiefly to persons of peculiar bent and aptitude for whom no other employment could then be found, namely, the romancists. In these days, such geniuses are restricted to fiction writing and the reportorial staffs of sensational papers; but at the remote period when man stood before all the great and complex facts of nature like a mere exclamation point, history was the only vent for his imagination. Hence it is safe to assume that very little of the numbering of the people at any time prior to the present century amounted to much. Every condition told against accuracy, even when it was sought in all sincerity, to true the record. The apathy or suspicion of the nation in regard to such a remote idea as its enumeration; the inability to secure a large force of skilled clerks; the obstacles of distance and primitive means of travel; the absence of comparative knowledge as to the best methods; and, finally, the doubt as to the treatment received by the returns when they were all in, even if every poll had been counted—these alone were drawbacks enough to stamp with uncertainty all the results that have come down to us.

As we have said, the art of census-taking is modern, and yet it is still, as practised in most countries of the world, as barbarous in its basis and methods as when just so many animals and a few herdsmen were told off into a patent lifeboat to try how a new start would improve social conditions. As a matter of fact, far as we here in America had gone in our plans for securing information not only as to the total of our population, but as to its peculiarities, we still used in the census of 1880 simple, crude tally sheets, which, save that the ruling on them was slightly neater, were practically the same as had done duty since the year 1. Anybody who will take up one of the old tally sheets, with its closely packed lines and serried columns, will see at a glance the difficulty and labor of transferring to them and thus massing the various interesting and important facts without which no census is now worthy of its name. The thing was as curiously inadequate to establish belief in its accuracy as is the cellar door with its chalk scratches that the saloon keeper brings to court to prove the length of a score. The only wonder to the writer is, that many of the clerks who toiled at the irritating slips of tally paper in the census of 1880 did not go blind and crazy.

II.

It was early evident that with our rapidly growing population, and the universal desire to see the returns before the generation it referred to had passed off the face of the earth, the old tallying, pencil-marking methods of 1880 would not do. The appointment of the Hon. Robert P. Porter, in April, 1889, as Superintendent of the Census, was soon followed by the naming of a commission to advise him as to the methods to adopt of tabulating census data, other than that of dallying with the primeval tally sheets. This commission, whose expert acquaintance with the subject is known to all, comprised Dr. J. S. Billings, Prof. Henry Gannett and Mr. L. M. E. Cooke. To this commission three schemes of tabulation were presented. That submitted by Mr. W. C. Hunt proposed to transfer the details given on the census enumerators' schedules to cards, distinctions being made in part by the color of the ink and in part by writing on them, the results being reached afterwards by hand sorting and counting. It should be stated here that Mr. Hunt's plan really represented the last refinement of the old methods, its author being an acknowledged authority with training in the Massachusetts Census, and now having charge of Population Statistics in the Eleventh Census as special expert agent. The next plan, that of Mr. C. F. Pidgin, contemplated the use of "chips," which should be duly assorted and counted. These chips were to be slips of paper of various colors embracing data printed in different colors so as to indicate the readings of the schedules. Thus the clerk seeking the most information would need the most chips, and, as in an analogous diversion, would wind up with having the most experience or valuable knowledge for his chips. Last, and foremost for the purposes of this article, came the system of Mr. Herman Hollerith. In this plan, the information given in the schedules was to be expressed upon cards by punching holes in them in certain positions. The tabulation from these cards was to be made by passing them through a press which would register their indications electrically on dials.

These three methods were now put to the test, four enumeration districts of the Census of 1880 in the city of St. Louis being taken. It was found that the time occupied in transcribing their contents by the Hollerith method was 72h. 27m.; by the Hunt method, 144h. 25m.; by the Pidgin method, 110h. 56m. The time occupied in tabulating was found to be as follows: Hollerith's electrical counters, 5h. 28m.; by the Hunt slips, 55h. 22m.; by the Pidgin chips, 44h. 41m. This settled it. The commission also estimated that on a basis of 65,000,000 population, the saving with the Hollerith apparatus would reach nearly $600,000. As a matter of fact, as the saving was based on an estimate of 500 cards punched per day, while 700 is the average, the saving is 40 per cent. more than was expected. It is needless to add that Mr. Hollerith's invention was adopted, and that an arrangement was entered into by the Government with its inventor.

III.

It had been from the first a matter of great interest to the writer to know how the Hollerith apparatus would go through the ordeal, and he made an effort more than once during the past six months to get such data on the subject as might prove of interest to the readers of THE ELECTRICAL ENGINEER. Each time, however, Mr. Hollerith replied that it would be better to wait until the system had given full evidence of its capacities, and that he was willing to abide by the results. His faith in his invention was certainly justifiable, but the efforts in various quarters to cast doubt on the figures obtained in the Census were such as to make a believer in the theory that electricity knows no politics, the more anxious to describe the work in progress. The statement by Mr. Porter that the population of this great republic was only 62,622,250 sent into spasms of indignation a great many people who had made up their minds that the dignity of the republic could only be supported on a total of 75,000,000. Hence there was a howl, not of "deep-mouthed welcome," but of frantic disappointment. And then the publication of the figures of New York! Rachel weeping for her lost children and refusing to be comforted, was a mere puppet-show compared with some of our New York politicians over the strayed and stolen of Manhattan Island citizens. The work of counting all those Charlie Rosses might still be going on, but perhaps this city now extracts consolation from the fact that her trans-Atlantic sister, Liverpool, finds herself similarly bereaved. As to the low "grand total" of population, Mr. Porter has the grim satisfaction of pointing to Canada. Her showing for the ten years is so bad that even if she were to call in whole provinces of the Old World to even up her ranking in the New, she would still be short many hundred thousand on the old bases of estimate. The happy truth is that as Mr. Hollerith, himself no mean mathematician, has shown, while the race is not multiplying so fast as before, its individuals are living longer. This is a state of affairs that all of us over 25 years of age, whether Republicans or Democrats, can view with equanimity. They who are loved on high no longer die between two Censuses.

Herman Hollerith.

It is needless to say that in all this hurly-burly of discussion over the Census and its figures, the electrical counting system came in for its share of abuse. Just why it would not work was never made clearly apparent, for all that appeared in print derogatory to the mechanism merely went to prove its wonderful simplicity and inability to go wrong. In one or two instances, the attempts to show faultiness were so puerile as to suggest that their author was either malicious or was being imposed upon. Later on, the absurdity of some of these criticisms will be shown, but it will suffice to say that they only made the present writer more anxious and keen to detect a flaw in the system and apparatus, if flaw there were. After a scrutiny as close and careful as it could be made, it seems only possible to say one thing, namely, that the apparatus works as unerringly as the mills of the Gods, but beats them hollow as to speed. The effort will be made now to describe the system in actual operation, as witnessed two or three weeks ago, at the different branches of the Census Office in Washington.

IV.

The Eleventh Census is still of so recent date that many of the readers of this journal will remember the broadsheet schedules that were presented to them by the official enumerator to be filled up. Each of these schedules provided for some thirty details regarding any of 10 individuals. Such a sheet would therefore serve for a family or household of ten people, but as a matter of fact it was found that the average fell slightly below five; so that in the neighborhood of 13,000,000 of these schedules were sent into the Census Office, representing the work of about 50,000 enumerators. To-day these sheets, tied up in about 50,000 packages, have been appropriately deposited in one of those time honored storehouses of vital statistics—a church—and constitute literally our modern Book of Numbers. The first thing, however, to be done with these myriad records was to get at their gross totals, and upon this work the Hollerith system was put through a kind of preliminary canter. The ingenious machine shown later in Fig. 5 was fitted with a small numbered key-board of ordinary construction, the keys being connected electrically with the dials, which were so arranged that one of them would furnish the grand total of families as a check against the separate totals of the others for families of different sizes. The keys were in three rows, of which the top one, stamped from 1 to 8, recorded the number of families in each house. The other two rows nearer the manipulator were numbered from 1 to 10 and 11 to 20, and recorded the persons in each family. The enumerators having given this information in a little space provided at the top of their schedules, it was easy for a quick-eyed and a quick-fingered clerk to transfer the items to the dials of the machine or make special note of such rare families as exceeded 20 members. Evidently the multiplying of the number of families by the number of persons in each class would, if correct, yield the result indicated by the "total;" and hence the work was capable of very thorough check. The expertness acquired in manipulating the Hollerith machines may be inferred from the fact that some of the women tabulators thus counted as many as 50,000 persons a day, or the inhabitants of a good-sized city. The average for the women tabulators, who worked in the day time, was about 47,950 each; while the men tabulators, handicapped perhaps by coming on at night, averaged 32,935.

In this ingenious and expeditious manner, thanks to the Hollerith machines, the first, or "Dwelling House" count of the whole population of the United States as it stood on June 1, 1890, was made. Practically only six weeks were needed for the gigantic task. The announcements from the Census Office as to population of various sections followed each other rapidly, and a "rough count" for the whole country was ready as early as October 30, 1890. The last returns did not reach Mr. Porter until November 10, but he was able to issue his celebrated bulletin, giving the "official count" of 62,622,250, exactly a month later, namely, on December 12. Yet all the figures had been thoroughly checked; in reality, the people of the United States had been counted twice over. As Mr. Porter put it at a dinner given by the chiefs of the Census Office to celebrate the occasion, "For the first time in the history of the world, the count of the population of a great nation has been made by the aid of electricity" and every single one of our 62 millions "had marched as it were under the vision of the young men and women who had done such remarkable work with such extraordinary rapidity and precision."

V.

But all that we have secured so far is the total of population and a few necessary details as to size of family, and persons to dwellings. This is most important, but, as has been stated above, there are between twenty and thirty details given on the schedules as to each of the 62 millions, and pretty nearly all of those details are of the first value in revealing the make-up of the nation. The problem that arises is, how to extract the honey from the lion's jaw; how, out of this enormous mass of returns, to elicit the facts that shall tell us what we want to know about the national characteristics—whether we are being Latinized or Teutonized in blood; whether the agricultural population increases in inverse ratio to the farm mortgages; whether city children are born merely to stimulate the trade in small coffins; whether naturalization is fashionable; whether attendance at school promises a higher state of education; whether protected industries employ many or few hands; whether a large or small proportion of the people suffer from mental or physical defect; and whether with a rising standard of comfort fecundity of the race declines. These are interesting questions, and something more. Yet it is very difficult to arrive at such combinations, and until now the obstacles have proved almost insurmountable. Thus, for example, in the Census of 1880, although the returns included statements as to the conjugal condition of each and every one of the 50,000,000 inhabitants of the United States, no attempt was made to tabulate it in any way, and hence to-day we do not know what proportion of the population is married or single!

Fig. 1.—Hollerith Keyboard Punch.

It was the absence of methods for getting speedily and surely at such results that arrested the attention of Mr. Herman Hollerith, while engaged in work upon the Tenth Census, that of 1880, and led him to the invention of the apparatus described in this article. He saw that with increasing population and increasing complexity of data, the difficulties were becoming such that unless improved means of compilation were devised, the work must be abandoned in despair or become more incomplete and unsatisfactory each decade. On the other hand, with the aid of new facilities, not only might time and money be saved, but the data could be thrown into combinations full of suggestion and teaching, but which had been utterly beyond reach before. Such facilities Mr. Hollerith has furnished in his electric tabulating system. The fundamental idea of this is, as said, to punch holes in cards so that the positions of these holes will correspond to certain data, and then to pass these cards through presses by which the perforations in the cards are made to control the operation of electromagnets or groups of magnets, which in turn energize counting mechanism or sorting boxes, or will bring both into play at once. There is no need to go into the history of the stages by which Mr. Hollerith has perfected his invention, but having already described how part of it was used for the "enumeration" and primary tabulation, it will suffice to show in what manner it performs the further and more delicate and exacting duty of compilation.

VI.

Once more, then, we come back to the returns sent in by the 50,000 enumerators. In order to transfer the particulars as to each individual from these 13,000,000 schedules, Mr. Hollerith devised the machine shown in Fig. 1, known as the "keyboard punch." It is about the size of a typewriter tray, having in front a perforated punch-board of celluloid, translated in Fig. 2. Over this keyboard swings freely a sharp index finger, whose movement, after the manner of a pantagraph, is repeated at the rear by a punch. The movement of the punch is limited between two guides upon which are placed thin manilla cards $6\frac{5}{8}$ inches long by $3\frac{1}{4}$ inches high, with the lower corner slightly clipped. The keyboard, as will be observed, has twelve rows of twenty holes, and each hole has its distinctive lettering or number that corresponds to the inquiry and answer respecting every person. Hence when the index finger is pressed down into any one of these holes, the punch at the back says "ditto" by stamping out a hole in the manilla card. At first glance, perhaps, the keyboard looks complicated, but it is scientifically grouped, and, as the writer can testify, it is very readily learned. For such inquiries as are answered by one of a very few possible classes—sex, for example, which recognizes only two parties in the State—

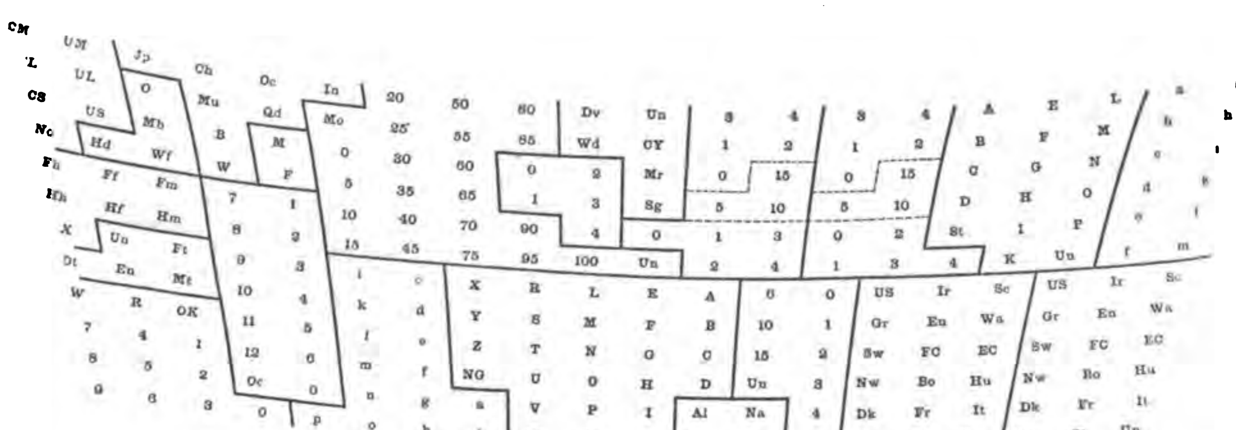

Fig. 2.—Symbols of Holes in Hollerith Census Keyboard.

the answer is simply "male" or "female," or "M" and "F," So, too, in regard to conjugal relationships, where the answer would be either single, married, widowed or divorced, and one punch suffices for each of these conditions of freedom or servitude. These holes may easily be found in "Dv," "Wd," "Mr.," or "CY," the last of which means that the person was married during the Census Year. Where, however, the answers would cover a wider range of classification, as in age, running from 1 to 100, recourse is had to a combination of two holes, the first indicating a group, as from 25 to 29 years, while the second hole designates the detail single year in that group. Up in the left-hand corner are double letters that bear upon the status of combatants in the Civil War, while down in the lower right hand corner are other double letters that tell one's place of birth and the place of birth of one's forebears.

To assist the clerks in memorizing the keyboard for punching, classification lists were used, which show that exactitude was sought without making it troublesome to the puncher. Thus, "Ka," standing for Germany, stands also for many divisions of the German Empire that a clerk without some such guide might be inclined to hand over again to France, Austria or Denmark. As regards the United States, each Commonwealth is designated by two letters, the first capital letter being the group, such as North Atlantic, while the small letter is the particular State. Thus, Georgia is "Bb," while Connecticut is "Ag." Now to get the run of these combinations is not difficult when once you have started. The larger percentage of all the population of any State is born within its borders, for which the hole marked "St." is provided, or else it is from two or three States near by. It follows, therefore, that, after all, the symbols "come easy" with each lot of schedules. The same remark holds true with regard to occupations. A clerk punching the card for an agricultural district has but few symbols to bother about. In many a New England town "cotton mill operative" will fit most cases. Down the Wyoming Valley, of Pennsylvania, coal miners will be apt to predominate; while out in California, fruit growers will be numerous. It will thus be seen that these innocent combinations, which a leading New York newspaper has epithetted as "refinements of torture," are no more burdensome on the memory than the details of a typewriter keyboard. On the contrary, they are vastly interesting. That the work of punching became as easy as any other

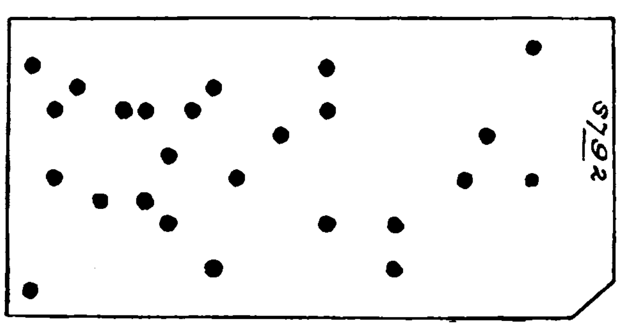

FIG. 4.—COMPLETE CARD FOR ONE PERSON.

task requiring ordinary intelligence is shown in the fact that the estimated average of 500 cards per day per clerk resolved itself very soon into an actual average of 700. It is stated that some of the more expert punchers, working from 9 A. M. to 4 P. M., have done 1,100 cards, with an aggregate of 18,700 holes, each card having 17 holes in it that relate specifically to the individual whose life history is thus condensed. Even close upon 2,000 population cards have been done in a day.

VII.

After the cards leave the punching clerks, they are kept in their Enumeration Districts, and they have now to be further punched to show the exact locality they belong to, —*i. e.*, the civil division of which the enumeration district formed a part. For this purpose the space of about one inch across the left-hand end of the card was left blank, no portion to the left of a fictitious line being punched on the keyboard punch. This space is further divided by imaginary lines into 48 squares, in the combinations of which every enumeration district can be recorded, and it is perforated by means of the "Gang Punch," shown in Fig. 3. The combination for any given enumeration district is arranged in this, and then all the cards of that district are passed through. From three to six cards can be punched at a time, hence the name, and pressure may be applied by either the hand or the foot. When this is done, the cards are complete, as shown in Fig. 4, which is a fac-simile,

FIG. 3.—THE HOLLERITH GANG PUNCH.

slightly reduced in size, of the card for the head of a family in Chicago.

So familar do the clerks become with the position of the holes in these cards, they can read them off at a glance. As a means of verifying, however, a "reading board" is provided for that purpose, the same size as the card, and having also each of the 240 abbreviations in a quarter-inch space, so that when a perforated card is put on this templet the abbreviation will show wherever a hole has been punched. This templet is, practically, a reduction of the original keyboard, and is about the size as our illustration of that part of the apparatus.

In one of the newspaper articles appearing recently on the subject, two alleged samples of these complete cards were given in order to show that the "chances of error were largely increased by the mechanical devices employed," while "there was small possibility of detection." The funny part about the exposé in question is that both cards lacked the impress of the gang punch, and therefore were not part of the Census record at all. In other words, they were imperfect cards that had been thrown aside by the punchers themselves, and had not even reached the Hollerith electric machines, which would have been as prompt and unerring in their rejection as are bank tellers in casting out false coin. The present writer, while in Washington, asked specially as to imperfect records, and was taken into the little room where cards rejected by the machines were being set right by reference to the original schedules. A glance at the handful of men there, revising the work made by the handling of half a million cards daily, showed the percentage of wrong cards to be very small. Where the errors were "Inconsistent," that is, where a child of 10 would be registered as of no sex, the machine would sooner or later spot the mistake and refuse to count the card. As to "consistent" errors, those namely in which a man who was a policeman might be punched with unconscious humor as a poolroom-keeper, it is safe to say that such errors were necessarily very few, if only for the reason that it is at least as easy to punch in the right hole as in the wrong one; and these errors would, moreover, on a mathematical basis, be less likely to occur in dealing with holes that are a quarter of an inch apart, than where the same record was made on lines only one-eighth of an inch apart. But besides the natural checks on errors consistent and inconsistent, was the further check of a frequent examination of the work as it proceeded day by day and hour by hour.

VIII.

These wonderful little cards have now come to stand for over 62,000,000 people. Each card is not only full of holes, but has its number, and is ready for the next stage of treatment, when each of the holes will tell its story in just the same manner as the perforations in an organette strip will cause certain notes of music to be played. The cards are stacked up on end in tin boxes, measuring 20 x 7 x 3½ inches, each box taking a trifle less than 2,000 cards. We here have a distinctively new American industry, that of canned statistics. In front of each tin box is a label stating its contents. These boxes are kept in racks in the basement of the Census quarters in the Interocean Building. They line up ten miles long. Across the street, in the old church, are the enumerators' schedules from which they were made. Those schedules might every one of them be burned up, and the Eleventh Census could be taken over again from beginning to end, by means of the little slips of manilla in these modest little tin cans. If the record relating to each person were written in a line across a strip of paper, and the lines were half an inch apart, the roll for the nation would be nearly 500 miles long. Truly here, on these shelves, is a Liebig extract, for each can contains the essence of 2,000 human lives. In this cellar Herbert Spencer could immure himself and study sociology with the aid of 1,000,000,000 independent facts about a single nation, but the labor-saving Hollerith machines upstairs will give them to him in significant totals down to the last degree of analysis.

IX.

Mounting by elevator to one of the upper stories of the Interocean Building, one reaches the departments where the machines are mainly in use, and where one is again impressed with the fact that women are entrusted with much of the work. As one enters, the ear catches the sound of crisp bell ringing, for all the world like that of sleighing. This music comes from the Hollerith machines, on each of which a bell, intercalated in the circuit, rings every time a card is counted, while its failure to ring indicates that there is something wrong with the card, or that it has not been slipped in properly. When the office was visited by the writer, there were 81 clerks at the machines, and their work showed 434,493 cards counted and 121,853 sorted, or a total of 556,346 for the day, making an average of 6,868 per clerk per day. In other words, the force was piercing its way through the mass at the rate of 500 feet daily, and handling a stack of cards nearly as high

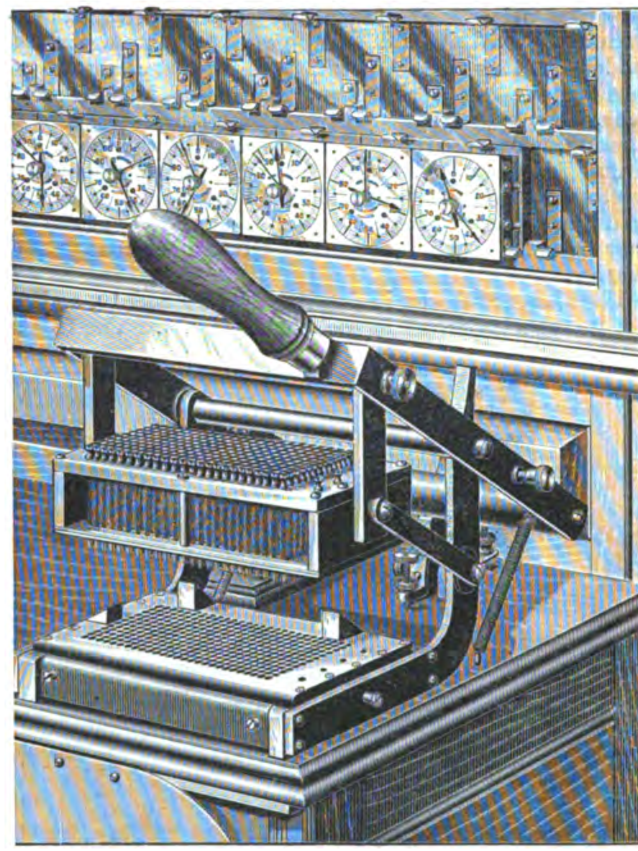

Fig. 6.—Perspective of Circuit Closing Press.

as the Washington Monument. The Hollerith machine, at which the clerks are seated, is shown in Fig. 5. It consists of three main parts, namely, the press or circuit-closing device, the dials or counters, and the sorting boxes. The press is shown in perspective in Fig. 6 and in detail in Fig. 7. It

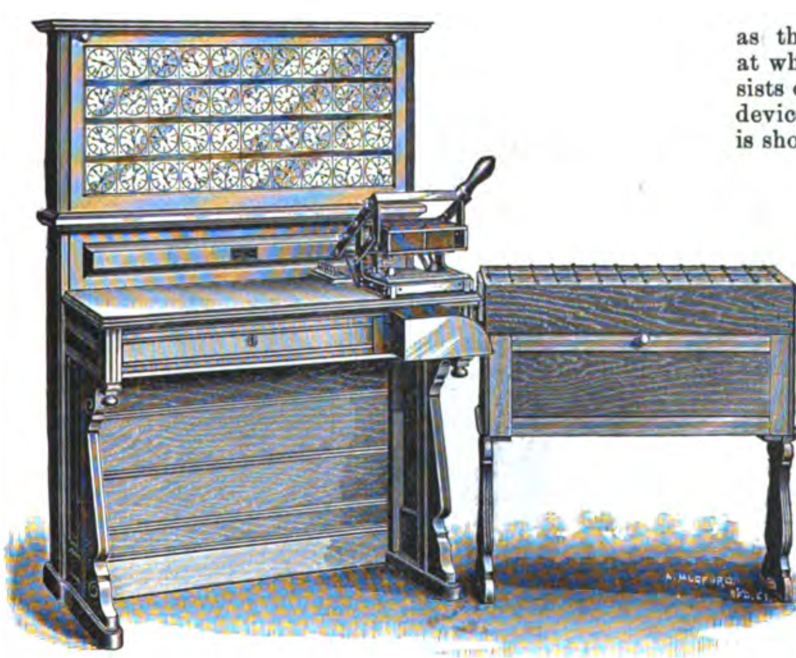

Fig. 5.—The Hollerith Electric Tabulating Machine.

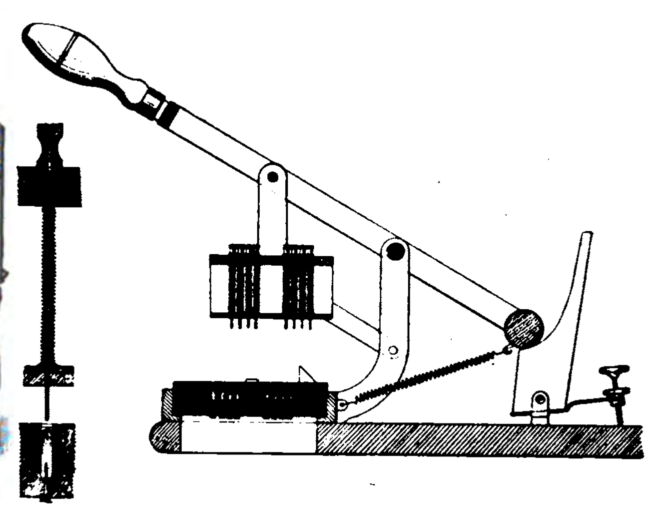

Fig. 7.—Details of Circuit-Closing Press.

consists of a hard rubber plate, provided with 316 holes or pockets, the relative positions of which correspond with those of the holes in the keyboard and gang punches. Each of these pockets is partially filled with mercury, and they are thus in electrical connection, when the circuit is closed, with the binding posts and switchboard at the back of the machine, as shown in Fig. 8, where a portion of the wooden case is broken away. Above the hard-rubber plate swings a reciprocating pin box, which is provided with a number of projecting spring-actuated points, so hung as to drop exactly into the centre of the little mercury cups below. These pins are so connected that when a punched card is laid on the rubber plate against the guides or stops and the box is brought down, all the pins that are stopped by the unpunched surface will be pressed back, while those that correspond with punched spaces pass through, close the circuit, and count on the dials. The circuit is really closed first through platinum contacts at the back of the press, and not seen in the cut. In this way no difficulty is experienced from the oxidation of the mercury from the spark, as would be the case without this precaution.

The dials are shown in detail in Figs. 9 and 10, and may also be seen grouped in position in Fig. 5. The front of

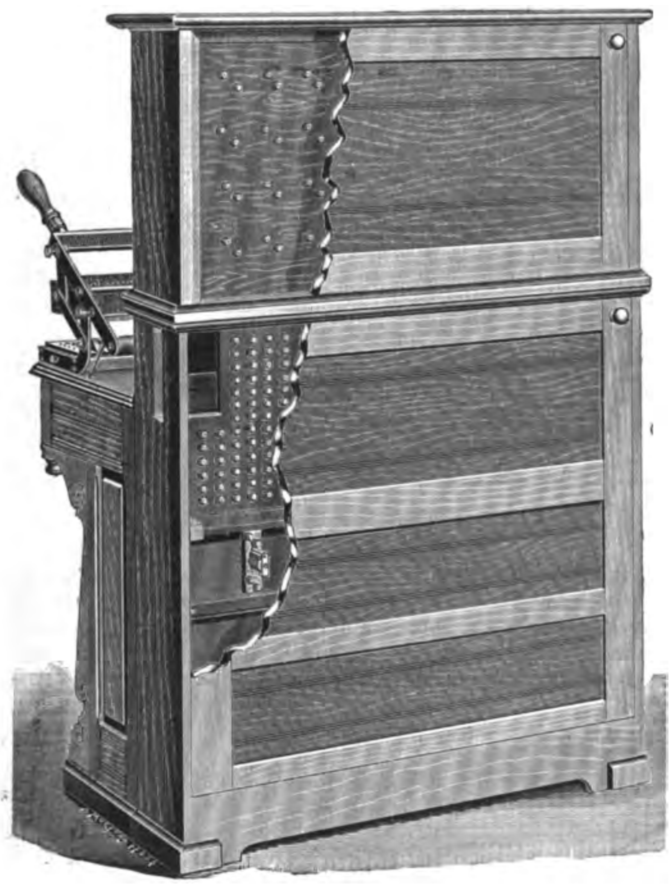

FIG. 8.—BACK OF HOLLERITH MACHINE, SHOWING SWITCH BOARD AND BINDING POSTS.

each counter is three inches square, and, as now made, consists of paper ingeniously coated with celluloid, ensuring a smooth, bright, clean face. Each dial is divided into 100 parts, and two hands travel over the face, one counting units and the other hundreds. The train of clockwork is operated electrically, by means of the electro-magnet, whose armature, as it moves each time the circuit is closed, carries the unit hand forward one division, while every complete revolution actuates a carrying device, which, in turn, causes the hundred hand to count. In this way each dial will register up to 10,000. A noteworthy feature of these ingenious little dials is, that they can quickly be re-set at zero, while they are also removable and interchangeable. The electrical connections are made simply by slipping them into the frames and clips shown in the upper part of Fig. 6.

The third element in the system is the sorting box shown in Fig. 11 in perspective, while Fig. 12 is a diagram of its mechanism. The box is divided into numerous compartments, each of which is kept closed by a lid. As seen in Fig. 12, the lid L is held closed against the tension of the spring S by the catch a at the free end of the arma-

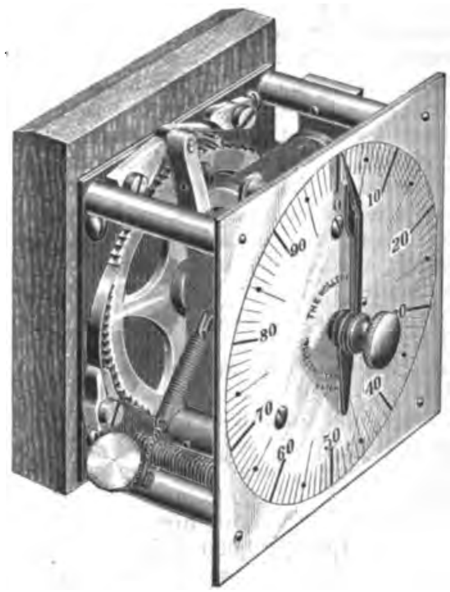

FIG. 9.—COUNTER.

ture A. If the circuit is closed, by the press on the machine, through the electro-magnet E, the armature **A** is pulled down, releasing the trigger of the lid L, which is at once thrown up by the spring S, and remains open until flipped back by a slight touch of the operator's hand. The connections with the machine are made by means of the short cable seen at the left of the sorting box. In the cut the wires are shown attached to binding posts on a small board, but a minor change has been made by which the board is pushed in between contact clips in the machine, thus saving valuable time by obviating the necessity of screwing and unscrewing so many binding posts whenever it is desired to remove the box for any reason.

X.

If now, it is desired to know in a given enumeration district, or all of them, the number of males and females,

FIG. 10.—BACK OF COUNTER.

white and colored, single, married, widowed, &c., the binding posts of the switchboard corresponding with this data are connected with the binding posts of the dials on which these items are to be counted. If it is also desired to assort the cards according to age groups, for example, the binding posts of the switchboard representing such groups are connected with the clips into which the sorting box plug fits. The circuits being thus prepared, when a card is placed in position in the press and the handle of the pin box is depressed by the operator, so that the circuit is closed through each hole in the card, not only will the registration be effected on the counting dials, but the sorting box that has been selected for a given age group is opened. The operator releases the handle, removes the card deftly from the press, deposits it in the open sorting compartment with her right hand and pats the lid down again, at the same time bringing another card into position under the press with her left hand. It is done much more quickly than it is described. When all the cards in the tin case of any district have thus gone through the press, the record taken from the dials will show the number of males, females, white, colored, &c., while the cards will have been assorted into age groups.

This is well enough, and evokes our admiration, but the Hollerith machine is capable of much more than this. In statistical work, it is found that the most valuable information does not consist in these elementary items, but in facts that are more difficult to obtain, namely, combinations of these items. Thus, it is interesting to know how many dwellers in this country are males and how many are females; also how many are white and how many are colored. But it is at least as essential to know how many of the white males are native born or foreign born, and how many are the children of native born or foreign parents. Hence it is desirable to provide means for counting not simply the number of white males, but the number of white males, native born, of native parents. Mr. Hollerith's machines do this as easily as they do the lighter work. The old familiar principle of the relay is brought into play very ingeniously by means of the special but simple form of relay shown in Fig. 13. These relays are mounted together in the racks at the bottom of the machine as illustrated in Fig. 8. In the case just suggested, the wire is brought from the binding post of the switchboard corresponding to male to one contact of the relay operated from the binding post corresponding to white. From this relay the circuit runs to another relay operated from the binding posts that correspond to native birthplaces. Thence again the circuit goes to the relay operated by the binding post that corresponds to native born father, thence again to the relay operated by the binding post corresponding to native mother; and finally to a counter. It will be seen therefore that the counter will only be operated when a card which has been punched for "native," "white," "male," "native-born father," and "native-born mother," and of the given age, is put under the press. If the card is not so punched, the circuit remains open at one or more points and no counting is effected. Evidently the most complex combination can be effected in this manner. An elementary manner of building up the combination is shown in diagram in Fig. 14. It is simply a question of arranging the counting dials and the relays, or, if desired, the sorting boxes can be treated in the same way. When the machine is once connected up, the combination sought yields its results just as readily as though it were a single item. It is obvious, too, that multiple contact relays could be used, carrying the ability of the machine even further, if one wanted to do it in that fashion. Moreover the machine is not confined to tallying one set of facts, but will take several at one and the same time, being limited only by the number of counters.

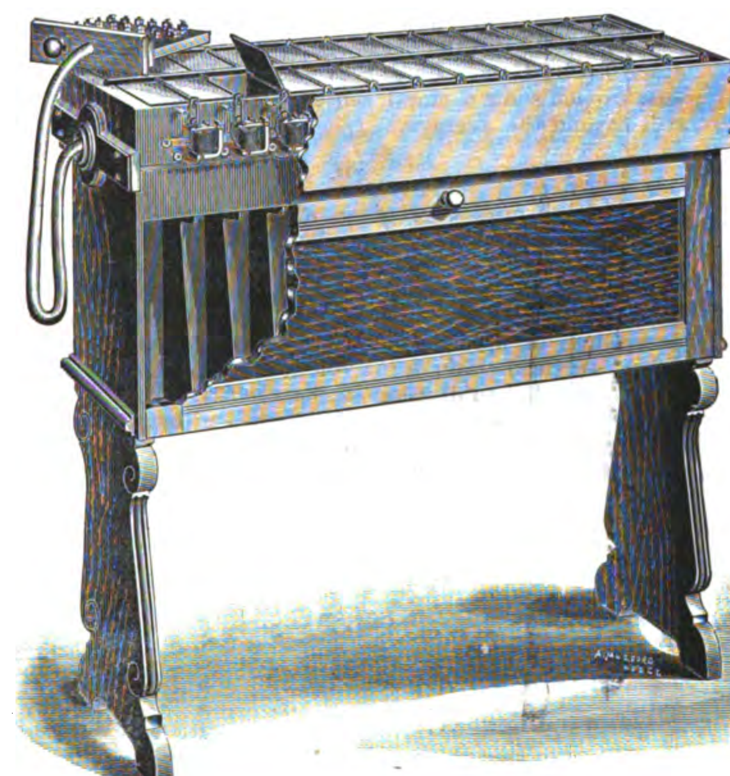

FIG. 11.—HOLLERITH SORTING BOX.

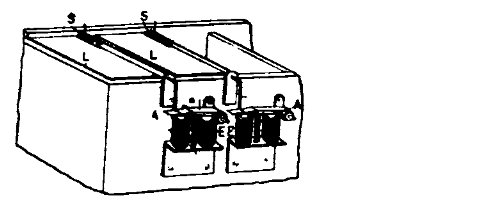

FIG. 12.—DETAIL OF SORTING BOX AND CIRCUIT.

FIG. 13.—RELAY.

There is another side of the Hollerith method. We have just indicated refinement in detail of one kind, but the machine lends itself to analytical work not less than synthetical. In statistical investigation the analysis naturally becomes finer as the area enlarges, and here the sorting box is of great service. As has already been stated, the cards are primarily massed in enumeration districts. For such small areas, the information required groups the population under comparatively few heads. In practice it is found that such classification can generally be counted on the 40 dials that the machine embraces normally as a full equipment; and the arrangement is made accordingly. But while counting this classification, the cards can also be assorted into groups that will form the basis of the analysis for the next larger group of territorial areas; so that if the cards are divided into twenty groups, we shall have at the next handling of the cards, a classification of 20x40, or 800 heads. If, at the next step, we subdivide each one of these twenty groups into twenty more, the third handling of the cards will give us 20x20x40 or no fewer than 1,600 heads. Thus a very few manipulations will give an extraordinarily fine degree of analysis, and the compilation will have a value from its minuteness that could be reached in no other way.

XI.

It is estimated that each of the machines thus compiles and registers information daily that would require the efforts of 20 clerks if sought by the old system of tally sheets. But that is not all. Added to the ability to secure special details, finer analysis, and the economy in time and

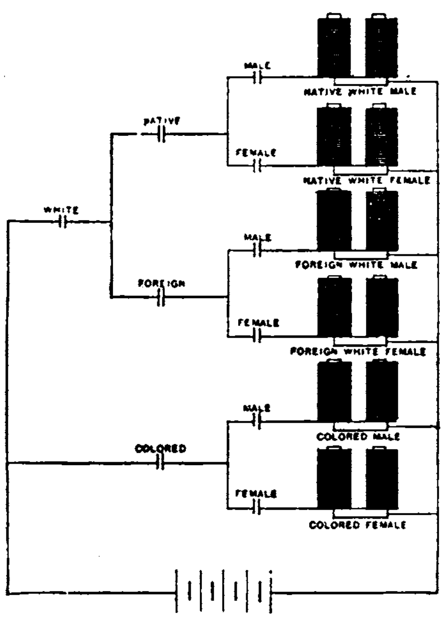

FIG. 14.—METHOD OF ARRANGEMENT FOR COMBINATION COUNTING.

labor, we have the greater accuracy. The machine automatically throws out any card that is wrong. Suppose, for instance, that age or sex has not been punched. Where there should be a hole for the plunger pin to go through, closing the circuit, the card is intact. The circuit is open, and the monitor bell just to the left of the press, refuses to give its cheery signal of correctness. It is then a very easy matter to refer back to the schedule stowed away in the old church across the street and fill up the deficiency by the paradoxical process of making a hole. Suppose it was desired to connect up the machine so that only cards for New York should be counted. A missorted card belonging to Chicago would at once be rejected with as much decision and hauteur as though it were a Knickerbocker turning the cold shoulder to a pork packer. The gang punches of the two cities not agreeing, the wrong cards would leave the circuit open. Moreover, the same indications are made of course by the same holes for all like data. If the cards of electrical engineers were assorted correctly, the hole designating the fact would show daylight through a thousand of them. If a banker fell among the bunch of thieves, the fact would be revealed again in a second, and he would be rescued from such bad company. That all are butchers in a batch of cards purporting to represent them, is simply ascertainable by taking one of their own meat skewers and sticking it through the holes that announce the fact. But this could evidently not be done with written cards, and the digging through the 150 tons of them for such as had thus gone astray would be a job preferably postponed until such time as second sight becomes an every-day accomplishment for government clerks.

It should be pretty clear by this time that the probabilities of error in reality narrow themselves down to the punching, and, as has been pointed out, even then the only errors that escape detection are those in which the information given, while it may not furnish the exact fact, is still consistent with the other facts punched. Even these could be eliminated by comparison or check of every card, but it is surely hypercritical to complain of results so close to absolute accuracy. It is to be borne in mind, too, that a card wrongly punched involves only the possible miscounting of a single unit, whereas in all previous methods the counting up on sheets has involved possible miscount at each footing up of a column. Another point worthy of remembrance is that a large part of the punching was done by women clerks, a fact that augurs well for its conscientious performance. Whether in the dull routine of American office toil or in the discharge of the Amazonian duties described by Robert Louis Stevenson in his South Sea letters, women show a moral sense of responsibility that is still beyond the average.

XII.

As a few figures were given of the records made with the punching machines, it may be worth while, in passing, to cite some that relate to the tabulation work. It has been stated that at the time of the writer's visit to the Census Office, 81 clerks had handled 556,346 cards that day, an average of 6,868 each. The "roll of honor" shown below, obtained through the kindness of Mr. H. Sutherland, chief of the fourth division of the Census Office, includes the best records on the work of tabulation for a week at a time, with the name of the clerk, showing the number of cards and the average "readings" per day.

Name.	Week ending—	Av. per day.	
		Readings.	Cards.
Alexander, Maurice.....	July 25th....	9	13,856
Richardson, Mrs. Z......	Sept. 26th....	7	11,351
Castillo, Angelo J......	Oct. 3d......	5	10,766
Johnston, Orphella......	Aug. 22d....	6	9,515
Werner, Edgar V.......	Oct. 3d......	5	9,475
Stockbridge, Lucetta....	Aug. 29th....	4	9,230

Below are given the six highest individual records for any one day:

Name.	Week ending—	Readings.	Cards.
Alexander, Maurice. ...	July 9th.....	9	**19,071**
Wasner, Mary..........	Oct. 2d	5	**17,814**
Castillo, Angelo J.......	Oct. 21st.....	7	**15,119**
Richardson, Mrs. Z......	Sept. 9th....	12	**15,068**
Ourand, Mrs. Rachel E..	Oct. 9th. ...	10	**13,327**
Mesick, Hattie S........	Sept. 4th.....	11	**13,067**

In explanation it may be stated that to run so many cards through the machine and take a reading means that each card has to be put under the press and counted for each district. Then the 38 dials in the face of the machine are counted, the results are set down according to the requirements of the various result slips furnished for the purpose, addition, verification—and correction, if needed,—are made, and the clerk then starts a new district. The day's work extends over 6½ hours, and these totals therefore show very creditable speed and expertness.

XIII.

The writer made a point while inspecting the Hollerith system, of ascertaining the opinion of the Superintendent of the Census as to the work. Mr. Porter stated emphatically that the office could not have dispensed with it. To use his own words, "he could not have got away from it." In a recent address before the American Statistical Association, Mr. Porter also dwelt upon its value for the special compilation of the statistics of mortality. Mr. W. A. King, chief of the Mortality Division of the Census Office, in a statement with regard to his own line of investigation, dwells very forcibly upon the superiority of the Hollerith apparatus for reaching detailed and accurate results. Mr. King was on the staff of the Tenth Census of 1880, and hence, is familiar with the tally sheets of that epoch. Speaking of them, he says: "In a compact tally sheet, the spaces in which the various details are tallied are close together and a very slight movement of the pencil is sufficient to produce an erroneous tally; and with any kind of a tally sheet the results sought are not known until the tally is completed, and if in the figures thus obtained a discrepancy is found by comparison with previous work, it is impossible to do more than determine the *gross* error. No means exist of locating the particular cases in which the error was made. If a re-tally is made, the error in that particular may be corrected while others are changed, or it may be made worse."

The Rev. Fred. H. Wines, another veteran of the Tenth Census, and now in charge of the statistics of Crime, Pauperism, and Benevolence, the schedules for which come from the various institutions, says in a most interesting document on the general features of the Census: "The essential difference between the Eleventh Census and that which preceded it was the adoption of the card system for the tallying of results and the use of the newly invented Hollerith electrical machine for counting the cards. Too much cannot be said in praise of this machine which has enabled us to compute results with much greater rapidity and accuracy than by the old method of tallying, besides giving the opportunity to make a much more thorough analysis of the figures." Mr. Wines remarks on the striking manner in which the cards become endowed with meaning and attributes, and adds that for the computer, "a card which means nothing to the uninitiated is converted into a pauper or a criminal, whose sin and suffering are as palpable as if the man himself were bodily present in the room."

It will be obvious that the special use of the Hollerith machine for mortality, crime and pauperism figures renders it equally available for other work. It would easily group, classify, and sum up, for instance, the multitudinous details of telegraphy, telephony or electric light and power. As a matter of fact, it has for some time past been in use by the Board of Health of New York City. This general utility of that which has given such remarkable proof of its ability in the Eleventh Census was recognized by the Franklin Institute, in conferring on Mr. Hollerith the Elliot Cresson Medal. The Committee on Science and the Arts of the Institute, after seeing the system in operation at Washington, said: "They are of the opinion that it is invaluable wherever large numbers of individual facts are to be summed and tabulated. They consider that the inventor is deserving of the greatest commendation for this useful and novel application of electricity, and strongly recommend that he be granted for his invention the highest award in the gift of the Franklin Institute."

But perhaps the most practical demonstration of the value of the Hollerith system is its adoption by the Governments of Canada and Austria for their respective censuses. This is the solid appreciation that an inventor most enjoys.

XIV.

It might seem that to have invented such a system as has been described, by which a great nation has been counted for the first time by electricity, is glory enough. But Mr. Hollerith, who, by the way, is a Ph. D. of Columbia College, is the patentee of the inventions upon which the Carpenter electric braking system is based, and has now worked out a novel and valuable integrating device which is deserving of description. In the compilation of census statistics, such as those of population, mortality, etc., or the bulk of the work to which the Hollerith apparatus has heretofore been applied, the person forms the unit, so that each card represents simply that unit. But the census includes agricultural, manufacturing and similar statistics, and it is evident that in the figures of agriculture or manufacture, while a card might represent a farm or a factory unit, the *value* of that unit might vary greatly. Thus it might be a farm of a hundred acres or of five hundred, and we would thus have to record *amounts*. This can be readily done by such a machine as that here shown in Fig. 15. The cards could be punched, as already described,

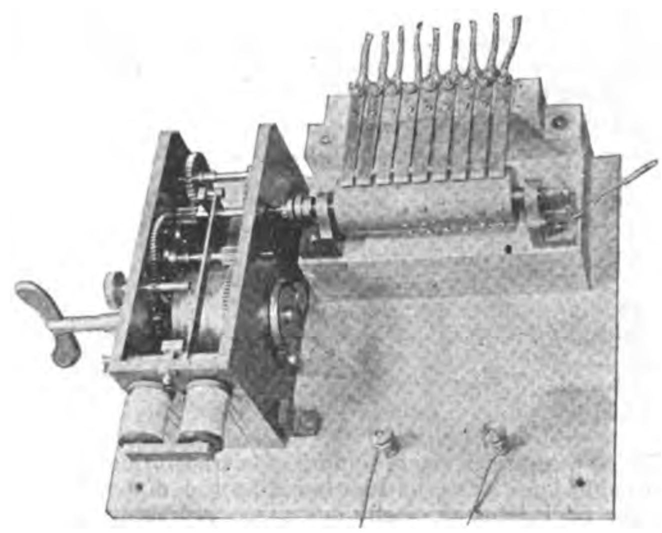

FIG. 15.—HOLLERITH INTEGRATING MACHINE.

but when they entered the tabulating machine, a dial would be energized and would operate not merely once, as in the ordinary population statistics, but would count from one to nine, according to the value of the hole, the counting being determined, as before, by the location of the hole. The device consists, broadly, in a cylinder around whose circumference studs are set; spring contact points connected to the mercury cups of the press; a motor for revolving the cylinder in conjunction with a train of ordinary registering mechanism, and a device for starting the motor so that the cylinder will make one revolution. The operation can be readily understood. A card being put in the press, the circuit is closed through a given counter to the battery, to the cylinder of the integrating device, from one of the nine contact strips of the integrator through the corresponding mercury cup uncovered by the punched hole of the card through the plunger of the pin box corresponding to that hole, and back to the counter. At the same time another circuit is closed through the magnet, when the handle is brought down, which allows the train to revolve the cylinder of the integrating device one revolution. During that revolution the circuit through the dial counter will be made and broken from one to nine times, according to the contact strip which is brought into operation. Any number of counters can thus be operated at the same time, they being connected in multiple arc. The registration thus secured gives totals from any number of different sizes or amounts, and the device, therefore, answers a most useful purpose.

XV.

Not a little skill and judgment was necessary in perfecting the mechanical details of the Hollerith electric tabulating system that has been described above, and Mr. Hollerith freely acknowledges his indebtedness for the assistance of the manufacturers who built his apparatus. To the Pratt & Whitney Co., of Hartford, Connecticut, he wisely entrusted the development and construction of the keyboard punches, and Mr. George M. Bond, the well-known expert of the concern, gave the work his direct personal supervision from first to last. The electrical apparatus is the production of the Western Electric Co., whose New York representatives, Mr. H. B. Thayer and Mr. Nickel, as well as others, took a deep interest in its refinement and perfection. Of course the work itself, which will continue at the Census Office for some time yet, is watched over by Mr. Hollerith, who is under contract to the Government to furnish the apparatus and maintain it in an efficient state. It may be added that the current for doing the work is derived from the local Edison lighting circuits in Washington, being first passed through a small set of Electrical Accumulator Co.'s cells grouped in a corner of the basement, with the usual attachments for charging in series and regrouping in multiple, as well as for making tests to see that they are up to the requirements of the daily work.

THE MEASUREMENT OF THE LOSS BY HYSTERESIS.

BY

Thos Spencer

It is necessary in the designing of a transformer that a thorough knowledge of the losses in the material used should be known, especially one which represents such a large part of the total loss as that by hysteresis. The loss from this cause varies greatly with the kind of iron used, and also has different values for different maximum inductions in the same sample of iron. Prof. Ewing, who is in a great measure the father of this subject, has given us several tables where the loss in watts per unit of volume is given for different kinds of wire for various maximum inductions, which have been very useful to the engineer. These tables were calculated by measuring the area of his celebrated hysteresis curve; for each value given in the tables one of these curves had to be plotted from a great many observations. Now what is wanted is some method which will abridge some of this work, and one which will not require such care to get accurate results.

The method I propose is based on two especially-designed electro-dynamometers, the general arrangements of which, as well as the electrical connections, are shown in the accompanying engraving. The dynamometer A has a double stationary coil of an equal number of turns, and a double suspended coil, also of an equal number of turns, rigidly connected together so that they will turn as one coil, but so arranged by means of the four mercury cups as to be electrically independent. These coils are each connected in series with one of the fixed coils; also they are connected with the two coils on the test ring P and S, which we will call the primary and secondary, having an equal number of turns.

The current which is supposed to be located at C must be an alternating current of known period and one following the sine law as nearly as possible, and should be so arranged as to be controlled by a rheostat so as to obtain the greatest possible range of readings.

The second dynamometer B has its stationary coils precisely like A, but its suspended coil is single, and through this coil the secondary current alone passes. The connections of the stationary coils can be seen from the figures. Now Maxwell has shown in his "Treatise on Electricity and Magnetism" that the energy stored in an electromagnet per unit of volume, if the magnetic force H and the magnetic induction B have the same direction, is equal to $-\frac{1}{8\pi} HB$. Now if we designate this value by E, we have for the increment of energy per unit of volume

$$d\,E = -\frac{1}{8\pi}(H\,dB + B\,dH).$$

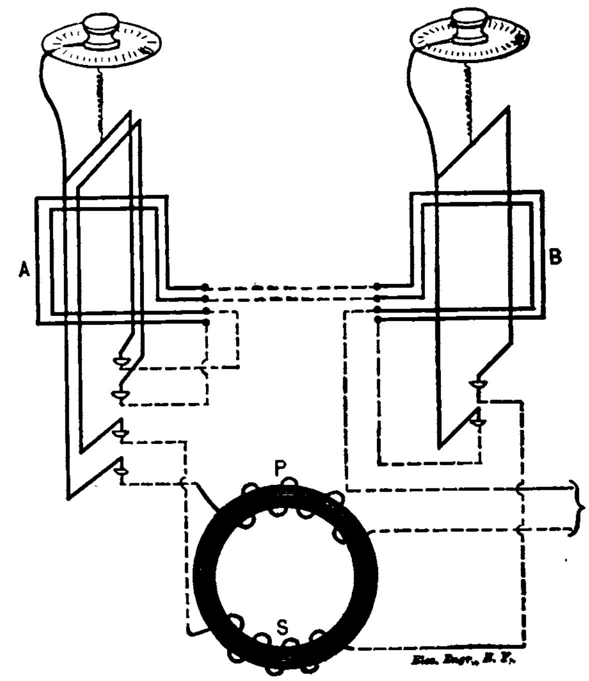
Now if we integrate this equation for Prof. Ewing's cycle, we see that

$$\int H\,dB = \int B\,dH,$$

because both stand for the area of the same closed curve, and therefore are equal to each other, and we have

$$E = -\frac{1}{4\pi}\int H\,dB.$$

Now as the current is alternating B is a function of the



ARRANGEMENT OF APPARATUS FOR THE MEASUREMENT OF THE LOSS BY HYSTERESIS.

time t, and if we represent by E^1 the loss in watts per unit of volume per unit of time, we have,

$$10^7\,E = -\frac{1}{4\pi}\int_0^1 H\frac{dB}{dt}\,dt, \qquad (1),$$

Referring again to the figure and defining the following symbols:

i_1 = Primary instantaneous current in amperes;
i_2 = Secondary instantaneous current in amperes;
N = Number of turns in the primary or secondary;
R = Resistance of secondary current in ohms;
C = Mean circumference of the test ring in centimetres;
s = Curve section of test ring in square centimetres;
α = Constant of the dynamometer A;
θ = Angle through which the torsion head is turned in A;
α^1 = Constant of the dynamometer B;
θ^1 = Angle through which the torsion head of B is turned.

Now we have for the dynamometer B,

$$\int_0^1 (i_1 + i_2)\,i_2\,dt = \alpha\,\theta. \qquad (2)$$

But we also know that

$$\frac{4\ \pi\ s\ N}{10\ C}\ (i_1 + i_2) = H, \tag{3}$$

remembering, of course, that H and B stand for the instantaneous values of these quantities.

Also we have, assuming that the secondary has no self-induction,

$$10^8\ R\ i_2 = S\ N\ \frac{dB}{dt},$$

substituting these two equations in (2) we have

$$\frac{1}{4\ \pi}\int_0^1 H\ \frac{dB}{dt}\ dt = \frac{10^7\ R\ \alpha}{C}\ \theta.$$

Comparing this with equation (1) we see that

$$-E^1 = \frac{\alpha\ R}{C}\ \theta. \tag{4}$$

For the dynamometer A, we have

$$\int_0^1 (i_1 + i_2)^2\ dt = \alpha^1\ \theta^1;$$

that is, by (3),

$$\left(\frac{10\ C}{4\ \pi\ S\ N}\right)^2 \int_0^1 H^2\ dt = \alpha^1\ \theta^1.$$

But assuming that H is a simple periodic function of the time whose maximum value is H^1, we have

$$H^2 = 4\left(\frac{\pi\ N}{10\ C}\right)^2\ \alpha^1\ \theta^1, \tag{5}$$

Equations (4) and (5) furnish us (ignoring the minus sign of E^1 in (4), a means with these special forms of dynamometers of finding the hysteresis loss for any given magnetizing force.

It can be easily seen that as i_1 and i_2 have phases differing by 180°, that $i_1 + i_2$ is very small in comparison to i_1 or i_2. So it is advisable to use as little iron (which, of course, must be laminated) as consistent with good results, and also to take the precaution to make the dynamometers with as large a current capacity as can be done without much reducing their sensitiveness.

ELECTRIC ANNEALING OF STEEL WIRE.

The electric current has been utilized since 1889 at the small arms factory at Saint-Etienne for annealing the steel wire of which the hammer springs of the rifle, 1886 pattern, are made. These springs are manufactured of steel wire, 7 millimetres thick, cut in lengths of 3.20 metres; the wire is rolled spirally, and a current of 23 amperes is passed through it. Heating is rapidly effected; when it is judged sufficient, the circuit is opened, and the hammer-spring is dropped into a water-tank. One man can anneal 20 springs in three minutes, equivalent to about 2,400 per day. Electric annealing being clean in operation, and cheap, will, no doubt, soon be applied in numerous cases analogous to the one indicated.

A NON-ELECTRIC INCANDESCENT PLATINUM LIGHT.

In a note in the *Comptes Rendus* of September 14th, M. Paquelin describes an incandescent platinum light devised by him. The apparatus consists of a strip of platinum coiled on itself and placed in a platinum bowl with a hollow stem. A gaseous mixture of air and some hydrocarbon vapor is then introduced under pressure in suitable proportions. The mixture is set alight, the flame disappears, and the platinum strip incandesces, the incandescence being the more intense the greater the pressure. With moderate pressures the light is comparable with that emitted by an electric lamp. The whole apparatus can be plunged into water without the light being extinguished.

SMALL ELECTRIC LIGHTING PLANTS FOR RESIDENCES.

BY

H. C. Dodge

There is a public want in the line of electric lighting that does not seem to have been fully met as yet, though it is a very simple matter. There are a great many dwellings and other buildings in cities, even where there is an electric light plant, in which the lights cannot be used because of the failure of the company to extend its wires anywhere except along the business streets and in a few of the more densely settled residence streets. Besides these, there are thousands of suburban residences, stables, shops, etc., in which people would like to use incandescent lights, if they could have them at a reasonable rate.

I have seen some indefinite statements floating about from time to time in the press, like clouds in the air, that where gas exists the electric light can be produced as cheaply, or even more so, than by using the gas direct, the idea being to use the gas in a gas-engine to drive a dynamo, and thus produce the electric light. Now, as gas can be had in all cities and large towns, and as by the use of portable gas machines it can be furnished in any suburban or country house, if the above statement is reliable, there is no longer any reason why everybody who desires it should not have electric lights.

But is it true? That's what the public wants to know—not by mere newspaper assertion, but by actual demonstration, with all the attendant facts and data—not theoretically on paper, but by actual tests, sufficient in extent to settle the question beyond doubt, that the public may have reliable information on which it can depend.

Now it has occurred to me that here is a field that some of our electrical companies can occupy to advantage. It would be an easy matter for them to conduct a series of experiments and ascertain exactly and fully just what can be done in that line. What is wanted is a complete plant for, say, from fifteen to fifty incandescent lamps. It should include the gas-engine, the dynamo, and the necessary shafting and belts, all ready to set up and run. The cost of the average quantity of wire and lamps, and the cost of putting them in, the companies know now, near enough for all practical purposes. If some company will take this matter in hand, conduct the necessary experiments, give the public the facts, keeping well within bounds as to the actual facts and cost, and then make a specialty of manufacturing and setting up such plants, I think a large trade could soon be built up. Not only that, but very many would want small motors for operating fans in hot weather, and for many other purposes. Of course, the apparatus should be of the simplest and most durable construction, more especially as in most cases they would be run by persons who are not skilled engineers.

It may be that this ground has all been gone over, and that such plants are already on the market, but if so, I am not aware of it.

In many cases where but few lights are required, wind wheels may be substituted for the gas-engine, but in that case a storage battery would of course be necessary, and hence the statement should include these also, with full data not only as to first cost, but as to how long they can be used effectively, cost of renewal, etc.

While the first cost of fitting up would of course be more than with gas lights, still there are many persons who would be willing to pay a reasonable additional amount because of the many advantages of the electric light.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, *150 Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XII. NEW YORK, NOVEMBER 11, 1891. No. 184.

The thread which was spun in darkness by those who sought a perpetual motion has conducted us to a universal law of nature, which radiates light into the distant nights of the beginning and the end of the history of the universe.—Helmholtz.

THE COLUMBIAN ELECTRICAL CONGRESS.

MR. J. Allan Hornsby, secretary of the Chicago World's Fair Department of Electricity, has just returned to this country, after a visit to Europe made specially with the object of studying the Exhibition at Frankfort, arousing interest in our own fair among the electrical manufacturers of England and the Continent, and of ascertaining the prospects of the Electrical Congress that is to be held in Chicago in 1893.

The report presented by Mr. Hornsby to Director-General Davis gives an excellent idea of the main features of the display at Frankfort, and is deservedly complimentary to the taste and skill shown in making the various exhibits. But the chief interest of this part of the report lies in the statements made as to the prospects of exhibits being made at Chicago by foreign houses. Mr. Hornsby is able to report that England will be represented by Siemens Bros., the Crompton Co., Mather & Platt, and Woodhouse & Rawson; Germany, by Siemens & Halske, Schuckert & Co., W. Lahmeyer & Co., O. L. Kummer & Co,. Helios Co., of Cologne; the Maschinen-Actien-Gesellschaft and the Allgemeine Elektricitäts-Gesellschaft; Switzerland, by the Oerlikon Works and Alioth & Co.; Belgium, by the Société l' Électrique and the Société Le Phenix, of Ghent; Austria, by Ganz & Co.; France, by Victor Popp & Co., Sautter, Harle & Co., Carpentier & Co., and Breguet & Co. To these may be added a number of makers of miscellaneous apparatus, and we have no doubt that the efforts of the European Commissioners who have now visited this country will lead to a great increase in applications for space.

What Mr. Hornsby says about the Electrical Congress is quite important. After seeing several of the leading electricians and electrical engineers of Europe, he says: "In arranging for such a congress as these men deem it necessary to have, they think the United States Government ought to father the invitations and that it ought to be held under Government auspices; that invitations ought to be issued to individual scientific men of the world by the United States Government through the government to which the individuals belong. This course of action, the gentlemen say, will insure an official character to the proceedings of the scientific congress, and will virtually pledge the various governments to a recognition and adoption of the standards created." This line of action, it is urged, will secure the co-operation of men without whom the congress would fall flat and fail of its purpose. Mr. Hornsby has put the case none too plainly, and we believe with him that success will be reached in just this way. It was thus that the last Electrical Congress was held in this country—that of 1884—and very much the same policy should be pursued now that was adopted then. The principal difference between then and now is that, while electricity at that time was largely a theoretical science without any representative organization, there is now a great electrical engineering profession which finds its exponent in the American Institute of Electrical Engineers.

CENSUS-TAKING BY ELECTRICITY.

OUR pages contain this week a description of the manner in which the Census of 1890 has been counted by the ingenious Hollerith electric tabulating machine. None but they who have seen the apparatus can realize the ease and accuracy with which it performs its task, dealing with the utmost facility with the most complicated combinations of statistical data. It will be remembered that in various quarters no little fault has been found with the census taken under the supervision of Mr. Porter. Possibly these criticisms may be well based so far as the selection of the local enumerators is concerned, and possibly all these enumerators did not perform their duty as well as might have been wished, but when it comes to the counting inside the Census Office, all we have to say is that we do not believe it could be better done than in the manner devised by Mr. Herman Hollerith. And this is said with the more emphasis because some of the bitter articles in the daily papers have been enough to lead one to think that, after all, the political bias shown in them might be justified by shortcomings in the methods adopted and in the failure of electricity to execute the great task laid upon it. So far from proving inadequate, the Hollerith system has more than fulfilled its promise, and in one important department alone effected a saving of 40 per cent. above the estimate of the expert commission that recommended its adoption.

Now that census authorities have had such admirable apparatus placed at their disposal, it is to be hoped that a permanent Census Bureau may be established, and a permanent staff be formed. The necessity of such a bureau is seen when men like Gen. Walker and Col. Carroll D. Wright join hands with Mr. Porter in efforts to secure it. It is painful to reflect that, in spite of the money and pains spent on the Census of 1880, the elementary information obtained by it as to the number of married and single people has never been elicited! Electrical people have lately had an experience of this kind in the starting out to secure electrical data and then the proposal to let the work drop to the ground because time and money were wanting. It seems to us that it would be nothing more than fair if part of the money saved by the Hollerith electric tabulating system were devoted to the perfection of the electrical census, giving us for the first time in history trustworthy figures as to the industry; and that the remainder were spent in founding a permanent bureau which shall give every industry and society at large, at all times, the data and statistics which, if rightly collected and interpreted, must be at the basis of all successful work and all intelligent advance.

THE ELECTRIC LIGHTING OF SUBURBAN RESIDENCES.

While the manufacture of small dynamos for isolated plants has been undertaken extensively by several electric companies both here and abroad, the suggestions of Mr. W. C. Dodge, which appear on another page, are novel in that they contemplate the combination of a small gas engine, requiring no expert attendance, and a dynamo of just sufficient capacity to supply the house, stable or shop in which it is placed. It would be both interesting and instructive to know just how economically such a plant could be operated. Mr. Dodge's windmill idea hardly seems feasible in this latitude, although such a combination might be advantageously operated in the region of the Trade Winds. The pros and cons of the matter, however, we leave to the reader, with the hope that the data asked for by Mr. Dodge may be forthcoming. Some of the gas engine isolated plants are said to make an excellent showing.

OVERHEAD ELECTRIC RAILWAY CONTACTS HERE AND ABROAD.

The earliest electric railways employing the rails as conductors and operating at low potentials naturally required a firm and positive contact, and the brush or sliding contact was applied for that purpose with good results. When the construction of overhead railway conductors was inaugurated a differentiation was developed in the practice of American and European—especially German—constructors. While Americans at once adopted the trolley wheel and have continued its use and are likely to retain it indefinitely, the Germans began with the sliding contact and appear still to favor this form. The Siemens & Halske electric road, at Frankfort-Offenbach, built in 1884, it will be remembered, was equipped with a slotted tube-conductor with internal slider, and is still in operation. Notwithstanding the extended and successful application of the trolley wheel on American railways since that time, Siemens & Halske still adhere to the sliding contact as exemplified in the road recently operated in connection with the Frankfort Exhibition. The illustration of the method of obtaining contact, which we give in another column, would hardly seem to bear out the statement that our methods, in this respect at least, are crude and unsightly. From an æsthetic point of view, the graceful trolley-pole is certainly to be preferred to the latticed support and wire-frame contact device. Aside from this point of appearance, however, we believe the sliding contact in general to be an unnecessary refinement, and that where one trolley wheel is insufficient to carry the current without undue overheating, a double trolley wheel will answer the purpose completely. The old overrunning trolleys were double-wheeled, but chiefly with the object of keeping them on the wire.

The Southwick Cookery School.

At the time of the recent electrical executions in this State, with their details of the manner in which the bodies of the criminals were affected by the current, a few remarks were made in these columns as to the features of the baking and boiling that were part of the operation. Our comments were satirical, or meant that way, but we now find that Dr. Southwick really intends to establish a cookery school so that he may learn how to do condemned men to a turn. His own language is: "The tendency of the electric current to hesitate in its flow through the human body and to develop arcs on the surface and so make the flesh boil or burn is what I am trying to overcome. Electricians have insisted that in this I shall not be successful, but I believe they are wrong." This is rather amusing, to say the least, in view of the strenuous denials that the bodies of the men executed were damaged or mutilated. It is stated by the *Buffalo Commercial* that Dr. Southwick has been experimenting with raw beef and now proposes to try conclusions with a calf. We are not aware as to the number of men and "lower" animals yet submitted to gerricide, but so far the lower animals have had much the worst of it, in the proportion perhaps of four to one. Hanging is at least preferable on the ground that when a murderer is strung up it is not necessary to hang half a dozen cows and horses with him to make sure he is dead.

The Measurement of Hysteresis.

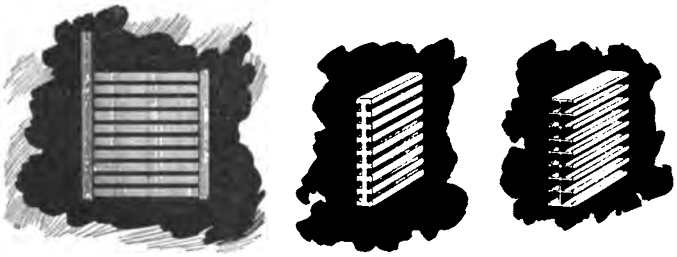
The importance of taking into account the work absorbed in overcoming the hysteresis in iron used in the construction of alternating-current machinery is too obvious to require further comment, but the actual methods employed have involved difficulties which may have deterred many from undertaking these important tests. The method described by Mr. T. Spencer in this issue, although involving two electro-dynamometers, is quite simple and, taken in connection with Mr. C. Steinmetz's work, which has appeared in our columns, affords an opportunity of determining and applying the results with the least expenditure of time.

THE ACCUMULATORS AT THE FRANKFORT ELECTRICAL EXHIBITION.—III.

BY

Dr Paul Schoop

THE most original exhibits are those of the firm of De Khotinsky, of Rotterdam. The lead supports for the paste, or active material, are not grids, and are not made by casting, but consist of lead strips made by pressing lead through a die. The mode of manufacture is the same as that of the



FIGS. 14, 15 AND 16.

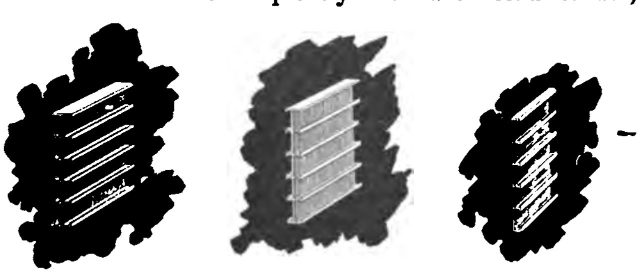
old Tudor plate. These strips are connected in two different ways. In the old way of connection the strips were laid horizontally in flat earthenware vessels, separated by glass rods. The new mode of connection consists in forming vertical plates out of such strips, as shown by Fig. 14. The strips are laid beneath each other, leaving a small distance between for expansion, and soldered or cast together at both ends by cross-bars. A number of such plates are then combined to form a positive or negative section in the same way as done with the old E. P. S. cells. Fig. 15 shows piece of strip for positive (oxidized) plates of long life and great durability.

Fig. 16 is a lead support for negative (lead-sponge) plates, as commonly used for batteries for all kinds of work.

Fig. 17 is a support for positive (oxidized) plates for the same purpose.

Fig. 18 is intended for positive plates for high rates of charge and discharge.

Fig. 19 is intended for negative plates for high rates of currents in charging and discharging; this special sketch shows an end plate. The strip is provided only on one side with ribs and consequently also with lead oxides,



FIGS. 17, 18 AND 19.

while the other side having no opposite positive plate, remains idle.

No doubt the Khotinsky lead strips do not cost half as much labor as cast lead-plates do, but only comparatively small strips can be easily obtained, and these have to be soldered together to form a plate.

Mr. Ch. Pollak, of Paris, has gone a step farther in this direction and makes lead sheets suitable for lead-oxides in the cheapest possible manner. Sheet-lead of, say, $\frac{1}{8}$ to $\frac{1}{4}$ inch thickness is passed through rollers of most ingenious construction, and so provided with numerous corrugations. After the sheets are cut into suitable shape they may be filled with paste and built up into elements. This mode of manufacture allows quite new and original departures from the accustomed methods of construction. Fig. 20 shows a front view of a piece of Pollak plate. With the Pollak plates the cost of the mechanical part of a cell ought to be reduced considerably. Fig. 21 shows the projection enlarged.

While all the described systems of batteries are only exhibited at Frankfort in regard to lighting purposes, we may now consider more closely the exhibits of the Oerlikon works, near Zürich, which are to demonstrate the practicability of storage batteries for driving electric launches, street car work, and the lighting of railway coaches; in short, for all cases where a battery is not always standing at the same place. It has ever been a difficult task to move whole batteries without spilling the acid. We must remember that such transportable cells must evidently not be provided with hermetically sealed covers since the development of gas bubbles has to be taken into account. The breaking of *one* jar or vessel is sufficient to destroy the insulation of the whole plant, and to necessitate expensive repairs and give trouble. This is also true of primary batteries.

Now, with the Oerlikon batteries the use of pure dilute sulphuric acid as an electrolyte is abandoned, and instead, a stiff, thick, gelatinous mass is applied to them. According to information contained in the price-lists of the Works, this gelatinous mass is obtained as follows:

Dilute sulphuric acid is mixed with the proper amount of a solution of silicate of soda or silicate of potassium

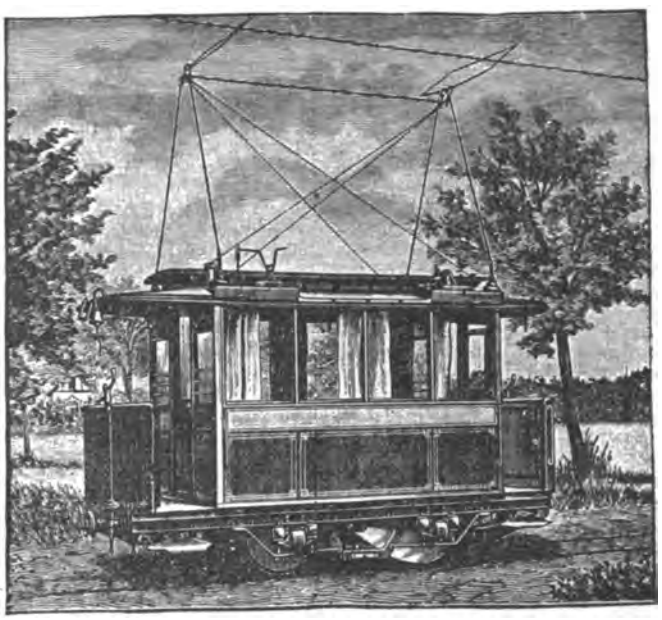
FIGS. 20 AND 21.

and some asbestos fibre. This mixture, at first fluid, becomes stiff after a short time, and is filled into the vessels containing the lead electrodes in the same way as has always been done with the pure dilute sulphuric acid. A cell filled thus may, after some hours, safely be reversed, holding the top of the cell downwards without spilling a single drop. But even this is not the best part of it. According to the use and destination of the cells, the dilute acid may be gelatinized in such a manner that the falling out of the active material from positive or negative electrodes is impossible. This seems very practical indeed at first sight, but how, if such a battery is overcharged occasionally, shall the gas bubbles find their way out of this stiff gelatine? This question is soon solved by observing the cells towards the end of charging; a lot of gas is evolved and escapes *between* the lead-plate and the stiff, but plastic, electrolyte. A split is formed, if large gas bubbles are escaping along the surface of the electrode, and as soon as the gas has escaped the gelatine again adheres to the plate. The manufacturers of this gelatinized battery claim a number of advantages for it, of which we may mention greater reliability, as short-circuits in the interior of the cell are impossible; more work per unit of weight (very heavy currents for charging or discharging) without subsequent rapid deterioration of the plates, because the gelatine not only causes a better distribution of the current all over the surface of the plates, but also allows this departure in the manufacture of the electrodes, and that the material to become active may be applied to the grids in as porous a state as desirable for such purpose.

THE SIEMENS AND HALSKE OVERHEAD SYSTEM AT LICHTERFELDE.

The London *Electrician* of Oct. 23 contains an article on the Siemens and Halske overhead system in operation at the Frankfort Electrical Exhibition, from which we reproduce the accompanying illustration, and quote as follows:

"The chief feature about the line is undoubtedly the simple and convenient system hit upon for making the contact with the overhead wires. Contact is made by means of a steel arm of T shape. The breadth of the arm is about the same as that of the tram, and the arrangement has a very neat appearance. The tram runs with the upper part of the arm lagging a little behind and pressing up on to the wire. When the tram reaches a terminus, the arm will therefore be leaning towards the direction in which the tram is going next; and at starting, the friction against the wire tends to keep the arm back, and the car gliding under the arm, forces the wire upwards for a moment until the arm is in the right direction for the return journey. The arm is kept pressed against the wire by the action of two spiral springs fixed on the axis of the T-piece, and also by the weight of the rod frame, the centre of gravity of which is below the horizontal axis. The arm occasionally jumps for an instant away from the wire at the joints. But, as the greatest current used is not more than 40 amperes, the sparking is not very formidable, and could have



Siemens and Halske Overhead System.

been cured almost entirely by the use of two arms such as were used on the cars made by this firm for the tramway at Lichterfelde, an illustration of one of which is given. The arms in this case, however, though similar in principle, are of a different and perhaps less elegant form.

It may possibly be thought that the contact cross-bar of the arm here described would soon wear away; but this has not been found to be the case. It is found that sidings do not offer the least trouble as far as the overhead contact is concerned."

HOLLYWELL'S ELECTRIC WELL.

A dispatch from Minneapolis of Nov. 2 gives the following account of a startling discovery. Now that natural gas wells are drying up, these new electric wells will come in very handily: "Charles J. Hollywell, who owns a farm near Red Wing, claims to have discovered what may be called an electrical well. Some weeks ago he employed two professional well diggers to drill a well. They had gone about 150 feet when they lost their drill rods and a diamond drill. The whole business had dropped to nowhere in an instant. There was quite a force of air coming out of the hole, and the men said there was no use going any further, because there wasn't any bottom. They concluded to fish for the rods and drill, but as soon as the rods were dropped into the hole they began to shiver in a queer way. One of the men took hold of the bar with a pair of leather gloves, and he was knocked down. Then Hollywell touched the rope and got a shock because it was wet. There seems to be a perfect natural storehouse of electricity. It is generated in some way in that pocket where the drills went, and there is enough of it to execute a whole county at once under the New York law."

Reports of Companies.

FORT WAYNE ELECTRIC CO.

The Fort Wayne Electric Company offers stockholders the right to subscribe to 80,000 shares of Fort Wayne trust securities, series A, at $6.50 per share, in proportion of 1 share to every 2 shares of Fort Wayne stock held. Rights expire Nov. 10; those not taken will be sold by public auction Nov. 11. The company has received an offer at subscription price for all stock not taken Nov. 12. The company has transferred to the American Loan and Trust Company as trustee a little over $800,000 of mortgage bonds, bearing 5 and 6 per cent. interest, and about $700,000 of stocks of various companies, acquired in the natural course of its business. It is expected that after the first 90 days of the operation of the trust the trustee will be able to disburse quarterly dividends at a rate of 12 to 15 cents per share.

Appointments, Etc.

Mr. B. J. Jones has been appointed general superintendent of the Riverside Park Railway Co., of Sioux City, Ia., vice C. W. Rickard, resigned, taking effect November 1.

Mr. R. J. Sherrill has resigned his position as superintendent of the Asheville, N. C., Light & Power Co., and has entered the service of the Edison Electric Co., at Schenectady, N. Y.

Mr. J. Knapp Ford has been appointed electrician and superintendent in charge of the West Troy, N.Y., electric light plant to succeed Wm. Waldron, resigned.

Mr. L. K. Perot, lately of the Thomson-Houston Co., has been appointed assistant engineer of the Equitable Engineering & Construction Co.

Mr. Irving W. Blake, of the Perkins Lamp Co., of Manchester, has joined the forces of the Mather Electric Light Co., in Chicago.

Mr. H. D. Halstead has been installed as electrician of the electric light plant at Milford, Mass.

Mr. Fred. Young has been appointed superintendent of the Willimantic, Conn., Electric Light Co.

THE PROPOSED PACIFIC CABLE.

The United States Fish Commissioners' steamer Albatross, which has been taking soundings in connection with the laying of the proposed cable between the United States and Hawaiian Islands, has returned to San Francisco. Silinas Landing, in Monterey Bay, is regarded as the most suitable landing place for the United States end of the cable.

Legal Notes.

STORAGE BATTERY PATENTS—JULIEN vs. ELECTRICAL ACCUMULATOR CO.

When the decision was given in the United States Circuit Court by Judge Coxe granting a permanent injunction against the Julien Electric Company from infringing the patents of the Electric Accumulator Company in using storage batteries on street cars and in other places, the defendants asked for a re-opening of the case on the ground that a Spanish patent of the Accumulator Company, by expiring, had invalidated their patents in this country. The Accumulator people said that it was a different patent. Judge Coxe decided on November 4, that the injunction must stand.

THE RANKIN KENNEDY ALTERNATING PATENTS.

The Marble City Electric Light Co., of Rutland, Vt., has filed its answer in the suit recently brought against it by the Westinghouse Company, alleging infringement of the patent of Rankin Kennedy for method of electrical distribution by transformers connected in parallel. The answer is in effect a general denial both of the validity of the patent, and of the allegation of infringement. In addition to numerous prior patents and publications, prior knowledge and use of the inventions is alleged on the part of W. K. Freeman, M. M. M. Slattery, T. A. Edison, Elihu Thomson, W. Stanley, Jr., R. M. Hunter, E. E. Ries and others.

OVERHEAD RAILWAY CIRCUITS—THOMSON-HOUSTON vs. ELECTRIC MERCHANDISE CO.

THE Thomson-Houston Electric Company last week began suit in the United States Court against the Electric Merchandise Company, of Chicago, to enjoin an alleged infringement of patents for overhead conductors and switches for electric railways. An injunction restraining the use and manufacture of the devices is asked.

Personal.

MR. WILLIAM DIERMAN, C. E., of Belgium, is now in this country, having been specially commissioned by the Belgian Government to make inquiry into the condition of the electrical industries of America. Mr. Dierman, during his stay of two months, will investigate the leading light and power systems, and visit various roads and plants, etc. Mr. Dierman, it is interesting to mention, is a graduate of the Montefiore Institute in Liege, among other seats of learning in Belgium and France, and enjoyed the instruction of Prof. Eric Gérard, so well known here and abroad in electrical science. Mr. Dierman is now in the active practice of his profession as a civil and electrical engineer, and will, when he leaves, be able to make a comprehensive and valuable report.

Letters to the Editor.

NOTE ON THREE-PHASE ALTERNATING-CURRENT MOTORS.

IN view of the marked interest which is now being taken in the three-phase alternate current motor, I would call attention to the fact that on looking over some old correspondence I find a letter written to me by Dr. Louis Duncan, of Johns Hopkins University, November 1, 1888, in which the following occurs:

"Do you know how the Tesla motor works? How does this strike you for a modification to be used with an ordinary alternating circuit?" [Here follows a diagrammatic figure of the field magnet of an alternate-current motor].

The letter then goes on to say: "What we want is a rotating field of force. Take a set of magnets, 1, 2, 3 (1', 2', 3', are the opposite sides); bring the main circuit to 1 and take it around 1 and 1'; then back. Then make the circuit of 2 and 2' around 1 and also 2, inducing in it a current of different phase from 1; make 3 a secondary of 2; adjusting the self-inductions and *R*'s so that the difference of phase in each is 60° at, say, full load. We have a rotating field as Tesla has, and can put in a closed circuit armature and get the same results. But I am doubtful if the relation of the phases of 1, 2 and 3 will be even approximately constant at different loads."

FRANK J. SPRAGUE.

NEW YORK, Nov. 6, 1891.

THE EDISON ELECTRIC RAILWAY SCARE.

IN your issue of the 4th inst. I find under "Letters to the Editor" an article headed "The Effect of Newspaper Inventions," as also your editorial on the same.

As one interested in electric railway construction in all its branches from the rail to the trolley wire, I would ask your indulgence and consideration wherein I differ from your views of the "effect of newspaper inventions." While you very kindly try to find an excuse for Mr. Edison, and say that "it is hardly fair to hold Mr. Edison responsible for the exaggerations and bulls crowded into these reports," the excuse is hardly well taken when it is currently reported that the articles are paid for and distributed throughout the country by the Edison General Company.

Your editorial goes on to say "if this talk arrests development the Edison General Company will suffer with the rest." Why, may I ask, should the "rest" be made to suffer with the Edison Co? If the machinery placed by them on the market and claimed to be superior to that invented and manufactured by them for that genius of electric railway locomotion, Frank J. Sprague, has left such superiority open to question and criticism by street railway managers, and which not even the name of the Wizard Edison attached to the same has been able to supress, why, may I ask, is it necessary for a company to use such methods, unless the reports are circulated to gain time? If this be the case, it is possibly the most natural thing they would do.

What the new system of electric railway locomotion is we are left to guess. Not even those who are familiar with the business are given any inkling of what it may be. Possibly Mr. Leo Daft, were he now in the East, could tell us something about the new system. The gullible public are ready to believe almost anything. The force of this struck the writer on perusing the New York Sunday *Herald* of recent date, where in adjoining columns we find descriptions of the work of the Wizard Keely and the Wizard Edison. It is a usual thing when well-known men make statements to the public to receive them without question, and it is considered as good as done. Unless one is deeply interested, they are not apt to follow up or remember the names and predictions of the men whose words mean either successful accomplishment of what they have predicted or the names of the men whose words and predictions are simply made use of either to manipulate stock or afford time to produce or perfect something to take the place of that which has not fulfilled the requirements called for.

I have a hazy recollection of seeing printed in newspapers articles similar to that with which the country has recently been flooded, describing the system of telegraphy from moving trains. Every train was to be fitted in such a way that we could telegraph to our friends and telegraph our business as we were whisked across the country. Similar printed statements of how we were to talk into a phonograph and do all our correspondence with little wax cylinders, revolutionizing the entire methods of conducting business and social correspondence, are still fresh to the memory of all. The dream of direct production of electricity from heat all passes before me. How successful and practical they have been the public are the judges. When men whose names are familiar to us do not carry into execution what they predict, and in doing so injure those who do, it is excusable to raise our voice in protest of such methods. You, no doubt, "see not the slightest reason why any railway project entered upon or even broached should not be carried to the conclusion," which, curiously enough, follows with this sentence, "When Mr. Edison puts his plant on the market it will be time enough to discuss its actual effect." Unfortunately you do not seem to have been in the place of a railway president or manager endeavoring to convince his board of directors and stockholders to the adoption of electric propulsion and use of present designs of motors, when these gentlemen are already skeptical and purse strings tight, without having arguments brought forth against their equipping backed up by statements of the Wizard Edison.

You seem ignorant of the fact that city councils are now opposing the passing of overhead ordinances for overhead wires, on the ground that the Wizard Edison has stated that there is no need for overhead wires. While it is impossible to reach the public with the true facts and status of the electrical business, yet it is within the province of our trade journals to assist in stopping such peculiar attempts made by one unsuccessful branch of the business to injure others which are successful. We know the power of the daily press; we also know the electrical trade press has power in its own field. Therefore, let it dare to do right and put the facts before its readers, which it may readily do by either sifting similar articles and explain the matter, or decry such methods with all the power that pen and printer's ink can supply.

REJECTED FRANCHISE.

CHICAGO, ILL., Nov. 6, 1891.

[Seeing that we expressly *deplored* the appearance of these rumors about Mr. Edison's electric railway work, we fail to see how our remarks can be twisted into "trying to find an excuse for Mr. Edison." But while *deploring* these rumors, we ventured to point out that the hopes or fears of many people had exaggerated the newspaper talk on the subject out of all proportion to its real importance. We do not know of a single electric railway project that has been abandoned because of these wild articles in the newspapers. If any have been, we would like to have the names furnished to us. As to its "being currently reported that the articles are paid for and distributed throughout the country by the Edison General Company," the "distribution" should be easily capable of proof; and we will be glad to receive the evidence and publish it. That the articles were paid for, might not be quite so easy to prove. The papers are the *New York Herald*, the *New York World*, the *New York Sun*, the *New York Evening Post*, and several others. Our readers can form their own opinion as to the "current report" that Mr. Edison bought these papers up, and further, as to whether the electrical press is also carried in Mr. Edison's vest pocket. The traditions and record of THE ELECTRICAL ENGINEER should at least protect it against such insinuations. As far as we are aware, the electrical press has generally "dared do right," when it came to a question of daring. That emergency does not seem to us to attend the present situation.—EDS. E. E.].

PHOSPHORESCENCE OF GEMS.

THE phosphorescence of gems under electric discharge in a high vacuum, which Prof. Crookes exhibited at the recent soirée of the Royal Society, London, evoked much admiration. Cape diamonds phosphoresce blue; Brazilian ones, red, orange, blue and yellow; Australian ones, yellow, blue and green. Crystallized alumina, that is to say, ruby, sapphire and corundum phosphoresce a deep red, and give a spectrum of a single sharp crimson line.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED OCTOBER 20, 1891.

Alarms and Signals:—

Non-Interfering Successive Signaling System and Apparatus, F. B. Wood, 461,464. Filed Oct. 24, 1890.
Relates particularly to fire and police systems.

Signaling Apparatus, C. T. Barrett, 461,518. Filed June 5, 1891.
Designed to notify, on the cars or engine of a railroad train, the condition of switch signals.

Bell-Ringing Attachment, W. W. Slater and H. C. Barnes, 461,718. Filed May 12, 1891.

Annunciator, L. F. Fouts, 461,748. Filed June 5, 1891.

Clocks:—

Electric Clock-Winder, J. W. and C. F. Du Laney, 461,423. Filed Feb. 12, 1891.

Circuit-Closer for Clock-Winding Mechanism, J. W. Du Laney, 461,424. Filed May 18, 1891.

Conductors, Conduits and Insulators:—

Composition of Matter for Insulating Purposes, M. O. Farrar and C. C. Howe, 461,467. Filed Mar. 6, 1891.
Consists of silica, alumina, peroxide of iron, magnesia, lime, soda, potash, water and asphaltum.

Insulating-Support for Electric Conductors, R. J. Hewett, 461,631. Filed July 30, 1891.

Electrical Conduit, E. T. Greenfield, 461,677. Filed May 11, 1891.
Claim 1 follows:
A conduit having interlocking sections and covers, in combination with individual spaced ducts surrounded with an insulating mass which unites the ducts and the conduit and holds the covers in place.

Dynamos and Motors:—

Field-Magnet for Dynamo-Electric Machines, F. J. Sprague, 461,552. Filed Jan. 19, 1885.
Claim 1 follows:
In a dynamo-electric machine, the combination, with the series of longitudinal plates forming a field-magnet core, of the outer clamping plates having extended portions and the cross-brace extending from one of said extended portions to the other.

Armature for Electric Motors or Dynamos, R. Lundell, 461,795. Filed Apr. 4, 1891.
Relates to mechanical construction.

Galvanic and Thermo-Electric Batteries:—

Thermo-Electric Element, C. W. Iden, 461,437. Filed May 13, 1891.
Relates to methods of jointing and connection.

Lamps and Appurtenances:—

Spring-Cushioned or Suspended Arc Lamp, C. F. Brush, 461,420. Filed May 26, 1890.

Arc Lighting System, R. S. Dobbie, 461,569. Filed Apr. 8, 1891.
Claim 1 follows:
The combination, with a circuit, of two or more arc lamps, each lamp having a shunt coil consisting of several sections acting together and connected with a like coil or coils in the other lamp or lamps.

Electric-Arc Lamp, A. Wirsching and R. Schefbauer, 461,659. Filed Nov. 15, 1890.
Relates to regulating devices.

Incandescent Double-Key Lamp-Socket, W. J. McCutcheon, Jr., 461,706. Filed Mar. 21, 1891.

Incandescent-Lamp Filament, J. T. Marshall, 461,797. Filed Nov. 9, 1885.
Claim 1 follows:
A carbon conductor for an electric lamp, having in combination a filament, enlarged ends for said filament, each composed of two pieces, electro deposits of carbon uniting such pieces together, and electro deposits of carbon uniting said enlarged ends to said filaments.

Measurement:—

Electric Meter, A. B. Herrick, 461,575. Filed Oct. 16, 1890.
Makes a periodic record.

Metal Working:—

Adjustable Transformer, E. Thomson, 461,526. Filed Apr. 17, 1889.
A transformer specially adapted for graduating the current employed in electric welding.

Miscellaneous:—

Electric Elevator, J. E. Byrne, 461,493. Filed Dec. 2, 1890.
Relates to means of actuation and control.

Electrical Valve-Controller, J. V. Stout, 461,554. Filed Mar. 26, 1891.

Shunt-Magnet for Valve-Controllers, J. V. Stout, 461,555. Filed July 1, 1891.

Electric Switch, A. Swan, 461,456. Filed Aug. 6, 1890.

Snap-Switch, H. P. Ball, 461,560. Filed Mar. 2, 1891.

Snap-Switch, H. P. Ball, 461,561. Filed April 19, 1891.

Thermal Cut-Out, L. B. Favor, 461,570. Filed Mar. 12, 1891.

Process of Purifying Bromine, J. C. Kautz, 461,681. Filed May 8, 1889.

Electric Switch, G. R. Lean, 461,761. Filed Jan. 17, 1891.

Automatic Electric Switch, S. Bergmann, 461,791. Filed Feb. 25, 1891.

Railways and Appliances:—

Electric-Wire Connector, G. R. Scrugham, 461,452. Filed June 15, 1891.
For trolley wires.

Contact-Plow for Electric Cars, E. M. Bentley, 461,548. Filed Nov. 21, 1885.

Conduit and Conductor for Electric Railways, W. H. Knight, 461,549. Filed Apr. 29, 1887.
Claim 1 follows:
The combination, in an electric railway, of a conduit formed of the upright slot pieces united to a common base, an electric supply conductor in the conduit supported from one of the slot pieces, and a contact device bearing on the under side of the said conductor.

Electric Wire Connection, H. P. Ball, 461,562. Filed May 12, 1891.
For trolley wires.

Electrical Connecting Device, H. P. Ball, 461,563. Filed June 13, 1891.
For connecting rails of an electric railway.

Coupler for Electric Wires, J. H. Delaney, 461,568. Filed Dec. 29, 1890.
For joining electric conductors between the cars of a railway train.

Hanger for Overhead Wires, C. A. Lieb, 461,582. Filed Aug. 30, 1890.
For trolley wires.

Trolley Switch, C. E. Hudson, 461,611. Filed Jan. 13, 1891.

Control Apparatus for the Position of Signal Discs, T. Weisser, 461,657. Filed Nov. 29, 1889.
For verifying at a distance the momentary position of switches, toll-gates, railway gates, etc.

Motor for Cars, G. M. Brill, 461,662. Filed June 19, 1890.
Claim 1 follows:
In a swiveling truck for electrically propelled cars, the combination, with the frame of the truck, of the driving-wheels larger in diameter than the truck-wheels, and an electric motor, one end of which is spring-supported from the frame of the truck, and connections between the armature of the motor and the driving wheels.

Electric Railway, F. Mansfield, 461,685. Filed Nov. 18, 1890.
Improvements upon the railway patented to the same inventor July 22, 1890, Nos. 432,673, 432,674 and 432,675.

Electric Railway, S. H. Short, 461,090. Filed April 24, 1890.
A two-trolley system.
Claim 1 follows:
In combination with two supply conductors, a car or vehicle and a motor on said car for propelling the same, two independent pole trolleys or travellers on said car, comprising each its individual pole and its individual hinge, and swivel spring mounting, and each having its contact independently pressed by the said spring against one of said conductors and electrically connected with a corresponding pole of said motor.

Electric Block Signal System, J. La Burt, 461,760. Filed July 14, 1891.

Electric Railway-Brake, A. I. Ambler, 461,770. Filed Dec. 18, 1890.
Electrical control of mechanical brake.

Trolley-Wire Support, L. S. Pfouts, 461,785. Filed July 8, 1891.

Telegraphs:—

Telautograph, E. Gray, 461,470. Filed June 13, 1889.
Writing telegraph. Improvement upon the apparatus shown in the same inventor's patents of July 31, 1888, Nos. 386,814 and 386,815.

Telautograph, E. Gray, 461,473. Filed Sept. 17, 1889.
Amplification of Mr. Gray's telautograph system.

Telautograph, E. Gray, 461,474. Filed Sept. 22, 1890.
Further amplification as above; includes the employment of fluid under pressure for giving movement to the circuit closer.

Art of Telegraphy, E. Gray, 460,471. Filed July 19, 1889.
Writing telegraph. Improvements as next above.

Art of and Apparatus for Telautographic Communication, E. Gray, 461,-472. Filed Sept. 17, 1889.
Further improvements as above.

Telephones and Apparatus:

Telephone System, C. C. Gould, 461,573. Filed May 28, 1891.
Relates to switching devices.

SOME FOREIGN THOMSON-HOUSTON WATER-POWER PLANTS.

AT St. Brieux, Cotes du Nord, France, two 1,300 light Thomson-Houston alternators are driven by two Hercules turbines of the vertical type, one of 125 h. p. and the other of 150 h. p. An interesting characteristic of this plant is that the two alternators are run in multiple upon the same circuits. The distance from the central station to the centre of distribution is 8.4 miles, and the pressure employed is 2,000 volts. It is interesting to note that the wire employed to convey the current for 2,600 16 c. p. incandescent lamps 8 4 miles is in this case only .31 inch in diameter.

At Guatemala, Central America, a combined arc and incandescent plant has been operated by means of water power since 1887. A part of the plant, consisting of two A-70 1,300 light alternators, is 3¾ miles distant from the city. The dynamos are driven by a countershaft from the 21-inch Rodney Hunt turbine of 250 h. p. The remainder of the plant, comprising seven 45 light 2,000 c. p. arc dynamos and three 18 light arc dynamos, is 7½ miles away from the city, and receives its power from a 15-inch double Rodney Hunt turbine of 260 h. p.

The city of Puebla, Mexico, possesses an electric lighting plant which is in many ways remarkable. Two hundred arc lamps of 1,200 c. p. are run by four 50 light arc dynamos in a station about 18 miles from the centre of the town, where the river Atoyac furnishes power for a 200 h. p. Leffel double turbine. Each of the four circuits is about 26 miles in length, and consists of a No. 4 insulated wire. The dam and all the masonry connected with the station itself is built of fine cut stone, forming probably one of the most substantial and best built structures in Mexico. As the station is so far from the town and in the midst of a country infested with bandits, the government finds it necessary to maintain at all times a guard, consisting of seven soldiers, to protect the station from injury by marauders.

A contract recently entered into by the Thomson-Houston International Co. provides for a plant to be worked by water power in the town of Piracicaba, San Paolo, Brazil. The system will probably comprise 50 arc lamps of 1,200 c. p. each and about 2,000 incandescent lamps of the alternating system. In this plant the power will be situated quite close to the lighted district, at about a distance of one mile.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

Advertising will not perform miracles, but it will develop a business in a very miraculous way.

A NEW CUTTER SWITCH.

A NEW departure in incandescent switches is soon to be introduced by the Cutter Electrical and Manufacturing Company, of 27 South Eleventh street, Philadelphia.

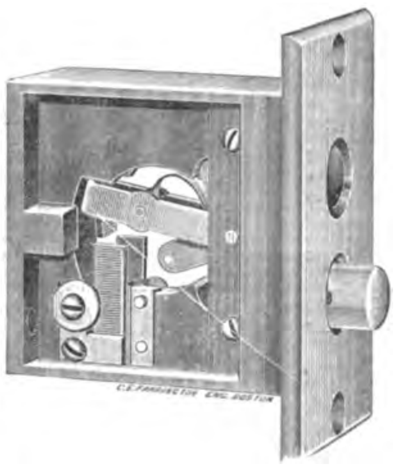


FIG. 1.—CUTTER SWITCH, OPEN.

In the subjoined illustrations, Fig. 1 shows the switch open, while Fig. 2 shows it closed. This switch is of the single-pole, double-break class, with the brushes and switching mechanism mounted upon a porcelain base, which is in turn enclosed in a casing of the same material. The copper terminal brushes are set one over the other, the distance between them being $\frac{1}{16}$ inch, the end of the switch bar acting as a bridge between them when the switch is closed, and giving a break of $\frac{1}{4}$ inch on each side when open, or an actual break of $\frac{1}{2}$ inch. The switch-bar is operated entirely by a flat semi-elliptical spring, which acts eccentrically in such manner that, until the switching lever brings the spring to centre, there is no movement whatever of the switch-bar; consequently, when it is moved past the centre, the full tension of the spring is brought to bear for the break, which is absolutely instantaneous, so that with ten amperes

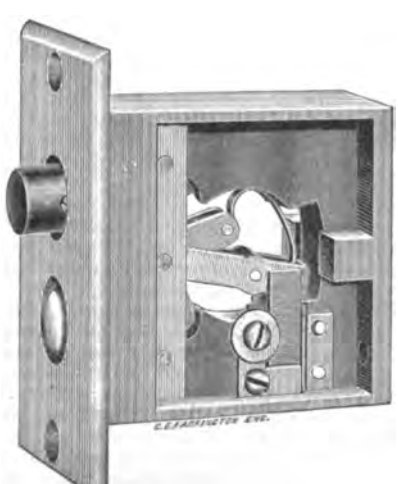

FIG. 2.—CUTTER SWITCH, CLOSED.

current this size of switch exhibits but the faintest indication of a spark.

The working parts are of hard brass plate put together in a substantial and workmanlike manner, and the mechanical and electrical construction is exceptionally good. But perhaps the most taking feature of the device is the fact that it is operated by two push buttons in a face plate, which is set in place flush with the wall or surface of the switchboard, the porcelain case containing the switch mechanism being recessed into the wall, so that nothing is presented to view but the face plate, which may be ornamented to correspond with its surroundings.

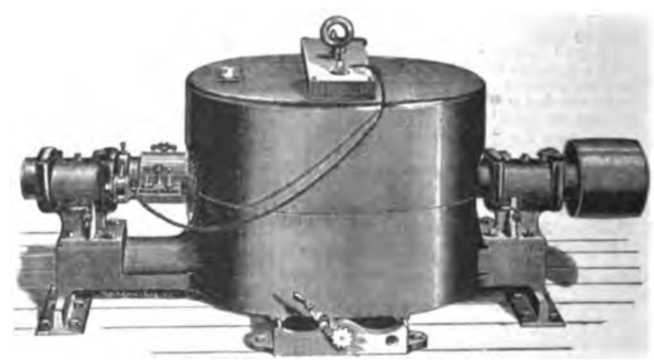
One of the push buttons is white, the other black. By pushing the white one the circuit is closed, while by pushing the black one it is opened, and in case the light governed by a particular switch is in a distant room, the condition of that light as to whether it is on or off is indicated by the relative positions of the push buttons.

The peculiar construction of this switch permits of an exceedingly convenient method of placing a number of switches in "gang" on the same face plate in a manner similar to that adopted in electric gas lighting. For instance, a gang of ten switches would exhibit only a face plate fifteen inches long by three and one quarter inches wide. The switch is also modified so as to be able to control one or more lights from two or more places.

THE MAYO IRON-CLAD MOTOR.

THE Mayo motor, made by the Rockford Electric Manufacturing Company, of Rockford, Ill., is the pioneer of the iron-clad type, the original machine of this kind having been designed by Mr. Geo. A. Mayo in September, 1884.

As will be seen in the accompanying illustration, the motor has a long armature of small diameter, of the Siemens type, and, with the field magnets and salient pole-pieces, is entirely surrounded by the cast frame, which is divided horizontally. The field coils are wound on removable shells, and slipped over the cores. The armature wires, on all motors over two h. p., are supported by Pacinotti projections, so that it is impossible for any



MAYO IRON-CLAD MOTOR.

motion to occur that might endanger the insulation. There being no free magnetism on the outside of these motors, their efficiency is said to be very high. The bearings are self-oiling and the brushes self-adjusting.

THE NEW ENGLAND WESTON ILLUMINATING CO.

THE New England Weston Illuminating Company has passed into the hands of the Boston Electric Light Company, and its real estate on Stanhope street has been deeded to the latter company. As the new owners have run the Stanhope street plant for the past four years under a lease, no change in the management takes place. The works are near the Columbus avenue station of the Boston & Albany Railroad. The purchase was made about a month ago and has just been made public. At that time the Boston company bought the Weston, not merely its property, but the concern itself. It, of course, made no difference practically in which name the realty stood, for the Weston Company had been absorbed by the larger concern. It was decided, however, to transfer the real estate.

THOMSON-HOUSTON ELECTRIC CO.

THE stock of the Thomson-Houston Electric Company has been admitted to the regular list of the Boston Stock Exchange. Par value of shares, $25. Amount of capital issued, preferred, $4,000,000; common, $6,000,000; authorized capital, preferred, $5,000,000; common, $10,000,000. H. A. Pevear, president; C. A. Coffin, vice-president and treasurer; E. Griffin, second vice-president; E. I. Garfield, secretary; directors, H. A. Pevear, C. A. Coffin, E. Griffin, J. N. Smith, B. F. Spinney, C. H. Newhall, T. J. Coolidge, Jr., S. E. Peabody, S. A. Barton.

EASTON ELECTRIC COMPANY SPECIALTIES.

The Easton Electric Company, of 647 Kent Ave., Brooklyn, are manufacturing a number of electrical apparatus peculiar to themselves, some of which are represented in the accompanying illustrations.

The Easton constant-current dynamo is shown in Fig. 1. Its chief claim to superiority lies in the construction of its various parts which are proportioned so as to provide against overheating. It is claimed that no automatic regulator is required.

The magnet coils of the dynamo are so proportioned as to be saturated by 75 per cent. of the normal current in their coils, while the armature does not become saturated with less than five times the normal current in its coils, and is also a relatively powerful magnet compared to the field coils.

While there is naturally a tendency to increase the current, when the resistance is reduced by cutting out any number of lamps, yet the field magnets do not feel the increase, because they are already saturated, whereas, the armature, not being saturated, opposes the field magnets more powerfully, and an actual reduction of voltage results. Meanwhile the current increases but very slightly, and far out of proportion to the reduction of the resistance. By this means the dynamo permits one to cut lamps in or out of circuit without affecting the dynamo injuriously. Another important characteristic of this dynamo is the fusible connection between each section of the armature and the corresponding commutator bar, intended to prevent damage to the armature from an injured or imperfect commutator. The method of mounting the armature on the shaft, shown in Fig. 2, is characteristic of the Easton dynamo, and is said to be very effective in preventing slip and securing practical ventilation.

Another peculiarity is the arrangement of the pole-pieces in such a manner that the centre of the armature is the most strongly magnetized portion, and the self-repellent property of magnetic lines of force is taken advantage of, to bring the entire core to saturation at once, thus securing the maximum of inductive action with minimum power and weight of dynamo.

The lubricating devices are automatic and reliable, and require very little attention. The brushes are small and light, are not expensive and require but little care.

The constant-potential dynamo, Fig. 3, is of the ironclad type, and is notable for its solidity and efficiency. The armatures are wound with but one layer of wire, and all sizes that have a capacity of more than 120 amperes, have but one turn per section. They are said to run with the least heating and to be sparkless. These machines are compounded, or over-compounded, to any desired extent, to compensate for the drop in line, and, it is claimed, are absolutely automatic in regulation. The bearings are self aligning and automatically lubricating, as in the constant-current Easton dynamos.

The Easton Electric Company manufacture two distinct types of arc lamps, which are designed respectively for use on currents of definite or indefinite ampereage. The one for definite ampereage, Fig. 4, is a balanced lamp, or one in which the feeding is governed by the different pulls of solenoid coils in the main circuit, and shunt off the arc, respectively. These lamps have been pronounced simple and satisfactory. They have no springs, dash-pots or other complications, and give excellent results if the current is uniform and of the proper ampereage. The lamp for indefinite ampereage has a "universal" movement, or one in which the feeding is governed by the pull of the solenoid shunt off the arc, balanced against the weight. The main coil has nothing to do with the feeding, but is only used to form the initial arc. This lamp is not quite so simple as the balanced movement, yet is claimed to be the simplest known which accomplishes the same or equal results. The universal lamp when once adjusted for any current may be placed on differing strengths of current, and will properly operate on each without adjustment.

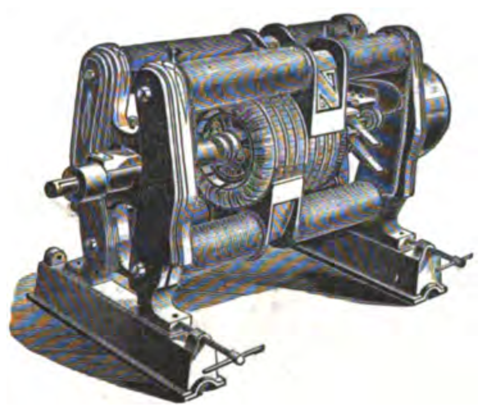


Fig. 1.

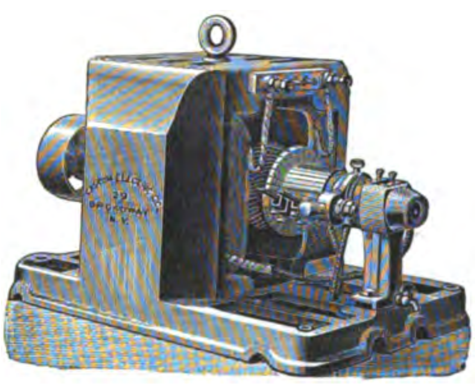

Fig. 3.

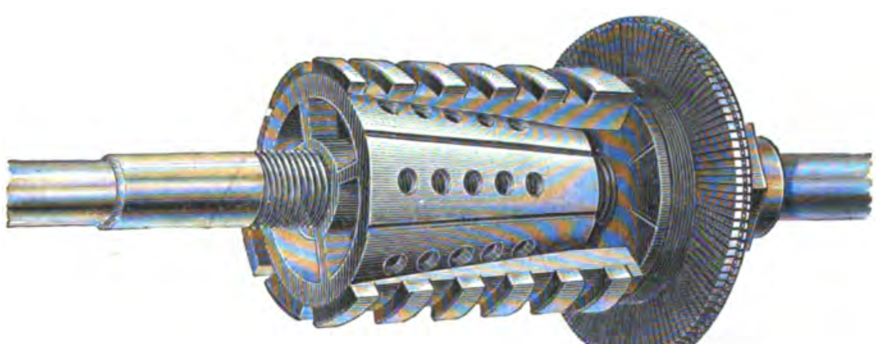

Fig. 2.

Fig. 4.

Easton Electric Company Specialties.

The "X" arc lamp is a combination of the balance movement and universal gearing, and especially adapted for use on circuits with incandescent lamps or motors. It may be operated two in series on 110 volt circuits. This type of lamp may also be placed eight in series on railway circuits of 500 volts.

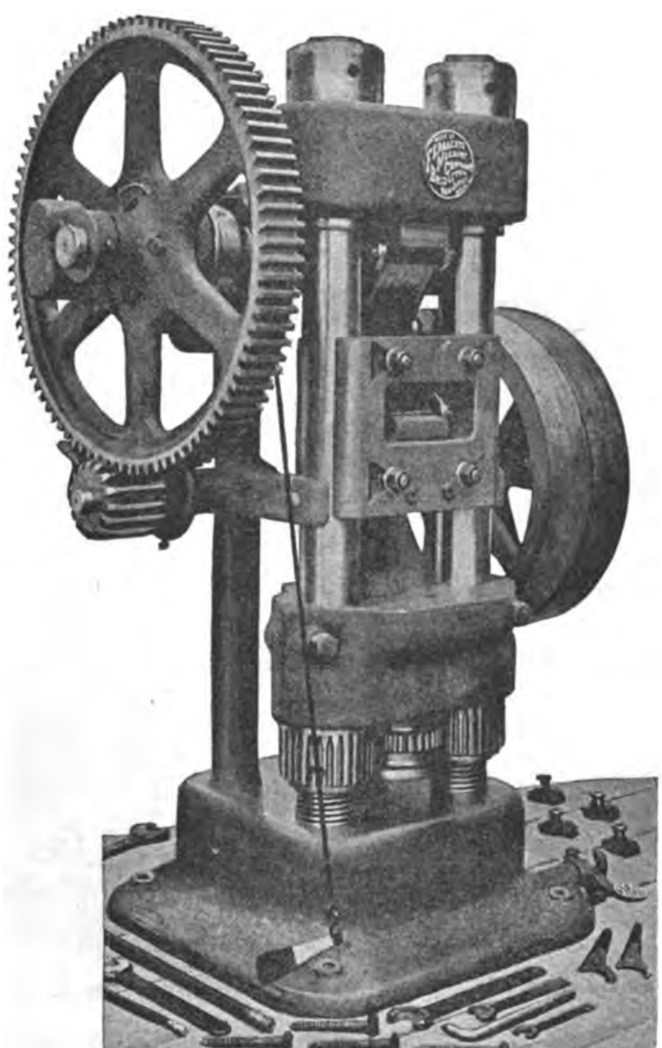
All these are single-carbon lamps, but by varying the size of the carbons they can be made to burn from six to fourteen hours. The Easton Company have been pioneers in advocating the single-carbon lamp for all-night work, and feel flattered that the ideas they have advanced and defended for many years received the endorsement of experts at the Montreal meeting of the Electric Light Association.

RIES ELECTRIC SPECIALTY CO.

The Ries Electric Specialty Co. of Baltimore, Md., reports being very busy supplying the demand for their new regulating sockets for alternating current incandescent lamps. This company is about completing an additional large plant to what they have already in operation, and in a few weeks will be ready to turn out these goods at the rate of 1,500 per day in the regulating socket department alone.

A NEW FERRACUTE COINING AND EMBOSSING PRESS.

THE Ferracute Machine Company, of Bridgeton, N. J., have introduced a new style of press for electrical work, which will be interesting to many of our readers. There are two sizes of these presses, one of which is shown in the accompanying illustration. They are designed for fine embossing and coining where a very heavy pressure is required, and for compressing and compacting any articles under six or eight inches in diameter. There are many special articles in electrical work where such presses can be used to advantage. They can also be used for cutting, forming, flattening and squeezing in a great variety of work. They are built with two solid forged steel columns to take the strains, and have an extra heavy shaft. All of the journals of the toggles, etc., are bushed with hard steel to prevent wear. They have a very long adjustment by means of the nuts underneath the bed, and a quick return motion of the slide-bar or ram. They are fitted up with cut gearing and a new form of automatic clutch, operated by the treadle. If desired, they can be built with a rim for the gear wheel and a sliding shaft, so that they can be run either with gearing, as shown, or without, for light work and quicker speed. They are built also without gearing, that is, with a heavy fly-wheel on the main shaft, arranged to engage with the automatic clutch. They can also be arranged without a clutch for continuous feeding on certain kinds of work.



NEW FERRACUTE COINING AND EMBOSSING PRESS.

Some of the dimensions of the size here illustrated are as follows: Weight, 5,500 lbs.; height from bed to slide-bar, when up, 11 inches; stroke of slide-bar, 2 inches; width between columns, 10 inches; adjustment of bed, 8 inches; speed of main shaft, 50 revolutions per minute; diameter of pulleys, 32 inches; total height of press, 80 inches; floor space, front to back, 42 inches, and right to left, 56 inches. This press will exert a pressure of about 300 tons. It is built of the best materials, and is of fine workmanship and finish.

THE ELECTRIC APPLIANCE CO.

UNDER the above name a new electrical supply house has been organized in Chicago, and will be ready for business about the middle of November. The officers of the new company are Willard W. Low, president; Harry B. Gilbert, vice-president; and Thomas I. Stacy, secretary and treasurer. Mr. Low has been well known to the Western electrical trade for the past eight years, and has a wide acquaintance among central station men and purchasers of electrical goods, and is thoroughly versed in all the details of the supply business. Mr. Gilbert and Mr. Tracey have been identified with electrical interests in Chicago for about five years, and are too well known among electrical people to need any introduction. It is the intention of the company to make a careful study of the wants of the trade, and place on the market only such goods as are in certain demand and of the highest quality. They will make a point of treating all their customers and patrons with fairness, and fill all orders, large and small, with the utmost promptness and dispatch. They have already secured control of several well-known and valuable specialties, and will be in a position before December 1 to meet every demand that can be made upon a general electrical supply house.

The new company has secured the large and well-appointed premises at 242 Madison street, which is in the heart of Chicago's retail electrical supply trade, and one of the officers will give this department his personal and undivided attention. Their facilities for carrying a large stock and making quick shipments are excellent, and their numerous friends among the electrical fraternity will wish them the fullest measure of success.

THE CUMBERLAND ELECTRIC CO.

THE Cumberland Electric Company has just been organized by the election of the following board of directors: James S. Humbird, F. S. Marr, Lloyd Lowndes, Johns McClave, Robert R. Henderson, Charles Pease and Harvey L. Chilet. Mr. James S. Humbird has been elected president, and Mr. Charles Pease vice-president and general manager. The capital stock is $100,000, and the purpose of the company will be the manufacture of electric light and railway supplies and specialties.

The company have leased the old Gephart or Paul foundry, on Front street, Cumberland, Md., for a term of years, and will immediately begin preliminaries for the erection of their plant.

THE GLOBE CARBON CO.

THE above company announce their removal to Ravenna, O. They will there have a capacity of 100,000 finished carbons per day, and will employ the most approved appliances for the manufacture of a superior article. Their simple programme is to "continue to make a carbon of long life without sacrificing any of the light." The freight rates from Ravenna are the same as from Cleveland. W. Gerrett is president; C. S. Britton is vice-president; H. E. Hayes, treasurer, and C. L. Rodman, general manager.

THE UNIVERSAL ARC LAMP.

THE Interior Conduit & Insulation Co. has acquired from the Universal Arc Lamp Co. the sole right to the manufacture and sale of the various arc lamps of that concern for use on incandescent circuits. The Interior Conduit Co. has also assumed the accounts of the Universal Co., transferring its current customers and settling outstanding bills.

TUCKER & HALL.

THE business carried on under the above title by W. H. Tucker and J. P. Hall has been dissolved. It will be continued by Mr. Tucker, at 432-434 Electrical Exchange Building, on his individual account.

PHILADELPHIA NOTES.

THE MAIN BELTING CO. have in addition to their Philadelphia and Chicago stores established a branch at 120 Pearl street, Boston, where a full stock of their Leviathan belting will be kept, and from which their growing New England trade can be supplied more promptly.

THE HEISLER ELECTRIC LIGHT CO. have just introduced their system of long-distance lighting into the towns of Kingman, Kansas, Union City and Homer, Mich.

MR. T. L. TOWNSEND, representing the Partrick & Carter Company, is sending in large orders from the West, and reports business as excellent.

NEW FREY MEASUREMENT APPARATUS.

THE E. S. Greeley & Company, have recently placed on the market a number of additions to their already large variety of standard testing apparatus The instruments referred to, and shown in the accompanying illustration, were all designed at the Greeley electrical laboratory by Mr. Charles P. Frey, electrician for the company. The chief aim in constructing these instruments has been to render them as light and portable as possible without endangering the essential features, namely, accuracy and accessibility.

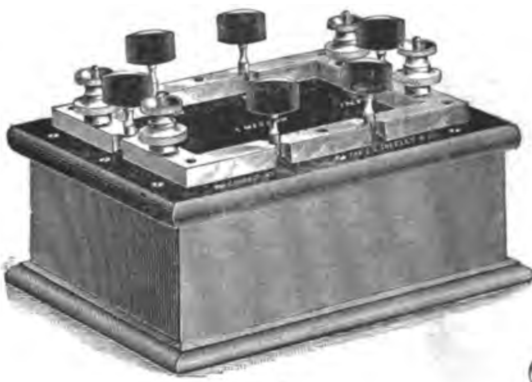


FIG. 1.

FIG. 2.

FIG. 3.

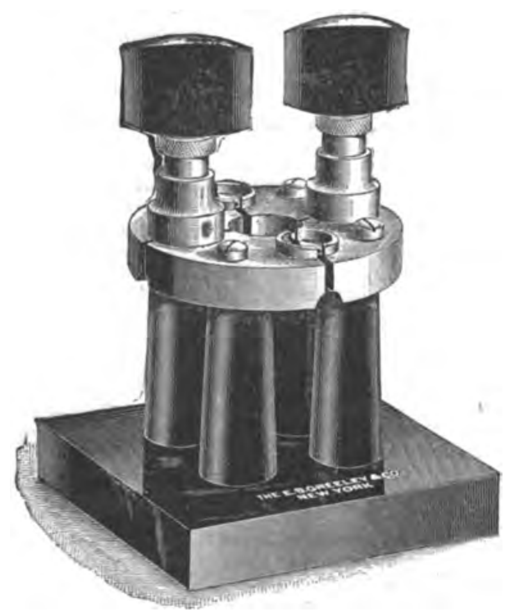

FIG. 4.

THE E. S. GREELEY & COMPANY'S NEW STANDARD MEASUREMENT APPARATUS.

Fig. 1 shows a megohm box having eight readings, embodying four readings of respectively 100,000, 200,000, 300,000, and 400, 000, ohms.

A one and one-tenth megohm box, also made by this company, has eight readings, as follows: 10,000, 20,000, 30,000, 40,000, 100,-000, 200,000, 300,000, and 400,000 ohms. Taking into consideration the large quantity of wire carried in these boxes, they are remarkably light and compact, especially since the wire is (with the exception of the four coils of 10,000, 20,000, 30,000, and 40,000 ohms) all wound on spools of 30,000 ohms each, and separately adjusted in order to secure the greatest possible accuracy.

Fig. 2 shows a four-coil Thomson reflecting galvanometer, of the Rowland type, placed on the market as a companion to the two-coil instrument of this variety, which is already well known. The Greeley Company have recently been engaged in conducting a series of elaborate and expensive experiments at their laboratory in order to determine what materials can be used to the best advantage in constructing commercial condensers for telegraphic and other purposes, with the object in view of eventually adding instruments of this type to their regular standard condensers. One of the necessary preliminary steps was to provide an improved ballistic galvanometer and some highly-insulated plug switches. Models of these were designed by Mr. Frey, and shown at the Montreal exhibit. In response to a general request, the Greeley Company have decided to regularly manufacture these instruments in the future and add them to their list.

Fig. 3 shows a cut of the ballistic galvanometer, which, although built to a certain extent on conventional lines, embodies several novel features. The casing for the mirror is provided with a hood which can be turned so that the reflection from the mirror may be observed from either side. The coils, two in number, are usually connected in multiple, but may be used independently by removing both of the coupling strips between the binding-post blocks. The coils may also be connected in series by removing but one coupling strip and giving the front coil a half turn. This galvanometer is equipped with a bell-shaped magnet, as designed by Siemens & Halske, is highly insulated, and is of superior construction and finish.

Fig. 4 shows a double-plug switch mounted on insulated pillars. The plugs are provided with caps which prevent the pillars from spreading when the plugs are inserted, and secure firm contact. A single-plug switch is also made on the same principle.

These instruments are on exhibition at the salesrooms of the E. S. Greeley & Company, Nos. 5 and 7 Dey street, New York City.

A. M. MORSE & CO.

MR. A. M. MORSE, until recently of the firm of English, Morse & Co., Kansas City, Mo., has removed to St. Louis, Mo., with offices in the Commercial Building, corner Sixth and Olive streets. During the eight years that Mr. Morse has been established in Kansas City he has gained a wide and favorable acquaintance among the steam users of the Southwest, and has designed and furnished a liberal proportion of the representative steam power plants in that section for electric lighting, electric railways, flour mills and manufacturing purposes.

The business in the future will be conducted under the style of A. M. Morse & Co., who will represent leading manufacturers of high grade steam engines, both Corliss and high-speed type, also improved boilers, steam pumps, and other specialties which go to make up complete steam power plants. They will offer only the best class of machinery at manufacturers' prices, and will make a specialty of designing and furnishing complete steam power outfits for any service, also the improvement and extension of plants already established.

LARGE ORDER FOR TURBINES.

ONE firm recently ordered eighteen large water-wheels of James Leffel & Co., Springfield, Ohio, builders of the famous James Leffel wheel. A large wood pulp mill, now under construction in Wisconsin, will use these wheels. This new enterprise is situated near large quantities of suitable timber, and where ample water-power can be obtained.

ENGINEERING EQUIPMENT CO.

By a recent enterprising move, the Engineering Equipment Co. has secured new offices and salesrooms most conveniently situated on the ground floor of the fine Central Building, 143 Liberty street, New York. The building is aptly named as to its location, being in the centre of electrical and allied interests, as well as for its connection with the New Jersey Central Railroad and its close proximity to the C. R. R. and Cortlandt street ferries. The Engineering Equipment Co. is therefore readily accessible to all buyers of steam and electric construction materials who desire to purchase directly from reliable manufacturers' representatives. The sale of cotton-leather belting is constantly on the increase. The electric railway department has been well patronized, resulting in the sale of thousands of pieces of line materials, wood and iron poles, and the furnishing of supplies for some of the largest electric railway contracts of the past year. Messrs. Perine, Tinker, Crane, Merrill and others will be happy to see their friends in their new quarters.

BURTON ELECTRIC HEATERS ON THE ESCANABA ROAD.

The following testimonial speaks well for the Burton electric heaters:

ESCANABA, MICH., October 27th, 1891.

ELECTRIC MERCHANDISE COMPANY,
11 Adams St., Chicago.

GENTLEMEN: The Burton electric heaters you sent to the Escanaba Electric Street Railway Company have been put to a good, thorough test and have been found equal to the emergency. We have had some cold weather and quite a fall of snow, but the cars have been as warm as toast. Your heaters are the simplest, cleanest, and most efficient of any heating apparatus in the market. You may use this in any manner you wish, or refer to me at any time.

Respectfully yours,
(Signed) GEORGE W. FINCH,
Electrical Engineer.

THE CHICAGO ELECTRIC MOTOR CO.

The Chicago Electric Motor Co., Springer Building, Chicago, recently received the following among other testimonials regarding their repair work, of which they make a specialty:

"GENTLEMEN: Replying to yours of the 18th inst., we can say that we are well pleased with the work done in the past two months by your Mr. J. G. Hart. He rebuilt three No. 32 Edison generators, and overhauled the general equipment of our road to our satisfaction. For general repair work on electric machinery, we are pleased to refer street railway and light station managers to your company, if first-class work and reasonable prices are desired.

"Yours truly,
"KEOKUK ELECTRIC STREET RAILWAY AND POWER CO.,
"H. C. REINER, Secretary."

JEWELL BELTING CO.

We have received from the Jewell Belting Co. two very tastefully bound copies of their pamphlets on the "Jewell Dynamo Belt" and "Transmission of Power by Leather Belting." These brochures describe the interesting process of making the belt, show cuts of details handled by the company, such as hooks, laces, fasteners, etc., views of tanneries, etc., and give a variety of most useful tables and data. The tables of transmission of power will be serviceable to every engineer, while there are a good many points of interest in the various records cited in detail as to sizes to pulley and belt, amount of power transmitted, life of belt, etc.

RIES ELECTRIC SPECIALTY COMPANY.

MR. ELIAS RIES, president of the Ries Electric Specialty Co., of Baltimore, Md., was a visitor to New York last week. Mr. Ries reports that his company is putting in new machinery as fast as possible to facilitate the rapid manufacture of the sockets. His company is now in a position to furnish regulating sockets for any kind of base, and a sharp increase of business is already noticeable.

BROWN, BOVERI & CO.

MR. C. E. L. BROWN having left the Oerlikon Works, has become a member of the new electrical engineering firm of Brown, Boveri & Co., of Baden, Switzerland.

A PRACTICAL WIRE TEST.

WITH the varied uses to which electricity is now being put, the tests given to the insulation used are often quite severe, and the way in which some wires stand these tests speaks well for the state of the art. George Cutter recently sent a large batch of Simplex braided rubber wire out to Utah, where it was apparently to be used for indoor wiring. But as it happened to be close at hand when some blasting was to be done at the Anchor Mine, at Park City, Mr. Ewing, of the United Electric Co., calmly used some of it for this purpose.

The object of the blast was to break through the bottom of a 900-foot shaft into the Anchor drain tunnel, whereby the mine could be drained. The water in this shaft was up to the 300-foot level, or 600 feet deep—260 pounds pressure. The dynamite was encased in a sheet-iron tube together with the electric exploders and lowered by means of a No. 14 Simplex braided rubber wire through the 600 feet of water to the bottom of the shaft. The first trial was not successful and the torpedo was pulled up, and it was found the water had got into the torpedo through a poorly soldered joint in the sheet-iron and wet the exploder wires. To test the leading wires 2,000 feet of wire was placed in a barrel of water and allowed to remain over night. The next morning six caps were successfully exploded through the 2,000 feet of wire in the barrel of water. The repaired torpedo was then lowered to the bottom of the shaft and exploded, using Simplex braided rubber wire that had been under water from 20 to 24 hours continuously. While the work was a complete success electrically, yet it failed to break the shaft through into the tunnel, as some error had been made in surveying the tunnel.

With an insulation that will stand such tests, it is not surprising that many of our leading architects feel as proud of the electrical fittings in their buildings as of any of the details which they work out themselves.

CROCKER-WHEELER ELECTRIC MOTOR COMPANY.

THE Crocker-Wheeler Electric Motor Company, New York City, have just issued a revised and extended catalogue. It is an interesting pamphlet of over fifty pages. To those seeking information regarding the electric motor, and its numerous applications, the Crocker-Wheeler catalogue must prove of great value. The text, which is profusely illustrated, discusses at length the construction of the Crocker-Wheeler motors, and their special features, with convenient and valuable table of dimensions, etc. There are also directions for setting up, connecting and running. An interesting chapter on "Windings" engages the attention, also a table of sizes and types of motor manufactured for constant potential circuits. The fireproof starting, regulating and reversing boxes made by the Crocker-Wheeler Motor Company are described, and considerable space is given to their small motors, one-sixth, one-eighth and one-twelfth h. p., together with their application to electric fans, electric pumps, etc.

The "arc" circuit or constant current motors, Crocker-Wheeler type, are fully described and illustrated. The pamphlet further contains "A Visit to the Crocker-Wheeler Electric Motor Company's Factory," reprinted from THE ELECTRICAL ENGINEER, New York, and an interesting paper on "Cost of Electric Power—Comparative Efficiency of Large and Small Motors," by Dr. S. S. Wheeler.

THE PULLMAN PALACE CAR "VENICE."

AMONG the social features of the Street Railway Convention was the entertainment of a party of men interested in street railway matters and members of the scientific press on board the palace car "Venice," which by the courtesy of the Pullman Palace Car Company and the *Street Railway Gazette* was placed at their disposal. Mr. P. G. Monroe, president of the *Gazette*, and Mr. W. S. Louttit, of the Pullman Car Co., entertained the party royally, and a hearty vote of thanks was tendered them for their many courtesies.

The "Venice" went by way of the Erie road to and from Pittsburgh, at which point it was side-tracked and used as a hotel during the stay. The party of guests was composed of W. H. Patton, George Standart, C. K. Harding, F. H. Stanwood, W. H. Edgar, Jr., N. P. Senat, John Roberts, E. L. Powers, G. G. McDuff, H. L. Webb, L. W. Collins and W. F. Collins.

THE CENTURY POTTERY, which has recently been established at 514 Liberty street, Camden, N. J., is turning out some very creditable work in the way of vitrified porcelain for electrical purposes. The general manager, Mr. H. Wareham, is a thoroughly practical man, having had many years' experience in the porcelain business both in Europe and the United States, and possesses some receipts known only to himself for mixing the ingredients which produce the best results.

BAIN'S COMPENSATING VOLTMETER AND AMMETER.

THE desirability or, rather, the necessity, of accurate instruments to measure the strength and voltage of currents is now so well recognized as scarcely to require further comment. Nevertheless, it cannot be urged too strongly that to obtain economy of operation in incandescent lighting, for instance, requires the maintenance of the proper potential, and that a slight increase above the normal entails a very much decreased life of the lamps. On power circuits, also, voltmeter and ammeter records continuously maintained will afford much valuable information.

To meet the demands for such instruments Mr. Forée Bain, of Chicago, has recently designed a set of voltmeters and ammeters, the manufacture of which has been undertaken by the Knapp Electrical Works, of 54 and 56 Franklin street, Chicago, and the general design of which is illustrated in the accompanying engraving.

The action of the instrument is based on the dynamic effect of moving electric currents and that due to electromagnetism, both affecting in a varying but compensating manner the movable armature, which is made of a small bit of chemically prepared sheet-iron, one-fortieth of an inch in thickness. The moving portion weighs only one-sixtieth of an ounce complete, the whole being mounted on very delicate trunnions. There is no appre-

BAIN'S COMPENSATING VOLTMETER AND AMMETER.

ciable friction, so that the pointer comes to rest every time at the same position, when not in use. The controlling force is gravity, with the parts balanced in such manner that its value is unchangeable during the entire range of the pointer. The two forces, electro-dynamic and electromagnetic, act from opposite sides, so that the increment of one of the forces is coincident with the decrement of the other to a degree that is exactly compensating. These forces in the relation described neutralize any tendency to magnetic lag or retardation. The instrument has no permanent magnets which are subject to change of strength and to tempered strain fracture. The instrument is absolutely dead-beat and yet extremely sensitive, having practically no inertia. The indicating pointer quickly and positively moves to new positions with slight variations of current.

The voltmeters are wound with a resistance wire which changes in resistance, but very slightly with increased temperature, so that it may remain in circuit indefinitely. The proportion of current necessary to operate these instruments is extremely small. They have a scale from 0 to 150 volts, and are wound for 15,000 ohms resistance, therefore requiring only one-hundredth of an ampere to deflect the needle the whole length of the scale.

The appearance is neat and substantial without being clumsy. The brass case is circular in form and is firmly mounted on a highly polished hardwood base. The relation between the scale and the movable indicator is firmly maintained by a metallic structure; the moving portions are light, weighing about one-sixtieth of an ounce, and are of such shape that they may be readily duplicated. The aluminum pointer extends over a mirror to an engraved metallic scale, so that an error by displacement, due to parallax, may not be made when taking readings. When used as a portable instrument, it may be hung on the wall or held in an upright position in the hand. Each instrument is enclosed in a neat mahogany case, with leather handle for use as a portable instrument.

WESTERN NOTES.

MR. GEO. H. MEEKER, manager of the New York Insulated Wire Co., No. 78, 80 and 82 Franklin street, Chicago, has received the first of the shipment of the three carloads of Grimshaw white core wires and B. D. wires from their factory at Wallingford, Conn. In this shipment there is one million feet of their celebrated trade Nos. 228 and 237 No. 14 B. & S. wire, or more than enough to reach in a straight line from Chicago to Davenport, Ia., and the total shipment if strung on poles would nearly reach across the United States. The flattering and satisfactory success that this company have made with the sale of their goods since opening the Chicago store has warranted such shipments. Their Vulca electrical wire ducts are about to be installed in the new Masonic Hall at Utica, N. Y., and are being extensively used throughout the West.

THE ILLINOIS ELECTRIC MATERIAL CO., 158 Fifth avenue, who recently secured the general Western agency for the Fibrous dry battery, manufactured by Thompson & Robertson, New York, report having already secured a number of large orders for these batteries, which are specially made for bell and open circuit work. This company have also placed upon the market a new form of "Canvas Jacket" insulated with a special waterproof tape and a single weave above it, making a very high grade line wire, and are already overrun with orders. They are also doing a large business in Bishop wires and cables. The sale of cedar poles, of which they have quite a large share, shows actively in construction work. Electrix socket-switch and other specialties are in good demand.

THE CHICAGO ELECTRIC MANUFACTURING CO., 73–75 W. Jackson street, recently equipped a testing department, and are already handling a large amount of work. This department pays special attention to calibration of testing instruments, has all necessary standards and apparatus for delicate and accurate work, and is in charge of an experienced electrician. Voltmeters or ammeters of doubtful accuracy, bridge sets, coils of which need adjusting or galvanometers of which are not sensitive, magneto bells that refuse to ring, galvanometers in which the needles require remagnetizing or the coils are burned out, can be tested, rewound, calibrated and adjusted on short notice and their accuracy guaranteed.

THE GRAY ELECTRIC CO., recently organized to manufacture the Telautograph, have purchased a 50 acre tract about a mile south of Highland Park, Ill., and have let their contracts for the erection of the factory building, which will be 60 feet wide and 140 feet deep, three stories, and will be pushed to completion with the greatest possible expedition. It is expected that the structure will be finished by March 1, and actual business of the manufacture will commence immediately thereafter. Prof. Gray is president; F.W. Cushing vice-president; Thomas G. Wheelwright, secretary and treasurer.

"THE ELECTRICAL NORTHWEST," published in St. Paul, Minn., has been purchased by W. L. Klein, publisher of the *Northwest Builder and Decorator*, and the name of the paper has been changed to that of the *Street Railway and Electrical News*, of St. Paul and Chicago. Mr. Gilbert G. McDuff, well known among the electrical fraternity in the West, has associated himself with the paper, with headquarters in Chicago.

MR. GEORGE CUTTER, the widely known dealer in electrical specialties at 332 "The Rookery," reports an astonishingly large demand for his "Lamp Supporting Pulley." This is conclusive evidence in Mr. Cutter's judgment that electrical construction work is active. In other lines of specialties he is also doing a good business and his devices, which are both highly practical and also ornamental, are becoming more largely used every day.

THE SUNBEAM INCANDESCENT LAMP CO. are now prepared to ship at short notice 10, 24, 25 and 32 candle-power lamps. They have been so rushed in their standard 10 c. p. lamps that they have been unable earlier to complete facilities for manufacturing promptly other sizes, but now have the new machinery and apparatus all installed, enabling them to open with a large business.

THE BOILER DEPARTMENT of the Pond Engineering Company reports increased activity, particularly in electric light and power work. Recent orders for steel boilers come from Kansas City, two; Jefferson City, two; Valparaiso, Ind., two; Waco, Texas, two; Laredo, Texas, second order; East St. Louis, Ill.; Waterloo, Ill.; Paducah, Ky.; Lawrence, Kan., and Arkadelphia, Ark.

THE ELECTRIC MERCHANDISE COMPANY, 11 Adams street, Chicago, is still engaged with the same rush of business that has occupied its attention during the summer and begins to wonder if the customary cessation is really to be experieneed this winter. Present indications are against it. For its standard line material, station and car equipment an ever-increasing demand is reported, while repeated large orders for Pratt's portable conductor's register and the Burton electric heater are being filled.

THE GREAT WESTERN ELECTRIC SUPPLY Co have issued a very handsome catalogue of their electric lighting snpplies. It is bound in cloth, and the typographical work and illustrations which, are very numerous, are of the highest class of work. Everything pertainining to electric lighting is illustrated and described, and the book forms one of the handsomest and most comprehensive catalogues ever issued by them.

MR. CHARLES E. LEE, Western manager of the Electric Gas Lighting Co., Lakeside Building, Chicago, reports business as brisk in their various specialties and general electrical supplies. Mr. Lee carries a large assortment of this company's well-known goods and electrical apparatus, and makes a special point of filling orders with promptness and despatch.

MR. WM. HOOD, 239 La Salle street, is having a brisk run of business with "Jewel' incandescent lamps and receiving numerous orders all the time. The Jewel lamps are giving excellent satisfaction, and the small amount of current they use, together with long life and freedom from blackening, are calling forth many commendations.

THE GREAT WESTERN ELECTRIC SUPPLY Co. have recently made some very large sales of line wire for extensions and new plants. The Sun arc lamp which they manufacture for both arc and incandescent circuits, is becoming quite a general favorite and they are continually booking large orders.

GEORGE CUTTER is putting out another size of his lamp-supporting pulley under the name of "Cutter's Petite Pulley." It is not exactly a pocket edition, but is intended for use with incandescent lamps and will find a ready market wherever such lights are hung over the centre of streets.

MESSRS. MCKINLOCK and W. F. RICHARDSON, of the Southern Electrical Supply Co., of St. Louis, spent a few days in Chicago last week. They report business in St. Louis and throughout their country as excellent.

THE STANDARD LAMP AND MOTOR CO., manufacturers of incandescent lamps for all systems, have removed to Oconto, Wis., where they have put in a new plant and built a large factory for the manufacture of lamps.

MR. THOMAS M. BROOKS, who is one of the well known belting men and for a long time sold Hoyt's belting, and later with the Page Belting Co., of Concord, N. H., has now associated himself with Fairbanks, Morse & Co., Chicago.

MR A. E. CURRIER, of the Faraday Carbon Co., of Jeannette, Pa., was in Chicago last week, and reports trade as very flourishing. The Faraday Carbon Co. have just completed their new factory, giving a capacity of 12,000,000 carbons per year.

GLEASON & BAILEY MANUFACTURING CO. report business as good in their electrical supply department. They are selling large quantities of the Steuben incandescent lamps, for which they are general Western agents.

THE ELECTRIC MERCHANDISE CO. are receiving some flattering testimonials regarding the "Chicago" trolley hanger. One enthusiast after trying them says they are good, and encloses a large order.

THE BALL ENGINE CO., of Erie, Pa., have recently opened handsome offices at 506 "The Rookery," Chicago, in charge of Mr. Albert Fisher, who is one of the best known among engine salesmen.

MR. CARL YOUNG has severed his connection with the Thomson-Houston Co. and will now handle the Jenney Electric Motor Co.'s apparatus, assisting Mr. Fred'k L. Merrill, as Chicago city agent.

MR. P. C. BURNS, of the Peru Glass and Carbon Co., was a Chicago visitor last week and found trade very brisk in his many well-known carbon, porcelain and other specialties.

THE KNAPP ELECTRICAL WORKS report a flourishing business in "Safety" insulated wire and cables, and a good demand for general electrical construction supplies.

THE CENTRAL ELECTRIC CO. are pushing the sale of Paiste switches, of which they have a large stock, and can fill almost any kind of an order from their warerooms.

MR. C. E. OLDACRE, the popular general agent of the Jenney Electric Motor Co., of Indianapolis, was a Chicago visitor last week.

MR. JAMES MCBRIER, president of the Ball Engine Co., of Erie, Pa., was a welcome visitor to Chicago last week.

NEW YORK NOTES.

MR. FRANCKE L. WOODWARD, of Albany. N. Y., member of the American Institute of Electrical Engineers, is making some valuable researches in the electrical field. At present he is developing a battery, it is said, on a principle that has never been used before, which, if a success, may be of use in aërial navigation.

MR. JAMES B. OLSON, of the New York Insulated Wire Co., has recently been on a flying trip through nearby States, taking in the American Street Railway Convention, en route for points in Pennsylvania.

THE new boiler-house for the Oswego Pulp and Paper Co., at Fulton, N. Y., will be of iron designed and built by the Berlin Iron Bridge Co., of East Berlin, Conn.

MESSRS. THOMSON & ROBERTSON, manufacturers of the Fibrous battery, have removed from 258 to 261 Broadway.

PHILADELPHIA NOTES.

MR. CHARLES K. WESTBROOK, manager of the Isolated Light and Power Department of the Thomson-Houston Electric Light Co., announces the following recent sales and installations of isolated apparatus by his department, viz., A. B. Farquhar & Co., York, Pa., 250 incandescent; W. A. King & Co., Columbia, Pa., 100 incandescent; Wilson Female College, Chambersburg, Pa., 300 incandescent; J. K. Mosser, Allentown, Pa., 150 incandescent; Chambers Brothers & Co, Philadelphia, Pa., 250 incandescent; S. S. White Dental Manufacturing Company, Philadelphia, 300 incandescent; Shaw, Esrey & Co., Chester, Pa., 625 incandescent; G. W. Blabon & Co., Nicetown, Pa., 155 incandescent; C. H. Reiser, Philadelphia, 300 incandescent: Wanamaker & Brown, Philadelphia, 75 arc; Bethlehem Iron Company, Bethlehem, 50 arc; Baltimore and Ohio Railroad Company, Baltimore, Md., 50 arc; Pennsylvannia Railroad Company, Altoona, Pa., 50 arc; William Sellers & Co., Philadelphia, 35 arc; Tyrone Iron Co., Tyrone, Pa., 18 arc; Norristown Steel Company, Norristown, Pa., 9 arc; Pencoyd Iron Works, Pencoyd, Pa., D 80 generator; Girard Estate for Burk & McFetridge, Philadelphia, 7½ h. p. motor.

THE WEST END ELECTRIC CO., whose plant has recently been put in motion to give light through the 29th ward, the district covered by their franchise, sent out about 800 invitations to their patrons and the electrical fraternity to inspect their plant a few evenings since. It is located at Thirty-first street and Girard avenue. The main building was brilliantly illuminated and in the centre were long tables bountifully filled with everything conceivable in the way of cold lunch and the beverage for which that neighborhood is famous. Their superintendent, Mr. A. J. Martin, did all in his power to entertain the many visitors present and explained the workings of the machinery and the many conveniences this plant possesses. The dynamos and electrical appliances were installed by the Thomson-Houston Electric Co. The engines are from the Providence Engine Works, the boilers of the Coatsville make, and over 15 miles of rubber insulated cables have been laid by the Bishop Gutta-Percha Co., of New York, through the McDonald conduit. The company has spared no expense in making this a model plant in every particular.

THE enterprising manufacturer of electrical specialties, Mr. H. T. Paiste, owing to increased business, has been obliged to move his factory and Eastern office from 12th and Market streets, Philadelphia, to the new Fuller Building, 10 South Eighteenth street, of the same city. He has taken the entire third floor of this elegant building, thereby trebling his floor space. It is the intention of Mr. Paiste to largely increase his stock of specialties. The Western office and storeroom, 341 the Rookery, Chicago, remains unchanged.

THE LA ROCHE ELECTRIC WORKS are installing a 500 light plant complete for Messrs. Wm. P. Froth, Jr., & Co. gingham manufacturers at Frankfort, Pa.; also a 50 light plant for Mr. T. J. Oliver, 19th and Reed streets. The latter will displace another machine of well-known make. The La Roche company are adding more power to their works in the way of a large Racine automatic cut-off engine. This engine will soon be in operation, and is intended to drive their plant at night.

THE STAR ELECTRIX CO. have since their recent cut in prices increased their force from 60 to nearly 150 operatives, and are shipping their specialties in large quantities throughout the United States and parts of Europe.

☞ Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Miscellaneous, etc., will be found in the advertising pages.

THE

Electrical Engineer.

VOL. XII. NOVEMBER 18, 1891. No. 185.

MR. EDISON'S LATEST STREET RAILWAY WORK.

THE interest manifested not only by electricians, but by the general public as well, in the inventions of Mr. Edison has naturally induced the daily press to seize every occasion to place before its readers any new work upon which Mr. Edison may be engaged, and generally to give wide publicity to everything with which Mr. Edison's name is connected. Unfortunately, however, those to whom the task of interviewing Mr. Edison on such occasions is delegated by the daily press are rarely, if ever, sufficiently equipped with a knowledge of electrical matters to comprehend thoroughly the plans and results which Mr. Edison communicates to them, and, as a result, we frequently find the most absurd stories set afloat in which "the Wizard of Menlo Park" is quoted as using language whose picturesqueness subsequently turns out to be largely due to the vivid imagination of the reporter. The most recent example of such a published interview is to be found in an article appearing in the New York *Herald* a few weeks since, followed up by others in other papers, in which the reporters put into the mouth of Mr. Edison a number of statements which, it cannot be denied, have had considerable influence in electric railway circles, and have called forth comments in various quarters similar to those which have appeared in the last two issues of this journal. Mr. Edison, according to the reports of the daily press, was credited with having invented a system which, operating at low potential and using the rails as conductors, would do away entirely with the necessity for the overhead trolley system. The effect of the publication of such a radical change in our methods of electric railway construction has been, in some instances, to lead intending investors in electric railway enterprises to defer proposed action until this new system should be thoroughly worked out or explained, and, on the other hand, is said to have afforded the authorities of cities in which railroad franchises were asked for, plausible ground for taking the stand that, since such a system as that credited to Mr. Edison was available, no franchise for overhead wires should be granted.

In order, therefore, that the feeling of uncertainty which seems to exist in electric railway circles at the present time may be removed and the ideas of, and actual work accomplished by, Mr. Edison on his new system should be comprehensively and accurately stated, we give below the results of a thoroughly exhaustive discussion of this subject had with Mr. Edison by a member of THE ELECTRICAL ENGINEER staff, and which we are certain will lead to the conviction that the work Mr. Edison has referred to is not merely the outcome of speculation, but is the result of an actual experiment on a commercial scale.

In order that our readers may be brought to a thorough understanding of Mr. Edison's recent work, it may be well to give a little of its early history. As far back as 1880, Mr. Henry Villard, at that time president of the Northern Pacific Railway, applied to Mr. Edison to devise for him a system of electric railways which should be comparatively cheap of operation and act as branch roads, and particularly as wheat feeders, to the Northern Pacific Railroad. Acting under this stimulus, Mr. Edison designed, and actually built, models of a system resembling in all essential details that which has been the subject of recent comment. Although not carried out in practice, the system devised for that particular purpose was kept constantly in mind by Mr. Edison, awaiting only the proper moment and a suitable time for its practical demonstration. About two years ago, Mr. Villard, having become president of the Edison General Electric Company, requested Mr. Edison, as electrician of the company, to devise a street railway system which should be applicable to the largest cities where the use of the trolley would not be permitted, where, if possible, the conduit should not be used, and where in general all the details of construction should be reduced to the simplest possible form. The limits within which Mr. Villard confined Mr. Edison were, simply, that the system so devised should not cost more than a cable road to install.

With these conditions placed before him, Mr. Edison reverted to his idea of nearly ten years before, and had thus settled upon a system in which current should be conveyed from the central station at high potential to motor generators placed below the ground in close proximity to the rails, and which should convert the current transmitted at the pressure of, say, 1,000 volts to one of 20 volts between rail and rail, with a corresponding increase in the volume of the current. This arrangement, of course, does not embody any striking novelty, and, as Mr. Edison puts it, might have been devised by any one of fifty electricians in this country. The working out of the details of this system, however, was by no means a small matter. With the utilization of heavy currents at low voltage it became, of course, necessary to devise apparatus which should be able to pick up with absolute certainty 1,000 amperes of current through two inches of mud, if necessary. Mr. Edison at once set about to devise such a contact. For this purpose he experimented with a metal wheel, imitating, as nearly as possible, all the conditions of electric railway street traffic as regards speed of wheel and condition of track. It was several months before he succeeded in getting even 100 amperes by means of the contacts which had up to that time been employed; but after persevering trials a device has finally been evolved which can readily pick up a thousand amperes through two inches of mud.

Having provided for this difficulty, it was next necessary to obtain a joint between contiguous rails such as would permit of the passage of several thousand amperes without introducing undue resistance. This has also been accomplished with the result that an experimental track of about a quarter mile in length has been in actual operation near Mr. Edison's laboratory for some time past, and working to his complete satisfaction.

The objections to which rails charged at a potential of 20 volts and carrying enormous currents would be open were early foreseen by Mr. Edison, and, as a consequence, provided for. Thus it has been said that carriages with iron wheels passing over the tracks would short-circuit the current and cause the destruction of the dynamo machines as well as "chew up" the short-circuiting vehicle. To test this, Mr. Edison actually short-circuited his experimental track with a carriage having iron wheels, and succeeded in getting only 200 amperes through the wheels, the low voltage used, as well as the insulating properties of the axle grease, being sufficient to account for the small quantity of current which actually passed through. Again, the experiment was made of short-circuiting the track with an iron bar. As a result it was found that with the iron bar polished, and contact effected by a man standing upon the bar, only 1,000 amperes passed through it, that is, the amount which would be taken by a single car, and hence far below the capacity of the generators.

Probably the first difficulty which would seem to stand in the way of the successful solution of the problem in the manner undertaken by Mr. Edison would be looked for in the apparently large leakage of current between the rails in damp and wet weather. On this point the experiments of Mr. Edison are decidedly interesting. They have proved to him conclusively that at a potential difference of 20 volts the loss of current due to leakage between the rails under the worst conditions, with a wet and salted track, is only five h. p. per mile, while very wet weather would involve a loss of only two and a half h. p. It is interesting to note that in this respect the leakage observed between the car tracks follows identically the phenomenon observed on telegraph lines. With the latter it is a matter of common knowledge that in damp, murky weather, with the insulators covered with wet dust, the leakage is far greater than during rainy weather, when the insulators are cleaned by the action of the water. In the same way a heavy rain storm will reduce the leakage between the rails by washing away the accumulations between the tracks due to the droppings of horses, which serve largely to increase the conductivity. In dry weather the loss, evidently, is practically nothing, but even under the most disadvantageous conditions a loss of five h. p. per mile, as shown, may be neglected in practice.

What has just been said with reference to the track applies equally well to the motor. While not differing in principle from the ordinary type of street railway motor, the motor on this system would be practically waterproof without necessitating any special protective covering for that purpose, and in the experiments actually undertaken by Mr. Edison to determine this point the motor was left out in the rain unprotected, without giving rise to any subsequent troubles, showing that the matter of insulation may be practically ignored. As regards the question of safety to human beings and animals likely to come in contact with the rails, it is needless to say that the effect of 20 volts upon the human body is imperceptible, and actual experiment has also shown that horses are not affected by it in the slightest degree.

The cost of this system, Mr. Edison estimates, will vary between $30,000 and $100,000 per mile of double track, not including the cost of the stations, and depending, between these limits, upon the amount of traffic. The running expenses, he estimates, will be exactly the same as those on the overhead trolley wire systems. With this high initial cost, it is evident that the system cannot be, nor is it intended to be, applicable to any but the largest cities and the largest short roads, where the traffic is such as to warrant an expenditure of such magnitude; and the criticisms which have been made on the system are largely based on ignorance of this fact, which, it will be acknowleged, is one of pre-eminent importance. Although the cost, as above stated, may appear to be heavy, it can be very easily shown that, where the traffic permits of it, the system can be applied with far greater economy than a cable road. In the first place the latter would involve a greater expense, in proof of which we need only cite the fact that the Third Avenue cable railroad, now in course of construction in this city, was contracted for at the rate of $150,000 per mile without stations, while the Broadway cable road is estimated to cost not less than $300,000 per mile. But in addition to the item of first cost in favor of the electric railway must be considered the fact that the cost of operation of the electric road would be far below that of the cable. The traction efficiency of cable roads under the most favorable circumstances, it is well known, hardly exceeds 18 per cent. to 25 per cent., while 50 per cent. ought to be readily obtainable with the electric system. Another advantage, which, though of secondary consideration, should not be overlooked, lies in the fact that to install the system devised by Mr. Edison would require no extended tearing up of the streets and would offer practically no interruption to the traffic of existing roads, which could be converted in a very short time to the electric system.

In conclusion, we may add that estimates are now being prepared for the conversion of one of the largest street railways in New York city over to the electric system, after the plan of Mr. Edison, and it is to be hoped that arrangements will soon be effected by which the system may receive a practical trial on a large scale in the near future.

ELEMENTARY GEOMETRICAL THEORY OF THE ALTERNATE-CURRENT TRANSFORMER.—XVIII.

BY

Chas. Steinmetz.

XI. Data of Some Commercial Transformers.

To see how the polar diagram looks in practical apparatus we produce as an instance two of the best types of commercial transformers, one of European make, a Ganz & Co. 10 h. p. transformer, tested by Prof. Kittler, and a small 1 h. p. Westinghouse transformer, tested at Cornell University by Prof. Ryan; both give fairly well the average shape of different types of transformer diagrams. One is a large "secondary generator," supplying a whole district, almost absolutely compounding and without magnetic leakage, a ring transformer with inside iron core and primary and secondary conductors wound on the ring over each other. The other is the smallest size of a high-frequency transformer, supplying only a few lights, with outside iron, and considerable magnetic leakage.

Of a commercial constant current transformer I am sorry that I could not gather any data. It would be of great interest, because just in these transformers many phenomena are more marked, which are of less importance in constant-potential transformers, as explained before.

A.—Ganz & Co. Low-Frequency 10 *H. P. Transformer.*

Tested or given data:

Cross-section of iron: 130 square centimetres.
Weight of iron: 95 kg.
" " copper: 40 kg.
Total weight: 175 kg.
Internal resistance of secondary: $r_1 = .0135$ ohm.
" " " primary: $r = 4.2$ ohm.
Number of secondary turns: $n_1 = 60$.
" " primary " : $n = 1080$.
Frequency: $N = 42.5$ complete periods per second.
Maximum output: 7500 watts = 10 h. p.

When running with full load:

Primary impressed E. M. F.: $E_0{}^1 = 1926$ volts effective.
" current: $C^1 = 4.28$ amperes effective.
Pressure at secondary terminals: $E_1{}^1 = 105$ volts effective.
Secondary current: $C_1{}^1 = 75$ amperes effective.

When running with open secondary circuit:

Primary current: $C^{\infty} = .17$ ampere effective.
Energy consumed by the transformer: 200 watts.

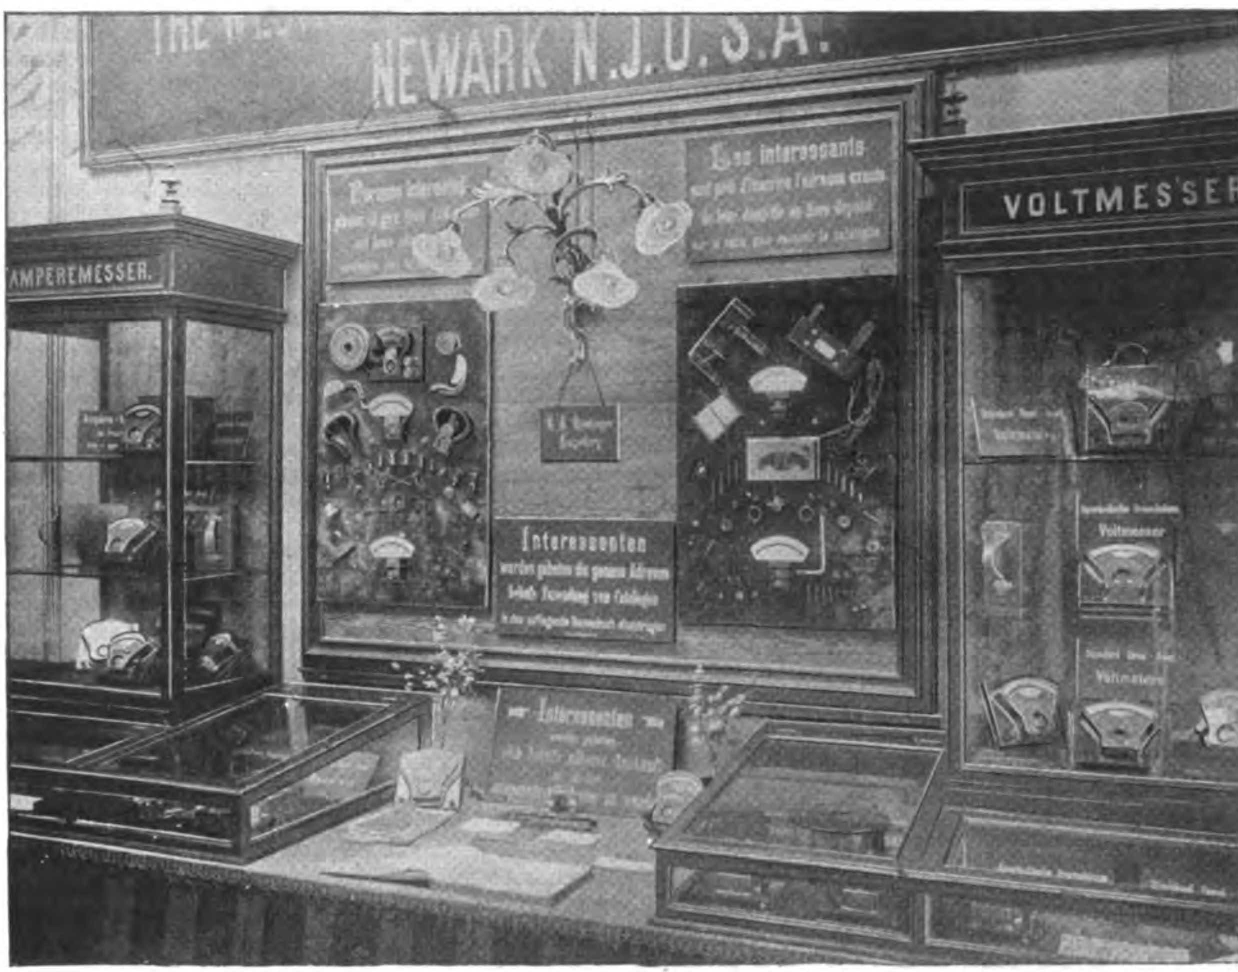
From this we derive, for the construction of the polar diagram, the results:

Magnetic resistance: $P = .00025$.
Magnetism: $M = 937000$ lines of magnetic force.
Magnetization, or induction: $H = 7200$ lines of magnetic force per square centimetre, maximum value.
Impressed M. M. F.: $K = 259$.
Ideal M. M. F. of hysteresis: $A = 114$.
Hence: resulting M. M. F.: $F = \sqrt{K^2 - A^2} = 233$.
Angle of magnetic lag: $\tan \alpha = \frac{A}{F} = .489$,
Angle $\alpha = 26°$.

speed at which the dynamo and engine run is 150 revolutions per minute, and the capacity of the dynamo is 19,250 watts running at 110 volts potential. There are three other dynamos shown, one driven by a steam engine of Swiderski, with a capacity the same as mentioned above; a second driven by a 12 h. p. gas motor at a speed of 375 revolutions per minute, and a third directly connected to an engine built by F. Voss, of Ehrenfeld; it has a capacity of 8,250 watts and runs at 280 revolutions per minute. Several motors of various sizes are also shown by this company in other buildings of the Exposition.

One of the most striking exhibits of its class is that of the Weston Electrical Instrument Co., of Newark, N. J. It might at first sight appear as a piece of hardihood for an American concern to attempt to compete with European manufacturers in the line of electrical measuring instruments, but it required just such an occasion as was presented by the Frankfort Exhibition to bring their merits before the European public. Perhaps no greater compliment could have been paid to Mr. Weston than the employment of his instruments by the official Testing Committee in their work.

The exhibit, which is illustrated in the accompanying engraving, was very tastefully arranged, and was in charge of Prof. R. O. Heinrich. It included a complete set of the various types of Weston voltmeters and ammeters. To those interested in fine electrical work the exhibit of the various parts which go to make up these instruments was somewhat of a revelation and demonstrated thoroughly the great care taken in their manufacture.



THE WESTON EXHIBIT AT THE FRANKFORT EXHIBITION.

THE FRANKFORT INTERNATIONAL ELECTRICAL EXPOSITION—X.

THE steam dynamo exhibited by the Electrotechnische Fabrik, J. Einstein & Co., Munich, in the "Haupt Maschinen Halle," consists of a dynamo directly coupled to a 125 h. p. engine built by Ph. Swiderski, in Leipsic; the dynamo has a capacity of 75,000 watts and works at a pressure of 125 volts. The speed is 200 revolutions per minute and the current is used for lighting the "Pfungstädter Bier Halle," the Cafés, the Labyrinth and Shooting galleries.

The exhibit of the Electrotechnische Fabrik, Carl Ilgner & Co., Minden i. W., consists of a dynamo directly coupled to a gas motor having a capacity of 30 h. p. The

THE ACCUMULATORS AT THE FRANKFORT ELECTRICAL EXHIBITION.—IV.

BY

D. Paul Schoop

It is easy to understand that the gelatinized cells are especially serviceable in all cases where batteries are moved or transported; for instance, in electric launches, street cars and velocipedes, and the lighting of ships, railway coaches, etc. There is a splendid electric launch on the River Main run by stored electricity. A battery of 34 cells, if the writer remembers aright, is placed at the bottom of the launch and connected with an electric motor of about 25 h. p. This launch, built to carry about 100 persons, was said to have been tried before on the Lake of Zurich, in quiet water, and absorbed between 10 and 15 h. p. at a speed of 10 to 14 kilometres per hour. The battery furnished the necessary current for 8 hours before becoming exhausted, and weighed about 3½ tons. All cells are filled with this stiff electrolyte, and the tops of the glass jars are covered by a layer of paraffine. The little ship may roll or pitch without causing any trouble in the battery, and is an object of interest to all visitors at the exhibition.

There is also a street car put into service by Messrs. Hostmann & Co., Hanover, making its daily regular trips from the Main River to the Jägerhaus (Waldbahn), a distance of some miles, which is said to give entire satisfaction. Of course, this does not mean very much, as this question depends entirely upon how much work an accumulator cell is likely to perform before its positive section has to be renewed, and what the cost of such accumulator work is per unit of cost of the accumulator plant. It seems worth trying, however, to get this experience with these cells containing gelatinized acid, as there is not the least doubt that these are superior to cells provided only with dilute fluid acid.

I may state right here, that at the time I was visiting the exhibition, not everything was finished, though it was at the beginning of August, and that the "Deutsche Accumlator-Actien-Gesellschaft" intended to put into use a street car and a small electric boat, both provided with so-called Tudor cells. It was a principal, fundamental point at this exhibition that it has been decided to make thorough tests of all electrical apparatus exhibited there by competent physicists and technical men, and to publish the results. Although it is hard to see how an opinion about a secondary battery cell could be given within so short a time, it will be, nevertheless, most interesting to know what has been found out. It is to be regretted that this exhibition is, in fact, *not* an "international" one, as claimed by the promoters, at least in regard to the accumulator show, since there are no English, American or French products to be seen. Where are the celebrated, but much abused, accumulators of the old Electric Power Storage and Light Co., London and of Elwell-Parker, Wolverhampton? Or the batteries of the French "Société Anonyme pour le Travail Élèctrique des Métaux," using the patents of Laurant Cély in a quite different way from the "pasting" of the English secondary battery cell? Is it just and right that all other kinds of reversible galvanic cells are lost to sight at this exhibition? Have the other types of accumulators no chance whatever to compete with the pure lead cell? We mean by this principally the copper accumulator as a perfection of the Lalande battery, well known in this country by the Edison-Lalande element, as first used for storage purposes by Commelin-Bailhâche and Demazures. Was it not claimed for that battery that the same work could be performed by it with only one-third to one-half the weight necessary with lead batteries? Is the form of the French copper accummulator not open to further perfection from both a mechanical and a chemical view, and is its rivalry with the lead cell out of the question?

Then there is the zinc accumulator, first adopted and worked out by Emile Reynier, Paris, put into a more promising shape in regard to the electro-chemical part by Meserole and taken up of late years in this country by Main. As is known, the voltage of such zinc accumulator is about 150 per cent. of that of the leaden cell, to wit, about three volts, and the capacity even higher than with the lead cells. Who can safely say that this cell will not be superior to the lead cell after it has been thoroughly experimented with and perfected?

The manufacture of electrical accumulators, as is known now-a-days, forms a part of that branch of electrical industry best designated by the name electro-chemistry. It is not the most important performance in this direction, as the electrical extraction and refining of copper holds already a larger amount of both work and capital occupied. If we mention here, as an appendix to the accumulator systems, the exhibits of the "Aluminium-Gesellschaft, Neuhausen," Switzerland, and the model of a plant for the electrical extraction of copper direct from the ore, put up by Messrs. Siemens and Halske, Berlin, we shall have mentioned nearly the whole of electro-chemistry. But last, not least, there is a little exhibit arranged by Professor F. Goppelsroeder, Mülhausen, Germany, of a striking appearance. Aniline dyes, made electrically, cotton printing by electrical reactions, and some other perfectly astonishing features are shown there. It is principally the artificial aniline-black and its production on the fibre itself, cotton, wool, or silk, which has been worked out during the last ten years by the inventor, and which are likely to be of practical use in a most promising manner soon. There are indigo and purple pieces of cotton, partly bleached or changed into sharp designs by means of electrical treatment for five minutes.

I may perhaps have occasion to consider more closely these other parts of the "Electro-Chemistry at the Frankfort Exhibition" in another article.

THE VARIATION OF THE ELECTROMOTIVE FORCES OF BATTERIES UNDER PRESSURE.

In a note contributed to *Comptes Rendus*, M. Henri Gibault states that the variation in electromotive force of batteries under pressure in cases where no gas is disengaged, may be expressed by a formula of the form

$$E_0 - E = a\,p - b\,p^2,$$

b being a very small quantity in cases where the pressures are not very great, the variation in fact being linear, which is in accordance with theory. In cases where gas is given off, the equation is

$$E_0 - E = A\,k\,p + c\,p,$$

c being very small; that is to say for moderate pressures the variation of force follows a natural logarithmic curve. The accord between theory and experiment is close, as may be seen by the following results:

Batteries.	Variations in $\frac{1}{1000}$ volt.

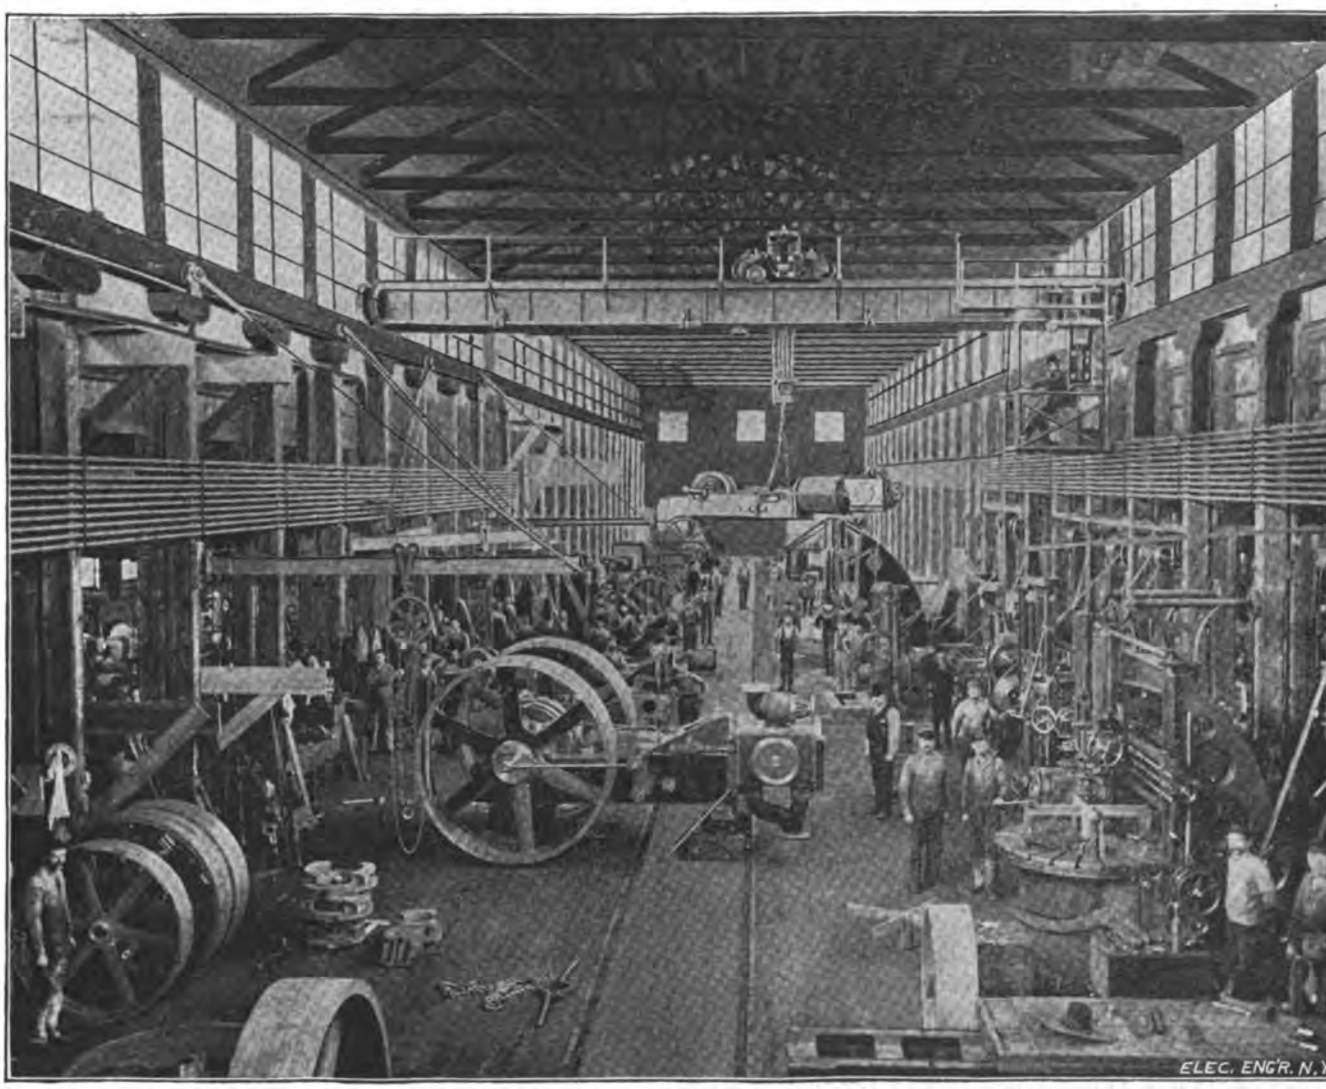
THE SHAW ELECTRIC CRANE AT THE McINTOSH, SEYMOUR & CO. WORKS.

THE use of traveling electric cranes in large shops has so greatly facilitated the handling of heavy parts of machinery that it may almost be said to have marked the beginning of a new era in machine-shop practice. One cannot but be impressed with the truth of this statement by a glance at the accompanying illustration, which shows a crane built by the Shaw Electric Crane Works, of Muskegon, Mich., at the works of McIntosh, Seymour, & Co., Auburn, N. Y., who have built so many large engines for electric light and power work, in the act of lifting a 150 h. p. compound engine.



HANDLING McINTOSH & SEYMOUR ENGINES WITH THE SHAW ELECTRIC CRANE.

This crane traverses the shop at the rate of 325 feet per minute and the carriage moves across at 120 feet, yet so delicate is the regulation that any weight, up to its full capacity can be moved $\frac{1}{16}$ inch in any direction. U. S. double reduction motors are used, two on the trolley carriage and one on the bridge, each one of which is entirely independent of the others, and an automatic brake controls the hoisting apparatus.

Messrs. McIntosh, Seymour & Co. say that this crane enables them to move heavy machinery twice as easily and five times as rapidly as the mechanical cranes previously used by them, and saves an enormous amount of labor. As an instance of this we may refer to the crane, recently shown in our columns, in the Baldwin Locomotive Works, which lifts a complete locomotive weighing 65 tons from one end of the shop and deposits it on the shipping track at the other end in about five minutes, an operation which used to take a large gang of men an entire night.

A NEW TELEGRAPH MACHINE.

A TELEGRAM from Berlin states that a new telegraphic transmitting machine has been invented by Herr Jaite, director of telegraphs. In the apparatus there are two electro-magnets, the one worked by a pocitive and the other by a negative current. These set in motion a perforator, whereby holes are punched in a tape. The holes, instead of consisting of mere dots and dashes, as in the Morse system, are so arranged that, on joining them with lines, the letters of the Roman alphabet are formed. The chief merit of the machine, says the report, is the extraordinary ease with which it can be worked. At a recent trial between the Berlin and Hamburg Stock Exchanges, a distance of nearly 200 miles, it was found possible to send from 65 to 85 messages per hour, or from 25 to 35 words per minute.

STANDARD FOR THE RESISTANCE OF COPPER.

BY

Silas W. Holman.

That the general adoption of a standard for the specific resistance of copper is much needed for technical purposes hardly admits of question. What that standard shall be is of far less consequence than that it shall be universally accepted. Now, it may safely be assumed that it is impossible to bring about the adoption of either a purely arbitrary standard (*e. g.*, soft copper, metre-gramme at 0° C., $=0.1400$ legal ohm), which would serve the purpose excellently, or a standard based on new investigations conducted, however thoroughly, by any local institution or society. It is therefore undoubtedly politic to turn to Matthiessen's classical work; and the American Institute of Electrical Engineers has acted wisely in following the current practice in that respect. To that extent therefore, I find myself in accord with the reports of its committee (on the Standard Wiring Table) which appear in the *Transactions* for November and December, 1890.

The object of the present note is, therefore, not to antagonize the efforts of the Institute in this matter, but rather to do what I may toward promoting the object in view. To this end I shall first point out a serious error in the temperature formula given by the committee, and, second, express my dissent from their main recommendation. In doing the latter I hope to show that a different recommendation might be more likely to meet with general acceptance, as well as prove otherwise more advantageous; and I trust that the opinions and reasons given may be those of many persons interested in the subject. I may also be permitted to express the hope that, as the matter is still far from a definite settlement, the attitude of the American Institute may yet be altered before the time comes for further action in reference to a universal convention on the subject.

The error referred to is as follows: One of the recommendations of the committee (*Trans.* p. 411) reads thus: "To find the conductivity of copper at temperatures other than 0° Cent., Matthiessen's formula may be used, viz:

$$C_t = C_0\,(1 - .00387t + .000009009\,t^2)\,; \qquad (1)$$

$$\text{or } R_t = R_0\,(1 + .00387t + .00000597t^2). \qquad (2)$$

The first of these, (1), is Matthiessen's formula for conductivity, and is correctly quoted, with a necessary change in the decimal point. The second, (2), purports to represent the same temperature variation expressed in terms of resistance. As (2) is identical in form with the formula given for the same purpose by G. B. Prescott, Jr., in an article in The Electrical Engineer (Vol. vii, p. 242, 1888), it is presumable that the committee adopted that formula. Unfortunately the Prescott formula, (2), is incorrectly deduced from the Matthiessen formula, (1), and its error is about 1.7 per cent. at 100° C. Before going into the cause of the discrepancy, however, I will give here, for convenience of comparison with (1) and (2), two correct formulæ deduced from (1) at my request by Mr. H. M. Goodwin, Assistant in Physics at the Massachusetts Institute of Technology. They are

$$R_t = R_0\,(1 + 0.004019t + 0.00000214t^2),$$
$$\text{Range } 0° \text{ to } 100° \text{ C.} \qquad (3)$$

$$R_t = R_0\,(1 + 0.003879t + 0.00000526t^2),$$
$$\text{Range } 0° \text{ to } 30° \text{ C.} \qquad (4)$$

They represent as nearly as such expressions with but two powers of t can do, the resistance-temperature function corresponding to the Matthiessen conductivity temperature formula (1). The reason for giving (4) in addition to (3) will appear latter.

The error in the Prescott formula, (2), arises from his use of the expression (*loc. cit.*)

$$r_t = r_0\,[1 + a\,t + (a^2 - b)\,t^2], \qquad (5)$$

by which to deduce the constants for (2) from those of (1). It is, of course, true that

$$\frac{r_t}{r_0} \times \frac{C_0}{C_t} = \frac{1}{1 - a\,t + b\,t^2}, \qquad (6)$$

where a and b are Matthiessen's conductivity constants. It is also true that

$$1 + a\,t + (a^2 - b)\,t^2 \qquad (7)$$

represents the first four terms in the quotient obtained by performing the division indicated in the last member of (6). The remaining terms, however, of the quotient which have been rejected by Mr. Prescott are not negligible except at low temperatures, but amount to 1.7 per cent. at 100° C. May it not be taken as certain that a formula so much at fault as this at high temperatures will never be generally accepted, although much less in error at the ordinary temperatures of practice?

The only available method of calculating the constants a' and b' for the desired expression

$$R_t = R_0\,(1 + a'\,t + b'\,t^2)$$

is to deduce values of $\frac{R_t}{R_0}$ for various temperatures, such as 20°, 40°, 60°, 80°, 100°, from values of $\frac{C_t}{C_0}$ computed from (1), and then to compute by the method of least squares the corresponding values of a' and b'. This is what Mr. Goodwin has done, arriving thus at formula (3). Matthiessen has given (*Phil. Trans.*, 1862, ciii, 25), values of $\frac{R_t}{R_0}$ deduced from (1), so that we may check our work at that point. These are quoted in the following table, which also shows the values computed from the Prescott formula (2), and from (3), and gives their percentage errors:

Temperature, Centigrade.	Matthiessen.	From (2) Prescott.	Percentage difference.	From (3).	Percentage difference.
20°	1.0797	1.0798	+ 0.01	1.0812	+ 0.14
40°	1.1633	1.1644	+ 0.1	1.1642	+ 0.08
60°	1.2497	1.2573	+ 0.33	1.2488	− 0.07
80°	1.3368	1.3478	+ 0.8	1.3352	− 0.12
100°	1.4222	1.4467	+ 1.7	1.4233	+ 0 08
			+ 0.6 Av.		0.1 Av.

It will be seen that both the extreme and the average error of the Prescott formula are from 6 to 12 times as great as those of (3), and that they are all of one sign. Nevertheless, (3) does not represent (1) as well as might, perhaps, be desired. This arises solely from the mathematical fact that using terms only up to t^2 in the series, it is impossible to have conductivity constants a and b and resistance constants a' and b', which will give results exactly coinciding.

Now, what we seek in connection with this matter of a standard is to obtain an expression reproducing Matthiessen's formula (1) as closely as possible, or rather closely enough to be generally accepted, regardless of how far his own various experimental data may have deviated from this. It has therefore seemed well to calculate constants for an expression whose range should be merely that of ordinary atmospheric and standard reference temperatures, as thereby an equation could be obtained which would, at the same time, cover all the conditions of technical practice, and exactly duplicate Matthiessen's values. This has been done by Mr.

Goodwin with the result given in equation (4). That this tallies with Matthiessen's figures with all desirable closeness appears from the fact that the values of $\frac{R_t}{R_0}$ computed from formula (4) exactly check those from (1) out to, and including, the fourth place of decimals (as far as Matthiessen carries his own computed values and further than they are reliable) at all temperatures up to the limit of 30°, and indeed somewhat above that limit. This is beyond the requirements of technical practice, as well as far beyond the concordance of Matthiessen's experimental data. Thus, formula (3) should be used for work above 30°, and (4) between 0° and 30° or 35°. Of course, if it were at all desirable, other formulæ could be computed to represent Matthiessen's values more closely at higher temperatures, *e. g.*, one serving between 30° and 60°, and another between 60° and 100° C. In recommending a formula for general adoption, it would doubtless be best to fix upon either (3) or (4) or some suitable expression, urging only a single formula.

It should be noted that Matthiessen's formula (1) is the mean of six (*Phil. Trans*, 1862.) obtained from three samples (the same which were used in the absolute specific resistance measurements) of copper, each sample being studied both before and after annealing. The material was electrotype copper in all three samples. Two of them were from the same piece, and all from the same source. Although the same sample gave a sensibly different temperature formula before and after annealing, yet the differences were less than the variations among the samples, so that Matthiessen preferred to use a mean of all. Thus (1) represents the change in hard drawn as well as annealed wire. It should also be remarked that, as these six formulæ differed among themselves at 100° C. by about 0.5 per cent., we cannot assume that (1) will apply with greater closeness than this to any sample which we may happen to have in hand. We adopt the Matthiessen formula, then, if at all, merely as represening the temperature variation of *his* copper, the same whose specific resistance we propose to adopt as a reference standard.

If we apply it to other copper, we must recognize that in so doing we presumably introduce an error of sensible, and perhaps of large, amount. For exact work the temperature correction of each sample must be tested, or the conditions of the test must be made such that the temperature correction is eliminated or the error introduced by the assumption that (1) applies to the sample is negligible.

Turning now to the question of a standard of specific resistance, it will be found that the committee, in the following words, quote, as a basis for further recommendations, Matthiessen's values for his pure copper: "A hard drawn copper wire, one metre long, weighing one gramme ('metre-gramme'), has a resistance of 0.1469 B. A. unit at a temperature of 0° Centigrade." From other data by Matthiessen (*Phil. Trans.*, 1864) they also deduce the value 1.0226 as the ratio of the resistance of his hard drawn to his annealed or soft copper.

These values check with those which I had deduced for my own work, and seem to be correct. But from the further recommendations of the committee I must dissent. The first of these is as follows, and it alone need be considered, as the others depend upon it: " . . . and the conclusion has been reached that the most correct and satisfactory 'Matthiessen Standard,' and the one which we recommend for general adoption, is as follows: A soft copper wire, one metre long and one millimetre in diameter ('metre-millimetre') has an electrical resistance of .02057 B. A. unit at 0° Centigrade."[1]

It must be perfectly obvious to any one who examines Matthiessen's work that the metre-gramme value, 0.1469 B. A. unit at 0° Centigrade, is the one which he held as best representing his own results on hard copper. From this and the ratio 1.0226 the metre-gramme of soft copper is 0.14365 B. A. unit at 0° Centigrade, or 0.14206 legal ohm at 0° Centigrade. Also, from the fact that for the specific resistance by length-section (metre-millimetre, cubic-centimetre, foot-mil,[2] etc.,) the computations were all based on diameter measurements of wires from 0.5 to 0.7 mm. in diameter, it is equally obvious that Matthiesen's metre-millimetre value is far less accurate than the 0.1469, and that he so regarded it. This fact is, of course, not a conclusive argument against its adoption, but why should we adopt it as the standard?

The primary reason appears to be that there is needed for engineers and dealers a table of pure, or at least of standard, copper wire, arranged according to size, rather than weight, of the wire. A length-section standard of resistance appears, at first sight, more directly in accordance with that desire. But on further consideration this reason loses its apparent weight, for *what we really need is two separate things, namely, first, a standard of conductivity or of specific resistance; second, a resistance table arranged according to size of wire.* The former will be used only in connection with accurate tests of the quality of copper, the latter never for that purpose, but only for wiring computations in engineering practice.

It is easy to see that such a wire table is not available as a criterion of the quality of a sample of wire, or at least only in a very rough way. Different wires of the same nominal size, in the market, are rarely of the same actual cross section. The differences are great enough to correspond to variations of several per cent. up to, say, No. 10 B. & S. Thus, of two wires of the same nominal size, the one of the poorer copper may have less resistance than the one of better copper, merely because actually of larger section, whether by design or accident. We cannot, therefore, except for rough work, depend on the measured resistance and *nominal* size, but must measure the section. And this can be done with sufficient accuracy to afford a test of the quality of the copper only by weighing in water. But this means that we must make a complete measurement of its length-section specific resistance, and if we have done that, then we have no use in that connection for the table, for we shall refer the resistance at once to the length-section standard which we may have adopted.

We come, therefore, directly back to a fundamental question, Is the length-section standard intrinsically better, or worse, than the length-weight standard? This is easily answered by showing that a length-section specific resistance measurement is more laborious and is subject to more sources of error than one in terms of length and weight. In both the electrical measurements are the same, and also the length measurement. For the length-section value we must weigh the wire in air and in water, with suitable precautions. For the length-weight value we have only to weigh in air. Thus the former determination involves the labor and sources of error incident to a specific gravity determination, which the latter does not. There seems to be no compensating advantage.

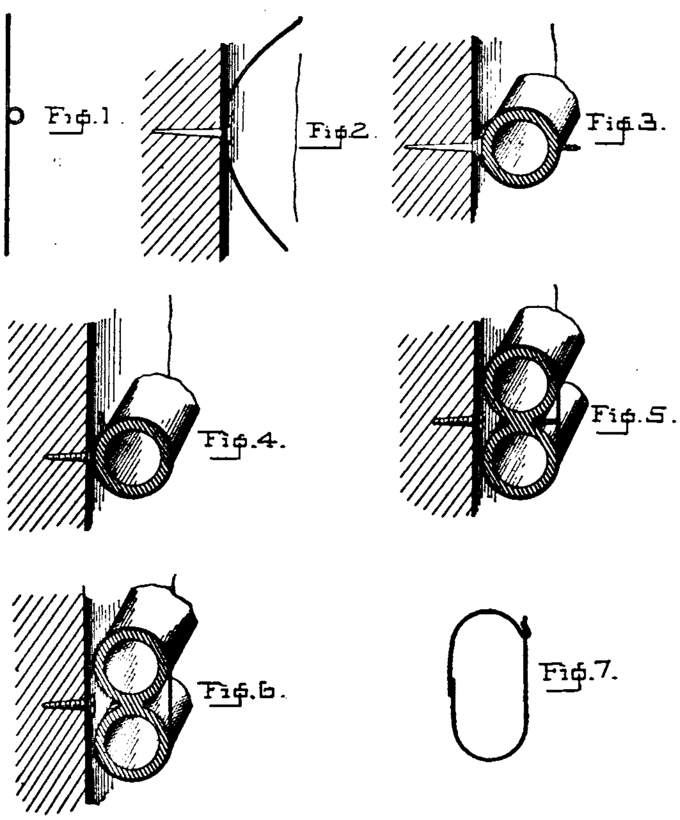
If a length-weight standard is adopted, then to compute the size-resistance table some value must be adopted for the specific gravity of copper. For this we may, if we choose, take a value deduced from Matthiessen's diameter measurements, as has virtually been done by the committee, or we may measure the specific gravity of a suitable variety of samples, and use the average value. The latter method would be by far the best, as it would give a value, and thus a table, not subject to sensible modification by later observers. For such a course there are three reasons. First, the Matthiessen value would almost surely be in error, and thus open to critical objection and to change. Second, the experimental value could be made so accurate

1. The fourth significant figure is in error in some of the values given by the committee, owing apparently to the retention of too few places in calculation.

2. This should be foot-mil, not mil-foot, both by analogy and because the prefix mil already carries another definite significance in scientific terminology.

that the residual error would be exceedingly small. Third, as the table is only useful for engineering purposes, a high degree of accuracy is not essential, so that the experimental value would be abundantly close, and there would be nothing to be gained by amending the table later, even if other investigations should lead to slightly different values for the specific gravity. Moreover, it is to be noted that, for similar reasons, it is of far less importance that there should be a universal adoption of a wiring table than of a standard of conductivity. Thus we can afford to throw over, altogether, the question of the adoption of a specific gravity, if by that simplification we can gain the main point, viz., a standard of conductivity.

The matter may then be summarized, as seen from the writer's point of view, as follows: Unless the whole subject is thoroughly reinvestigated by some such body as the International Bureau of Weights and Measures, or the German Standards Commission, the best and simplest value for the standard of specific resistance of copper, and the one most likely to receive general sanction, is;



Clamps for Interior Conduits.

Resistance of metre-gramme of Matthiessen soft copper at 0° Centigrade = 0.14365 B. A. unit = 0.14206 legal ohm. For this the Matthiessen conductivity-temperature formula (1) and a proper modification of it into a resistance-temperature formula should also be adopted.

A NEW DRY CELL.

A new dry cell, brought out by Herr Leo Graef, in Rotterdam, is said to possess a high electromotive force with extremely good recuperative properties. From tests made it appears that a cell on open circuit gives 1.55 volt. On being closed on a 50 ohm circuit for 13 minutes the volts fell to 1.50, but had again risen to 1.54 after four minutes' rest. On external resistances of 10 ω, 5 ω, and 10 ω respectively the volts after 15 minutes fell to 1.41, 1.31, and 0.95; but a four minutes' interval was sufficient in the last case to raise them again to 1.30.

CLAMPS FOR INTERIOR CONDUITS.

BY

Augustus Noll

The ordinary method of fastening interior conduits to sidewalls and ceilings is unduly expensive, both in point of time and the cost of a special band or buckle of brass. The use of staples makes it possible for the man driving them to miss his aim and strike the tube, cracking or breaking it. Being out among the users of tubing, and hearing the various complaints, I have given this matter a little attention and have struck what I think is the best way.

Instead of using the broad, thin strips of brass, bought by the hundred, I use a thinner piece of brass or galvanized iron, No. 12 or 14, B. and S. This piece is twisted once around the nail or screw, which is then driven into the wall. Fig. 1 shows the twisted wire. Fig. 2 shows the twisted wire with the nail, and Fig. 3 shows the nail driven home and the wire holding the tube in position. Fig. 4 shows the twist of the wire on top of conduit, where it will be out of sight. This can be done when the tube work is exposed.

Fig. 5 is the same as Fig. 3, except that a duplex instead of a single tube is used.

Fig. 6 represents a duplex tube held in place by a wire clamp or pin. Instead of twisting the ends, it is held in position like a safety pin. Fig. 7 shows the design. The twist is where the nail or screw is inserted, and when this is driven into the wall the pin is held in position. These can be put up first, and then the tubing can be laid in and locked. This is a handy and neat way of fastening the tubing where it is exposed, as the only thing that will show is the small line of wire across its face.

THE DETERMINATION OF THE AVAILABLE ENERGY OF WATER POWERS.[1]

BY

Francis R. Hart.

The total work which a given quantity of water, falling a given number of feet, is capable of doing is expressed by the following formula:

$$W = L \times h,$$

where W, is the total work in foot-pounds,
L, the weight of water in pounds,
and h, the height in feet through which it falls.

If we let Q be the quantity of water falling in cubic feet per minute, and call 62.34 pounds the weight of a cubic foot, we have the total energy in horse-power,

$$E_t = \frac{Q \times h \times 62.34}{33{,}000}.$$

Of the total energy of the falling water, a certain proportion, varying chiefly with the size and description of the water-wheel or turbine used, can be utilized. This proportion represents the efficiency of the system. Calling this efficiency, or percentage of total power which is available, k, we have for the available energy in horse-power,

$$E_a = \frac{Q \times h \times 62.34}{33{,}000} \times k.$$

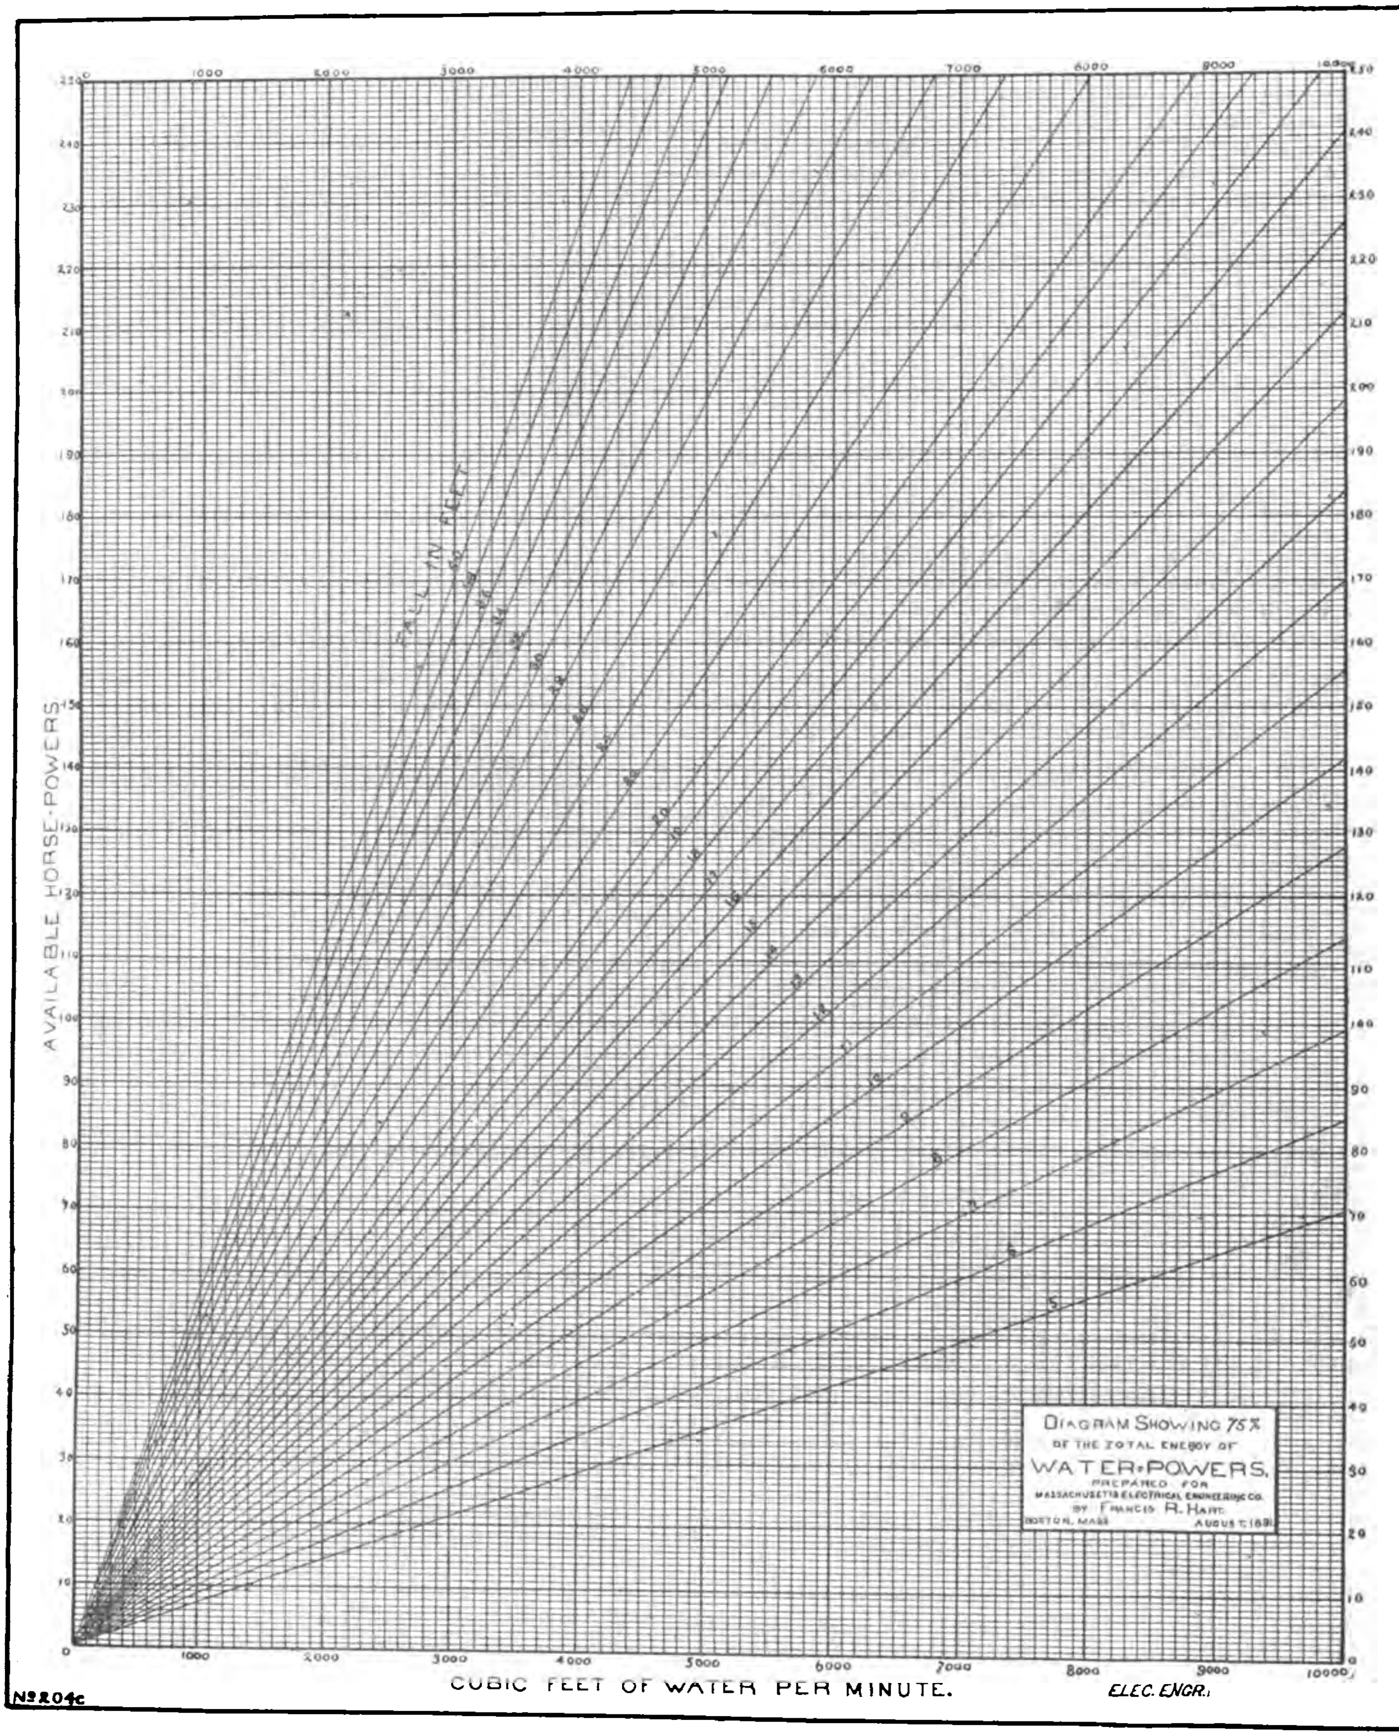
The accompanying diagram showing Available Horse-Power has been calculated with an assumed efficiency of 75 per cent.

To determine the available horse-power from the diagram, it is necessary to know the flow of water in cubic feet per minute and the fall in feet. The abscissæ repre-

1. Contribution from the Laboratory of the Massachusetts Electrical Engineering Company.

sent the cubic feet per minute, the ordinates the available horse-powers, and the diverging lines the fall in feet.

To illustrate the use of the diagram, suppose we have a water privilege with a flow of 8,300 cubic feet per minute and a fall of 20 feet: the ordinate intersecting the junction of the cubic feet and feet fall lines represents 235 available horse-power. This checks with the calculation by the formula. If the flow had been 83,000 cubic feet instead of 8,300 or if the fall had been 200 feet instead of 20, the available horse-power would have been ten times as great, or 2,350. In this manner, practically, all possible combinations of flow and fall can be applied to the diagram.



THE STROWGER AUTOMATIC TELEPHONE EXCHANGE.

WITH a view to providing a means whereby telephonic connections at the central office may be made electrically without the assistance of an operator, Mr. Almon B. Strowger, of Chicago, Ill., has devised the arrangement shown in the accompanying illustrations.

In Mr. Strowger's system the same general plan is adopted as in that now in use, in having a central station and a number of sub-stations placed in electrical connection with each other at the central office by line-wires, but differs in having an additional series of wires to operate the mechanism at the central office. At the sub-stations are the appliances which are used to transmit and receive communication, while at the central office are arranged as many switch-cylinders, with their attendant mechanisms, as there are sub-stations. From each line-wire "connectives" extend to the inside of each cylinder, there being as many connectives attached to each line-wire as there are sub-stations.

In the accompanying illustrations, Fig. 1 represents the system in perspective, showing at a distant sub-station one telephone and its exchange device at the central office and also the main-line-wires connecting the central office with the sub-station. Fig. 2 represents four of such devices, showing the manner in which the cylinders are connected, and Fig. 3 is a plan view of a series of cylinders, line-wires and connectives, showing the normal position of the circuit. Fig. 4 is a sectional view of the cylinders, showing more clearly the construction of the circuit-closer and feather-and-groove attachment.

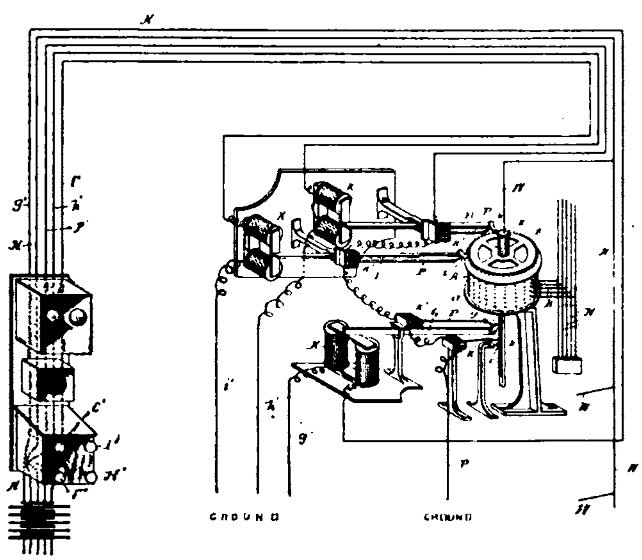


FIG. 1.

As will be seen, a hollow glass cylinder, A, is provided with perforations, *a*, arranged in transverse and vertical rows. The wire connections B extend from the inside of this cylinder through the perforations, and are attached to the main-line-wires N. The function of these connections is to conduct the current to any desired sub-station when brought in contact with a circuit-closing needle C C′. The terminals of these connections are shown at *b*, Fig. 4. Here the circuit-closing arm is represented in parts. Within the sleeve C is closely fitted the circuit-closing needle C′, held in such a manner as to be in perfect electrical contact with the wire-terminal *b* by the spring *c*. The rod D, Fig. 4, is placed along the axle-line of the cylinder and is free to rotate and move longitudinally. The lower end of the rod D has a sleeve into which is inserted the upper portion of the ratched-rod D′. This sleeve construction between the rods allows the ratchet-rod to have a longitudinal motion only and keeps the ratchet-teeth *d* continuously toward their attendant pawl.

The ratchet-rod is provided outside of and below the

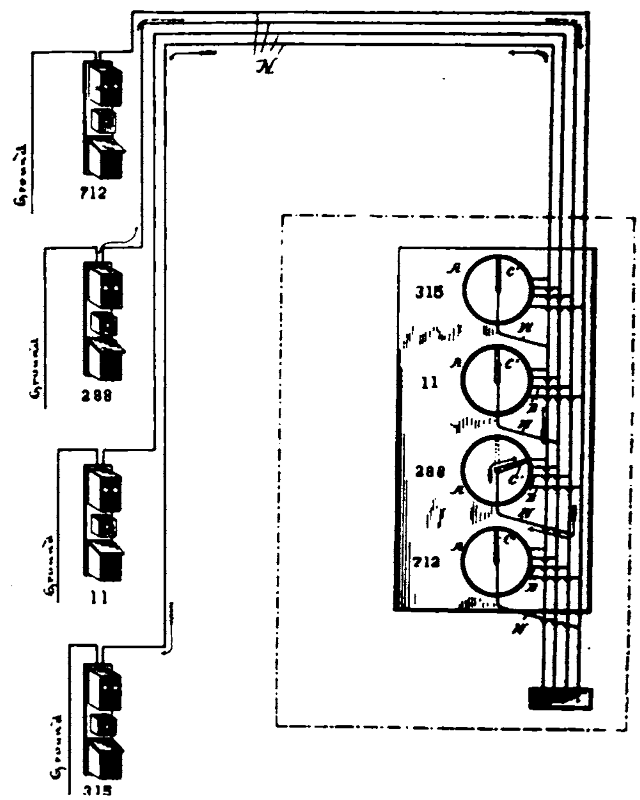

FIG. 2.

cylinder A with a series of ratchet-teeth *d*, by means of which both rods are moved longitudinally. The wheels E and E′, through the hub of which the rod D extends with a feather-and-groove connection, R, Fig. 4, so as to cause the rotation of the rod D and at the same time admit of its longitudinal sliding movement, are provided on their peripheries with a series of ratchet-teeth by which the rod is rotated, and with it the circuit-closer C and C′.

The levers G H I have pawls *g h i* pivoted in their ends in position to engage the ratchet-teeth, with which they are in contact. Each lever has a vibratory movement and is oscillated by the alternate energizing and de-energizing of its respective magnet. At each pulsation of the push-button at the sub-station the needle C′ moves from row to row and from wire to wire in the row. At each sub-sta-

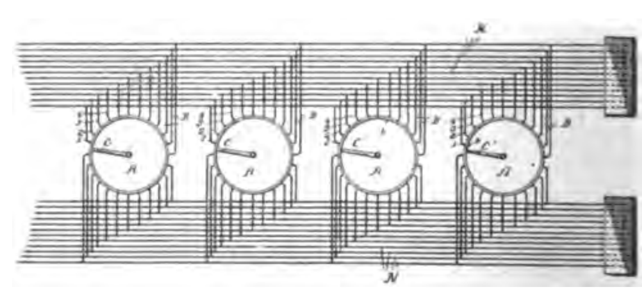

FIG. 3.

tion there is a set of keys marked, respectively, G′, H′, I′ and P′. Each key is connected by wire with its respective lettered magnet at the central office.

Each perforation *a* of the cylinder A is numbered with respect to an initial or starting point on the cylinder—for example, in rows numbered 1 2 3 4, etc.—from the lower end of the cylinders upward and by places in each row—as, for example, 1 2 3 4, etc.—to the right or left of a given vertical row; so that, supposing there were one hundred perforations in each of the rows, No. 310 would be in the third row from the bottom, ten spaces to the right or left of the vertical initial line.

The operation will now be clearly understood. The person wishing to place his transmitter in connection with that of another, will do so by successively pressing the keys which move the circuit-closer C C′. For example, if telephone 288 wishes to place himself in connection with telephone 315 he does so by pressing the key marked G′ three times, then the key marked H′ once, and then the key marked I′ five times. His circuit-closer is then in contact with wire-terminal No. 315. In Fig. 2 sub-station No. 288 is represented as being in connection with sub-station No. 315. This is known by the positions of the circuit-closer of cylinder No. 288.

Had its circuit-closer been turned to the next wire indicated in the figure, 288 would be in connection with 11. When conversation is ended, the person calling up hangs

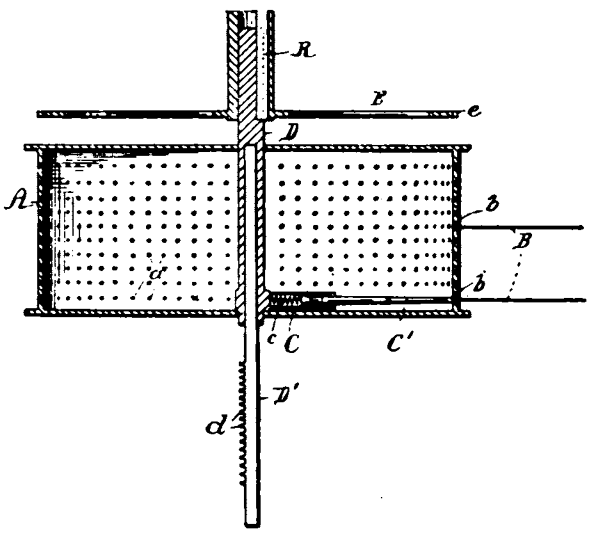

FIG. 4.

up his earphone, depresses the key marked F′, which causes the magnets K to be energized, withdrawing the several pawls from their engagement with the ratchet-teeth and allowing the circuit-closer to fall and return to its initial point.

TOMMASI'S MULTITUBULAR STORAGE BATTERY.

IN a recent issue, we gave a brief description of a new type of storage battery designed by M. Donato Tommasi, of Paris. Since then the inventor has introduced several improvements, having in mind specially the arrangement to obtain solidity and simplicity of construction, and long life. Each electrode is composed of a perforated tube of lead, ebonite, porcelain or celluloid, the bottom of which is closed by a plate of ebonite, in the centre of which is fixed a rod of lead, which acts as a conductor. The space between the central rod and the walls of the tube-electrode is filled with the oxide of lead. Metallic contacts connect respectively the rods of the positive tubes with the rods of the negative tubes, so that the current, in order to pass from one to the other, is obliged to spread over the entire active mass and thus produce a chemical circuit without loss and with uniform action throughout the active material.

The tubular electrode from which the best results have been obtained is in the form of a rectangular cylinder, as shown in the accompanying illustration, Fig. 1, and in this form of the central lead rod is provided with a number of wing-like projections. Special precautions are, of course, taken to prevent the coming in contact of electrodes of different polarity. As a result of this arrangement, the active matter, and hence the capacity of the cell, is greatly increased, and its weight is said to be from two to six times

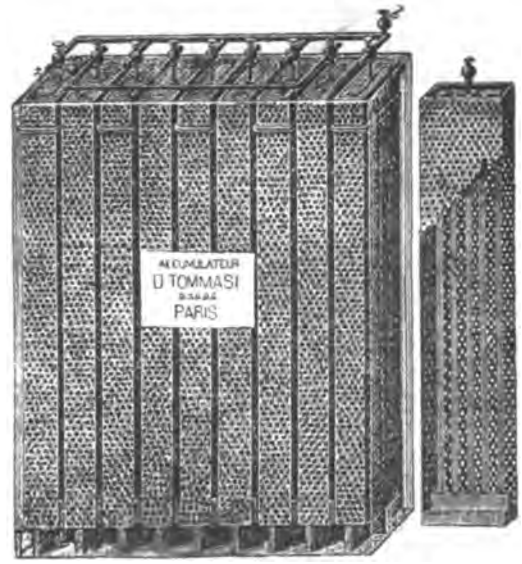

FIG. 1.—TOMMASI'S MULTITUBULAR STORAGE BATTERY.

less, and its volume four to eight times less, than that of the accumulators at present in use. M. Tommasi also claims that in forming or charging his multitubular battery a current of 60 amperes per kilogramme of electrode may be employed, as against one ampere employed in present practice. On account, also, of the absence of allsoldered joints in the connections between the different elements, all interruptions in service are prevented. This type of cell also is free from expansion of the tube, and the active matter, being entirely enclosed, does not fall, and hence a short circuit cannot take place. The illustration, Fig. 2, shows a set of these cells connected up for work. The Tommasi accumulator includes 67 per cent. of active matter, the ratio of active matter to that of lead in weight being about 2.1 to 1; that is, for 100 grammes of lead there are 210 grammes of active matter. The following tables give the principal electrical details of the cell: E. M. F., 2.4 volts; capacity per kilogram of electrode, 16 ampere

FIG. 2.—TOMMASI'S MULTITUBULAR STORAGE BATTERY.

hours; current efficiency, 95 per cent.; watt efficiency, 80 per cent. Mr. Tommasi has also undertaken the manufacture of light tubes, such as celluloid or ebonite, which also tend to reduce the weight of the cell still more.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XII. NEW YORK, NOVEMBER 18, 1891. No. 185.

I do not perceive that a mathematical mind, simply as such, has any advantage over an equally acute mind, not mathematical, in perceiving the nature and power of a natural principle of action. It cannot of itself introduce the knowledge of any new principle.—Faraday.

MR. EDISON'S ELECTRIC RAILWAY.

AFTER the occurrences of the past five or six weeks, who will be inclined to deny the hold that Mr. Edison has on the public imagination? However much some may have doubted it before, they now know that his utterances on electricity catch the public ear and eye irresistibly, as do those of no other man, and that what he says is caught up and echoed and amplified in most exaggerated forms; while should there be any great problem that people would like settled offhand between meals, the difficulties are at once referred to him as to a kind of universal inventor simply waiting for hard questions to be put at him so that the solution may at once be given.

Whether we like it or whether we don't, the public will go on this way, choosing its heroes and crediting them with all manner of ability and power. That is one side of the matter. The other side is the responsibility resting on the man thus picked out for such proud preëminence. Here, perhaps, ground may fairly be found for some of the sharp criticisms lately made against Mr. Edison for his statements as to electric railroading. Mr. Edison to-day is unfortunately just as free and unconfined in the expression of his hopes and beliefs and opinions as when he was a humble operator; and he is just as fond of turning over in his mind all sorts of extraordinary projects as the day when he made his first invention. The result is that, knowing how eager the public is to see anything he has said, the "bright and breezy" newspapers of the day are everlastingly interviewing him. They look upon him as a nickel-in-the-slot machine; they drop in a reporter whenever they feel like it, and take out a full-page talk on any subject they want him to enlarge upon. The trouble with these reporters is that few of them, even when highly educated, as most are, know where the statement of fact ends and the discussion of theory and possibilities begins. Few of them are informed on electricity and mechanics, and probably still fewer of them are aware that Julian Hawthorne once said that if Mr. Edison would quit inventing and go in for fiction, he would make one of the greatest novelists this country ever saw.

And this brings us to the recent scare in electric railway circles over one or two of Mr. Edison's late remarks on what might be done with electricity in traction work beyond what had already been accomplished. The public knows that Mr. Edison has made a few inventions that render his name immortal, and, therefore, aided by various reports in the papers, has at once jumped to the conclusion that his optimistic prophecies and boyishly vigorous belittling of difficulties point to actual achievements rather than to something which is yet to be. They know that electricians are constantly predicting the arrival of a time when the steam roads of the country will be operated by electricity, and therefore when their Colossus of electrical inventors thinks aloud that he is "getting there," that settles it. He is there!

We took occasion lately to deprecate the wild newspaper talk on this matter, but it has seemed to us that we might go further and explain with some definiteness just what it was that Mr. Edison had been working at. So far all the talk in electrical and lay papers has been aimless, because no authoritative statement had been made that could be depended upon. We now publish in this issue a very full and clear statement of Mr. Edison's work, and while for obvious reasons as to patents the article does not go into the minute details of construction, enough is said to show that Mr. Edison has attacked a well-defined problem in a well-defined way, and has reached some well-defined results. It is also clear that for the present the trolley system will be left in undisturbed possession of an enormous field. How it could be otherwise with direct current we fail to see. But we do believe that at no distant date, with the alternating current, which Mr. Edison thus far for some occult reason has let severely alone, electrical engineers will find a way of operating long roads and of abolishing the now indispensable overhead wire. In the meantime, and as we have said before, if Mr. Edison has furnished one more means of operating roads electrically, it is universal cause not for complaint, but for congratulation. Every electrical engineer must have regretted seeing the recent heavy investments in cable roads on Broadway and Third Avenue in this city, and will therefore be quick to welcome any new method that shall make such roads electrical, while avoiding the various objections to which electric and cable methods have hitherto been open, when applied to heavy city work.

PAYING LOADS FOR STATIONS.

"Does electrical distribution pay?" In answer to this question it may safely be asserted that where the business has been in the hands of competent and conscientious managers, and where there has been fair capitalization, it is paying, and paying well. The experience which is now available as the result of ten years of active work ought to be a sufficient guide to the station manager, and if his own experience is not adequate, the means for supplementing it are now at hand. We are confirmed in these views in perusing the able paper read by Prof. W. D. Marks, supervising engineer and general manager of the Edison Electric Light Company of Philadelphia, before the recent Edison Convention in this city. In this paper, entitled "How to Get Paying Loads of Stations," Prof. Marks states that his station was started about two years ago, with the price per lamp hour fixed at $1\frac{1}{8}$ cent, which would be the equivalent of gas at $2.25 per M. As gas was selling at $1.50 per M in Philadelphia, the company had to acknowledge that electricity cost more than gas and that it was a luxury. The deterrent effect of such an admission became so apparent that after a few months the price was reduced to $\frac{3}{4}$ cent per lamp hour, thus placing it on a par with the cost of gas. With the cost the same, and with the acknowledged superiority of electricity, the result was not long in making itself manifest.

On the vexed question as to who should undertake the wiring and who should pay for it, it is interesting to note the course pursued by Prof. Marks. His company did no free wiring, but at first furnished service, meter and lamps free of charge. At the end of a year's trial of this system, they furnished only the meter free, and the consumer paid for service and the first installation of lamps; and they still renew lamps free of charge, when not broken. The company preferred also not to do house wiring, and encouraged the establishment of wiring firms by the payment of 15 cents premium for all lights secured, with the result that thirteen wiring firms are now engaged in this business in Philadelphia, all working according to the rules, and under the inspection, of the company. In the same way Prof. Marks encouraged the establishment of agencies of the various motor companies, with the result that no less than nineteen motor firms are represented in Philadelphia. These, together with the wiring firms, constitute no fewer than thirty-two active canvassing agents, who make a profit if they secure customers for the Philadelphia company, but who receive no salary whatever. The company sells power for all 110 volt motors at lamp rates; for 220 volt motors the rate is $7\frac{1}{2}$ cents per horse-power hour. If a consumer takes more than 1,000 horse-power hours, and less than 1,500, the price is fixed at $75 per month; all power above $1,500 is sold at five cents per horse-power hour. Prof. Marks also points out in his paper that motors which run during the day, say from 7 A. M. to 6 P. M., are advantageous as giving the machinery of the station a uniform load, but in winter, when the lighting begins at 4.30 P. M., they overlap the lighting load, making a maximum load occurring between 5 and 6 P. M., and sometimes a very high maximum as compared with the average load. Small factories, business houses, stores and buildings used for offices, closing at 6 P. M., all add largely to this maximum load without burning on an average more than $1\frac{1}{2}$ hours in 24, and for this reason should not form too large a proportion of the station load. With 55,064 lamps connected each lamp yields a gross income of $51\frac{4}{10}$ cents per lamp per month, or $1\frac{71}{100}$ cent per day, the average burning of each lamp being $2\frac{56}{100}$ hours, giving an average selling price of $\frac{668}{1000}$ cent per lamp hour.

PIONEERS IN MULTIPHASE CURRENT WORK.

The attention which the electrical transmission of power between Frankfort and Lauffen has served to call to the multiphase current motor, has led some of our London contemporaries, in their recent issues, to cast doubts upon the utility of this type of motor, and in a witty and caustic editorial the London *Electrician* goes so far as to characterize "the whirling of the three-phase armature at Frankfort as, in more senses than one, a *tour de force*."

To this animadversion Mr. Gisbert Kapp replies at some length, and takes our contemporary to task for thus attempting to throw obstacles in the way of deserving pioneers, who ought to be encouraged in their work.

The editorial of our contemporary has also called forth a letter from Mr. C. E. L. Brown, late electrical engineer of the Oerlikon Works, in which he points out some chronological errors into which our contemporary has fallen. Thus he says:

> "In your article on 'multiphase currents' I find that you are overlooking some of Tesla's patents. This inventor describes quite clearly in his patents from '87 to '88 the three-phase current as applied at Frankfort; and the only novelties which this (Frankfort) Exhibition brings to light are important constructive improvements in its application."

This brings out, in a striking manner, the position occupied by Mr. Tesla in this field, and is a strong confirmation of our recent editorial relative to Mr. Tesla's early work in alternating current motors with two-phase and multiphase currents.

If any further testimony were required on this point, we need only cite a letter by Prof. George Forbes, appearing in the last issue of the *Electrician*, from which we quote as follows:

> "I was also anxious to support the claims of Tesla secured by his twenty-five American patents on this subject, and the practical results of whose work I have examined and tested in America, though they are little known here. I had a remarkable proof of the necessity in all fairness of doing so, for one of the greatest electrical authorities confessed to me yesterday his ignorance of the fact that the dynamo used with Tesla's motors generated separate currents of distinct phases."

Prof. Forbes here states what we have long known to be a fact, viz., that many otherwise well-informed electrical engineers are almost totally ignorant of the principles involved in the construction of rotary field alternating motors. Under such conditions it is not to be wondered at that impressions have gone abroad and statements have appeared that time alone can set right. Mr. Tesla need not be anxious for his fame. We only hope that he may speedily secure also the substantial and tangible justice that every meritorious inventor is entitled to look for.

THE LOCALIZATION AND REMEDY OF TROUBLES IN DYNAMOS OR MOTORS.—VIII.

BY

Francis B. Crocker and S. S. Wheeler.

DYNAMO FAILS TO GENERATE.

This class of troubles is, of course, confined to dynamos and corresponds somewhat to the previous class for motors. This trouble is almost always caused by the inability of the machine to sufficiently "excite" or "build up" its own field magnetism. The starting of a dynamo requires a certain amount of residual magnetism, which must be increased to full strength by the current generated in the machine itself.

1. Cause.—*Reversed residual magnetism,* due to (*a*) reversed current through field coils, (*b*) reversed connections, (*c*) earth's magnetism, (*d*) proximity of another dynamo, (*e*) brushes not in an effective position.

Symptom.—Little or no magnetic attraction when pole-pieces are tested with piece of iron.

Magnetism weaker when machine is running and field circuit closed than when machine is stopped or field open, because current generated tends to build *down,* as it were, or neutralize the magnetism.

Remedy.—Send a magnetizing current from another machine or battery through field coils, then start and try machine; if this fails, apply the current in the opposite direction and try machine again.

Reverse field and armature with respect to each other, *i. e.,* reverse connections of either one or shift brushes.

---

2. Cause.—*Too weak residual magnetism.* Symptoms and remedies of this trouble are substantially the same as in the previous case, but the attraction for a piece of iron is even weaker—in fact, practically nothing.

---

3. Cause.—*Short circuit in the machine or external circuit.*

This applies to a shunt-wound machine, and has the effect of preventing the voltage and the field magnetism from building up.

Symptom.—Magnetism weak, but still quite perceptible.

Remedy.—If short circuit is in the external circuit, the opening of the latter will allow the dynamo to build up and generate full voltage. If the short circuit is within the machine, it should be found by careful inspection or testing. In either of these cases do not connect the external circuit till short circuit is found and corrected.

A slight short circuit, such as that caused by a defective lamp socket or copper dust on the commutator, may prevent magnetism from building up.

---

4. Cause.—*Field coils opposed to each other.*

Symptom.—If pole-pieces are approached with a compass or other freely suspended magnet, they both attract the same end of the magnet, showing them both to be of the same, instead of opposite, polarity.

For similar reasons the pole-pieces are quite strongly magnetic when tested separately with a piece of iron, but show less attraction when the same piece of iron is applied to both pole-pieces at once, whereas the attraction should be much stronger. In multipolar machines these tests should be applied to consecutive pole-pieces.

Remedy.—Reverse the connections of one of the coils, so that the polarity of the pole-pieces is opposite and not the same.

---

5. Cause.—*Open circuit.*

(*a*) Broken wire or faulty connection in machine, (*b*) brushes not in contact with commutator, (*c*) safety fuse melted or absent, (*d*) switch open, (*e*) external circuit open.

Symptom.—If the trouble is merely due to the switch or external circuit being open, the magnetism will be at full strength, and the machine itself may be working perfectly, but if the trouble is in the machine, the field magnetism will probably be very weak.

Remedy.—Make very careful examination for opening in circuit; if not found, test separately the field coils, armature, etc., for continuity with magneto or cell of battery and electric bell. (See Instructions for Testing.)

CONCLUSION.

It is obviously difficult, if not impossible, in the treatment of dynamo and motor troubles to give complete directions for locating or identifying all the various troubles, but in most of the cases this will be found possible; and moreover it is a fact that a mere list of these troubles, particularly if it is systematically arranged, is of the greatest help in overcoming these difficulties. It is in the promptness and intelligence with which such troubles are dealt with that the ability or inability of a man is most clearly shown.

PRELIMINARY NOTE ON A METHOD FOR DETERMINING THE PERIODIC CURVES OF ALTERNATING CURRENTS.

BY

Louis Duncan.

(Johns Hopkins University.)

THE experimental methods heretofore used for the determination of current and electromotive force curves in alternating circuits present many difficulties and are cumbersome and tiresome. Most of those now in use are based on the experiments of Joubert, who obtained the E. M. F. curve of a De Meritens dynamo by making instantaneous contacts between the dynamo circuit and measuring circuit at different points on the E. M. F. curve. This method was modified by Messrs. Wilkes, Hutchinson and myself[1] to give curves of primary and secondary E. M. F. and current in alternating circuits containing transformers, condensers, etc. Our method has been copied by Prof. Ryan and others, and the results which we obtained some years ago have been duplicated and extended. M. Blondlot has

1. *The Electrical World,* March, et seq., 1888. It is a mistake to imagine that any special electrometer is needed for this method; an ordinary Thomson quadrant electrometer was used in our work and our measurements were apparently made as easily as those of later experiments.

recently still further modified the method by using a galvanometer through which a condenser, charged to a potential representing different points on E. M. F. curves, is discharged, the deflections being photographed. By using two contact-making arrangements or wipers, with two galvanometers, two curves were obtained at the same time.

The difficulties of most of these methods lie in the very considerable potentials used on the commutators—as much as 1,500 volts in some experiments—the fact that only one curve can be obtained for each commutator; with the possibility of error due to the contacts.

The following method is simpler and gives better results: To get the four curves representing the primary and secondary E. M. F.'s and currents, four small dynamometers are made and their stationary coils wound for primary current, primary E. M. F., secondary current and secondary E. M. F., respectively, their movable coils being connected in series in circuit with a few storage or other cells; this latter circuit having one end connected with a contact point on the dynamo shaft, the other end connected to a wiper touching the contact point at each revolution. The wiper is movable through the arc of a circle (180° is sufficient if the curves are not to be photographed). These dynamometers may be cheaply and quickly made with wooden spools and a quartz fibre suspension, the current being carried by pieces of coiled tinsel or fine wire as in a d'Arsonval galvanometer. Four of them may be easily made in a day.

In making the experiments the deflections of the dynamometers are either observed or photographed. It is evident that if the instantaneous current in a movable coil occurs when the current in the stationary coil is zero, there will be no deflection; if the latter current is at its maximum, the deflection will be a maximum; while for intermediate values the deflection (I am considering small deflections, of course) will be proportional to the instantaneous value of the current in the stationary coils. By moving the wiper through 180° uniformly, if we are photographing, we get all of our curves simultaneously, without the possibility of changed conditions changing their relative values. A galvanometer in circuit with the movable coils allows an absolute scale to be applied to the curves, after the dynamometers have been once calibrated, and eliminates any error caused by the wiper. We are thus able to obtain any number of curves simultaneously with only one commutator, with only a few volts on this commutator, and with no possibility of errors due to the contacts.

FIRE HAZARDS FROM ELECTRICITY.[1]—I.

BY C. J. H. WOODBURY.

ONE of the many innovations arising from the introduction of electric lighting has been the development of a new feature in underwriting, which is the beginning of methods of practice which will in time greatly modify systems of insurance.

There have been two methods of dealing with questions involving the insurance of elements of unusual hazard: the one being that of underwriting pure and simple, estimating the hazard from the best data at hand, and charging a rate commensurate with that risk,—the correct principle being that the hazard of the whole is equal to the greatest hazard of any part of the risk.

The other method has consisted in eliminating the hazard of the more dangerous parts by removing such processes to another building, or at least placing them in a portion of a building where the chances of their imperiling the whole would be controlled by special methods of construction and also by additional fire apparatus, or, in other words, bringing the hazard to conform to the rate of insurance.

The latter method is confined to class insurance of such limited range that the detailed supervision of risks can be within the personal scope of the administration of such insurance companies.

When electricity was first used for lighting on a commercial scale, no small part of the knowledge gained of phenomena was the fact that it became a frequent cause of fire, and in such unexpected ways that a general alarm ensued, which would have stopped its use if electric lighting had not so completely filled a need for more light that a prohibition was out of the question. Electricity had come to stay, and the problem of its status must be met and not evaded.

Those whose familiarity with electrical lighting appliances is only that of to-day, with every element of the apparatus established in commercial affairs, can have but little appreciation of the condition of such matters a little over ten years ago.

Everything was new, crude and undeveloped. The leading inventors were pursuing their investigations under great difficulties, not the least of which was the lack of trained assistants. Mechanics had much to learn in the construction of the apparatus; the proper manufacturing supplies were not in the market; and the steam engines especially designed for operating dynamos had not been made. The development of the whole business required invention, education and organization from one end to the other.

Electric lighting then pertained to apparatus for the physical laboratory; now it is one of the great commercial features in the business world, reaching in all its applications in the United States to investments estimated by Lieut. Allen R. Foote, special agent United States Census, to be $232,202,850, out of a total of $552,202,850 invested in electrical enterprises, and divided as follows: Telegraph companies, $125,000,000; telephone companies, $100,000,000; isolated lighting plants, $6,000,000; central station plants, $155,202,850; electric railways, $70,000,000; fire alarm and police patrol, $10,000,000; steamboat plants, $1,000,000; sundry industries, $10,000,000; manufactures, $75,000,000.

The introduction of electric lighting in this country was followed by numerous fires caused by this new method of illumination. After the disturbance incident to the first scare, careful investigations were made into the subject, the greatest result of which was the establishment of the opinion that the elements of excessive hazard were not necessarily inherent in such applications of electricity. In other words, such fires were to be classed as preventable fires within the limits of ordinary practical means; and on this basis the rules for electrical installations were first prepared, only to be followed by other rules, drawn up by various parties, to apply to new conditions for the use of electricity for the transmission of power and alternating currents, as well as to improvements in both arc and incandescent lighting.

The electric lighting interests have always, and without exception, co-operated with the underwriters in these investigations, which, indeed, could not have reached to successful results had it not been for the indispensable services afforded by the skill of those engaged in this manufacture.

The results have fully justified the means, for electricity is today the safest method of artificial illumination. This safety is not due to the absence of possibilities of danger, but to the entirety with which these elements of danger may be held in control, and also the elimination of the hazards inherent to lighting by either gas or oil.

The essentials of safety consist in confining the electricity to its metallic circuits, the prevention of undue arcs in switches and lamps, and the prevention of sparks or carbons falling from arc lamps; but in their applications these precautions are necessarily involved in order to meet all of the complex conditions of the apparatus used in the various applications of dynamo currents.

The danger of fire from dynamo currents is almost entirely due to the diversion of a portion of the electricity from the system, and to the fact that the miscellaneous conductors forming these outside circuits are not adequate to convey the current without undue and dangerous heating. Moisture on an otherwise poor conductor generally plays an important part in such conversions of electricity into heat, because the small trickling of water is readily dissociated, and then the resistance at the place is increased to a sufficient amount to cause the electricity to be converted into heat of sufficient temperature to ignite any combustible material in its path.

Rain-water, or that from ponds used for a public water supply, is a rather poor conductor, but in passing over whitewash it takes enough salt and lime solution to become a very fair conductor, and the same applies to water used in washing floors.

About ten years ago I made some experiments upon this matter for the purpose of investigating into the conditions of two fires caused by arc lighting circuits.

From the binding posts of an arc lighting dynamo with forty lights in circuit, two wires about six feet in length were secured, one foot apart upon a broad board, thus providing the greatest difference of potential in the circuit, amounting to about two thousand volts, in a place where it was convenient for experiment. The board was washed with a clean mop wet with pure water, but without producing any effect. Then a little salt was thrown into the water, and the water was rapidly dissociated and evaporated, and the board set on fire, not merely on its surface, but well into its interior.

These matters are cited in advance of their proper place for the purpose of presenting the importance of protecting a system in buildings from exposure to water, and also the urgency of keeping the system free from electrical connection from the earth; for

1. A lecture delivered at Cornell University, Nov. 6, 1891.

while it is a rare coincidence that a single conductor should connect two wires of opposite polarity, yet, if one ground exists, any second connection to earth will establish an outside circuit.

A few months ago an electric lighting wire chafed against an automatic sprinkler pipe until the insulation was worn by the abrasion. The first ground already existing at some other part of the system completed a circuit, and the heat of the arc was sufficient to melt a hole in the pipe, although it was full of water.

It should be remembered that when a single arc is formed it can be blown out as readily as the flame of a candle. This is seen in the air jets used to break the arcs on the commutator of a Thomson-Houston dynamo of the squirrel-cage pattern. In the lightning arresters of the same system, the arc being dia-magnetic, it is broken by the repulsion of an electro magnet.

I wish to submit to you some of the principal considerations covering the several conditions of installations, presenting what should be considered as a consensus of the opinions of underwriters and electricians who have made a specialty of questions pertaining to the fire hazard of electricity, and these opinions are mainly based upon the experience of actual fires, or experiments in which conditions of possible hazard have been simulated.

Dynamos, generators, and motors should be considered as machines rather than merely as electrical apparatus. The shafts of the armature should be provided with journals well suited to maintaining free lubrication and to run without undue heating. The oil pans should be arranged so as to prevent any oil from being spilled on the floor, and moreover, the oil should be drawn from these pans so frequently as to prevent any accumulation of oil therein.

The dynamo should rest upon substantial foundations adequate to keep it from jarring, and if used to generate currents at a tension of over 350 volts, there should be a space under the floor, as that is about the only means of preventing the attendants from receiving severe shocks if there should be a ground on the circuit.

Dynamos should be protected from exposure to water, and for this reason it is generally unadvisable to place automatic sprinklers over a dynamo-room, as a discharge of water from any of these might cause a great deal of injury. Each dynamo should be provided with a waterproof cover, which is to be placed over it when not in use.

The use of motors and dynamos for trolley systems of street car propulsion introduces special features which must be provided for. In the present state of the art, the single trolley wire with a return current through the earth is the only feasible means of operating an electric system of street car propulsion; and the question of the extra hazard of the motors must be met by placing the generators in special buildings, and thoroughly protecting the system of overhead wires by suitable guard wires.

The reason why the double-trolley wire system is not practically effective is due to matters pertaining to mechanical questions, such as the difficulty in arranging switches, and also the necessary complexity of the double trolley in comparison with the single trolley.

The single-trolley system is not advocated, as has been alleged, on account of any economy of copper wire, because in order to insure ground returns of low resistance, copper wires are buried between the tracks the whole length of the line and connected to each rail by branch wires riveted to the web and soldered to the buried wire.

One of the more recent applications of electricity for illumination is the use of alternating currents in connection with transformers or converters. This apparatus should be situated in a secure place outside of the buildings, except in case of underground service, when the converter may be put in any convenient place that is dry and does not open into the interior of the building.

Converters should be equipped with safety fuses at the junctions of all feeders and mains, and furthermore, the wires of the secondary circuit should be protected against the current of the primary circuit from reaching the interior of the building by the use of air or film cut-outs connected with both poles of the wires of the secondary circuit near to the converters, in order that if there should be any direct electrical conductivity from the primary to the secondary circuit, the primary circuit would be grounded at once. These cut-outs are generally adjusted to operate whenever the current reaches a potential of 350 volts.

It is not desirable to permanently ground one of the wires of the secondary circuit, because in such case the wires have the same fire hazard as if the circuit was furnished with electricity from a dynamo, which would be diverted from the system whenever a second ground occurred; and it should also be borne in mind that the alternating currents tax an insulation more severely than a continuous or even pulsating current, and that as a practical matter the primary circuits of an alternating system conveying currents of high potential are almost always grounded.

Switchboards are a frequent cause of fire, because at these points are concentrated most of the extreme differences of potential due to the system, and arcs are frequently formed in the ordinary use of the switchboards. A switchboard should not be placed against a hollow partition or in any other place where it might readily communicate fire to the building. Thus far, slate appears to be the preferable material for the construction of such switchboards, but when such switchboards conduct currents of high potential there is a slight leakage across slate, and it is necessary that the holes should be bushed with hard rubber or other material. Switchboards should not be made in any event of plain wood surfaces, but whenever the circumstances are such that it is not practicable to use an incombustible material, an open skeleton of wood will best serve the purpose.

Whenever resistance boxes or equalizers are placed, precautions should be taken for the prevention of any accident in case they should become heated. Most of the frames of such apparatus are now made of metal, and asbestos paper is placed behind them if they are secured near to wood.

The lightning arresters should be connected to the earth outside of the building, and gas pipes should not be used in such connections. Water pipes are the best base to which to attach wires from lightning arresters.

The matter of outside wires cannot be adjusted on the basis of the electric principles involved, because the numerous difficulties arising from other features of the subject render the question still an unsettled problem. The wires for the most part are either over buildings not lighted by electricity, whose occupants, not being patrons of the lighting company, have no interest in the functions of these wires; or the wires are carried on the poles along the streets, where their status pertains to the rights of the general public to the unobstructed use of the highway. These qustions have not been settled, and will not be settled until there is found a way to settle them.

The matter is not helped by any such enactment as that passed by one of the States several years ago, to the effect that all wires should be underground before November 1, 1885, or to similar ordinances passed by numerous municipalities during the last six or eight years.

It is not surprising that there should be a general opposition to overhead wires, of such a widespread and determined nature that they would have been placed underground years ago had there been any means which were feasible in every respect. The only reason for this suffrance of overhead wires has been the fact that the uses of electricity have been essential to the needs of the community.

Underground wires are no new thing. In fact, they preceded aerial wires, and nearly strangled the invention of the telegraph; for when the first line was being laid in 1843 between Baltimore and Washington along the line of the Baltimore and Ohio Railway, subject to the conditional consent of the board of directors that "the wires should be removed in case that the electric fluid caused any injury to the property of the company," the wires, as a part of Prof. Morse's invention, were covered with an insulation placed in lead pipes, and for nine miles from Baltimore to Relay Station, laid underground by means of a special plough invented by Ezra Cornell. This line did not work, and Ezra Cornell made the invention which expanded the telegraph from an apparatus to a system, by placing the wires overhead attached to insulators at points of support.

Since that time ingenious inventors have endeavored to devise methods for running the wires underground, without producing anything financially practical except to a limited extent, and not feasible in any event except in densely populated localities where the patronage is sufficient to meet the excessive expense. All must recognize the great work of Edison in his invention of an underground system adapted to his system of incandescent lighting.

One of the pioneer efforts to devise an underground system fitted to American practice in arc lighting was that of Prof. W. A. Anthony, who laid wires under the Campus at Cornell University in 1878, but I have been informed that this did not stand the test of the deteriorating influences of time and the drain layer's pick.

The fall of a pole is always a misfortune, and may be a disaster. In all events it is an occurence to be avoided, and I believe that in cities it will be found a wise precaution to use wood treated by some of the antiseptic processes, or to substitute tubular iron masts for wood poles in accordance with the best American practice for supporting trolley wires.

WORLD'S FAIR NOTES.

At a meeting of the committee on electricity, electrical and pneumatic appliances, of the World's Columbian Exposition, held October 26th, the following names were decided upon as those of eminent electricians not now living to be placed over the Electricity Building at the Exposition:

Franklin, Galvani, Ampere, Faraday, Ohm, Sturgeon, Morse, Siemens, Davy, Volta, Henry, Oersted, Coulomb, Ronald, Page, Weber, Gilbert, Davenport, Soemmering, Don Silva, Arago, Daniell, Jacobi, Wheatstone. Gauss, Vail, Bain, De la Rive, Joule, Saussure, Cooke, Varley, Steinheil, Göericke, La Place, Channing, Priestley, Maxwell, Coxe, Thales, Cavendish.

Letters to the Editor.

Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents.
Anonymous communications cannot be noticed.
The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.
In order to facilitate reference, correspondents, when referring to any letter previously inserted, will oblige by mentioning the page on which it appears.
Sketches and drawings for illustrations should be on separate pieces of paper.
All communications should be addressed EDITOR OF THE ELECTRICAL ENGINEER, *150 Broadway, New York city.*

HUMAN COOKERY.

YOUR remarks as to the experiments that Dr. Southwick proposes to inaugurate to ascertain how much the electric current will cook or burn human beings and animals, recalls the statement I used to read when I was a boy, in *Fox's Book of Martyrs*, illustrated by a cut representing one of them on a gridiron being broiled alive over a slow fire. The author represents the victim as saying to his tormentors:

"This side enough is toasted,
Then turn me, tyrant, and eat,
See whether raw or roasted
I am the better meat."

As the electric current renders speech impossible, of course we shall have no such heroic utterances, though it is not unreasonable to imagine that such thoughts may occupy the mind in advance of its application.

Personally, I have no objection to the use of electricity for executing criminals, even though it should raise a blister, for that certainly is far less cruel than the scenes witnessed not infrequently at hangings, and is nothing like so repulsive as the bloody beheadings by the guillotine or the headman's axe.

The question in which the public is mainly interested is the certainty that crime will be punished and not so much how the punishment shall be inflicted, though of course the less barbarous and revolting the better.

No thoughtful person can doubt that the great prevalence of violent crime in this country is due to *the uncertainty of its punishment*, the chances being three to one, if not more, in favor of the escape of the criminal from any punishment. That, however, is the fault of the courts, our played-out jury system, and the efforts of the criminal lawyers, who, for money, become parties to the crime after its commission by their clients, and who I consider but little, if any, less guilty than the principals.

W. C. DODGE.

WASHINGTON, Nov. 11, 1891.

Literature.

Central Station Management and Finance. By H. A. Foster. New York, *C. C. Shelley*, 1891. Paper, 50 pages. Illustrated. $1; cloth, $1.50.

THE series of articles contributed to the columns of THE ELECTRICAL ENGINEER during the present year by Mr. Foster have now been put together in book form. We are glad to know that the articles have met with very cordial approval from authorities on the special subject, and that the book has already been adopted for use in some of the collegiate courses in electrical engineering. A station superintendent or electrical engineer who has thoroughly mastered Mr. Foster's scheme of organization and accounts—and it is not at all difficult—will find his work very much improved in efficiency, and the margin of profit greatly increased. Not a little of the value of the book lies in its reproductions of the various forms, tables, blanks, etc., which are recommended for use. As the first and only book on the subject, this treatise by Mr. Foster will enjoy a large sale.

How to Make Inventions. By E. P. Thompson. New York, *D. Van Nostrand Co.*, 1891. Paper, 161 pages; price, $1.

THIS is a unique book. Probably nobody but Mr. Thompson himself could have written it, for very few men combine with industry and ability the experience gained as mechanical engineer, electrical engineer, chemist, professor, editor, expert, lecturer, inventor, and patent attorney. It is a cross between Smiles' *Self-Help*, a manual on physics and a patentee's guide; and while the mixture may seem incongruous, we can only say that the result is a book of intensely interesting character. It is a volume to be put in the hands of every ardent student or ambitious young inventor, and we do not believe anybody can read it without being in some way benefited. Many of its hints—and there are thousands of them—are most valuable, for Mr. Thompson often goes so far that he leaves little to be done by the inventor of the actual apparatus which shall embody his suggestions. Here and there Mr. Thompson makes a most useful survey of the work done in certain fields, and shows why some paths are hopeful, while others cannot possibly lead to success. Chapter IX, for example, on the principles involved in light and heat as tools for inventions, is an extraordinary example of pith and point; and Chapter XII, dealing with chemistry, is almost as good. Chapter XXIII, suggesting some problems still to be worked out, provides not a little food for thought, and shows Mr. Thompson to be a very keen observer of the drift of invention. It is a funny thing, but nevertheless a fact, that inventors tail after each other like so many sheep. One of them hits on a new idea, and then five hundred other fellows pitch in, and the consequence is that there is an awful amount of reinventing and wasted work in duplication of hopeless experiments. Mr. Thompson brings out the fact very clearly that there is a New World for every man if he have but courage, perseverance and genius—these three, and principally the first two. We note few mistakes in the book. One is the statement that Frank J. Sprague was in the army. Mr. Sprague is one of the numerous exiles from the navy.

Electricity Simplified. By. T. O'Conor Sloane, E. M., Ph. D. New York, *Norman W. Henley & Co.*, 1891. Cloth, illustrated, 158 pages; price, $1.

THIS is an excellent little book, well worth perusal. The keynote is touched in the preface, when the author says: "A theory which is far from complete has been constructed by modern scientists, and may eventually acquire perfect shape. The hypothetical luminiferous ether is at its base. The probable identity of species of electromagnetic and light and heat waves gives us an additional right to use the ether in explaining these manifestations of electricity." Developed along these lines, we get a very forcible treatment of the whole subject; and, at the same time, the book is practical in the best sense of the word. The author is to be commended for the careful subdivision and grouping of his matter and for the complete index.

Society and Club Notes.

NEW YORK ELECTRIC CLUB—GOVERNMENT TELEGRAPHS.

THE New York Electric Club will have the pleasure, within a month, of listening to a lecture by Mr. E. Rosewater, editor of the *Omaha Bee*, a leading Republican newspaper of the West, on Government Telegraphs. This gentleman has recently returned from Europe, where he has been studying the subject in behalf of our own Government and of Postmaster-General Wanamaker. He is himself a strong advocate of national control of the telegraphs, and has accumulated a large amount of data on all sides of this question, which is destined to become a big political issue sooner or later. Mr. Rosewater has had exceptional qualifications for his investigation, being himself an old telegrapher. He is now president of the Old Time Telegraphers' Association. The Entertainment Committee of the club expect that the meeting will be one of the most fully attended of the season, and are already being pressed for invitations, the subject being one of very important social and political, not less than electrical, bearings. The club is to be congratulated on having before it an authority who will thus make public some of the results of his European mission.

THE FRANKFORT ELECTRICAL EXHIBITION BEFORE THE INSTITUTE AND ELECTRIC CLUB.

AT a joint meeting of the American Institute of Electrical Engineers and the Electric Club, to be held at the clubhouse, 17 East Twenty-second street, Tuesday evening, November 24, Dr. Carl Hering will present a paper entitled "Notes on the Frankfort Electrical Exhibition," illustrated with lantern slides. Dr. Hering was chairman of the delegation of the American Institute of Electrical Engineers to the Electrical Congress, and was given every facility to investigate thoroughly all departments in the Exhibition. To those who were not able to visit Frankfort this occasion will afford the best possible opportunity for obtaining full information from an intelligent and expert observer.

Through the courtesy of the officers of the Electric Club, the privileges of the house will be extended to all members and guests of the Institute who may present the usual notice of meeting issued by the secretary.

NEW YORK ELECRICAL SOCIETY.

A SPECIAL feature of the New York Electrical Society is that it is composed of peripatetic philosophers. In other words, it makes a point of visiting as many places of electrical interest as possible, and its members have thus enjoyed some rare and most delightful opportunities. Another of these occasions will be furnished this week, on Thursday, at 8 P. M., when, through the kindness of the Fire Commissioners and of Mr. J. Elliot Smith, the superintendent of fire-alarm telegraphs, the Society will make a thorough inspection of the fire headquarters at 157 East Sixty-seventh street, and see how the alarm apparatus works. Every New Yorker is proud of the efficiency of the city's fire service, and there is no doubt that there will be a big crowd of members at the headquarters that night.

CHICAGO ELECTRIC CLUB.

MR. W. P. SULLIVAN has resigned the managership of the Chicago Electric Club, which position he has ably filled for the past year. This step will be regretted by the members, amongst whom he has a host of warm friends, who appreciate his unfailing courtesy and attention while in charge of the club.

THE THOMSON SCIENTIFIC CLUB.

AT a meeting of the above club at their rooms in Lynn on Thursday evening, Nov. 5, a very interesting paper was read by Mr. Caryl D. Haskins on "Electric Meters." Mr. Haskins is quite a veteran in the field of electric meters, having been in that line of work for a number of years. He was with Ferranti in England and has latterly been engaged in meter work in this country. He described the growth of the meter to its present state of perfection, when we find meters on the market that record the consumption of electric energy with surprising accuracy. Various types of clock, motor and photographic meters were exhibited.

The club's public lecture course began on Wednesday, Nov. 11. The first lecture was delivered by Prof. Thomson. The other lecturers are as follows: Prof. Chas. P. Cross, Mass. Inst. of Tech.; Rev. Dr. J. M. Pullman, of Lynn; Prof. A. E. Dolbear, of Tuft's College; Prof. Helen L. Webster, Wellesley College; Prof. Wm. A. Anthony, of Manchester, Conn.

Legal Notes.

ELECTRIC ANNUNCIATORS FOR ELEVATORS—WESTERN ELECTRIC COMPANY vs. ELECTRICAL CONSTRUCTION CO. AND G. A. HARTER.

ON November 9, Judge Blodgett, of the U. S. Circuit Court, Northern District of Illinois, rendered a decision imposing a fine of $50 and costs upon the Electrical Construction Company and Gustav A. Harter for infringement of the patent of Elisha Gray, No. 173,998, granted February 1, 1876. An injunction was ordered in the same court in January last restraining the defendants from infringement of patent No. 148,447, March 10, 1874, to Augustus Hahl, as well as of the Gray patent above noted. The Hahl patent covered the use of a flexible cable. The Gray patent covered "the combination of a movable elevator car, the annunciator attached thereto and moving therewith, circuit-closing and breaking signal-keys on different floors, and mechanism whereby an electric current is maintained between the signal-keys and annunciator without interruption by the movement of the car." Both patents had previously been before the same court and held valid. Proofs showed that defendants had directly infringed the Gray patent in May last by putting an electrical annunciator in an elevator at the Haymarket Theatre in Chicago. Meantime the Hahl patent had expired in March. The court held that the expiration of the Hahl patent did not affect the merits of the case as regards the Gray patent, which has still a considerable period to run.

EDISON GENERAL COMPANY vs. H. T. PAISTE ELECTRIC LAMP SOCKETS.

A BILL in equity has been filed in the United States Circuit Court, Philadelphia, by the Edison Company against Henry T. Paiste, of Westchester, Pa., complaining of an alleged infringement by the defendant on patented improvements in sockets or holders for electric lamps.

GOD FORBID!

ONE of the attractions of the Chicago Exhibition is to be a pyramid of 400 pianos connected by electricity and manipulated by one woman.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED OCT. 27, 1891.

Accumulators:—

Secondary Battery Electrode, J. B. Entz and W. A. Phillips, 461,823. Filed Oct. 31, 1890.
Electrode is made up of wire bent upon itself and forming a mat or plate; wire loops or straps surround the plate.

Secondary Battery, M. Waddell and J. B. Entz, 461,858. Filed Oct. 31, 1890.
Claim 1 follows:
In a secondary battery, the combination of a positive and negative electrode, one contained within the other and one being entirely covered or protected with insulating material.

Dynamos and Motors:—

Electric Generator, C. G. Young, 461,862. Filed April 25, 1889.
An alternating-current dynamo.

Dynamo Electric Machine or Motor, M. Mayer, 461,979. Filed May 5, 1891.
Relates to design and methods of construction, with a view to cheapness.

Automatic Regulator for Dynamo Electric Machines, W. L. Silvey, 462,030. Filed July 5. 1889.
Employs a solenoid and a liquid resistance.

Galvanic and Thermo-Electric Batteries:—

Galvanic Battery, C. N. Souther, 461,965. Filed March 28, 1891.

Lamps and Appurtenances:—

Incandescent Electric Lamp Socket, C. P. Poole, 461,898. Filed March 5, 1891.

Rheostat for Electric Lamps, T. A. Lacey, 462,058. Filed May 5, 1891.

Metal Working:

Method of Welding or Working Metals Electrically, C. L. Coffin, 462,207. Filed Dec. 22, 1890.
The material to be heated is connected with one pole of a generator and is placed in contact with a conductor in proximity to the point of contact between such conductor and a second conductor, which latter is connected with the other pole of a generator; the heating current passes through the material and the conductors and the material is heated not only directly by the current, but also by the heat developed at the point of contact between the two conductors.

Miscellaneous:—

Electric Heater, J. V. Capek, 461,814. Filed Oct. 30, 1890.
The heating conductor is in the form of a volute spiral, the several turns being separated and covered by insulating material; an impervious casing surrounds the conductor.

Electric Connection, J. H. Fleming, 461,868. Filed Jan. 9, 1891.
A wire-joint.

Lightning Arrester, E. W. Van Brunt & W. M. Raynor, 461,991. Filed May 16, 1891.

Circuit-Controller, W. B. Cleveland, 462,088. Filed June 17, 1891.
For cutting out a portion of a light or power circuit in case of emergency.

Railways and Appliances:—

Electric Car-Brake, La M. C. Atwood, 461,808. Filed Jan. 10, 1891.
Employs a motor for actuating the brake.

Signaling System, F. P. Benjamin, 461,809. Filed Feb. 9, 1889.
Enables a car in motion or at rest to signal other trains on the same track.

Signaling System, F. P. Benjamin, 461,810. Filed Apr. 19, 1889.
For signaling between trains by inductive effects.

Trolley for Electric Cars, C. A. Lieb, 461,840. Filed Mar. 23, 1891.

System of Distribution for Electric Railways, S. H. Short, 461,851. Filed Jan. 4, 1890.
Claim 1 follows:
In a system of electrical distribution for electric railways, the combination, with an electric generator and a continuous trolley line or conductor, of a trolley line consisting of a series of insulated sections, an individual conductor connecting each of said sections with the generator, and an automatic cut-out for opening the circuit on the passage of an abnormally heavy current included in each one of said connecting conductors.

Electric Railway, W. B. Vansize, 461,969. Filed Sept. 1, 1890.
A combination of a storage-battery supply with a trolley and central station system; includes an arrangement of sectional conductors and a series of storage-battery outfits along the line, at each section.

Electric Railway, G. W. McNear, 462,014. Filed Oct. 11, 1889.
Relates to contact devices and the insulation of conductors.

Electric Railway Switch, H. C. Spaulding, 462,082. Filed Sept. 26, 1890.

Underground System for Electric Railways, S. D. Nesmith, 462,158. Filed Aug. 4, 1890.
Claim 3 follows:
In an electric railway, the combination of a conduit having sluiceway, drainage, a longitudinal plate arranged diagonally within said conduit and electric conductor supported beneath said plate, and a trolley-arm adapted to slide on said conductor, and provided with a branch arm, substantially as and for the purpose specified.

Electric Railway, C. W. Thomas, 462,177. Filed May 6, 1890.
An underground system employing a sealed conduit or tunnel for both outgoing and returning conductors with contact devices at short intervals.

Electric Railway Trolley, R. M. Hunter, 462,219. Filed July 1, 1891.

Telephones and Apparatus:—

Multiple System for Telephone-Exchanges, W. E. McKivitt, 461,887. Filed Mar. 30, 1885.
Relates to switchboard connections.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED NOVEMBER 3, 1891.

Accumulators:—

Secondary Battery, J. H. Palmer, 462,449. Filed Jan. 3, 1891.
Plate is formed of laminated pillars connected together by metallic bars; the pillars are composed of thin pieces of lead or other material separated by interposing parts or projections.

Alarms and Signals:—

Electric Signaling System, F. B. Wood, 462,345. Filed Jan. 6, 1890.
Adapted for a central and sub-station and provides for operating sub-stations individually or collectively.

Electric Alarm Bell, C. A. Hale, 462,381. Filed June 5, 1891.

Conductors, Conduits and Insulators:—

Method of and Apparatus for Constructing Electric Light or Other Lines, H. Lemp, 462,263. Filed March 30, 1891.
Relates to splicing or jointing conductors. Employs electric heating; employs the current traversing the conductors to be spliced or joined for heating purposes.

Electric Wire Support Bracket, O. B. Hall, 462,315. Filed Aug. 6, 1891.

Conductor for Three-Wire Systems, E. H. Johnson, 462,489. Filed Sept. 2, 1891.
A cable having three conductors, one surrounding the other two, the outer conductor being connected to the neutral wire of the system.

Cross-Tree for Suspended Electric Wires, J. Levy, 462,564. Filed Aug. 7, 1881.

Threading Rod for Underground Conduits, F. G. Bolles, 462,648. Filed Sept. 8, 1891.

Distribution:—

Method of and Apparatus for Electrical Conversion and Distribution, N. Tesla, 462,418. Filed Feb. 4, 1891.
Claim 1 follows:
The method of the electrical conversion herein described, which consists in charging a condenser or conductor possessing capacity and maintaining a succession of intermittent or oscillating disruptive discharges of said conductor into a working circuit containing translating devices.

System of Electric Lighting, F. M. Garland, 462,311. Filed Sept. 9, 1890.
Adapted to lighting railway cars or similar vehicles. Employs the rotation of the axle of one pair of wheels to drive a dynamo.

Dynamos and Motors:—

Gearing for Electromagnetic Motors, C. E. Chinnock, 462,348. Filed Aug. 26, 1890.

Controlling Device for Electric Motors, F. O. Blackwell, 462,369. Filed July 13, 1889.
Claim 1 follows:
The combination, with an electric motor, of a current-controller and circuit-reverser therefor, a common actuator positively actuating both, but allowing the controller a predetermined amount of lost movement relative to the reverser.

Commutator Brush, F. O. Blackwell, 462,466. Filed March 5, 1889.

Lamps and Appurtenances:—

Electric Lighting System, J. I. Conklin, 462,237. Filed Feb. 9, 1891.
Combines the use of dynamos and storage batteries.

Incandescent Lamp, E. Thomson, 462,338. Filed Dec. 27, 1886.
Provides for the automatic completion of circuit in case of the rupture of the incandescing conductor of the lamp.

Incandescent Lamp, E. Thomson, 462,339. Filed Mar. 12, 1887.
A thermostatic device for shunting or short-circuiting a lamp in case of rupture of the incandescing conductor.

Electric Lighting Apparatus, H. B. Meech, 462,444. Filed Nov. 24, 1890.
Employs a series of electric lamps contained in an outer enclosing globe, the whole rotating together.

Covering for the Bulbs or Globes of Electric or other Lamps, A. Duval and H. Nelson, 462,477. Filed May 13, 1890.

Incandescent Electric Lamp, T. A. Edison, 462,540. Filed Mar. 25, 1889.
Designed to prolong the period of efficient candle-power. Relates to the process of preparing the filament. After the lamp is exhausted the filament is heated to a red heat, or to a heat much below its normal incandescence temperature.

Electric Lamp Cover and Switch, E. T. Mueller, 462,571. Filed Apr. 30, 1891.

Key Socket for Double Filament Incandescent Lamps, W. J. McCutcheon, Jr., 462,574. Filed June 18, 1891.

Electric Arc Lamp, T. Conroy, 462,624. Filed Feb. 16, 1891.
An arc lamp for employment on incandescent circuits.

Electric Arc Lamp, F. H. Carpenter, 462,660. Filed May 1, 1891.
Relates to the mechanism of a disc carbon lamp.

Electric Arc Lamp, F. H. Carpenter, 462,661. Filed May 7, 1891.
Relates to the frame of lamp and globe supporter.

Carbon Holder for Electric Arc Lamps, H. E. Chapman, 462,662. Filed May 1, 1891.
Relates to disc carbon lamps of the kind described in the patent of E. C. Russell, July 15, 1890, No. 432,284.

Pencil Carbon Holder for Electric Lamps, H. E. Chapman, 462,663. Filed May 7, 1891.

Stay for Suspended Electric Lights, F. A. Johnson, 462,669. Filed July 21, 1888.

Electric Arc Lamp, E. C. Russell, 462,673. Filed May 21, 1891.
Improvements in disc carbon lamps of the class described in the same inventor's patent, 432,284, July 15, 1890.

Incandescent Lamp Socket, T. J. Fay, 462,677. Filed Jan. 22, 1891.

Measurement:—

Electric Current Meter, J. W. T. Olan, 462,504. Filed Apr. 16, 1891.
Claim 1 follows:
The combination, in an electrical meter, of a needle or pointer, a coil or magnet for moving it, through which the current to be measured passes, a plate over which the needle moves in a regular arc, a record sheet between the plate and the needle, mechanism for advancing the sheet, and means operating through the needle while it is out of contact with the sheet for marking on the sheet the position of the needle.

Metallurgical:—

Electromagnetic Separator, R. R. Moffatt, 462,321. Filed Jan. 20, 1891.

Electromagnetic Separator, R. R. Moffatt, 462,322. Filed Feb. 2, 1891.

Amalgamating and Extracting Gold from Refractory or other Ores, W. Crookes, 462,535. Filed Jan. 10, 1891.
Consists in submitting the ore to the combined action of a solution of a mercurial salt and an alternating electric current.

Metal-Working:—

Automatic Electric Welding Machine, H. Lemp & C. G. Anderson, 462,261. Filed Feb. 2. 1891.
Relates to devices for manipulating the objects to be operated upon.

Laminated Die, Hammer, etc., for Electric Metal Working Apparatus, H. Lemp, 462,262. Filed Feb. 24, 1891.

Miscellaneous:—

Ceiling Block, A. Ekstrom, 462,349. Filed May 29, 1891.

Electric Switch, M. Hoopes, 462,353. Filed Aug. 4, 1891.

Electric Gate, H. Gillette, 462,403. Filed Dec. 10, 1890.

Electric Switch, R. M. Hunter, 462,407. Filed May 22, 1891.

Electric Fuse Cut-out, E. W. Rice, Jr., 462,452. Filed Oct. 18, 1890.

Switch and Cut-Out Device, H. P. Ball. 462,463. Filed Mar. 23, 1891.

Electric Elevator, H. H. Blades & W. J. McKee, 462,527. Filed Jan. 11, 1890.
Employs rack-bars at the sides of the well, gearing engaging the rack-bars to the armature shaft; circuit switch located on the elevator; a running rope extends from the top to the bottom of the well and is connected with the switch on the car, enabling a person on any floor to operate the switch and start the car up or down.

Electric Cooking-Stove, J. V. Capek, 462,532. Filed Dec. 15, 1890.

Electric Hair-Brush, A. Stanton, 462,599. Filed Aug. 3, 1891.

Railways and Appliances:—

Automatic Signal Apparatus, J. B. Stewart, 462,518. Filed Dec. 23, 1890.
Relates to railway block-signals.

Electric Railway, E. M. Bentley, 462,231. Filed Nov. 23, 1888.
A conduit system; trolleys or brushes under-running the conductor or conductors in the conduit.

Clamp for Trolley-Wires, C. A. Lieb, 462,359. Filed July 28, 1891.

Trolley for Electric Cars, R. D. Nuttall, 462,578. Filed June 19, 1891.

Electric Railway, J. B. Sheldon and D. J. Murnane, 462,595. Filed Feb. 12, 1891.
Employs a series of yieldingly-secured rotating switches in the conduit and having connection with a source of electricity and devices on the motor car.

Conduit Electric Railway, A. J. Robertson, 462,672. Filed Dec. 10, 1890.
Employs an open duct or receiver extending longitudinally along the track-rails and provided with insulation for a main conductor, which latter is a slack, naked wire which is under-run by a trolley projecting below the car; the conductor rising out of the duct and falling back as the car moves along.

THE NEW DOWN-TOWN EDISON STATION.

The station of the Edison Electric Illuminating Co., now being built at the corner of Pearl and Elm streets, this city, comprises many ideas which are entirely new in this field. Its capacity will be 30,000 h. p., the engines being of the vertical four-crank quadruple expansion type, with an initial pressure of from 210 to 220 pounds. These engines, it is said, will be of 5,000 h. p. each. A model 1,000 h. p. engine of the same type is being built by the Dixon Company for the Twenty-sixth street Edison station. This engine occupies only 92 square feet of floor space, exclusive of the overhang of the shaft.

The boilers of the new station will be of the water-tube type and will probably be internally fired. This latter point, however, has not been definitely settled. The system for collecting the radiant heat and returning it to the furnace is peculiar to this station. The doors and windows will be kept closed, and a constant supply of fresh air forced into the building at its lowest level. This air during its passage upward accumulates heat from engines, machinery and piping, and then is made to flow over the boilers and through a piping gallery and an arrangement of pipes in the chimney flue, being finally discharged into the ash-pits and over the grates in the proportion of 80 and 20 per cent. respectively, at a temperature of about 300 degrees.

The steam mains will be of copper and will be run in rows, no single pipe being larger than 8 inches in diameter. Each pipe will be wound with steel wire for its entire length and corrugated into the flanges, no brazed joints being used.

This system, which we have only briefly touched upon, is the result of the deep study and extended observation of Mr. John Van Vleck, chief electrician of the Edison Electric Illuminating Co. of New York, who promises to reduce the consumption of coal to one pound per h. p. per hour. This, if accomplished, will result in a saving for this one station of the interest on nearly a million dollars. We are indebted to Mr. Van Vleck for these very interesting details.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

Effective advertising is a large element in business success.

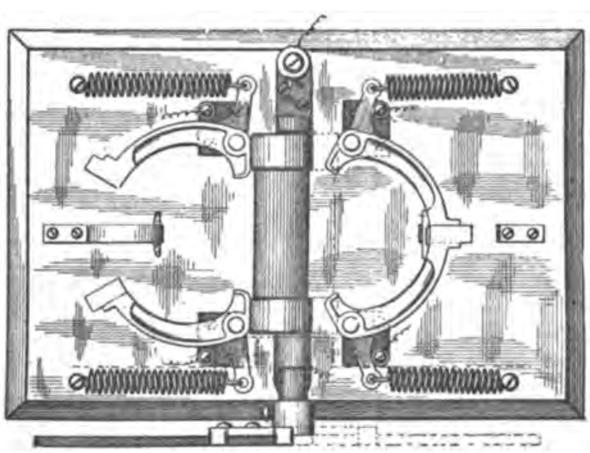
CROCKER-WHEELER.

THE Crocker-Wheeler Electric Motor Company have a large exhibit of their perfected motors and dynamos at the Industrial Exposition to be held in Augusta, Ga., from Nov. 2d to Nov. 28th. Mr. George C. Field, of that company, is now in Augusta arranging their exhibit, and will shortly be joined by Mr. George W. La Rue, general sales agent, who is now on a tour through the South visiting the many agencies of the Crocker-Wheeler Company in that section of the country.

The Crocker-Wheeler Electric Motor Company have, by the way, found it necessary to very much increase their facilities in order to keep up with the large demand for their popular goods. They have recently furnished a 3 h. p. motor of their popular perfected type to run a large church organ in Ottawa, Ont. Other late installations of note are a 5 h. p. special dynamo to the Cornell Electric Company, Hamilton, Ohio; one hundred and twenty-five 1/8 h. p. and six 1/4 h. p. 10 ampere arc motors to a well-known firm in Baltimore, Md.; one 1 h. p. to the Alabama Polytechnic Institute, Auburn, Ala., and 1 h. p. to the Berlin Dry Goods Store, Brooklyn, N. Y., to run a cash carrier system, besides very heavy shipments to the West Indies and other foreign countries for the Thomson-Houston International Electric Company, Boston, Mass.

THE VAN NORT TRANSFER SWITCH.

IN the operation of electric motors on constant-current circuits it often becomes necessary to transfer the motor from the day or regular power circuit to one of the night or regular arc light



VAN NORT TRANSFER SWITCH.

circuits. This would be the case when power is wanted during the night after the regular power circuit has shut down. The accompanying engraving illustrates the Van Nort transfer switch for making such a tranfer. The motor is connected to two metallic rings upon an insulated eccentric shaft, the connection being effected by means of the bearings in which the shaft rotates, each bearing being provided with a binding post to which the terminals of the motors are connected. The eccentric is rotatable by means of the handle. The two supply circuits are connected respectively to the two circuit breakers.

In the position shown in the cut, the handle being thrown to the left, the motor is placed in connection with the left-hand circuit; throwing the handle to the right transfers the motor to the right-hand circuit. The circuit-breaking levers have a wide throw at their break ends, so as to break the arc, and a central piece placed near their contacts also serves to split or divide the arc. Continuity of the supply circuits is maintained at all times. The break points do not separate until after the eccentrics have connected the motor thereto, and in switching off the break points make connection with each other before the motor is disconnected, the motor being put on short circuit for an instant in either operation. This switch has just been patented by Van Nort Bros., No. 515 Walnut street, St. Louis, and is being placed on the market by them.

BARTLETT & CO.

A GREAT many readers of THE ELECTRICAL ENGINEER will be interested to learn that a reorganization, so to speak, has been effected in the above well-known firm, with the object of greatly enlarging and extending its business. As a firm of engravers, it stands certainly at the very head of the craft, and having long made a specialty of mechanical and electrical apparatus, it has won and long enjoyed a reputation of which any concern might be proud. The best wood-cuts appearing in electrical journals are its product, while in the publication of artistic catalogues for electrical companies it has never been equaled. The new company will continue this work, but will add a number of new departments in the higher branches of engraving and printing. Mr. E. E. Bartlett will be its artist and Mr. Theo. von der Lühe its chief engraver, and these two gentlemen have done so much to raise the standard of art work in illustrating electrical appliances and plants that we can only wish for them as much business in their newer field as they have already enjoyed in the old. With them will be associated Mr. L. H. Orr, in charge of the fine art printing. Mr. Orr is a practical printer, familiar with all the details of typographical work, and has had a large experience in very responsible capacities with some of the largest establishments in the East. The business will be carried on at the "new central station."

THE CLARK SEARCH-LIGHT.

THE Clark arc lamp now being exhibited at the American Institute Fair by the Clark Electric Co., of 192 Broadway, is made especially for search-light purposes. It is attracting a great deal of attention and is of great interest to those interested in navigation. It is mounted on swiveled trunnions and can instantly be turned to throw light in any direction. Mr. Ernest P. Clark, the inventor of this lamp, illustrated the operation by revolving it and placing it in every conceivable position. The lamp burned steadily and uniformly during all the various movements. There are no flexible cables used, all connections being made through the trunnions by means of insulated joints.

As there are no cords or weights used in the construction of this lamp, and as its action is entirely independent of the effects of gravity, it will work as freely on a vessel in a heavy sea as on land.

It is the object of the Clark Electric Co. to place on the market the most reliable and durable search-light for every purpose yet known, and their exhibit has attracted considerable attention.

CARBORUNDUM.

THE Carborundum Company, of Monongahela City, Pa., have succeeded in producing a substance which has been proved a perfect substitute for bort. Carborundum, as this substance is called, is of a beautiful crystaline structure, the octahedron formation predominating. The crystals are transparent, and of a variety of colors. Carborundum, it is said, is not affected by any reagent, and remains permanent at high temperatures. In hardness it is 10 on Mohr's scale, being equal to the diamond. Its qualities are such, in fact, that may with propriety be called manufactured diamond powder. The company have recently issued a most attractive little folder containing a number of flattering testimonials. Mr. E. G. Acheson is prominently connected with the company.

BALL ENGINE CO.

J. W. PARKER & Co., 38 South Fourth street, Philadelphia, report the following sales, within a month, of the Ball engine: Thomson-Houston Electric Co., Boston, Mass., one 250 h. p. compound condensing engine for electric railway duty at Brockton, Mass.; Johnstown Electric Light Co., Johnstown, Pa., one 200 h. p. standard engine for electric lighting; Columbia Electric Co., Philadelphia, Pa., one 200 h. p. standard engine for electric lighting; Lock Haven Electric Light and Gas Co., Lock Haven, Pa., one 150 h. p. standard engine for electric lighting; Sauquoit Silk Mills, Scranton, Pa. one 35 h. p. standard engine.

MANHATTAN ELECTRICAL SUPPLY CO.'S CATALOGUE.

THE catalogue of the Manhattan Electrical Supply Company, 36 Cortlandt street, is one of the most complete we have ever seen. It is fully illustrated by excellent cuts, descriptions accompanying those whose application is not seen at the first glance. This catalogue contains telegraph instruments and appliances, Mesco and other batteries, burglar alarms, and general electrical supplies. There is a list of electrical books in the back, as well as a set of directions for setting up different kinds of cells.

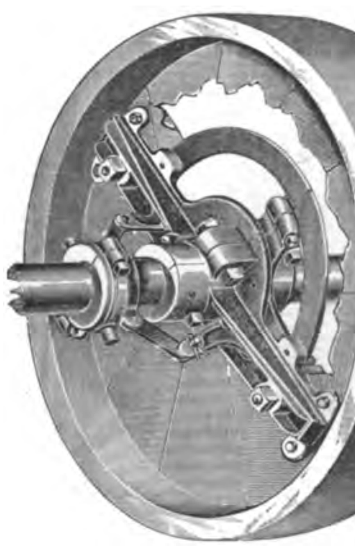
WESTERN ELECTRIC CO.

We have received from the Western Electric Co. the "pocket edition" of their general catalogue of July, 1891. It is a photographic fac-simile of the larger book, and is so neat and clear that it suggests the doubt whether the larger size is, after all, necessary. Catalogues, like journals, gain greatly in appearance by this compactness and refinement in size, and the company is certainly to be congratulated on its Elzevir edition of a standard trade publication, for such its general catalogue became long since.

A NEW "TAPER SLEEVE" FRICTION CLUTCH.

The success with which the clutches of the Taper Sleeve Pulley Works, of Erie, Pa., have met, instead of satisfying the concern, has acted as an incentive to still better work. The light, strong friction clutches of this company, with their segmental wooden webs, and their firm grip and ready release, are already familiar to our readers; their latest piece of enterprise, however, is not yet so well known, and is shown in the accompanying illustration.

The peculiarity of the new clutch lies in the fact that the clutch proper, which is usually keyed to the shaft and revolves with it, even while the pulley is at rest, is in this case fastened to the pulley and stops when the pulley is released. It is believed



New "Taper Sleeve" Friction Clutch.

that this is the only clutch made in which this is the case, and those already installed have given the utmost satisfaction.

THE HOWARD MULTIPLE BALL BEARING.

Experience with ball bearings has shown that, owing to but a small portion of the actual surface being used in contact with the balls, the tracks in which they roll soon become worn. In order to obviate this difficulty, and provide a bearing suitable for very heavy work, ex-Governor Henry Howard, of Providence R. I., who has long been actively interested in mechanical and manufacturing pursuits, has devised the ingenious arrangement shown in the accompanying illustrations.

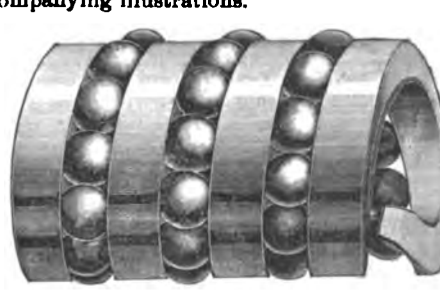


Fig. 1.—Howard Multiple Ball Bearing.

As will be seen in Fig. 1, the balls are held loosely between the coils of a helix, the sides of which are concave, so that they may turn freely, the helix being partly closed at the ends to prevent them from running out. The shell thus made is held in place by collars which prevent any lateral movements, and turns freely as the balls rotate. It will be noticed that, as the balls are placed helically in the shell, and revolve in an annular direction, in planes at right angles to the centre line of the journal, and as the lateral play of the shell is sufficient to cover the pitch of the balls (usually about $\frac{1}{16}$ inch), the entire surface of both shaft and box is utilized. That this is practically, as well as theoretically, true is shown by an inspection of these surfaces after extended use.

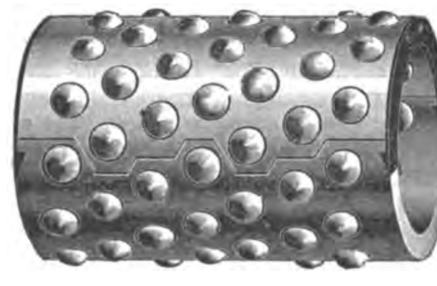

Fig. 2.—Howard Multiple Ball Bearing.

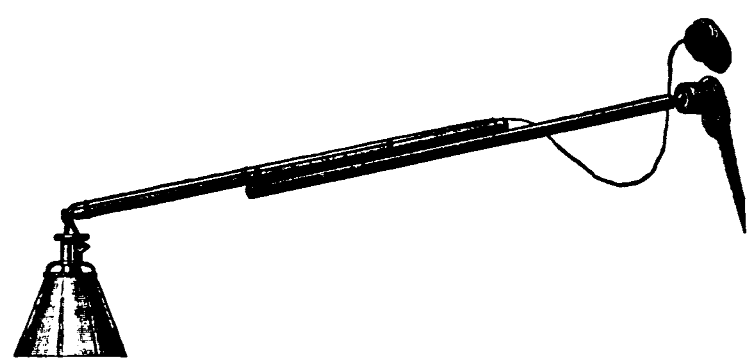
The Howard bearing, shown in Fig. 2, differs from that already described in the form of the shell which holds the balls in holes, placed in a helical line, instead of in a groove. This shell is divided longitudinally, and may be placed upon any part of a shaft without slipping it over the end.

Tests of this bearing have shown very satisfactory results. Our contemporary, the *American Machinist* reports some striking results in reduction of loss by friction, obtained in experiments made by its editor. It seems to us that the Howard bearing should find a very wide application in mechanical and electrical work. These bearings are to be made by the Mossberg Manufacturing Co,. Attleboro, Mass.



Dawes Electric Light Support.

THE DAWES ELECTRIC LIGHT SUPPORT.

The accompanying illustration shows an ingenious device, controlled by Messrs. R. Hollings & Co., of 547 Washington street, Boston, for conveniently holding an incandescent lamp in any position and at any angle. As will be seen, the rod can be lengthened or shortened at will, its range in this instance being from 20 to 36 inches, and will remain at any angle without further adjustment. The lamp is also adjustable at the end of the rod. This same principle is applied to a variety of both wall and ceiling brackets, ranging in length from 6 feet to 20 inches,

THE UNION DRAWN STEEL CO.

An important and promising departure has been made by the above concern, of Beaver Falls, Pa., in securing as Eastern sales agent, Mr. Thomas Towne, well known to the electrical and mechanical trade as buyer for the Garvin Machine Co. The fact that Mr. Towne should engage with the concern, after an intimate acquaintance with the merit of goods in this line, speaks volumes for the excellence of the company's product. The company have made a specialty of cold die rolled steel and iron shafting, piston rods, pump rods, slides and shapes; screw rod; key stock, tongue stock, and gib stock; as well as tool steel for milling machine jaws, etc. Their shafting is remarkably fine and true, with polished surface and machine-cut ends, and is made accurately down to thousandths of an inch with a very slight advance in price for accurate drawing. Mr. Towne is well posted as to the peculiarities of electrical concerns in expecting extreme accuracy in such work, and that is just the line of trade he is on the hunt for. He has established headquarters at 584 Electrical Exchange, Liberty street, and is already actively pushing these goods.

Mr. H. E. Bradford, has been appointed superintendent of the Marlboro, Mass., street railway.

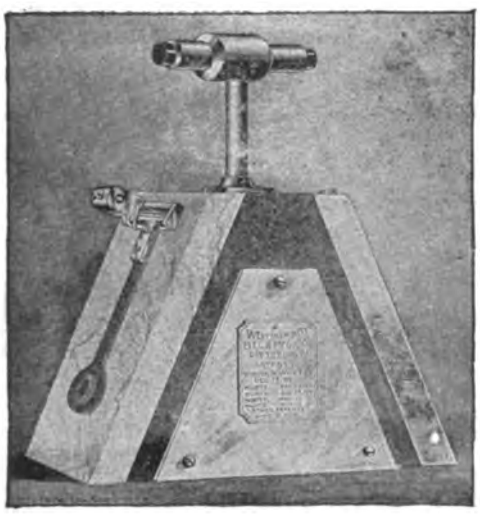
THE NEW WESTINGHOUSE LIGHTNING ARRESTER.

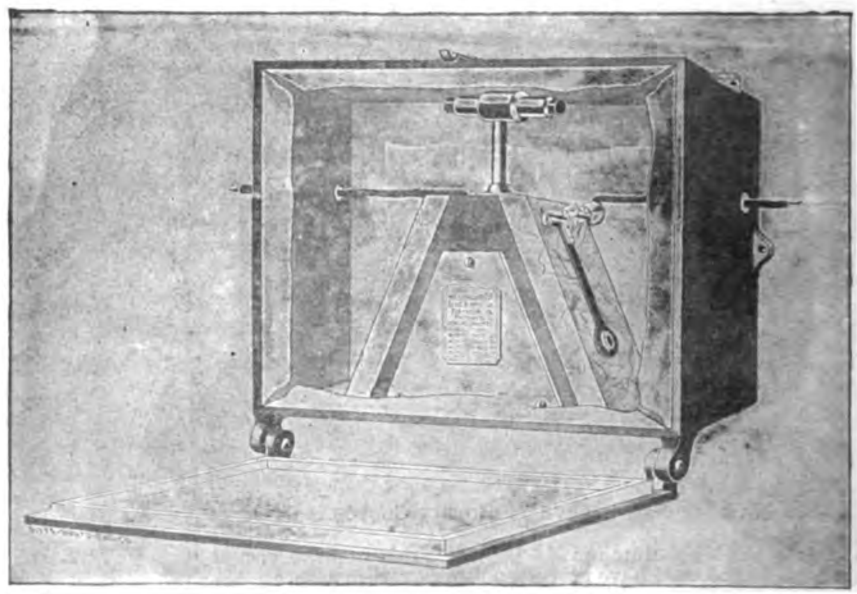
A LIGHTNING arrester to fulfil the purpose for which it is designed must have a very small air-space, across which the discharge has to jump, in order to present as little resistance as possible; be free from any inductive resistance, automatic in its action, simple in construction, and must provide means for surely and quickly destroying the arc which follows the discharge.

All of these conditions are claimed for the Westinghouse lightning arrester, the most improved forms of which are shown in the accompanying illustrations. The operation of this instrument does not depend upon magnetic action. The air-space is adjustable and may be made as small as necessary, and the arrester is entirely automatic. To meet the last of the above-named conditions a very simple principle is utilized. The heat of the arc is made to expand the air in a closed chamber, the only outlets from which are closed by two movable arms. The sudden expansion of the air drives these two arms outward and the arc is at the same time drawn out and blown out. The arms fall back into place by gravity and the arrester is ready for a second discharge. So rapidly is this done that the entire action requires only a small fraction of a second.

The accompanying illustration, Fig. 1, is a view of this lightning arrester as constructed for use on the switchboard at the power station. A triangular iron box, having for two of its sides marble slabs, is mounted on a marble base. Near the upper end of each of these slabs is fastened a small brass casting, part of which serves as a binding post for making connection with the trolley or ground wires. From each of the castings hangs by a hinge a light metal arm which carries at its lower end a carbon point. This point makes contact with a carbon block inside the chamber by passing through a circular hole in the marble. The discharge takes place between two "saw-teeth" carbons inside the chamber, and the arc is first formed at this point, but the air instantly expands and drives out both of the movable arms. The circuit is thus broken in two more places and the rupturing of the arc takes place instantly. By removing the triangular plate of brass on the front of the arrester the carbon points may be examined and adjusted. The "T"-shaped arm which projects from the top of the iron box carries two insulated bumpers, against which the hinged arms strike when blown out.

The form of arrester for use on electric cars is similar to the one described, the only difference being that the arrester proper is placed inside of an asbestos-lined iron box, which thoroughly protects it. A view of a car lightning arrester is given in Fig. 2. As this arrester requires no attention further than an occasional inspection, it may be placed out of sight under the platform of the car. These arresters are suitable for any system of electric railways, and are giving excellent satisfaction.





FIGS. 1 AND 2.—THE NEW WESTINGHOUSE LIGHTNING ARRESTER.

CHANGES IN THE MEXICAN TARIFF.

THE Bureau of American Republics is informed that, in the new Mexican tariff, which went into effect November 1, the following commodities, among others, have been added to the free list: Insulators for telegraph and telephone purposes, batteries and lightning rods.

ELECTRICAL SLATE.

MR. T. J. MURPHY, of 136 Liberty street, has orders for two of the finest slate switchboards ever installed. One of these is for R. H. Macy & Co.'s new building, and the other goes to the Four Seasons Hotel, Cumberland Gap, Tenn. The outside dimensions of the first of these switchboards are 12 feet 2 inches by 8 feet 1 inch. This is built up in seven sections. Four of the sections, each 5 feet long, go at the top of the board, the two outside pieces being 3 feet 1 inch wide, which allows 1 inch for moulding, while the two centre sections are 3 feet wide. Under these centre pieces an open space is left 18 inches high and 6 feet long for the accommodation of rheostats, and under the rheostats, so as to raise them from the floor, is another section of slate 5 feet long and 18 inches high, the whole being finished by two corner pieces each 8 feet high and 3 feet 1 inch wide, the odd 1 inch being for the moulding, which will surround the whole. This slate is highly polished and presents the appearance of marble, being made in imitation of Bardillo. The second switchboard is 8 feet 8 inches wide and 7 feet 5 inches high and is made in three top sections of equal dimensions, each 5 feet high. A space of 15 inches underneath is entirely blank, with the exception of two small pieces at the extreme sides each 2 inches wide to finish the ends, rheostats filling the balance of the space. The bottom is in two sections, each 4 feet 4 inches long and 12 inches high.

The fact that these boards are built up in sections does away with the necessity of cutting a solid piece of slate to make room for the rheostat, and it also makes the shipment of material easier and safer. Another point in their construction is that the rheostats do not project, but are flush with the face of the slate, and all switches are mounted on the board itself, doing away with extra bases, and making an even face on the whole of the apparatus.

The holes for contacts are drilled before shipment, so that the contractor simply places the sections in position.

These installations seem to speak well for the growing demand for marbleized slate in the electrical business. We may add that Mr. C. L. Eidlitz, of 10 West Twenty-third street, has charge of the installation of both the plants above mentioned.

THE JEWELL BELTING CO.

THE Jewell Belting Co., of Hartford, Conn., have been making some very large sales of big driving belts within the last week or two. They report sales aggregating 102 feet of 40-inch three ply, 97 feet of 40-inch double, 241 feet of 36-inch double, 384 feet of 30-inch double, 70 feet of 26-inch three ply, 216 feet 24-inch double, 89 feet of 22-inch double, and 416 feet of 20-inch double, and numerous smaller belts. A good part of this amount is to be used in electric light and power stations.

Their factory is completely equipped for turning out large belts very quickly. As an instance of this it may be stated that one day last week they received an order for two driving belts, one a 36-inch and the other a 30-inch, both double, and on the following day they were on the road to their destination, being completed in twelve hours.

THE ELECTRIC APPLIANCE CO.

The Electric Appliance Company are rapidly filling their capacious store at 242 Madison street, Chicago, with a well-assorted and desirable stock of general electrical supplies, and will very shortly be in a position to meet any demand that can be made upon them in the way of orders.

In addition to putting themselves in shape to do a large country business, they will give special attention to meeting the wants of the city trade. The large and varied experience of the officers of the company in this line, added to their wide acquaintance among Chicago's electricians, will materially aid them in this respect, and is a sufficient guarantee that their facilities for handling this trade will be unexcelled.

They also report having secured several valuable specialties for the Western market, some of which, it is said, will create considerable interest when announced, and fill a long-felt want in their respective lines. Full particulars will be given out as soon as they can get in shape to be ready to meet the demand that will certainly arise upon the announcement.

The work on the offices of the company is being rapidly pushed and matters are beginning to assume a business appearance, and give promise that they will have a perfect arrangement particularly suited to the requirements of their trade.

We are advised by the Electric Appliance Co., of Chicago, as we go to press that they have just closed negotiations for the general Western agency for Paranite wires and cables. This is a new rubber-insulated wire of the highest grade and possessing, it is claimed, merits not found in any other wire now on the market. The insulation is made up of an inner layer of white rubber which is an absolutely pure Para, hence the name of the insulation. This layer of pure Para prevents the slightest corrosion of the wire and at the same time adheres with a wonderful tenacity, preventing any chance of peeling the wire in drawing over rough corners and surfaces. This layer of the insulation is covered with a thick layer of rubber, to which just enough sulphur has been added to permit the vulcanizing process. The whole is then vulcanized, leaving, when the process is completed, an insulation composed of a white, pure Para core and an outer layer of black rubber possessing the highest possible insulating qualities and a wonderful toughness. It is so tough, in fact, that it can only be removed with a sharp knife or edged tool. After being thus prepared the wire is covered with either a tough tape or strong braid, being furnished either taped or braided, as desired.

The manufacturers make very strong claims for their wire, and the Electric Appliance Co. undoubtedly have a very valuable specialty—a wire with which they can compete with anything on the market.

AN INTERESTING TEST.

A most severe, and very interesting test was made last week by Messrs. Wm. Sellers & Co., of Philadelphia, upon a motor operated under the new principle invented by Mr. H. Ward Leonard. The motor used was a 10 h. p. standard shunt-wound Sprague motor. The motor's normal speed was 1,500 revolutions a minute. The motor was belted to a countershaft, and upon the countershaft was placed a brake. In addition to the brake there was placed upon the countershaft a large fly-wheel such as is used upon punching machines, the purpose of the fly-wheel being to supply the inertia and momentum met with in practice in a great many kinds of work.

The motor was made to operate in either direction at any rate of speed desired, and it was found possible to run perfectly and regularly under the full brake load, at 15 revolutions per minute, that is, one per cent. of its full speed. While operating at full speed in one direction, the motor could be instantly reversed, the reversal being perfectly gradual and entirely without any spark or troublesome feature of any kind.

In order to get the most marked effect in overcoming the momentum of the fly-wheel, the brake was taken off, and when the fly-wheel was running at its full speed of 300 revolutions a minute the motor was reversed instantly. In thirteen seconds the motor had brought the fly-wheel to rest, and in thirteen seconds more had it running at full speed in the opposite direction, the entire operation being effected with the greatest smoothness and without any spark whatever.

The performance of the motor was extremely satisfactory to all concerned, and showed its perfect adaptability to any class of work to be met with in practice.

The Porter & Leavitt Electric Motor Co., 82 Laura street, Providence, R. I., are erecting a factory near their present one, which they expect to occupy about December 1st, where with increased facilities they hope to be able to meet their steadily increasing business. They have just filled a large order for fan motors from Hong Kong, China.

THE PENNSYLVANIA ELECTRIC ENGINEERING COMPANY.

This company, engineers and contractors, Penn Mutual Building, Philadelphia, are prepared to submit proposals and specifications for any electric work, and will contract to equip lighting and power stations and isolated plants; furnishing plans for dynamos, power generators, motors, line construction, and inside wiring, and also for buildings, engines, boilers, pumps, etc. They supply to plants already in operation all fittings necessary for their successful maintenance, and have carefully selected from each of the various electrical companies that particular article of manufacture which has merit, irrespective of price, for its recommendation. The president and manager of the company, Mr. Arthur L. Bosley, has been connected with the Heisler Electric Light Co. for the past four years, and prior to that time was with the Edison, Thomson-Houston, and Sawyer-Man companies. He has had ten years experience in the electrical business.

Mr. L. P. Schultz, the secretary and treasurer, has been connected with Mr. C. M. Blanchard, representing the National Electric Manufacturing Co., Germania Electric Co., and Western Electric Co., prior to which time he was secretary and treasurer of the Electric Trust, which comprised the Brush, United States, Thomson-Houston, Excelsior and Underground, and has had about eight years' experience.

The company have sufficient capital to carry out any contract which they undertake.

ELECTRICAL USES OF GRAPHITE.

It is probable that there are many expert electricians who have but a small idea of the important part that graphite, sometimes called plumbago or blacklead, plays in the electrical industry. The Jos. Dixon Crucible Co., Jersey City, N. J., inform us that they make for several electrical companies graphite sticks, varying in resistance from ¼ ohm to 100 ohms to the inch.

The Dixon Company also prepare for laboratory use a graphite 99 per cent. pure, and make to order from drawings sent them any number of curious articles in graphite without having the faintest idea of what their function is to be. Electrical experts are just beginning to realize the manifold uses that graphite in one form or another can be put to.

A. L. IDE & SON.

The list of engine sales made by A. L. Ide & Son since August 1, 1891, is a long and imposing one. It shows sales of some 72 engines of a total of over 7,500 h. p. A large number of these engines have gone to electric light plants and electric railway power houses, while others have been taken for electric mining work.

ST. LOUIS NOTES.

H. H. Humphreys, St. Louis agent of the Edison General Electric Co., has during the past month made the following sales: The *Globe Democrat* Building, 2,000 lights; Central Distillery Co., 200 lights; Beaby Manufacturing Co. 270 lights; The Madison Car Co., Madison, Ill., 160 arc lights; Standard Oil Works, Madison, Ill., 200 lights: Chester, Ill., 1,500 lights; Butler, Mo., 400 incandescent and 35 arc lights; Decatur, Ill., 110 lights. A contract has also been taken for the wiring of the new Security Building for 3,000 lights. The "Interior Conduit" system will be used. The Cupples Building plant of 3,400 lights has been finished and put into successful operation. It ranks among the largest isolated plants in the West.

The Municipal Electric Light and Power Co. have determined to enter the incandescent lighting field and will install a 10,000 light plant in their mammoth arc light station. The Slattery 1,000 volt alternating system will be used. The first part of the installation will consist of two 3,000 and one 1,000 light generator. Others will be added as the demands of business may require. The company are also installing a 500 volt constant potential power circuit. A 250 h. p. Thomson-Houston generator will be put in for this purpose. A Hamilton-Corliss engine of 600 h. p. will be put in to supply power for these additions to the station.

Mr. A. W. Dutton, Southwestern agent for the Brush Electric Light Co. and the Short Electric Railway Co., has just returned from a four months' trip in the Southwest and reports the introduction of the Short motor on the Houston, Texas, street car lines with good prospects for its introduction at other important places in the South.

Mr. James I. Ayer, general manager of the Municipal Electric Light and Power Co., has assumed charge of the Citizens' Electric Light and Power Co., of East St. Louis. A 1,000 light alternator and a Russell engine, 14x20, have lately been added to this station.

MR. G. PANTELEONI, Western representative of the Westinghouse Electric and Manufacturing Co., has made the following sales: Moberly, Mo. 750 incandescent lights; Lagrange, Texas, 750 lights; Paris, Texas, 500 lights; Waco, Texas. 500 lights; Hot Springs, Ark., 1,500 lights; San Luis Potosi. Mexico, 1,500 lights; and the Missouri Electric Light and Power Co., St. Louis. two 400,000 watt alternators. These generators are the largest yet manufactured in this country and are being constructed on a special order.

THE EMERSON ELECTRIC MANUFACTURING CO. have removed to their new quarters, Nos. 1110 and 1112 St. Charles street, where they have ample room to provide for their large and rapidly extending business. The building has a frontage of 50 feet on St. Charles street, and a depth of 100 feet, and is three stories in height. A handsomly fitted up office is located on the ground floor.

THE ST. LOUIS AND SUBURBAN RAILROAD have discontinued the use of their narrow-guage locomotives on the central section of their road from Vandeventer avenue to Wells station, and have substituted electric cars. The cable section will be put into operation with electric power as soon as new rails can be laid and bonded.

NEW YORK NOTES.

THE GOUBERT MANUFACTURING COMPANY, 32 Cortlandt street, New York City, are doing a very large trade in their well-known "Goubert Feed-Water Heaters." They report the following among their sales for the month of October: The Edison Electric Illuminating Company of New York, one 400 h. p., one 600 h. p. and one 2,000 h. p; J. B. Ford & Co., Wyandotte, Mich., 1,000 h. p.; Hathaway Manufacturing Co., New Bedford, Mass., 1,200 h. p.; Ottumwa Railway, Electric and Steam Co., Ottumwa, Ia., 350 h. p.; The De La Vergne Refrigerating Machine Company, New York City, 2,250 h. p.; Lonsdale Company, Lonsdale, R. I., 1000 h. p.; Wamsutta Mills, New Bedford, Mass., 1,600 h. p.; Detroit Electric Light & Power Co., Detroit, Mich., 1,000 h. p., besides a number of smaller heaters.

MR. M. T. DAVIDSON the well-known steam pump builder of Brooklyn, finds business extremely good. He has recently made a sale of a large air pump and jet condenser to the Kilmer Manufacturing Company, of Newburgh, N. Y. A number of the same style pumps have also been furnished the Glengon Iron Company at Glengon, near Easton, Pa. A steady demand for Davidson pumps comes from the East, and Mr. Davidson has shipped a very great number to that part of the country of late.

THE SAFETY INSULATED WIRE AND CABLE CO., of 232 to 242 West Twenty-ninth street, have recently issued a pamphlet entitled "Underground Electric Light Cables," containing a number of testimonials from electric light companies, both at home and abroad, speaking in the highest terms of the cables made by this company.

MESSRS. H. WARD LEONARD & CO. have issued a thirty-two page pamphlet of testimonials and references regarding past work, and indicating their experience and standing.

WESTERN NOTES.

THE ST. LOUIS AND SUBURBAN RAILWAY COMPANY, formerly a combined cable and steam railroad, but which has recently been changed to an electric line, has had some remarkable experiences at its new power plant. As in all electric railway stations, the work varies enormously, sometimes changing from nothing to over 600 h. p., in less than one minute. This has caused the boilers to foam, or prime, and on two occasions, it is reported, the large Corliss engine would certainly have been wrecked had it not been for the Pond separator, which is located in the main steam pipe near the engine. Two additional Corliss engines are now being installed, and they also, will be protected by the Pond separator. This device for removing the entrained water from steam is manufactured by the Pond Engineering Company, St. Louis. They report additional orders from M. Beatty & Son, Welland, Ont.; Union Mfg. Co., Champaign, Ill., Du Pont Paper Co., Louisville, Ky.; Cicero and Proviso Railway, Chicago, Ill., two; St Louis Smelting and Refining Co., St. Louis, and John Ranning, St. Louis.

THE ILLINOIS ELECTRIC MATERIAL CO. have recently closed a large order for cedar poles and also secured a considerable order for their new taped "Canvas Jacket," which consists of a special tape next the copper and a single weave over all. This wire, it is claimed, is one of the strongest and best insulated wires in the market. Star Electrix sockets and specialties, for which this company are the general agents, are in great demand, and the Bishop rubber-covered wires and cables are general favorites. The Illinois Electric Material Co. recently received an order from Cuba for a nice bill of miscellaneous electrical supplies and are opening quite a trade with the Spanish-American countries.

THE QUAKER CITY ELECTRIC CO. report the following recent installations: An arc and incandescent plant for the Cantrell Tool Co.'s new works, Millmont, Reading, Pa.; an incandescent plant on the large Penn Valley stock farm of Mr. H. S. Henry, Morrisville, Pa.; a large incandescent plant in the wall paper factory of Messrs. Cresswell & Washburn, Phila., comprising an Ideal automatic engine; an incandescent plant in the factory of Valloth & Wadlinger, Phila., proprietors of the High Art Embroidery and Needle Work Establishment, which is an entirely new industry in this country. This plant also comprises a Williams automatic engine.

THE ENTERPRISE CONSTRUCTION AND SUPPLY CO., 167 Gravier street, New Orleans, La., the general agent for the Southern States of the Ball Electric Light Co., are installing a large number of these popular arc-light plants in mills, factories, etc. The subdivided arc lamps of 800 nominal c. p. are in special demand and giving great satisfaction. With this system also incandescent lamps are being used from the same dynamo which operates the arc lamps, with great success.

MR. J. R. BURDICK, the popular and well-known representative of the H. W. Johns Co., was in Chicago last week and called at the Western office of THE ELECTRICAL ENGINEER. Mr. Burdick is now furnishing his famous Vulcabeston insulating spools and magnets, commutator rings, etc., to almost all of the Western manufacturing companies both East and West. Mr. John Markle, of Detroit, also dropped in at the office of THE ELECTRICAL ENGINEER last week.

THE GOODRICH-COLEMAN ELECTRICAL WORKS, No. 31 S. Canal street, are very busy manufacturing their various specialties. Among other electrical devices they are manufacturing a new bell of special construction, which is giving excellent results. They have a well-equipped shop and all necessary tools for the economical manufacture of electrical apparatus of all kinds and of the very best workmanship.

MR. WM. HOOD, No. 239 La Salle street, is now furnishing the well-known "Jewel" lamps with hooked filaments for street car York and locations where the lamps are subjected to vibratory strains, and they are meeting with a ready sale. He is also placing "Jewel" lamps on the market in various colors, including red, green, blue, etc. These latter lamps are especially suitable for interior decorative work.

THE CENTRAL ELECTRIC COMPANY report that their new Gladiator dry battery is meeting with the most unexpected success; the factory supplying them is already doubling its capacity, so as to meet the increased demand for these cells. The company also report a very satisfactory trade in the Bryant goods, such as sockets, switches, cut outs, etc.

WORLD'S FAIR NOTES.—The contract for the fire alarm and police telegraph system for the World's Columbian Exposition has been let. The Gamewell Fire Alarm Co. secured the contract for the fire alarm telegraph system, and the police telegraph portion of the work was awarded to the Chicago Police Telephone and Telegraph Co.

THE NEW YORK AND OHIO CO., manufacturers of the Packard high-grade incandescent lamp, have transferred their Chicago agency to the Electrical Engineering & Supply Co., No. 931 The Rookery, and they will immediately lay in a stock of Packard lamps, so that they can fill all orders promptly from stock.

THE NEW YORK INSULATED WIRE CO., through their Western manager, Mr. Geo. H. Meeker, are securing some large orders for Grimshaw wire and cables. The new Vulca interior wire ducts are also meeting with a ready sale and attracting considerable attention.

A NEW STYLE OF DUCT.—A striking sight in the streets of Chicago is the new horse and handsome truck bearing cases of wire and the familiar trade-mark of Grimshaw white core wire and Vulca wire ducts of the New York Insulated Wire Co.

CLARK & MARSHALL, No. 500 Insurance Exchange Building, Chicago, dealers in electrical supplies, recently started in business, are working up a nice trade. They are making a specialty of fixtures and incandescent lamps.

MR. DECKER, of the Thomson-Houston Electric Co., has come from the factory at Lynn, Mass., and will be stationed with the Western office of the company.

MR. C. K. LONGENECKER, superintendent of the Weston Engine Co., of Painted Post, N. Y., was a recent visitor to Chicago.

☞ ***Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Miscellaneous, etc., will be found in the advertising pages.***

SUPPLEMENT TO

THE BERLINER MICROPHONE—A BROAD PATENT ISSUED TO-DAY.

During the past week the daily press has put forth a number of more or less startling announcements of an extension of the Bell Telephone patent, alleged to have been made or about to be made by the Patent Office. Probably few if any persons at all acquainted with the present patent laws were much disquieted by such reports. Such persons well knew that the strongest hold of the American Bell Telephone Company in maintaining its grasp upon the telephone service of the country through patent protection after the expiration of the Bell patent in 1893 lay in the possibility of controlling the fundamental features of the microphone transmitter. Much has been said and written touching the interference in the Patent Office between the principal rival claimants to the invention of the microphone, Berliner and Edison; both of whose claims have since the autumn of 1879 been owned by the American Bell Telephone Company. That company has been severely and bitterly criticised—apparently not wholly without reason—on account of the extraordinary delay in bringing the interference to a final adjudication. It has been obvious that the later the decision of the case, the further into the future the period of the resulting patent would extend.

The interference is now terminated and a very broad patent has been issued to Emile Berliner this day. It is entitled "Combined Telegraph and Telephone;" its number is 463,569, and it is dated November 17, 1891. Mr. Berliner's application was filed June 4, 1877—more than fourteen years ago. The drawings show a transmitter having a metal diaphragm in contact at its centre with a metallic screw, the pressure of which upon the diaphragm can be regulated; the contact end of the screw is shown in part of the drawings as carrying a metal ball or sphere; in other drawings the end of the screw is merely rounded. The specification contains the following:

My invention consists in a new and useful improvement in transmitters for electrically transmitting sound of any kind, of which the following is a specification.

It is a fact that if at a point of contact between two conductors forming part of an electric circuit and carrying an electric current the pressure between both sides of the contact becomes weakened the current passing becomes less intense—as, for instance, if an operator on a Morse instrument does not press down the key with a certain firmness the sounder at the receiving-instrument works much weaker than if the full pressure of the hand had been used. Based on this fact I have constructed a simple apparatus for transmitting sound along a line of an electric current. * * *

The said ball and plate are included in circuit with an electric battery, so that they form electrodes, the current passing from one of them to the other. By making the plate vibrate the pressure at the point of contact becomes weaker or stronger as often as vibrations occur, and the strength of the current is thereby varied accordingly.

It is not essential that the plate should be of metal. It can be of any material able to vibrate, if only at the point of contact suitable arrangement is made so that the current passes through that point. The plate may be of any shape or size, or other suitable vibratory media may be used—a wire, for example. Any other metallic point, surface, wire, etc., may be substituted for the ball. There may be more than one point of contact to be affected by the same vibrations. Both of the electrodes may vibrate, although it is preferable that only one should.

The following disclaimer is made:

I do not claim that I am the first inventor of the art of transmitting vocal and other sounds telegraphically by causing electrical undulations similar in form to the sound waves accompanying said sounds. Neither do I claim that I am the first who caused such electrical undulations by varying the resistance of an electric circuit in which a current was passing.

The claims are as below:

1. The method of producing in a circuit electrical undulations similar in form to sound waves by causing the sound waves to vary the pressure between electrodes in constant contact so as to strengthen and weaken the contact and thereby increase and diminish the resistance of the circuit, substantially as described.

2. An electric speaking telephone transmitter operated by sound waves and consisting of a plate sensitive to said sound waves, electrodes in constant contact with each other and forming part of a circuit which includes a battery or other source of electric energy and adapted to increase and decrease the resistance of the electric circuit by the variation in pressure between them caused by the vibrational movement of said sensitive plate.

3. The combination, with the diaphragm and vibratory electrode, of a rigidly held opposing electrode in constant contact with the vibratory electrode, substantially as described.

4. In a telephonic transmitter, a vibrational plate made concave for condensing the sound, substantially as set forth.

5. In a telephonic transmitter, a vibrational plate provided with one or more apertures, as and for the purposes set forth.

6. A speaking-telephone transmitter comprising a diaphragm or disc sensitive to sound waves, combined with a rigidly held but adjustable electrode in contact with the same, whereby the electric current is transformed into a series of undulations corresponding with the vibrations of said diaphragm.

On July 20, 1877, Thomas A. Edison filed in the Patent Office an application for a patent for an improvement in speaking telegraphs, in which he stated that the object of the invention "is to transmit the human voice over telegraphic wires for conversational purposes." This application was assigned to the Western Union Telegraph Company, and was one of those which were transferred to the American Bell Telephone Company under the provisions of the contract entered into when the Dowd case was settled.

The important claim in this application is one which was inserted by amendment after the case had been for some time pending in the Patent Office. It is as follows:

Third. In a telegraphic apparatus operated by sound, the combination with the diaphragm of one or more contact points of plumbago or similar inferior conductor, in the electric circuit, whereby the rise and fall of the electric tension is proportionate to the pressure exerted upon the said point or points by the diaphragm, substantially as set forth.

The specification describes a metallic diaphragm mounted at the inner end of a mouthpiece of the ordinary type, and a contact point of plumbago mounted upon a slender spring, by the resiliency of which the plumbago is lightly pressed against the centre of the metallic diaphragm. This is the Edison case that has been in interference with Berliner.

That interference is said to have been actually discontinued or disposed of some years ago, although we recall no public notice of the fact.

The claims of the Berliner patent appear to be of a very broad character, and to cover an essential element in about all the transmitters employed in telephone service. The approaching issue of the patent was doubtless known to many persons. Rumors in regard to it were probably the source of the newspaper reports of a probable extension of the "Bell patent." The price of American Bell shares five days ago was 185; to-day shares were sold at 210. Evidently persons were to be found who believed they had good reason to anticipate increased value.

The famous interference case has been a theme of much curiosity and interest now these many years; little has been publicly known of its status beyond its apparent immobility. Commissioner Simonds decided against Drawbaugh, who was a party, a few weeks ago. That decision is said to have cleared the way for the allowance and issue of the Berliner patent of this day.

It is too early to undertake any critical examination of the patent or to express an opinion as to its scope. Should it be found broad enough to control the use of all practicable microphones, it is considered doubtful, in view of the circumstances of the long delay in its issue, whether the United States Courts would sustain it to the extent of permitting its owners to enjoy its protection for the next seventeen years.

THE

Electrical Engineer.

VOL. XII. NOVEMBER 25, 1891. No. 186.

MULTIPOLAR DYNAMOS AT THE FRANKFORT EXHIBITION.—I.

BY

E. Kolben.

ALTHOUGH the multipolar machine has always been exclusively used for alternating-current generators, this type has not until recently found more general application for continuous currents, chiefly on account of the mechanical difficulty of building up large commutators with a great number of divisions, a necessary adjunct to multipolar continuous-current machines. The expense, however, incurred in the labor and material for these large commutators is small as compared with the saving that can be effected in iron and copper, by making all machines of considerable output multipolar in preference to bipolar, even though the bipolar type may be run at very high speeds. The Edison 200 K. W. dynamo, which has found so much favor in this country as a railway generator, is probably the largest bipolar dynamo ever built. Although its electrical and commercial efficiency is the highest obtainable, it is heavy for its output, and its weight would be looked upon with astonishment by German electricians. Most of the machines exhibited at Frankfort were multipolar, and this is the reason why Mr. Ravenshaw, in the London *Electrician*, notices particularly that their commutators are so "immense." There were exhibited two distinct types of multipolar machines, the designs of which differ very considerably from one another. The largest type is the "slow speed" for central station work and the smaller is the high speed, belt-driven type. It will be convenient to notice these under the respective headings, "Central Station Dynamos," and "Belt Driven Dynamos."

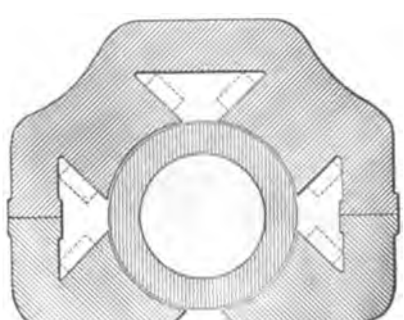


FIG. 1.—TYPE NO. 1. IRONCLAD TYPE OERLIKON DYNAMO.

CENTRAL STATION DYNAMOS.

These are exclusively direct-driven slow-speed machines. Of the various types of field magnet frames that have been employed in practice, the following three patterns only have proved to be the most efficient and have been exclusively adopted by the largest firms.

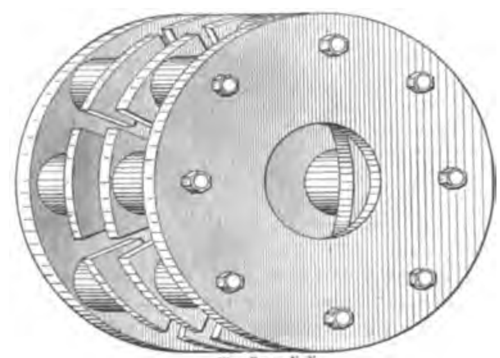

FIG. 2.—TYPE NO. 2. DIRECT FIELD TYPE.

Type No. 1. *Iron Clad Type, Fig.* 1.—These are built by the Allgemeine Elektricitäts-Gesellschaft, Berlin; Oerlikon Machine Works, Oerlikon, Switzerland; Société Gramme, Paris; Lahmeyer & Company, Aachen, Germany; Gisbert Kapp, London.

Type No. 2, *or Direct Field Type, Fig.* 2.—These are built by Schuckert & Co., Nuremberg, Germany; Fritsche & Pischon, Berlin.

Type No. 3, *or Innerpole Type, Fig.* 3.—These are built by Siemens & Halske, Berlin and Vienna; C. F. Fein, Stuttgart, Germany; Ganz & Co., Budapest; Compagnie de Construction Alsacienne, Belfort, France.

The field, Type No. 1, seems to meet with the most general favor. It is very economical, cheap to manufacture, permits of the armature being supported centrally, and does not limit the number of poles. As to the weight, a comparative calculation will readily show that it stands between Type No. 3, which is the lightest, and Type No. 2, which is the heaviest, on account of the magnetic circuit being split into two parallel halves. A field of Type No. 2 can only be used to advantage with flat ring and wheel armatures.

A field of No. 3, or the innerpole type, necessitates the construction of an overhanging armature. This construction is good enough for small sizes, but does not seem safe for large central station machines. It also limits the number of poles, a serious disadvantage for large size machines running at a very slow speed. In this type the advantage of the materially reduced length of magnetic circuit is much counter-balanced by the reduction in the number of poles, and the machine becomes almost as heavy as Type No. 2. The small number of poles also makes it necessary to design the machine with heavy armature effect; this makes the machine very sensitive to changes of load, and consequently increases the liability to sparking. Another disadvantage of this type is that the limiting circumferential speed is not the effective speed on the internal circumference, but this ineffective external speed is the wound with copper bars which form a commutator on the external circumference. The writer has seen its construction as well as its operation in the large central stations of Berlin and Vienna, and also the running of several of the

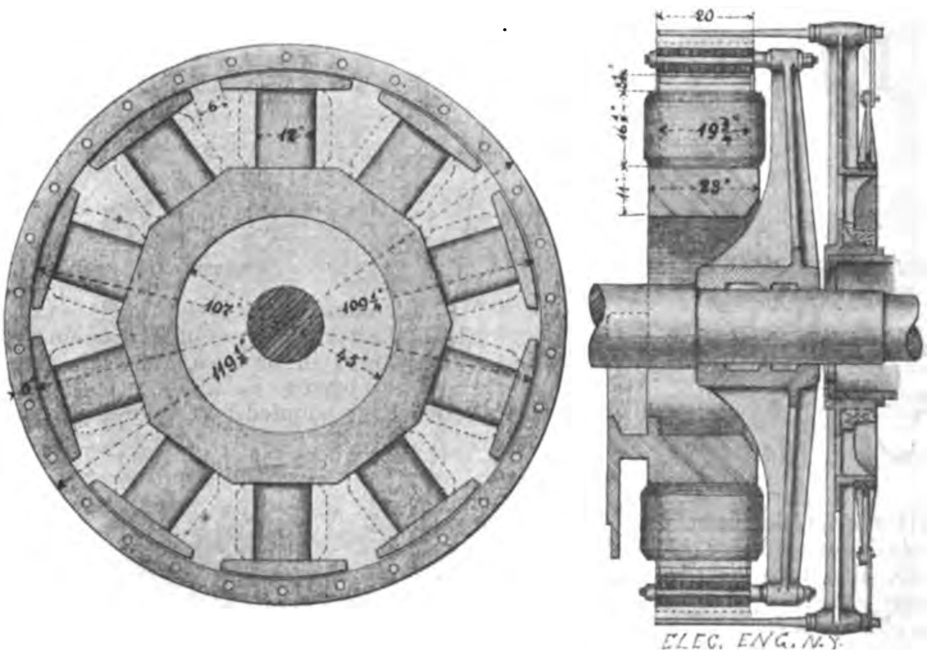

FIG. 3.—TYPE NO. 3. INNERPOLE TYPE. 10 POLAR, 330 KILOWATT, SIEMENS & HALSKE DYNAMO.

mechanical speed limit, and also the brush-friction speed limit. As a consequence of the fact that the circumferential speed is not the effective speed, these machines must run at a slower speed than those with field No. 1. This condition is still more disadvantageous with machines of Type large sizes at the Frankfort Exhibition. The largest size now manufactured has an output of 330 kilowatts. This runs at a normal speed of 65 revolutions per minute.

The armature bars are thin and high, and they are cotton covered. There are large open spaces between bar and

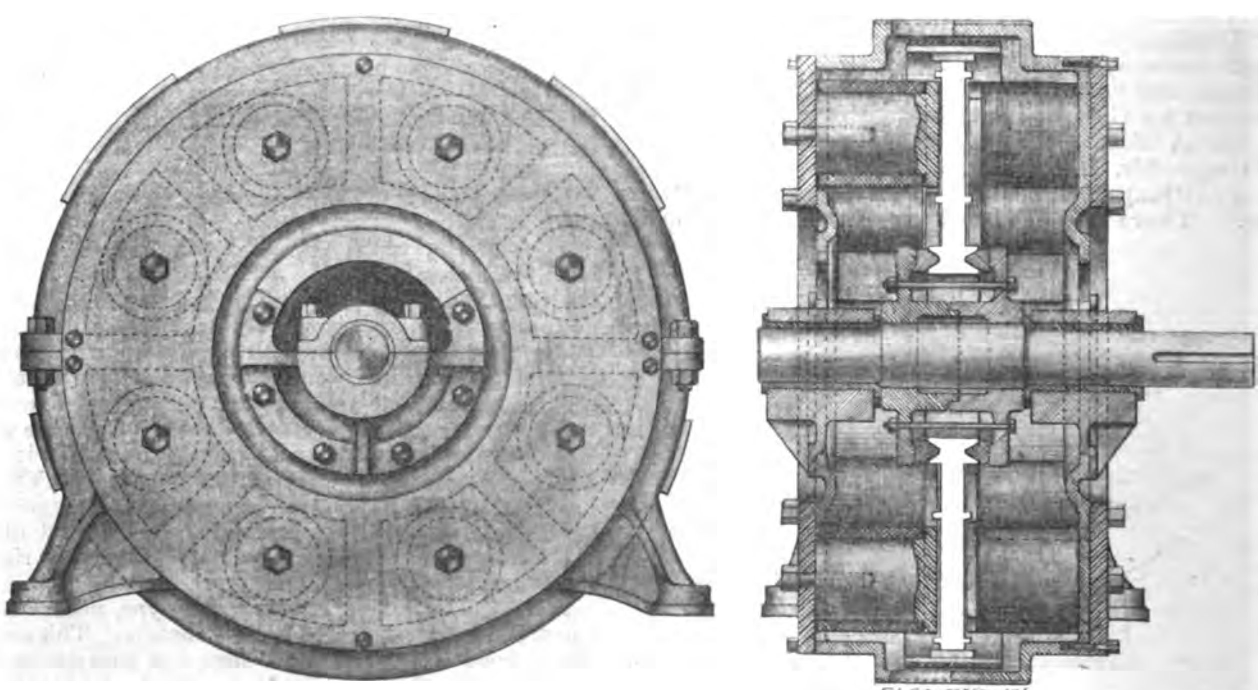

FIG. 4.—END ELEVATION AND SECTION OF FRITSCHE-PISCHON DYNAMO.

No. 2, where the internal circumferential speed is very much reduced, thus increasing the size of the machine required for a given output.

The innerpole machine is chiefly built by Siemens & Halske as a central station machine, having armatures bar. The body is assembled from sectional sheet-iron discs. The following data may be of interest :

Output, 140 volts, 2,360 amperes, at a speed of 69 revolutions per minute.

Internal diameter of armature body....109¼ inches.

External diameter of armature body	119¼ inches.
Length of body	20 "
Total number of bars on circumference	810
Number of poles	10
Cross-section of wrought-iron cores, 12 x 19¾ inches.	
Neutral space between pole-pieces	6 "
Height of armature bar	⅞ "
Thickness of armature bar	$\frac{1}{16}$ "

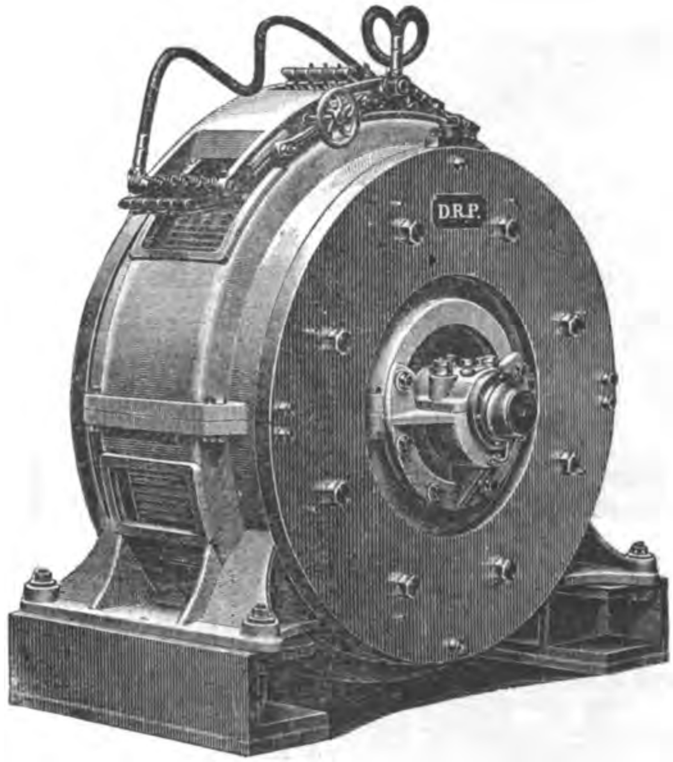

FIG. 4A.—FRITSCHE-PISCHON DYNAMO.

Armature resistance	.00164 ohms.
Field magnet resistance	2.8 ohms.
C^2r loss in armature at full output	9,130 watts.
Hysteresis loss at an induction of 12,500 lines per square centimetre	3,130 watts.

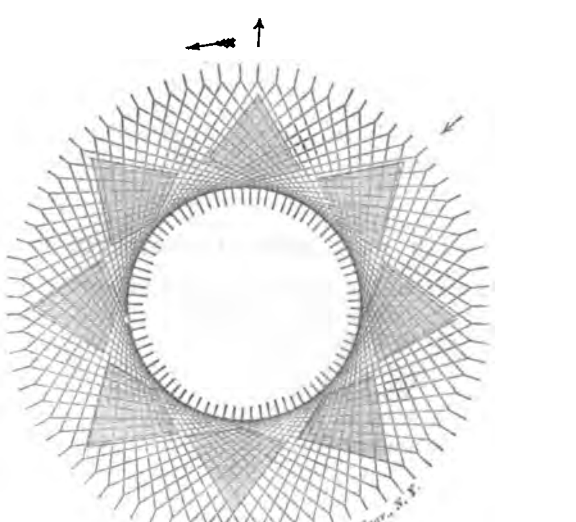

FIG. 5.—DIAGRAM OF FRITSCHE-ROSE WINDING (WELLEN-WICKLUNG) FOR WHEEL ARMATURE.

From these figures it would appear that the machine has not quite the efficiency that might be expected of a central station machine of this size.

Type No. 2, or Direct Field Type.—This has been adopted by Fritsche & Pischon and by Schuckert & Co. The Fritsche wheel dynamo was probably the most original continuous-current machine in the exhibition, and although the machine in its present form is expensive to build, both in respect to magnet frame and armature, a detailed description of its construction will be of interest to American readers.

The magnet frame proper is built up entirely of wrought iron, and is enclosed in a cast iron shell, which protects the

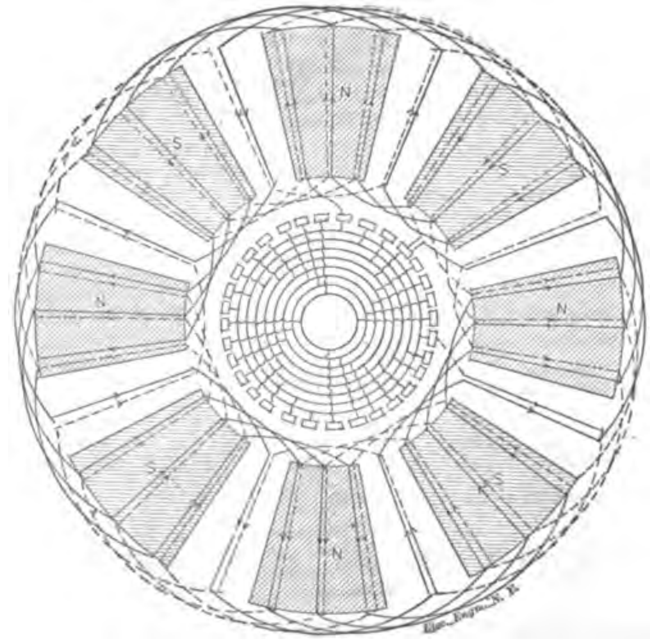

FIG. 6—DIAGRAM OF SERIES CONNECTIONS FOR FLAT RING OR WHEEL ARMATURE.

whole machine, Fig. 4. The wheel armature is a fine piece of elaborate European workmanship. The armature was originally provided with the well-known Fritsche "rose winding," Fig. 5, described in the German Patent No. 45,808, but this method, on account of manufacturing difficulties, has now been abandoned. A single layer of straight radial strips is employed, together with a series of cross-connection (similar to H. Mueller's method, U. S. patent No. 331, 762), using insulated copper strips, partly

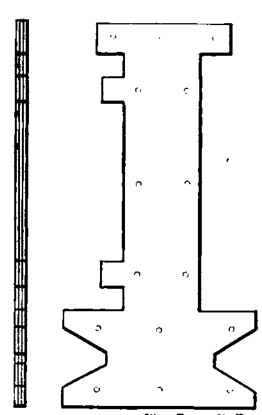

FIG. 7.—ARMATURE BAR OF FRITSCHE WHEEL DYNAMO.

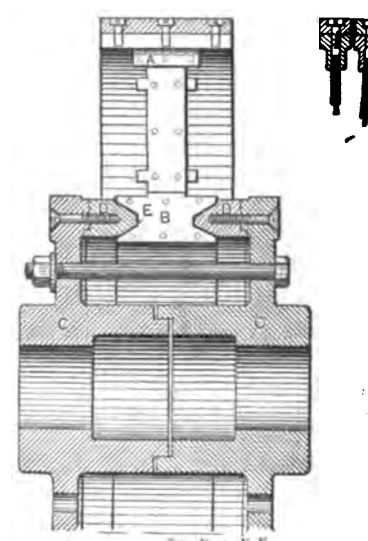

FIG. 8.—SECTION OF ARMATURE OF FRITSCHE DYNAMO.

upon the external and partly upon the internal circumference of the armature, as shown in Fig. 6.

The armature bars consist of specially shaped punchings of sheet iron and sheet copper, which are riveted together. They are long and thin, and are illustrated in Figs. 7 and 8. The punchings are soldered and riveted at the top and bottom to the specially shaped brass castings A and B. Copper bars are screwed on to the castings A, which are then turned off on the circumference and serve as commutator blocks. As the armature loops are connected in series, two sets of brushes only are required. The lower castings B are mortised on both sides, and by this means the whole armature is clamped together with strong cast iron hubs, C, which have brass end rings, D, in order to magnetically insulate the hub from the armature bars. Pressed board insulation, E, is used between the ring D and the armature spokes. The largest machine that is being built at present is designed for 180 K. W., and the following data regarding it will be interesting;

Output	150 volts 1,200 amps.
Speed	100 revs. per minute.
Weight of armature	8,800 lbs.
Weight of copper on fields	1,080 lbs.
Total weight of machine complete	20,240 lbs.
Loss in magnet and armature conductors	3.5 per cent.

The following is a table of sizes and general data of the standard Fritsche machines:

	Output in Kilowatts.	Volts.	Amps.	Speed.	Number of poles.	Weight complete in lbs.
Exhibition Machine	32	160	200	400	4	5,280
	48	160	300	140	8	8,800
	180	150	1,200	100	12	20,240

Fig. 4A shows the machine in perspective.

THE CENTRAL STATION AT BARRANQUILLA, U. S. C.

THERE has lately been a marked increase in the number of electric light stations in the West Indies, Central America, etc., and a notable feature of this work has been the fact that American apparatus is used almost entirely. We have recently illustrated and described the central stations at Kingston, Jamaica, equipped with a Thomson-Houston plant, and at Havana, Cuba, equipped with a Westinghouse outfit; and we now have the pleasure of showing the station at Barranquilla, United States of Colombia, where a Fort Wayne plant has been installed. It is interesting to learn that this plant has already proved

FIG. 1.—FORT WAYNE STATION, BARRANQUILLA, U. S. C.

inadequate for the needs of a city of 30,000 inhabitants, and that it is to be largely increased. Moreover, the lighting for the neighboring city of Cartagena is now under negotiation, with every prospect of an early settlement of the matter.

The station at Barranquilla, shown in Figs. 1 and 2, consists of a Fort Wayne alternating dynamo, of 650 lights, of 16 c. p., separately excited. The dynamo is driven by a 12x12 Ball engine, to which steam is supplied by a boiler of 80 h. p. constructed by the Erie City Iron Works. For street lighting seventy 25 c. p. lamps are used in ten circuits, each circuit being run in series. On the "commercial" circuits five hundred 16 c. p. lamps have been wired up and are now in use for lighting stores, residences, etc.

FIG. 2.—FORT WAYNE STATION, BARRANQUILLA, U. S. C.

The work of installing the electrical plant was under the direction of Mr. W. H. Coles, of this city, who was engaged by the company to undertake the task; and the results have proved very satisfactory. The officers of the Empresa del Alumbrado Electrico de Cartagena y Barranquilla are Ed. Meyer, president; J. M. Larralde, secretary and treasurer; and J. M. Lamadrid, superintendent. The company's New York offices are at 18 Broadway.

In spite of political troubles and financial disquietude, electrical progress in South America during the past year has been very striking and encouraging. Central stations and isolated plants, electric roads, and electrical power plants for mining have been in demand, and have been installed all over that continent; and it is gratifying, to say the least, to state that two-thirds of the material has been furnished from the United States. We are indebted to Mr. W. H. Fleming, E. E., of this city, for the photographs and data of the above plant, that gentleman giving his attention specially to electrical engineering work in the Spanish-American field.

A NEW KENNEDY ALTERNATOR.[1]

THE alternator we illustrate herewith has been constructed by Mr. Rankin Kennedy, of Glasgow, and belongs to that class in which both the exciting and the generating coils are fixed, the revolving part consisting of laminated iron inductors. Machines of this class have been made by many inventors, such as R. Knight, Wheatstone, Henley, and lately by Kingdon on a large scale. Such dynamos have also been designed by Mordey and Forbes.

The points of novelty in this new machine are chiefly the arrangement of the coils of wire and the construction of the magnetic circuits, whereby only two exciting coils and two generating coils are required, however large it may be made, and however great may be the pressure and frequency of the alternating current required. The machine very much resembles a transformer in its parts, and is about as simple in construction. The iron field magnet portions surround the copper coils, which are simple rings

1. *Industries.*

of insulated wires; the inductors are carried on gun-metal wheels, and in revolving alternately open and close the magnetic circuit round the copper coils, thus inducing current in them. There is no reversal of magnetism in any part of the operation of the machine, only a simple rising and falling of the magnetic flow without reversal. The iron is made of very ample sections, so that the induction is never high, and never falls to zero. The excitation is constant, but the induction varies with the position of the inductors. In a machine recently built, and which is illustrated in Figs. 1, 2, 3 and 4, the E. M. F. was 8 volts per turn of generating coil, the speed 750, the excitation 15 amperes under 35 volts, the inductors were 6 on each side; the total pressure was 2,400 volts; with 300 turns of wire on generating coil the output was 24,000 watts. Fig. 3 is a general view of the machine. Fig. 1 is a view of the inductors on the shaft. Fig. 2 is a view of one pair of coils, and Fig. 4 shows the construction of one of the field magnet blocks.

There are two pairs of coils in the machine, and two sets of inductors placed as shown in Fig. 1. The generating coil is wound first and insulated, then the exciting coil is wound over that, and the whole is insulated and fixed in the machine in the recesses formed in the field blocks, as shown in Fig. 4. By using two pairs of coils and two sets of inductors, and exciting the coils so that the field blocks are magnetized with a pole in the middle and similar poles at each end, as marked in Fig. 4, when the two exciting coils are in "series" with each other, any inductive effects on the one exciting coil are exactly and entirely neutralized by those effects on the other exciting coil. The two generating coils can be coupled either in series or in parallel, but the exciting coils must always be in series. This machine is exceedingly simple and inexpensive to build, and there is no difficulty with insulation or in constructing them for any pressure or frequency required. In large dynamos there are four pairs of coils and four sets of inductors. In the machine illustrated the inductors are 21 inches diameter, the coils being 21¼ inches inside diameter; the electromotive force of the generating coil is about 1.35 volts per foot working at very moderate inductions and at moderate speed, and this can be safely raised to 2 volts per foot. For low-pressure alternating currents this machine is equally applicable.

In central stations for electric lighting supply in districts where the stations are surrounded by consumers it is advisable to use low-pressure dynamos, so as to supply the immediately surrounding neighborhood direct from the dynamos, and to supply the distant consumers through step-up transformers. As a motor this machine works well, but has to be brought up to synchronism, like all other synchronizing alternators.

A machine with inductors 4 feet in diameter gives an output of 150,000 watts (100 volts 1,500 amperes) at a speed a little over 200 revolutions per minute. This is suitable for low-pressure distribution near the station, and high-pressure at a distance by means of step-up transformers.

In Fig. 2 P^1 P are terminals of the exciting coil, S^1 S are the terminals of the generating coils. By using only two coils in large slow-speed machines it is expected that the complications hitherto met with in large machines are obviated, most of them requiring two generating coils for each period per revolution. An ordinary machine making one revolution per second would require 200 coils to give a frequency of 100 per second. The machines are specially designed for continuous running at central generating stations.

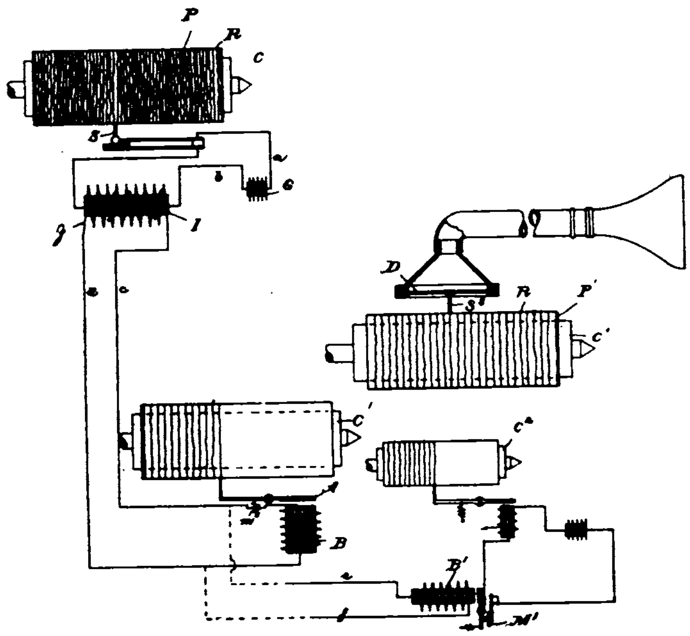
The New Kennedy Alternator.

THE GIBBONEY LONG-DISTANCE TELEPHONE.

In order to increase the distance through which the articulations of the human voice may be electrically transmitted, Mr. John W. Gibboney, of Lynn, Mass., has devised a system which consists in making a phonographic record of the sound waves, and causing this record to produce corresponding undulations at a reduced pitch and transmitting them over the line, where they are again recorded at the receiving end of the circuit.



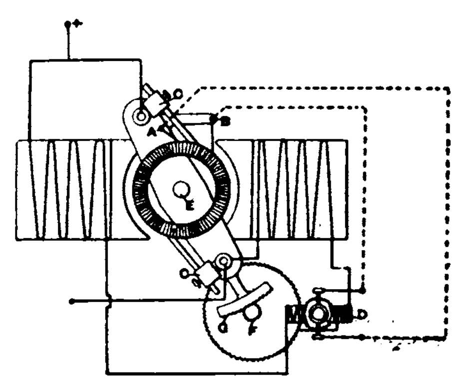
The Gibboney Long-Distance Telephone System.

The accompanying illustrations clearly show the operation of the system. Here Fig. 1 shows the application of the record to the production of electric impulses, Fig. 2 shows the sound reproduction through the agency of an electric wave record, and Fig. 3 is an illustration of the method of recording at the receiving end of the circuit. After the record is first made the stylus is substituted for the follower s, Fig. 1, which controls a variable resistance transmitter in an electric circuit *a b*, this circuit passing around an induction-coil I. If now the cylinder P be rotated at the same rate as when the record was made, electric undulations will pass over the line *c d* to the further end of the circuit; but if this circuit be of considerable length, or have a large amount of self-induction or impedance and the electric waves are rather quick in character, it is well known that their transmission becomes difficult and even impossible, because they are smoothed out, obliterated, or distorted in such manner that they cannot be recognized as representing faithfully the original impulse. This difficulty is obviated by rotating the cylinder C at a reduced rate from that at which the record was made, whereby the electric undulations of current, while having a character corresponding to the sound waves, are prolonged in period. These waves may be passed over the circuit *c d*, and because of their slowness may be transmitted with greater fidelity than would be the case were they made to correspond in period with the pitch of the sound wave. At the receiving end of the circuit these waves are passed through a magnet B, whose armature operates or controls the movements of a stylus, reproducing upon a phonogram-blank upon the cylinder C′ a record corresponding to the electric waves transmitted over the line *c d*. If now the stylus s, Fig. 1, be replaced by the follower s², Fig. 2, and the cylinder C² revolved at the same rate as when the electric-wave record was put upon it, the sound produced would correspond in pitch to the pitch or period of the electric waves which produced the record; but if its speed of rotation be increased sufficiently, the sounds emitted may be made to coincide in pitch with the original sound used in making the initial record at the sending-station.

When desirable to relay the current at the receiving end of the line, the slowness of the period of the waves renders this an easier matter than ordinarily. Thus in Fig. 3 the current between the lines *c d* passes through a magnet B′, operating a variable circuit-controller M′, controlling a local circuit, and passes about a magnet B², which operates a stylus bearing upon a phonogram-blank, upon the cylinder C². The record R² will correspond in character to that upon the original cylinder.

A NEW DYNAMO BRUSH REGULATOR.

A novel system of regulation for dynamo brushes has recently been devised and patented abroad by Messrs. H. Cuénod, E. Sautter and G. Hochreutiner, of Geneva, Switzerland. By this invention a precise adjustment of the brushes to the line of commutation is obtained, and it consists of the combination with one of the collecting brushes of the dynamo of two tell-tale brushes, placed the one in front, the other in the rear of the collecting brush, and with such an arrangement that a difference of potential existing between the two tell-tale brushes may produce the necessary displacement of the collecting brushes so that they may be turned into their proper position. Several methods of carrying this into effect are described, one of which is shown in the accompanying illustration. Here A B are the two tell-tale brushes placed the one in front and the other behind one of the principal brushes C which require to be regulated. The brushes A B are connected to the armature of a small motor, D, separately excited. This motor D governs the brush carrier E by means of a train of gearing F and a toothed segment, G, and the brush carrier E can be turned in one or the other direction around the axis of the dynamo according as the current traverses the armature in one direction or the other. The tell-tale brushes are adjusted in such a manner that in the mean position the principal brush is exactly adjusted upon the line of commutation, and there is no difference of tension between A and B. When any displacement of the principal brush takes place a current will be immediately sent in one direction or the other through the motor.



Dynamo Regulation with Auxiliary Brushes.

A NEW ELECTRICAL MACHINE.

At a recent lecture M. Henri Becquerel exhibited an ingenious frictional electrical machine, devised by his demonstrator, M. Peignot. Mercury is forced by means of a pump through the pores of a piece of chamois leather, and electricity in considerable quantities is generated by the friction. Ducretet, the well-known Paris instrument maker, has just finished a machine of this kind for the Conservatoire. The column of mercury is 1 metre high and 30 centimetres in diameter.

ECONOMY IN ELECTRIC POWER DISTRIBUTION. LEONARD'S FACTORS "1000" AND "7.5."

BY

J. Stanford Brown.

It has been shown (Electrical Engineer, XII, No. 179, page 397, 7 O., '91) that Mr. Leonard's formula

$$(1) \qquad M = \frac{K.\ W. \times D \times 21{,}400}{V(E - V)},$$

(Electrical Engineer, XII, No. 174, page 249, 2 S., '91) can in the lettering of Mr. Sprague be written

$$M = \frac{(2\ l)\ (10.5)\ (K.\ W. \times 1{,}000)}{E\ V},$$

where the latter writes

$$M = \frac{(2\ l)\ (10.5)\ (n \times 746)}{E\ V\ a}.$$

K. W. has been defined as "Kilowatts at terminals of translating device" . . "Electric energy at the end of the conductor, *i. e.*, at the brushes of the motor," while n is the number of horse-power (watts) to be delivered by the motor on its shaft.

The first question then is, What determines the amount of energy to be delivered at the end of the conductor? For the whole problem is to proportion our conductor so that we can deliver *some amount of energy* at the far end with due regard to least first cost consistent with maximum economy of future operation.

What are the commercial conditions? We have, say, a piece of machinery to operate, requiring 2 h. p. to run it. We propose to use a motor to run that machine, and we will, for simplicity, couple them shaft to shaft. Now the amount of power at the motor terminals must be such as will enable us to get 2 h. p. out of the motor or we are not accomplishing our purpose. Furthermore, there has never yet been built a motor which would give out all the energy delivered to it, so that it is impossible in any commercial problem (problems with which engineers have to deal) to omit the motor efficiency, for if we do, as shown in above, we fail to solve the problem.

The factor "1,000" has misled several readers. One engineer suggested to the writer that the figuring had been in *K. W.*'s per 1,000 feet of transmission; but such is not the case. The expressions "*K. W.* × 1,000" and "n × 746" both represent watts. The only difference is in the number of watts contained in the unit of power selected. In the one case it is 746 and in the other 1,000, and in the latter some seem to have been somewhat confused because the unit kilowatt contained the name watt. The latter is, however, really the simplest, for it is on the metric system, and Mr. Leonard starts in the right direction when he adopts the metric system. And besides, it has been proposed to adopt 1,000 instead of 746 as the number of watts to be called an electric horse-power.

It is rather curious to note that in the case in hand the quantity (*K. W.* × 1,000) is expressed in the inverse to the usual way, that is, our unit is expressed by a number while its "numeric" is represented algebraically by n in the one case and by *K. W.* in the other. We usually have the "numeric" given in figures and perhaps this fact aided a misunderstanding at first glance.

In short (*K. W.* × 1,000) *is not the same as* "1,000 *K. W.*"

Instead of using n or m or x or any other *single letter* to denote the number (the numerical factor) of *K. W.*'s, the author of the paper under discussion preferred to make use of the double letter designation *K. W.*, which, most unfortunately for clearness, were at the same time *the initials of his unit*. That is, as used by him "*K. W.*" is the number of "*K. W.*'s." to be transmitted.

With his reply to the query in Electrical Engineer, XII, No. 182, page 472, 28 O., '91, will the author of the original paper kindly show how the factor "7.5" is obtained in the denominator of equation

$$(2) \qquad T = \frac{D^2 \times K.\ W.}{V(E - V) \times 7.5}.$$

For if 1 mil 1 ft. of cu. = .000,003,027 lb.; therefore,

$$1 \text{ lb. cu.} = \frac{1 \text{ mil } 1 \text{ foot}}{.000{,}003{,}027}, \text{ and} \qquad ``$$

if T lbs. correspond to M mils and D feet, "

$$T = \frac{M\ D}{.000{,}003{,}027}; \text{ or}$$

substituting for M its value as given in (1)

$$T = \frac{\left(\dfrac{K.\ W. \times D \times 21{,}400}{V(E - V)}\right) D}{.000{,}003{,}027}; \qquad \text{or}$$

$$T = \frac{K.\ W. \times D \times 21{,}400\ D}{V(E - V)\ (.000{,}003{,}027)}; \qquad \text{or}$$

$$T = \frac{K.\ W. \times D^2}{V(E - V)} \times \frac{21{,}400}{.000{,}003{,}027}; \qquad \text{or}$$

$$T = \frac{K.\ W. \times D^2}{V(E - V)} \times \frac{1}{\left(\dfrac{.000{,}003{,}027}{21{,}400}\right)}$$

which apparently will not give

$$T = \frac{D^2 \times K.\ W.}{V(E - V)\ (7.5)}.$$

ISOLATED ELECTRIC PLANTS FOR RESIDENCES.

BY

Francis L. Woodward.

Being much interested in an article which appeared in a recent issue of The Electrical Engineer on small electric plants for residences, by Mr. W. C. Dodge, I herewith briefly state the result of my various practical investigations upon the subject.

First, in regard to the gas engine. On a large scale, as for lighting theatres, manufactories, etc., I find in regard to the economy of electric lighting, as compared with gas lighting, that, I might say, the poorest and least economical plant for electric lighting, at present on our market, can be successfully, that is economically, operated by means of a gas engine, and will produce a much greater amount of light than could be obtained from an equal amount of gas if consumed by burners for illumination; but for residences using about fifteen 16 c. p. lamps I hardly think the gas engine a saving, in any way; at least, at the present time.

But this will not be a hindrance to the installation of small electric plants, for by the use of an automatic engine, using petroleum for fuel, which is comparatively much cheaper than gas, a satisfactory result can be obtained. There are three important points which should be regarded in selecting the engine. The principal and most necessary of these is that it should be automatic, so that practically the only attention required is that in starting and stopping the engine. The second is uniformity of speed, and the third a steady pressure. I will not discuss the requirements of the engine, however, but rather the cost of successfully operating a plant.

A first-class plant, complete, including dynamo, engine, belting, wiring, cost of installation, etc., on a basis of furnishing fifteen 16 c. p. lamps with the necessary current, can be placed at a cost not to exceed $325, and operated at a cost of about three cents an hour. To furnish the same amount of light by gas burners, consuming five cubic feet per hour, at $1.50 per 1,000, the cost would be about 11¼ cents per hour; or in one year the cost of furnishing this amount of light on an average of three hours a day is.. $394.20

With a dynamo, operated by a petroleum engine..............................	$98.55	
Incidentals to electric plants..............	25.00	
Total cost of maintaining electric plant one year..............................		123.55
Net saving in favor of plant operated by petroleum engine....................		$270.65

In many cities the cost of gas is higher than $1.50 per 1,000, in such cases the saving, by the use of electricity, would be greatly increased.

THE HUM OF MOTORS.

BY

THE hum or musical note given out by motors when working under heavy loads being a matter of interest, as having a practical bearing upon the subject of "motor design," I undertook some experiments with a view to learning more of the location and cause of this hum. The hum often being so pronounced—as in street railway motor of some types—it has undoubtedly attracted attention generally and led to no little experimenting as to its cause and cure; and it is with a hope of drawing out the result of some of these experiments that I report this one.

The motor selected for the experiment was an eight-pole machine, wrought-iron field cores and pole-pieces, with a Gramme ring toothed armature. The brushes were removed and the armature shaft so belted up that it could be driven at varying speed; while the fields were connected with a dynamo—a resistance box being placed in circuit so that the current in the fields could be varied at will. When the fields had no current flowing through them and the armature was revolved at any reasonable speed there was no sound given out, but so soon as a strong current was sent through the fields a musical hum was heard, the note increasing in force with the increase in current through the fields and increasing in height of pitch with the increase in speed of the armature. This was tried repeatedly with the same result. The armature was then replaced by a bare armature core and this was put through a similar test, with the same result.

The hum varying in pitch with the variation in speed of the armature suggested the idea of getting the pitch of the note given out for any definite speed of the armature, and hence the number of vibrations per second of the vibrating part for any definite speed of the armature, and by comparison get some idea as to the cause or location of the musical note. Not having convenient anything of known pitch, I hit upon the plan of observing at a time when the note given out was just beginning to be audible to the human ear, and hence at a time when the vibrations producing this note must be about 16 per second. From a number of observations it was found that when the note given out was barely audible the speed of the armature was about 120 revolutions per minute—2 revolutions per second. So when the part producing the hum was vibrating at the rate of 16 vibrations per second the armature was making a speed of 2 revolutions per second. Now since the motor had 8 poles, at the time of observation any point in the armature was passing from one field pole to the next 16 times per second (8x2); and since the number of vibrations per second causing the hum corresponds exactly with the number per second of changes in polarization of the armature as it passes from one field pole to the next, it is but natural to conclude that the change in polarization of the armature as it passes from one field pole to the next is the cause of the musical note so often given out by motors.

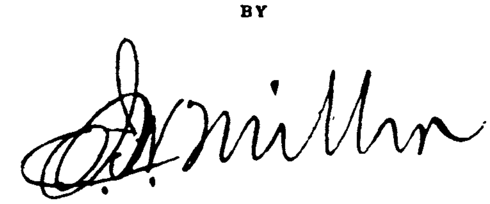
This would most probably account for the fact that this hum is most frequently met with in "multipolar" machines.

This annoyance has been often lessened by modifying the design of the machine, such as the reshaping of pole-pieces, and this experiment would seem to indicate the line along which the same thing might be accomplished to a degree without change of general design. The fact that the force of the musical note increased with increase in the current through the fields would seem to show that the note increased in force with increase in saturation in the magnetic circuit taken as a whole—field core, pole, air space and armature—and that a reduction in the possible saturation through the magnetic circuit as a whole would decrease the force of the note, but it is not so clear that a reduction in the saturation through the armature core alone—the rest of the magnetic circuit remaining the same—would accomplish the same result, although I am inclined to think that it would to a certain degree.

The experiment seeming to indicate that the musical note takes its pitch from the speed of the armature and that the note in vibrations per second corresponds to the number of times per second that the armature passes from one field-pole to the next would lead to the conclusion that in machines with armatures changing pole less than sixteen times per second there would not be given out any musical hum; but should the other necessary conditions for the hum be present to a marked degree there might be a succession of sounds. I very much hope that others will discuss this matter.

A RELIABLE CIRCUIT PROTECTOR.

BY



IN THE ELECTRICAL ENGINEER of August 26th appears an editorial upon the subject of fusible cut-outs. The conclusion reached was that neither fuses nor electromagnetic cut-outs were entirely satisfactory, and that the problem of protection against undue heating caused by excessive currents was unsolved.

Having devoted considerable time to the consideration of this subject, I would like to offer a few suggestions that may lead to better results than have yet been attained. My experiments have been made with a view of securing a reliable protector for use on telegraph and telephone lines and the results have been highly satisfactory.

It is well known that a current of one-half an ampere will set an ordinary telegraph instrument or telephone on fire if allowed to pass through it for a sufficient length of time. A protector to be effective should therefore protect against currents of one-half an ampere and upward. Fuses that will burn out with one-half an ampere of current will be destroyed by wholesale during lightning storms and render the wires practically unserviceable. As the fuses cannot be protected by lightning-arresters, their general use on all classes of lines is impracticable. The same objections hold good with the electromagnetic devices; they operate freely during lightning storms and require constant attention in order to prevent the circuits from being left open. After satisfying myself that favorable results could not be attained with either device referred to, I turned my attention to the combination of a heat coil and fuse; the former to protect against currents of from one-half an ampere to five or six amperes and the latter for all in excess of six.

The heat coil is made by winding around a lead core $\frac{1}{4}$ inch in diameter and $2\frac{1}{2}$ inches long, number 25 gauge insulated German silver wire to a resistance of 25 ohms. A lever $4\frac{1}{4}$ inches long is trunnioned at $\frac{1}{4}$ inch from one end and through this short end passes an adjustable screw which rests against the upper end of the lead core. The long end of the lever has a hook which engages a second lever. The operation of the instrument is as follows:

Whenever a current of one-half ampere or over passes through the heat coil, the lead core is heated and the expansion raises the short end of the lever and causes the disengagement of the long end, thus opening the circuit permanently. One end of the lever being sixteen times as long as the other, the expansion of the core is multiplied by 16 at the long end. A current of one-half ampere opens the circuit in 50 seconds, and as the current increases the time of opening decreases. A current of five amperes opens the circuit in two or three seconds, which is before any damage would result to telegraph or telephone instruments. Ordinary lightning discharges do not generate enough heat to open the circuit, and the instrument does not operate unless a dangerous current is introduced for two or three seconds of time. As currents over five or six amperes might cause excessive heat in two or three seconds, a fuse which will burn out with six amperes of current is placed in circuit; but its conductivity is too great to be easily burned out by lightning. This form of protector, while it protects against all dangerous currents, does not unnecessarily open the circuit. For intermediate offices, it can be arranged to cut the instruments out of circuit and at the same time leave the circuit closed throughout. At terminal offices it is arranged to leave the circuit open.

Nearly all of the largest telegraph offices in the United States and many of the telephone exchanges have been destroyed by fire within the last five years, and in almost every instance the cause has been traced to excessive currents being led into them which the wires had not sufficient conductivity to carry safely.

A reliable protector is certainly needed, and I believe it will be found in the combination of a heat coil and high conductivity fuse.

HOW BERLINER INVENTED THE MICROPHONE.

In view of the decision of the U. S. Patent Office, awarding Mr. Emile Berliner a patent on the microphone, as noted in our special Bulletin last week, the following account of the manner in which he made his discovery and invention will be of great interest. It is taken from the biographical notes prepared by him at the request of the editors of The Electrical Engineer, and upon which an illustrated biographical sketch was based, appearing November 19, 1890:

"As soon as I had returned to Washington, in 1876, I began electrical experiments, and for the purpose of learning something, paid visits to the Fire Alarm Office, where the operators were kind and ready to answer all questions.

"I had just commenced making diaphragms and contacts, and had looked up Bell's patent of 1876, when one day Mr. Richards, one of the operators, at my request, showed me how to manipulate a telegraph key. 'You have to press down harder, otherwise it may happen that the sounder at the other end will not respond well.'

"I immediately asked him for a thorough explanation of this, because it had flashed through my mind that if pressure made a difference in an electrical contact, and modified the current passing the contact, then a vibratory contact would transmit speech by means of undulatory currents. In this manner the telephone transmitter, afterwards known as the microphone, was invented.

"I at once set to work to study this principle and tried to transmit speech, using for a receiver an apparatus as shown in Bell's patent of 1876. For a transmitter I used metallic diaphragms touching screws tipped either with platinum, steel, or broken lead pencil points. One day in April, 1877, I had adjusted the transmitter—a soap box and a black sheet-iron diaphragm against a steel ball—to the utmost nicety, *i. e.*, an extremely loose contact, and closing the two wire ends leading to the battery, I suddenly heard a scraping sound coming from the transmitter. I had discovered that a microphonic contact could be vibrated by a current, and that such a transmitter would act as a receiver of sound as well.

"This analogy with the Bell telephone," he says, "struck me very forcibly, and immediately making a duplicate transmitter, two days afterwards I actually transmitted speech and music with these two simple contrivances, almost as simple as a lover's telegraph. This work was mostly done before, or after business hours, or on Sundays. I now tried all sizes of instruments, and various metals as diaphragms, and finding that distance would weaken the effect very considerably, hit upon the idea of placing the transmitter in the primary of an induction coil, thereby transforming the undulations into high-tension currents, passing these over the line wire, and re-transforming them again into low-tension currents at the other end to actuate the microphone receiver. No Bell telephones were used in these tests, but each instrument was used both for transmitter and receiver. My patent for this was issued Jan. 15, 1878, and was later re-issued. Without this, practical telephone work would be impossible. When, soon afterwards, I was introduced by a prominent Washingtonian, Mr. A. S. Solomons, to Prof. Henry, this great scientist was particularly pleased with the use to which I put the induction coil. I mentioned to him at the time that telephone circuits were found to be affected by parallel wires on which Morse signals were sent. He then related to me that he himself had traced signals on long lines between two wires which were a mile apart.

"I made some attempts to interest practical electrical men in the transmitter principle, and in Jan., 187[illegible], visited the New York local branch of the Bell Telephone Co., but they refused to pay a very modest sum for the invention, which was then not yet perfected. It was not until during the summer of the same year that, by request of Mr. Anthony Pollok, the attorney of the Bell company, Mr. Thos. A. Watson, general superintendent of the Bell company, visited Washington and examined the transmitter, when he immediately declared that his company would want it. As one of my conditions, I asked to become a member of their electrical staff, and a contract was closed in Sept., 1878, in New York. Returning to Washington, a few nights later, to prepare for leaving, I sank into a severe nervous prostration, which lasted seven weeks, and from the effects of which I suffered many years afterwards. Leaving the hospital, I went to New York to enter upon my new duties."

ELECTRIC RAILWAYS IN BERLIN.

The local authorities of Berlin are examining the projects of Siemens and Halske for an elevated railway, and the General Electricity Company for an underground system consisting of three lines.

THE
ELECTRICAL ENGINEER.
[INCORPORATED]
PUBLISHED EVERY WEDNESDAY AT
150 Broadway, New York City.
Telephone: 3860 Cortlandt. Cable Address: LENGINEER.
GEO. M. PHELPS, President. F. R. COLVIN, Treas. and Business Manager.
Edited by
T. COMMERFORD MARTIN AND JOSEPH WETZLER.
Asso. Editor: GEORGE B. MULDAUR.
New England Editor and Manager, A. C. SHAW, Room 70—620 Atlantic Avenue, Boston, Mass.
Western Editor and Manager, W. FORMAN COLLINS, 347 The Rookery, Chicago, Il
New York Agent, W. E. STOW, 150 Broadway.
Philadelphia Agent, W. F. HANKS, 501 Girard Building.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XII. NEW YORK, NOVEMBER 25, 1891. No. 186.

The discovery of magneto-electricity is the greatest experimental result ever attained by an investigator. It is the Mont-Blanc of Faraday's achievements.—Tyndall.

THE BERLINER PATENT.

NOT often has the issue of a patent elicited so immediate and widespread comment and discussion—in the columns of the press and in general conversation—as have attended that of Emile Berliner for a "Combined Telegraph and Telephone." The SUPPLEMENT to THE ELECTRICAL ENGINEER of last week gave the leading points of the specification and the claims in full, together with such facts touching the long-pending Berliner-Edison interference proceedings as were then at hand.

Berliner's application was filed June 4, 1877; Edison's, July 20, of the same year. The interference was declared May 27, 1880. Account had to be taken of Drawbaugh's application of 1880. If found entitled to a patent, that inventor would have had to be joined in the interference. Within the last three weeks—or more than eleven years after its declaration—the interference has been dissolved and two of the cases have been disposed of. The Commissioner of Patents denied Drawbaugh's application October 29, on the ground of public use for more than two years before its date. On the same day the interference was dissolved—Berliner having filed amendments—and the Commissioner directed the allowance of the Berliner patent. Mr. Berliner's amendments, the filing of which practically terminated the interference with Edison, date back to February, 1886; since which time the interference has, apparently, existed in form only. The Commissioner's attention was called to the readiness of the case for issue by Examiner Bissing, who, in his communication of October 29, characterized the application as "containing generic claims for the microphone and the art of microphony." Mr. Bissing said further, that in his opinion, it was "*of the highest importance that the term of the patent granted on this application should begin to run at the earliest possible moment.*" The Commissioner replied, on the same day, as follows:

DEPARTMENT OF THE INTERIOR,
UNITED STATES PATENT OFFICE,
WASHINGTON, D. C., Oct. 29, 1891.

EXAMINER BISSING: I have carefully read your letter of Oct. 29, 1891, concerning the application for patent filed by EMILE BERLINER June 4, 1877, for a combined telegraph and telephone. As this applicant has technically perfected his rights to the allowance of a patent, I think the allowance should issue, largely because well-settled principles of public policy forbid you to give any further opportunities for holding this application in the office. Very respectfully yours,
W. E SIMONDS, Commissioner.

It now remains to be seen what will become of the Edison application, now freed from interference.

There can be little if any doubt as to the scope of the Berliner patent. Its first claim is exceedingly comprehensive, viz.:

> The method of producing in a circuit electrical undulations similar in form to sound waves by causing the sound waves to vary the pressure between electrodes in constant contact so as to strengthen and weaken the contact, and thereby increase and diminish the resistance of the circuit, substantially as described.

This seems to include all types of transmitters now employed in practice; yet it may not prove exhaustive for the next seventeen years. It is worthy of note that the patent wholly excludes a possibly important class of variable resistance transmitters which depend for their action upon variations of the area of surface in contact, excepting cases in which such variation is produced by variations of pressure; a circumstance which perhaps may leave open a most fruitful field for the researches of future experimenters and investigators. Broad as the patent undoubtedly is, yet it constitutes a *species* rather than a *genus*, and is thus much inferior in scope to the Bell patent, which is truly generic. Until the now accepted theories of the propagation of sound and of electricity can be upset, it is hardly conceivable that articulate speech can be reproduced electrically without the employment of undulatory currents; but it does not seem improbable that research and ingenuity will arrive at a satisfactory method of producing the undulatory current other than that of variable pressure between electrodes.

Intimations have appeared in the course of the prevalent discussion on Mr. Berliner's patent, to the effect that it might perhaps ultimately be held void by reason of the issue to him of a prior foreign patent. There is apparently no foundation for such an expectation. The invention of Berliner, as fully set forth in his application, is to all intents and purposes identical with the microphone of Professor Hughes, the first description of which, published in May, 1878, nearly a year later than Berliner's application, attracted a great amount of attention in scientific circles throughout the world, and became the subject of a somewhat acrimonious controversy, as to the question of Hughes' priority, between Mr. Edison and Mr. Preece. No serious doubt existed, even at the time, among those well informed of the facts, as to the originality of Hughes's discovery of the microphonic principle; but, as it now appears, he had been anticipated in point of time by Berliner, whose priority over Edison has also been affirmed in the interference proceedings. As Berliner took no British patent prior to the date of Hughes's publication, he, of course, could not have had a valid one afterwards. He did, however, subsequently take a British patent through his agent, Lake (No. 91 of 1880), for a microphone, in which the scope of the invention is carefully limited to a movable electrode held against a stationary one by gravity. It will be observed, however, that the Berliner patent just issued involves an essentially different principle from this: that of a continuous pressure of one electrode against the other, a pressure which is varied solely by the action of the diaphragm in yielding to the impact of the atmospheric sound waves.

Respecting the extraordinary period during which the Berliner application has been held up in the Patent Office—14 years—and the possible effect of that delay in prolonging the monopoly of the American Bell Telephone Company by a similar period, that company is extensively accused of contributing to postpone the issue of the patent, aided by the inability of the Commissioner, under existing statutes, to force action within a reasonable time. If, as seems not unlikely, the charge be true, it amounts merely to saying that the Bell company has done all it could, under supposed legal rights, to protect and prolong its control of the telephone service; finding a convenience to its hands in the power to suspend the interference proceedings between two applications owned by itself. The morals or policy involved need not be discussed at this time. Yet it would be a public misfortune should the Berliner patent result in maintaining the company in undisturbed possession of its present field for 15 years after the termination of the Bell patent; a misfortune as enabling the company to exact such royalty as may please it for that period, and as exhibiting a defect in the existing patent laws which apparently provide no means for preventing unreasonable and collusive delay in interference cases. The question whether the Bell company is blameworthy—whether it ought or ought not to avail itself of its legal advantage—is one of casuistry rather than of business—more academic than practical. The important consideration for the electrical and general public is: What can be done to defeat the threatened prolongation of the Bell monopoly and what should be attempted in the way of legislation designed to preclude for the future the indefinite suspension of applications in the Patent Office?
